Fields on Shelves .....	114
Fields on the Marks card .....	116
Sheets in the Dashboards and Worksheets pane .....	117
Fields in the Calculation editor .....	117
Tableau Concepts .....	118
Structure Data for Analysis .....	118
How structure impacts analysis .....	119
Data Structure .....	119
What is a row? .....	119
What is a field or column? .....	120
Categorizing fields .....	121
Binning & Histograms .....	122
Distributions and outliers .....	124
Data Types .....	126
Pivot and Unpivot Data .....	127
Wide data .....	127
Tall data .....	130
Normalization .....	133
Join Types .....	135
"Tidy" Data .....	136
Find Good Data Sets .....	136
The reality of data sets .....	136
What makes a good data set .....	136
1. A good data set has the elements you need for your purposes .....	137
2. A good data set is disaggregated (raw) data .....	138
3. A good data set has dimensions and measures .....	139
Dimensions and Measures .....	140

- Discrete and Continuous ..... 141
- 4. A good data set has metadata or a data dictionary ..... 142
- 5. A good data set is one you can use ..... 143
- Relabel your data ..... 144
  - Relabel to make fake data ..... 145
  - Re-alias to make the data easier to use ..... 145
- Re-alias with the CASE function ..... 145
- Tips when looking for data sets ..... 146
- Places to look for data ..... 147
- Dimensions and Measures, Blue and Green ..... 148
  - About data field roles and types ..... 148
    - Blue versus green fields ..... 148
    - Possible combinations of fields in Tableau ..... 148
  - Examples of continuous and discrete fields used in a view ..... 149
  - Dimension fields in the view ..... 150
  - How dimensions affect the level of detail in the view ..... 152
    - Notes ..... 153
  - Measure fields in the view ..... 154
  - How continuous and discrete fields change the view ..... 156
    - Continuous fields produce axes ..... 156
    - Discrete fields create headers ..... 157
    - Discrete versus continuous fields on filters ..... 157
    - Discrete versus continuous fields on color ..... 158
- Data Types ..... 158
  - Data type icons in Tableau ..... 158
  - Change the data type for a field in the Data Source page ..... 159
  - Change the data type for a field in the Data pane ..... 160

---

Change the data type for a field in the view .....	160
Mixed data types in data from files .....	161
Tableau's Order of Operations .....	162
About the order of operations (aka query pipeline) .....	163
Example 1: Convert a Dimension Filter to a Context Filter .....	164
Example 2: Convert a Table Calculation to a FIXED Level of Detail Expression .....	167
Data Aggregation in Tableau .....	173
Change the Aggregation of a Measure in the View .....	173
Aggregating Dimensions .....	174
List of Predefined Aggregations in Tableau .....	177
Set the Default Aggregation for a Measure .....	180
How to Disaggregate Data .....	182
Example: Scatter Plots, Aggregation, and Granularity .....	183
Start building the scatter plot .....	183
Use dimensions to add detail .....	184
Try adding more fields to the rows and columns shelves .....	186
Try disaggregating the data .....	188
The Bookshop data set .....	189
Download the files .....	190
About the data set .....	190
Data Dictionary .....	191
If you build your own data source .....	191
Bookshop Libraries .....	192
Data Dictionary .....	192

# Tableau Desktop and Web Authoring Release Notes

This topic describes what’s new in the latest release. Use the viz below to explore new features in Tableau Desktop and web authoring. Click a feature name to display a tooltip with a link to documentation for that feature. Apply filters to refine your search.

- Click **Search by Feature** to see a list of new features for a product or version, or to explore when a feature was released. The dashboard currently defaults to Desktop (which includes web authoring features) and the latest released version of Tableau Desktop.
- Click **Upgrade Desktop** to see a list of all features specific to Tableau Desktop and web authoring.

**Tip:** Click the **Download** button in the viz toolbar (while no feature names are selected), and then select **Data** to export the list to a CSV file that you can customize.

- Build basic chart types: [Build Common Chart Types in Data Views](#) on page 1417 and [Choose the Right Chart Type for Your Data](#) on page 203
- Build maps: [Maps and Geographic Data Analysis in Tableau](#) on page 1593
- Get started with using Tableau Cloud and Tableau Server: [Use Tableau on the Web](#) on page 3106.

## Build a Basic View to Explore Your Data

This topic uses the Sample - Superstore data source to walk through how to create basic views and explore your data. It shows how your view of data in Tableau evolves through your process of exploration.

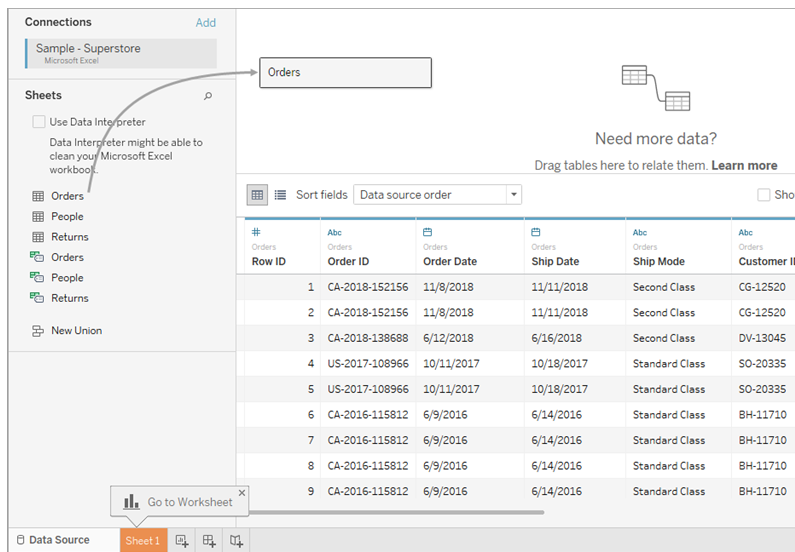

If you're using Tableau Cloud and Tableau Server to explore data and edit views, see [Use Tableau on the Web](#) on page 3106.

## Connect to your data

The first step is to connect to the data you want to explore. This example shows how to connect to Sample - Superstore data in Tableau Desktop.

1. Open Tableau. On the start page, under **Connect**, click Microsoft Excel. In the Open dialog box, navigate to the `Sample - Superstore Excel` file on your computer. Go to `/Documents/My Tableau Repository/Datasources/version number/language`. Select `Sample - Superstore`, and then click **Open**.

2. After you connect to the Excel data, the Data Source page shows the sheets or tables in your data. Drag the "Orders" table to the *canvas* to start exploring that data.

Depending on how your data is structured, you might need to do more data preparation and integration before you start exploring it in Tableau. For more details on connecting to your data, see [Connect to and Prepare Data on page 233](#) and [Tips for Working with Your Data on page 239](#).

3. Click the sheet tab to go to the new worksheet and begin your analysis.

## About the Data pane

In the worksheet, the columns from your data source are shown as fields on the left side in the **Data** pane. The **Data** pane contains a variety of fields organized by table. For each table or folder in a data source, dimension fields appear above the gray line and measure fields appear below the gray line. Dimension fields typically hold categorical data such as product types and dates, while measure fields hold numeric data such as sales and profit. Sometimes a table or folder will contain only dimensions, or only measures to start with. For more information, see [Dimensions and Measures, Blue and Green on page 148](#).

For more information about parts of the workspace, see [The Tableau Workspace](#) on page 27.

If you have more than one data source in a workbook, click the data source connection name in the Data pane to select it for use. For more details, see [Navigating Data Sources in the Data Pane](#) on page 45.

For details on the many ways you can customize the fields in the data pane, see [Organize and Customize Fields in the Data Pane](#) on page 999, [Edit Default Settings for Fields](#) on page 1011, and [Work with Data Fields in the Data Pane](#) on page 37.

If you have related dimension fields, sometimes you might want to group them in a folder, or as a hierarchy. For example, in this data source, Country, State, City, and Postal Code are grouped into a hierarchy named Location. You can drill down into a hierarchy by clicking the + sign in a field, or drill back up by clicking the - sign in a field.

## Build the view

A **view** is a visualization or viz that you create in Tableau. A viz could be a chart, a graph, a map, a plot, or even a text table.

Before you start building a view, consider the question or questions you're hoping to answer with data. Every view that you build in Tableau should start with a question. What do you want to know?

Every time you drag a field into the view or onto a shelf, you're asking a question about the data. The question varies depending on the field you choose, where you place it, and the order in which you add it to the view.

For every question you ask, the view changes to represent the answer visually with marks represented by shapes, text, hierarchies, table structures, axes, color.

## Different ways to start building a view

When you build a view, you add fields from the **Data** pane. You can do this in different ways.

For example:

- Drag fields from the **Data** pane and drop them onto the cards and shelves that are part of every Tableau worksheet.
- Double-click one or more fields in the **Data** pane.
- Select one or more fields in the **Data** pane and then choose a chart type from **Show Me**, which identifies the chart types that are appropriate for the fields you selected. For details, see [Use Show Me to Start a View](#) on page 1173.
- To start creating a tabular view, drop a field on the **Drop field here** grid.

For more details on building visualizations with fields, see [Start Building a Visualization by Dragging Fields to the View](#) on page 1135.

As you start exploring data in Tableau, you'll find there are many ways to build a view. Tableau is extremely flexible, and also very forgiving. As you build a view, if you ever take a path that isn't answering your question, you can always undo to a previous point in your exploration.

- To undo or redo, click undo ← or redo → on the toolbar.

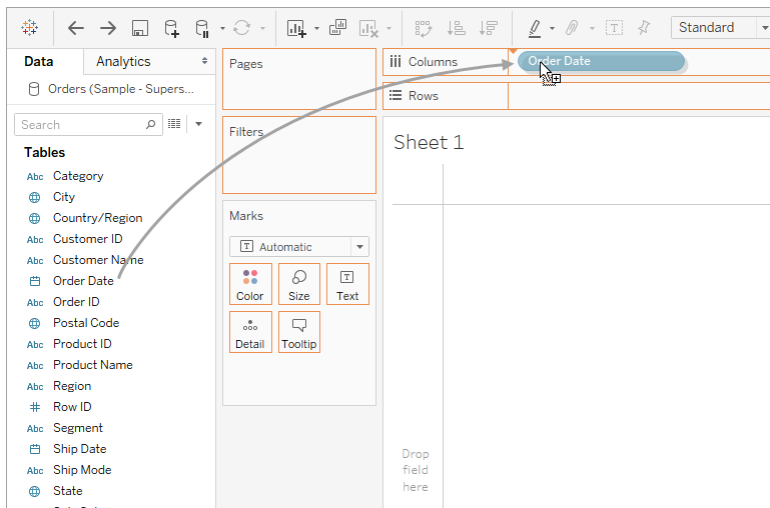

You can undo all the way back to the last time you opened the workbook. You can undo or redo an unlimited number of times.

## Build a view from scratch

These steps show how to build a basic view that shows year-by-year profit.

1. From the **Dimensions** area in the **Data** pane, drag the **Order Date** field to the **Columns** shelf. You might need to expand the Order hierarchy to see Order Date.

When you drag a field over a shelf, a plus sign indicates that the shelf can accept the field.

The resulting table has four columns and one row. Each column header represents a member of the Order Date field (the default date level is YEAR). Each cell contains an “Abc” label, which indicates that the current mark type for this view is text.

A screenshot of the resulting Tableau view. The Columns shelf contains a blue pill labeled 'YEAR(Order Date)'. The Rows shelf is empty. The view displays a table with the following structure:

Order Date			
2016	2017	2018	2019
Abc	Abc	Abc	Abc

Notice that the field is colored blue, which indicates that it's *discrete*. For more information, see [Dimensions and Measures, Blue and Green](#) on page 148.

The default date level is determined by the highest level that contains more than one distinct value (for example, multiple years and multiple months). That means that if **[Order Date]** contained data for only one year but had multiple months, the default level would be

month. You can change the date level using the field menu.

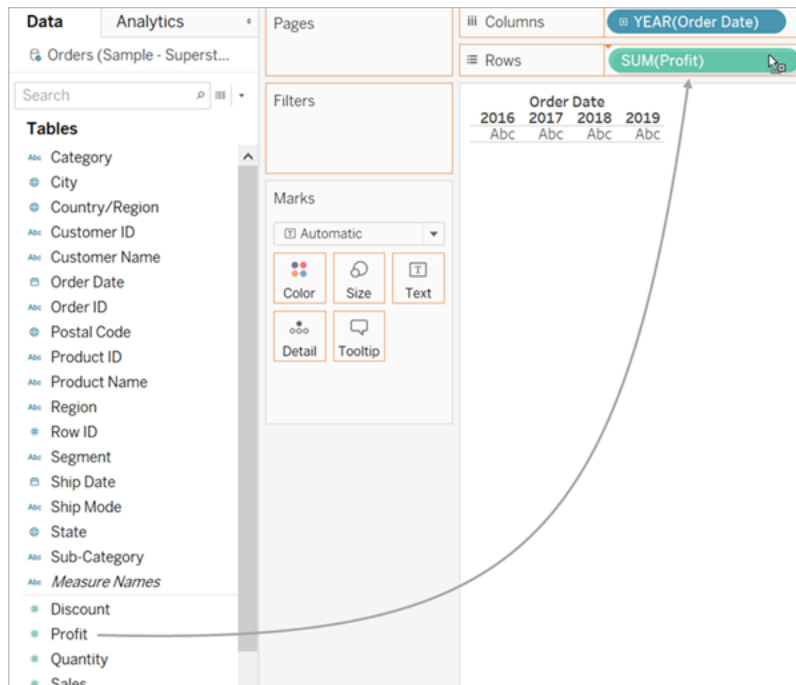

If you're wondering why there are two sets of date levels (from Year down to Day), the first set of options uses date parts and the second set of options uses date values. For more information, see [Change Date Levels on page 1101](#).

**Tip:** To hide the title on the sheet, select the drop-down to the right of the title (Sheet 1), and select **Hide Title**.

2. From the **Data** pane, drag the **Profit** field to the **Rows** shelf.

## Tableau Desktop and Web Authoring Help

The **Profit** field is colored green on the **Rows** shelf, indicating that it's continuous. Also, the field name changes to **SUM(Profit)**. That's because measures are automatically aggregated when you add them to the view, and the default aggregation for this measure is SUM. For more information on what happens when you add a measure to a view—and why—see [Dimensions and Measures, Blue and Green](#) on page 148.

Tableau transforms the table into a line chart and creates a vertical axis (along the left side) for the measure.

A line chart is a great way to compare data over time and identify trends effectively.

This line chart shows profit over time. Each point along the line shows the sum of profit for the corresponding year.

The next step is to drill a little deeper into the time dimension.

## Drill into the data

This step shows how you can modify the view to show quarters in addition to years. As you drill down into the hierarchy, the view changes to become a nested table.

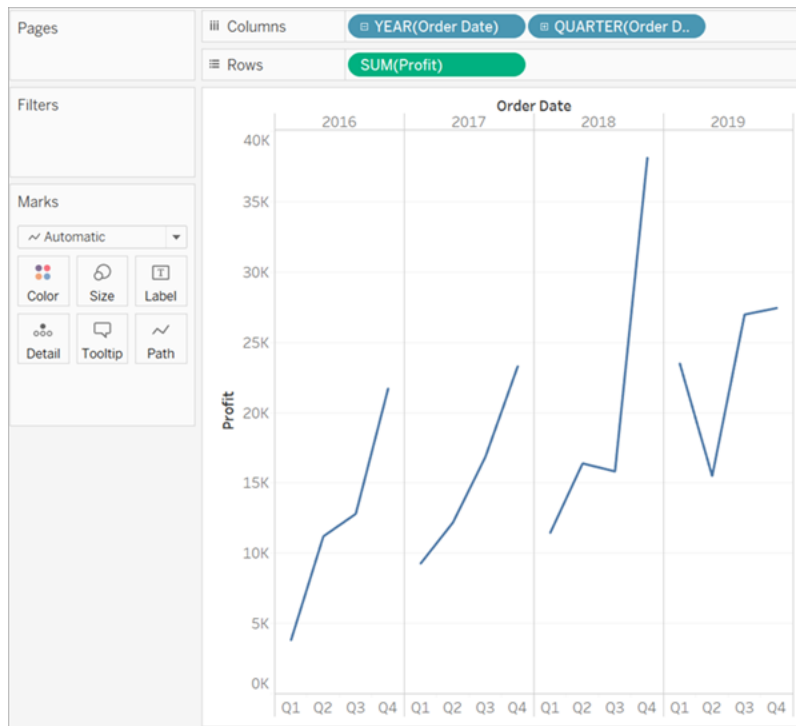

You can show **[Order Date]** by quarters using either of the following methods:

- Click the plus button  on the left side of the field **YEAR(Order Date)** field on Columns.

- Drag the **Order Date** field (again) from the Data pane and drop it on the **Columns** shelf to the right of **Year(Order Date)**.

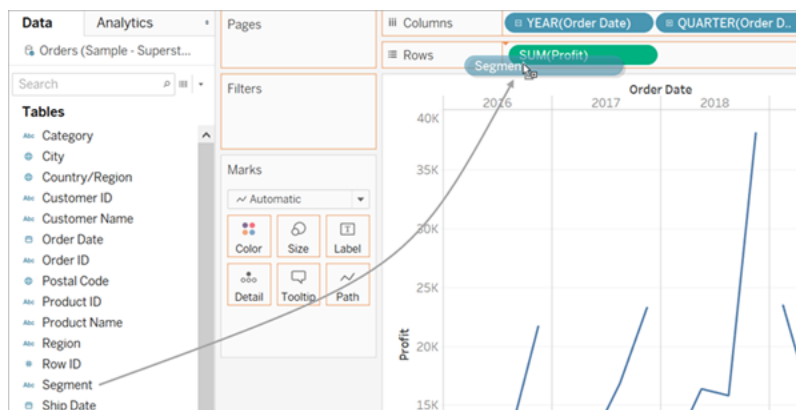

The new dimension divides the view into separate panes for each year. Each pane, in turn, has columns for quarters. This view is called a nested table because it displays multiple headers, with quarters nested within years. The word "headers" is a little misleading in this example because the year headers are displayed at the top of the chart, while the quarter headers are displayed at the bottom.

## Increase the level of detail with small multiples

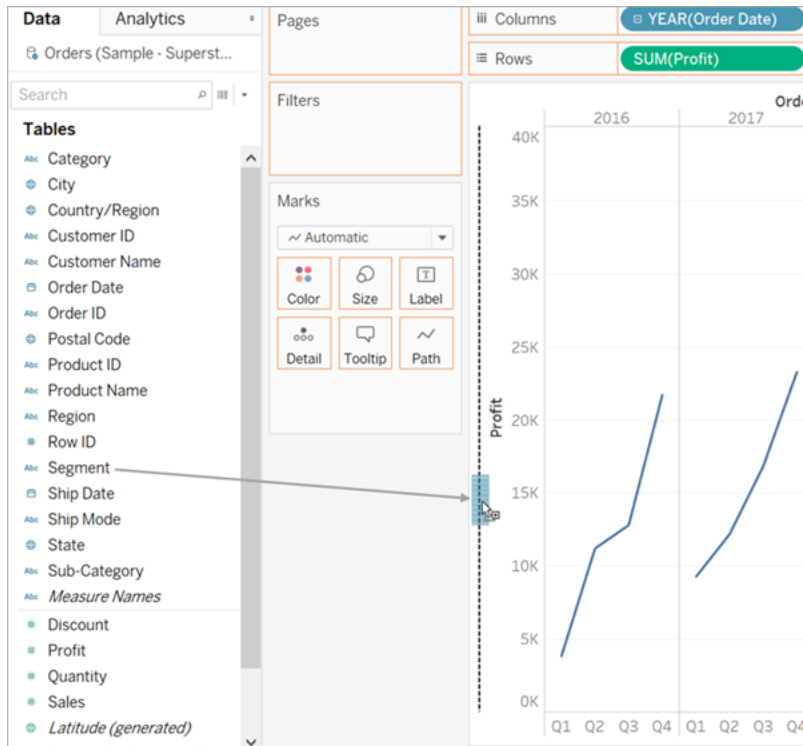

This step shows how you can modify the nested table view to add customer segment. It creates what we call a *small multiples* view.

Drag the **Segment** dimension from the **Data** pane, and then drop it just to the left of **SUM (Profit)** on Rows.

The field is added to the Rows shelf and row headers are created. Each header represents a member of the Segment field.

Optionally, you can achieve the same result by dropping **Segment** just to the left of the Profit axis in the view (shown in the image below). Tableau often supports multiple ways to add fields to the view.

**Note:** Tableau doesn't allow you to place a dimension to the right of a measure on either the Rows or Columns shelves because that visual structure doesn't make sense in the view.

The new dimension divides the view into 12 panes, one for each combination of year and segment. This view is a more complex example of a nested table. Any view that contains this sort of grid of individual charts is referred to as a small multiples view.

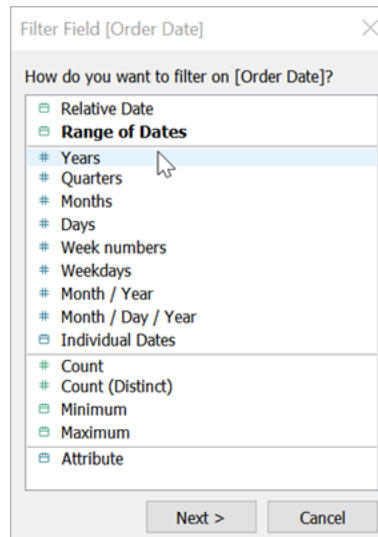

This could be the right amount of granularity for the view. Another option at this point would be to filter some of the data out of the view to simplify it.

## Filter the view to focus your exploration

This section shows how you can focus your exploration by only showing a subset of the data, such as modifying the view to show only data for orders in 2018 and 2019.

1. Drag the **Order Date** measure from the **Data** pane and drop it on the **Filters** shelf.

2. In the Filter Field dialog box, choose the date level you want to filter on—**Years**. Then click **Next**.
3. In the next pane, clear any two years that you do not want to include in the view.
4. When you are finished, click **OK**.

The view updates to only show data rows where Order Date is 2018 or 2019. Tableau can now allocate more space to the data that interests you.

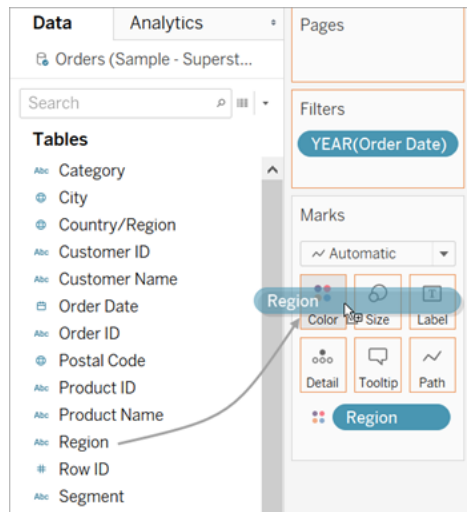

Next, you'll increase the detail in your data exploration by dragging a field to the Color property on the Marks card.

## Use the Marks card to add depth to your analysis

This step shows how you can modify the view to color the marks based on the region.

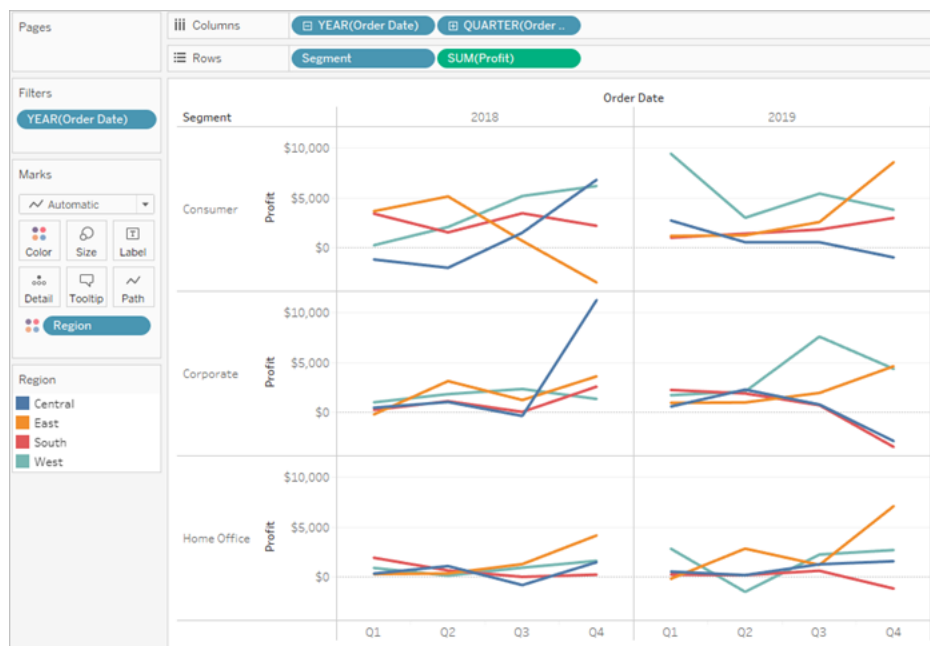

1. Drag the **Region** dimension from the **Data** pane and drop it on **Color**.

Placing a dimension on **Color** separates the marks according to the members in the dimension, and assigns a unique color to each member. The color legend displays each member name and its associated color.

Each pane now has four lines, one for each region. The viz is now showing profit data summarized the Region level of detail.

The view now shows profit for each customer segment and region for 2018 and 2019.

For more information on the Marks card and level of detail, see [Shelves and Cards Reference](#) on page 57, [Marks](#) on page 83, and [How dimensions affect](#)

[the level of detail in the view](#) on page 152. Also see [Understanding the grain in your data](#) from Tableau Tim.

## More resources

**Watch a video:** You can see many Tableau concepts and product features discussed and demonstrated on the [Tableau Tim website](#) and [YouTube channel](#).

# Tableau Desktop and Tableau Desktop Public Edition Feature Comparison

This guide provides an overview of the differences between Tableau Desktop and the free Tableau Desktop Public Edition.

**Tip:** Visit the Tableau Desktop [pricing page](#) to learn more about pricing options for Tableau Desktop

Both Tableau Desktop and Tableau Desktop Public Edition allow you to publish and showcase your visualizations on your Tableau Public profile. You can download from Tableau Public and reverse-engineer visualizations in the Desktop application.

## Who should use Tableau Desktop Public Edition?

**Important:** Tableau Desktop Public Edition is not for commercial use.

- Individuals seeking to learn how to use Tableau
- Individuals looking to tell data stories using public datasets by publishing to Tableau Public

- Organizations looking to broadcast public information or embed public visualization on their own sites

## Who should use Tableau Desktop?

Individuals or businesses that need to:

- Connect to Tableau Server or Tableau Cloud
- Connect to data sources that aren't supported by Tableau Public
- Analyze data with more than 15M rows
- Work with live data other than Google Sheets

## Comparison guide

Features and Capabilities	Tableau Desktop Public Edition (free)	Tableau Desktop
Privacy and security		
Save visualizations locally		
Autorecovery		
Unlimited storage		
Publish or embed visualizations on other public sites		
Download or copy published workbooks		
Publish visualizations to Tableau		

Public		
Infrastructure deployment	 (Infrastructure available at no cost)	Self-hosted on premise  (Role-based licenses)
Share visualizations to Tableau Cloud or Tableau Server		
Live data refresh	Limited data refresh (Google Sheets only. Data is refreshed automatically once every 24 hours)	
Data sources	Limited data source options (Google Sheets, JSON files, Microsoft Excel 2007 or later, OData, PDF, Spatial files, Statistical files, Text files, and more with Web Data Connector)	  (Can connect to all data sources)
Data source row limit	15M rows	Unlimited
Monitoring and metrics	Limited monitoring and metrics	

## Tour the Tableau Environment

This section provides information on Tableau pages and its workspace, including panes, shelves, icons, and other elements in Tableau Desktop.

- [The Tableau Workspace](#) on page 27
- [Start Page](#) on the next page
- [Data Source Page](#) on page 24

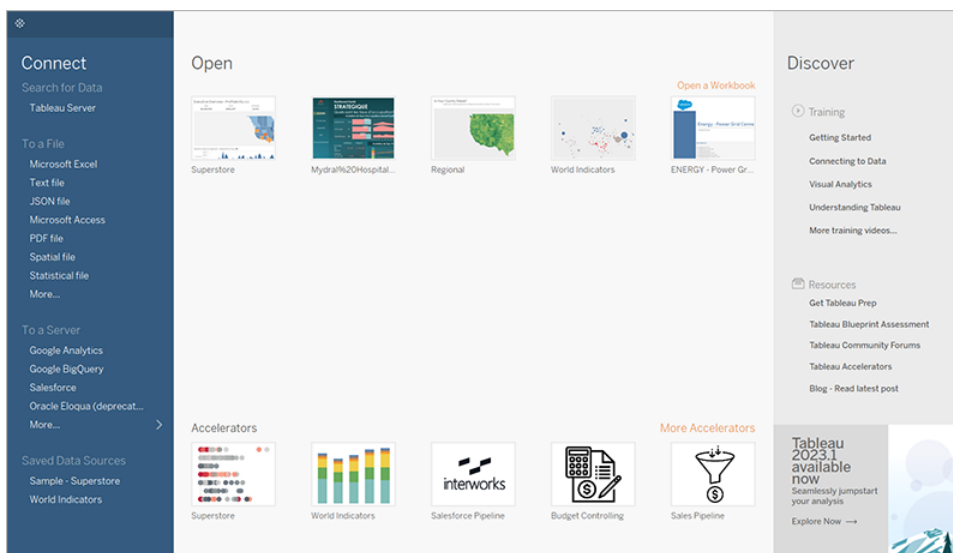

If you are using Tableau on the web, see [Creators: Get Started with Web Authoring](#) on page 3126 and [Tour Your Tableau Site](#) on page 3109.

## Start Page

The start page in Tableau Desktop is a central location from which you can do the following:

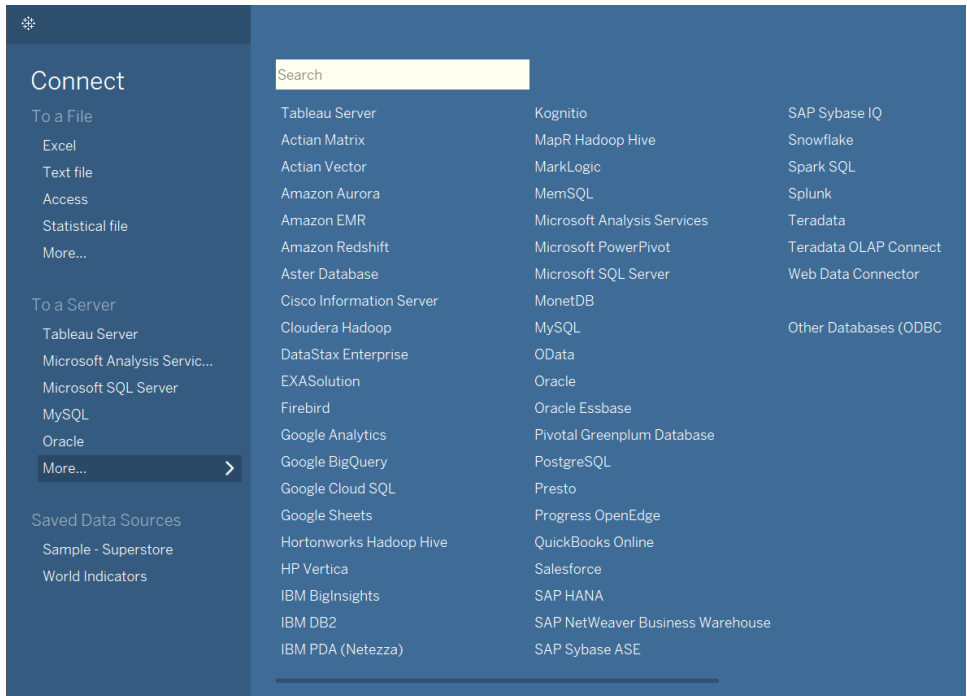

- Connect to your data
- Open your most recently used workbooks
- Discover and explore content produced by the Tableau community

The start page consists of three panes: **Connect**, **Open**, and **Discover**.

### Connect

Connect to data and open saved data sources.

On the **Connect** pane, you can do the following:

- **Connect to data:** Under **To a File**, connect to data stored in Microsoft Excel files, text files, Access files, Tableau extract files, and statistical files, such as SAS, SPSS, and R. Under **To a Server**, connect to data stored in databases like Microsoft SQL Server or Oracle. The server names listed in this section change based on which servers you connect to and how often.
- **Open saved data sources:** Quickly open data sources that you have previously saved to your My Tableau Repository directory. Also, Tableau provides sample saved data sources that you can use to explore Tableau Desktop functionality. To follow along with examples in the Tableau Desktop documentation, you'll usually use the **Sample – Superstore** data source.

## Open

Open recent workbooks, pin workbooks to the start page, and explore Accelerator and sample workbooks.

On the **Open** pane, you can do the following:

- **Open recently opened workbooks:** When you open Tableau Desktop for the first time, this pane is empty. As you create and save new workbooks, the most recently opened workbooks appear here. Click the workbook thumbnail to open a workbook, or if you don't see a workbook thumbnail, click the **Open a Workbook** link to find other workbooks that are saved to your computer.
- **Pin workbooks:** You can pin workbooks to the start page by clicking the pin icon that appears in the top-left corner of the workbook thumbnail. Pinned workbooks always appear on the start page, even if they weren't opened recently. To remove a recently opened or pinned workbook, hover over the workbook thumbnail, and then click the "x" that appears. The workbook thumbnail is removed immediately but will show again with your most recently used workbooks the next time you open Tableau Desktop.
- **Explore Accelerators:** Open and explore Accelerators and sample workbooks. The Superstore and World Indicators workbooks are samples that demonstrate what you can do with Tableau. The other three workbooks are Accelerators from the Tableau Exchange. Accelerators are pre-built dashboards targeted at different industries and applications that you can add your data to for quick analysis. **More Accelerators** shows all Accelerators from the Tableau Exchange. Prior to 2023.2, this section showed only sample workbooks.

## Discover

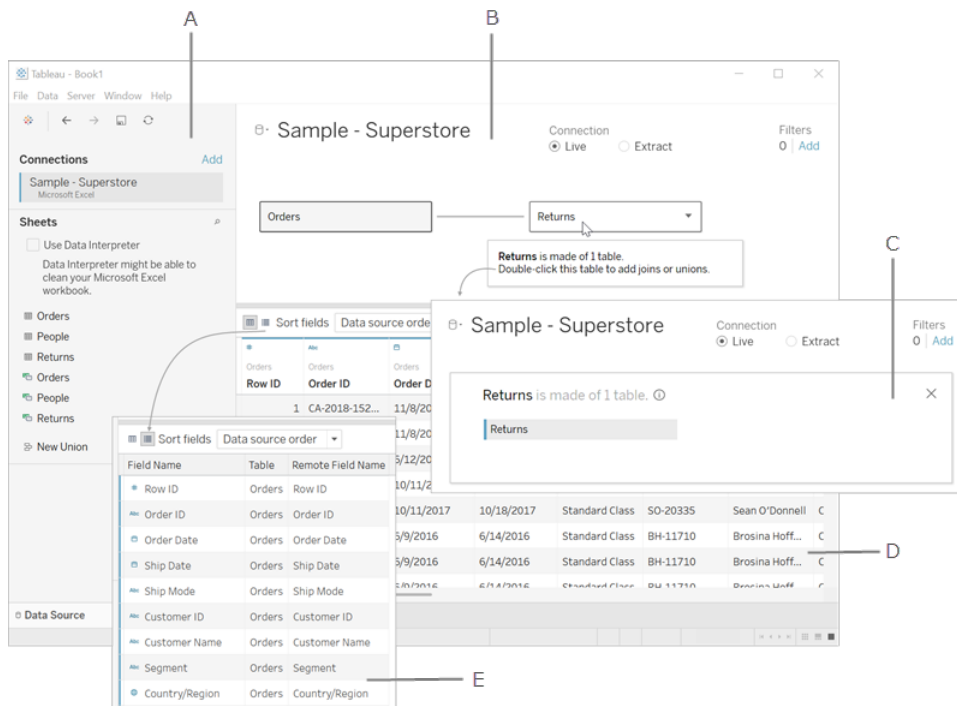

See popular views in Tableau Public, read blog posts and news about Tableau, and find training videos and tutorials to help you get started.

The screenshot displays the 'Discover' section of the Tableau help page. It features a 'Training' section with four video links: 'Getting Started', 'Connecting to Data', 'Visual Analytics', and 'Understanding Tableau', each preceded by a play button icon. Below these is a link for 'More training videos...'. The 'VIZ OF THE WEEK' section highlights a visualization titled 'Brexit on Social Media' with a right-pointing arrow. The visualization itself is a line chart with two data series, one blue and one yellow, showing fluctuating trends over time. Below the chart, there are links for a blog post 'If I Were New to Tableau Again: 3 Things No One Told Me', the 'Tableau Conference 2016', and 'Forums'.

## Data Source Page

During your analysis in Tableau, you have the flexibility to modify the data source. This can be done on the data source page, which Tableau directs you to after you establish the initial connection to your data. Additionally, you can access the data source page by selecting the **Data Source** tab from any location within the workbook.

The data source page generally consists of four main areas: left pane, canvas, data grid, and metadata grid.

**A. Left pane on the facing page:** Displays the connected data source and other details about your data.

**B. Canvas on the facing page:** logical layer - The canvas opens with the logical layer, where you can create relationships between logical tables.

**C. Canvas on the facing page:** physical layer - Double-click a table in the logical layer to go to the physical layer of the canvas, where you can add joins and unions between tables.

**D. Data grid on page 26:** Displays the first 1,000 rows of the data contained in the Tableau data source.

**E. Metadata grid on page 27:** Displays the fields in your data source as rows.

---

## Left pane

The left pane of the data source page displays details about your data. The data that Tableau Desktop is connected to. You can also use the left pane to add more connections to the data source to create cross-database joins.

- For file-based data, the left pane displays the file name and the worksheets in the file.
- For relational-based data, the left pane displays the server, the database, or schema, and the tables in the database.

**Note:** The left pane doesn't display for cube (multidimensional) data.

## Canvas

When connecting to relational and file-based data sources in Tableau, you can drag tables onto the canvas area to begin setting up your data source. The canvas is divided into two layers: a logical layer and a physical layer. By default, the logical layer is displayed, showcasing the relationships between logical tables. To switch to the physical layer, double-click on a logical table in the logical view and start creating joins and unions between tables in the physical layer.

When working with cube data sources, the top section of the data source page will show the available catalogs, queries, and cubes that you can select from to configure your Tableau data source. This allows you to easily connect to and analyze data from cube sources within Tableau.

**Note:** Based on the type of data you are linked to, you have the ability to update your data whenever changes occur by utilizing various options. For instance, if you are connected to a data extract, you can refresh a specific extract by selecting the **Refresh** button located next to the Connection area on the left side of the pane. For more information about refresh options see [Refresh Data Sources on page 915](#). For more information about refreshing data extracts, see [Refresh Extracts on page 886](#).

## Refreshing your data source

Depending on the type of data you're connected to you can refresh your data when that data has changed using a number of options.

## Data grid

To analyze the fields and the first rows of data within the Tableau data source, utilize the data grid. The data grid allows for various modifications to be made to the Tableau data source, such as sorting or hiding fields, renaming fields, creating calculations, adjusting column or row sorting, and adding aliases. When working in the logical layer, you can view the data specific to the selected table.

The physical layer displays merged data resulting from joins and unions. For Web Data Connector, file- and relational-based data sources in Extract mode, the grid provides access to extract data, including extract only calculations.

- When you're in the logical layer, you see the data for the selected table.
- In the physical layer, you see the merged data based on the joins and unions.

### Select fields

To select multiple fields in the grid, select a column, and then drag the mouse to select more columns.

To select all fields, click the area in the upper-left corner of the grid like in the following example.

The diagram illustrates the process of selecting all fields in a data grid. It shows two instances of a data grid. In the first grid, the upper-left corner of the header area is highlighted with a red box. A curved arrow points from this box to a second grid, where a dashed line indicates that all fields in the grid have been selected.

#	Abc	
Orders	Orders	Orders
Row ID	Order ID	Order Date
1	CA-2013-152156	11/9/2013
2	CA-2013-152156	11/9/2013
3	CA-2013-138688	6/13/2013

**Note:** The grid isn't displayed for cube (multidimensional) data.

## Metadata grid

The metadata grid will show the fields in your data source as rows, allowing you to analyze the structure of your Tableau data source and carry out regular management tasks like renaming fields or hiding multiple fields. When connected to cube or some extract only data, the metadata grid displays by default.

## The Tableau Workspace

The Tableau workspace consists of menus, a toolbar, the Data pane, cards and shelves, and one or more sheets. Sheets can be worksheets, dashboards, or stories. For details on dashboard or story workspaces, see [Create a Dashboard](#) on page 2633 or [The Story Workspace](#) on page 2763.

If you are using Tableau on the web, see [Creators: Get Started with Web Authoring](#) on page 3126 and [Tour Your Tableau Site](#) on page 3109.

## Workspace area

- A.** Workbook name. A workbook contains sheets. A sheet can be a worksheet, a dashboard, or a story. For more information, see [Workbooks and Sheets on page 95](#).
- B.** **Cards and shelves** - Drag fields to the cards and shelves in the workspace to add data to your view.
- C.** **Toolbar** - Use the toolbar to access commands and analysis and navigation tools.
- D.** **View** - This is the canvas in the workspace where you create a visualization (also referred to as a "viz").
- E.** Click this icon to go to the Start page, where you can connect to data. For more information, see [Start Page on page 20](#).
- F.** **Side Bar** - In a worksheet, the side bar area contains the **Data pane** and the **Analytics pane**.
- G.** Click this tab to go to the Data Source page and view your data. For more information, see [Data Source Page on page 24](#).
- H.** **Status bar** - Displays information about the current view.
- I.** Sheet tabs - Tabs represent each sheet in your workbook. This can include worksheets, dashboards, and stories. For more information, see [Workbooks and Sheets on page 95](#).

## Tableau Toolbar Button Reference

When you are creating or editing a view, you can use the toolbar at the top of the view to perform common actions.

In Tableau Desktop, you can hide or display the Tableau toolbar by selecting **Window > Show Toolbar**.

The table below explains the functions of each toolbar button. Some buttons are not available in all Tableau products. Also see [Visual Cues and Icons in Tableau Desktop on page 111](#).

Toolbar Button	Description
	<p><b>Tableau icon:</b> Navigates to the start page. For more information, see <a href="#">Start Page on page 20</a>.</p> <p><b>Note:</b> Tableau Desktop only.</p>

Toolbar Button	Description
	<p><b>Undo:</b> Reverses the most recent action in the workbook. You can undo an unlimited number of times, back to the last time you opened the workbook, even after you have saved. For more information, see <a href="#">Undo and Redo on page 2607</a>.</p>
	<p><b>Redo:</b> Repeats the last action you reversed with the <b>Undo</b> button. You can redo an unlimited number of times.</p>
	<p><b>Save:</b> In Tableau Desktop, saves the changes made to the workbook. For more information, see <a href="#">Save Your Work on page 3013</a>.</p> <p>In Tableau Server or Tableau Cloud, click <b>File &gt; Save</b> or <b>File &gt; Save As</b> to save your changes.</p>
	<p><b>New Data Source:</b> In Tableau Desktop, opens the <b>Connect</b> pane where you can create a new connection or open a saved connection. For more information, see <a href="#">Connect to Your Data on page 233</a>.</p> <p>In Tableau Server or Tableau Cloud, opens the <b>Connect to a Data Source</b> page, where you can connect to a published data source. For more information, see <a href="#">Connect to published data sources while web authoring on page 289</a>.</p>
	<p><b>Pause Auto Updates:</b> Controls whether Tableau updates the view when changes are made. Use the drop-down menu to automatically update the entire sheet or just use filters. For more information, see <a href="#">Refresh Data or Pause Automatic Updates on page 3249</a>.</p>
	<p><b>Run Update:</b> Runs a manual query of the data to update the view with changes when automatic updates are turned off. Use the drop-down menu to update the entire worksheet or just use filters.</p> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>Note:</b> Tableau Desktop only.</p> </div>
	<p><b>New Worksheet:</b> Creates a new blank worksheet, use the drop-down menu to create a new worksheet, dashboard, or story.</p> <p>For more information, see <a href="#">Create new worksheets, dashboards, or</a></p>

Toolbar Button	Description
	<a href="#">stories</a> on page 96.
	<b>Duplicate:</b> Creates a new worksheet containing the same view as the current sheet. For more information, see <a href="#">Duplicate a sheet on page 98</a> .
	<b>Clear:</b> Clears the current worksheet. Use the drop-down menu to clear specific parts of the view such as filters, formatting, sizing, and axis ranges.
	<b>Swap:</b> Moves the fields on the <b>Rows</b> shelf to the <b>Columns</b> shelf and vice versa. The <b>Hide Empty Rows</b> and <b>Hide Empty Columns</b> settings are always swapped with this button.
	<b>Sort Ascending:</b> Applies a sort in ascending order of a selected field based on the measures in the view. For more information, see <a href="#">Sort Data in a Visualization on page 1289</a> .
	<b>Sort Descending:</b> Applies a sort in descending order of a selected field based on the measures in the view. For more information, see <a href="#">Sort Data in a Visualization on page 1289</a> .
	<p><b>Totals:</b> You can compute grand totals and subtotals for the data in a view. Select from the following options:</p> <ul style="list-style-type: none"> <li>• <b>Show Column Grand Totals:</b> Adds a row showing totals for all columns in the view.</li> <li>• <b>Show Row Grand Totals:</b> Adds a column showing totals for all rows in the view.</li> <li>• <b>Row Totals to Left:</b> Moves rows showing totals to the left of a crosstab or view.</li> <li>• <b>Column Totals to Top:</b> Moves columns showing totals to the top of a crosstab or view.</li> <li>• <b>Add All Subtotals:</b> Inserts subtotal rows and columns in the view, if you have multiple dimensions in a column or row.</li> <li>• <b>Remove All Subtotals:</b> Removes subtotal rows or columns.</li> </ul>

Toolbar Button	Description
	<p><b>Note:</b> Tableau Server and Tableau Cloud only. In Tableau Desktop, click <b>Analysis &gt; Totals</b>. For more information, see <a href="#">Show Totals in a Visualization on page 1298</a>.</p>
	<p><b>Highlight:</b> Turn on highlighting for the selected sheet. Use the options on the drop-down menu to define how values are highlighted. For more information, see <a href="#">Highlight Toolbar Button on page 1343</a>.</p>
	<p><b>Group Members:</b> Creates a group by combining selected values. When multiple dimensions are selected, use the drop-down menu to specify whether to group on a specific dimension or across all dimensions. For more information, see <a href="#">Correct Data Errors or Combine Dimension Members by Grouping Your Data on page 1038</a>.</p> <p><b>Note:</b> Tableau Desktop only. In Tableau Server and Tableau Cloud, create groups using the <b>Group Members</b> button on the tooltip.</p>
	<p><b>Show Mark Labels:</b> Switches between showing and hiding mark labels for the current sheet. For more information, see <a href="#">Show, Hide, and Format Mark Labels on page 1228</a>.</p>
	<p><b>Fix Axes:</b> switches between a locked axis that only shows a specific range and a dynamic axis that adjusts the range based on the minimum and maximum values in the view. For more information, see <a href="#">Edit Axes on page 2886</a>.</p> <p><b>Note:</b> Tableau Desktop only.</p>
	<p><b>Format Workbook:</b> Open the <b>Format Workbook</b> pane to change how fonts and titles look in every view in a workbook by specifying format settings at the workbook level instead of at the worksheet level.</p>

Toolbar Button	Description
	<p><b>Note:</b> Tableau Server and Tableau Cloud only. In Tableau Desktop, click <b>Format &gt; Workbook</b>. For more information, see <a href="#">Format at the Workbook Level on page 2859</a>.</p>
	<p><b>Fit:</b> Specifies how the view should be sized within the window. Select Standard, Fit Width, Fit Height, or Entire View. <b>Note:</b> This menu is not available in geographic map views.</p> <p>The <b>Cell Size</b> commands have different effects depending on the type of visualization. To access the <b>Cell Size</b> menu in Tableau Desktop click <b>Format &gt; Cell Size</b>.</p>
	<p><b>Show/Hide Cards:</b> Shows and hides specific cards in a worksheet. Select each card that you want to hide or show on the drop-down menu.</p> <p>In Tableau Server and Tableau Cloud, you can show and hide cards for the <b>Title</b>, <b>Caption</b>, <b>Filter</b> and <b>Highlighter</b> only.</p>
	<p><b>Presentation Mode:</b> Switches between showing and hiding everything except the view (i.e., shelves, toolbar, <b>Data</b> pane). For more information, see <a href="#">Reorganizing the Workspace on page 105</a>.</p> <p><b>Note:</b> Tableau Desktop only.</p>
	<p><b>Download:</b> Use the options under <b>Download</b> to capture parts of your view for use in other applications.</p> <ul style="list-style-type: none"> <li>• <b>Image:</b> Displays the view, dashboard, or story as an image in a new browser tab.</li> <li>• <b>Data:</b> Displays the data from the view in a new browser window with two tabs: <b>Summary</b>, showing aggregated data for the fields shown in the view, and <b>Underlying</b>, showing underlying data for the selected marks in the visualization. If the new window does not open, you may need to disable your browser's popup blocker.</li> <li>• <b>Crosstab:</b> Saves the underlying data for the selected marks in the visualization to a CSV (comma-separated values) file which can</li> </ul>

Toolbar Button	Description
	<p>then be opened in Microsoft Excel.</p> <ul style="list-style-type: none"> <li>• <b>PDF:</b> Opens the current view as a PDF in a new browser window. From there you can save it to a file. If the new window does not open, you may need to disable your browser's pop-up blocker.</li> </ul> <p><b>Note:</b> Tableau Server and Tableau Cloud only.</p>
	<p><b>Share Workbook With Others:</b> Publish your workbook to Tableau Server or Tableau Cloud. For more information, see <a href="#">Simple Steps to Publish a Workbook</a> on page 3052.</p> <p><b>Note:</b> Tableau Desktop only.</p>
	<p><b>Show Me:</b> Helps you choose a view type by highlighting view types that work best with the field types in your data. An orange outline shows around the recommended chart type that is the best match for your data. For more information, see <a href="#">Use Show Me to Start a View</a> on page 1173.</p>

[Back to top](#)

## Show and Hide the Side Bar (Data pane)

The Side Bar contains the **Data** pane and the **Analytics** pane when you are editing a worksheet. Different panes are visible depending on what you are doing in the view (Data, Analytics, Story, Dashboard, Layout, Format). The most important thing to know about the Side Bar is that you can expand and collapse this area in the workspace.

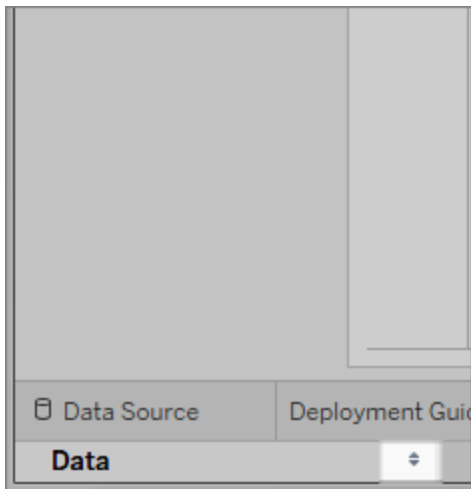

**To hide the side bar in Tableau Desktop,** click the collapse arrow in the side bar.

**To hide the side bar on the web,** click the collapse arrow in the side bar.

**To show the side bar on Tableau Desktop**, click the expand arrow in the bottom-left of the workspace (in the status bar).

**To show the side bar on the web**, click the expand arrow in the side bar.

[Back to top](#)

---

## Status Bar Information

The status bar is located at the bottom of the Tableau workspace. It displays descriptions of menu items as well as information about the current view. For example, the status bar below shows that the view has 143 marks shown in 3 rows and 12 columns. It also shows that the SUM (Sales) for all the marks in the view is \$2,297,201.

You can hide the status bar by selecting **Window > Show Status Bar**.

Occasionally, Tableau will display warning icons in the bottom right corner of the status bar to indicate errors or warnings. Below are the possible warning icons and what they mean.

Warning Icon	Description
	<p><b>Cancel query indicator:</b> When you cancel multiple queries, an indicator appears to show you how many queries are still running on the database and using resources.</p> <p>When you cancel a query in Tableau, the database is told to stop processing the query. However, some databases do not support cancel (MS Excel, MS Access, Essbase, Microsoft Analysis Services 2000). If you cancel a query using one of these types of data sources, the query is abandoned by Tableau but is still running in the background and using resources. When you have abandoned queries, an indicator appears in the bottom right corner of the workbook showing the number of queries still running . As queries in the background complete, the number will go down. It is important to monitor the number of queries running and not let the number get too high, otherwise you will see performance degradation of both Tableau and the underlying database.</p> <p><b>Note:</b> Text, Microsoft Excel, and Microsoft Access data sources may be temporarily unavailable after canceling a query because of a lock performed internally. You may have to wait until the abandoned query has completed before re-connecting.</p>
	<p><b>Precision warning:</b> Some fields are more precise in the database than Tableau can model. When you add a field to a view that contains values with more precision than Tableau can model, a warning icon  is displayed in the bottom right corner of the status bar.</p> <p>For example, a value in the database may have 22 decimal places but Tableau only supports up to 15. When you add that field to the view, you get a precision warning. If you click on the warning, you can read more details including the number of decimal places that have been truncated in the view.</p> <p>Remember that the precision of the data displayed in Tableau will always first be dependent on the data in your database. If the values in your database exceed 15 decimal places, when you add them to the view, the</p>

Warning Icon	Description
	<p>value is truncated and a precision warning appears.</p> <p><b>Note:</b> Extracts of relational databases always use the Hyper double precision type, and never use the Hyper numeric type. So if you create an extract of a relational database, you only get 15 digits of precision. You can write to the Hyper API and use the numeric type to get up to 18 digits. For related information, see <a href="#">Numeric Types</a> in Hyper API documentation.</p>
	<p><b>Special values indicator:</b> If your data contains null values, unknown geographic locations, or negative or zero values on a logarithmic axis; the values are shown with an indicator in the lower right corner of the view. Click the indicator for options for handling these values. See <a href="#">Handling Null and Other Special Values</a> on page 1167 to learn more about this indicator and how to handle these values.</p>

[Back to top](#)

## Work with Data Fields in the Data Pane

Tableau displays data source connections and data fields for the workbook in the **Data** pane on the left side of the workspace.

**Note:** For details on how to start creating visualizations, see [Get Started](#) on page 3. For details on the many ways you can customize the fields in the Data pane, see [Organize and Customize Fields in the Data Pane](#) on page 999 and [Edit Default Settings for Fields](#) on page 1011.

### Areas of the Data pane

After you connect to your data and set up the data source with Tableau, the data source connections and fields appear on the left side of the workbook in the Data pane. For details on connecting to data, see [Connect to and Prepare Data](#) on page 233.

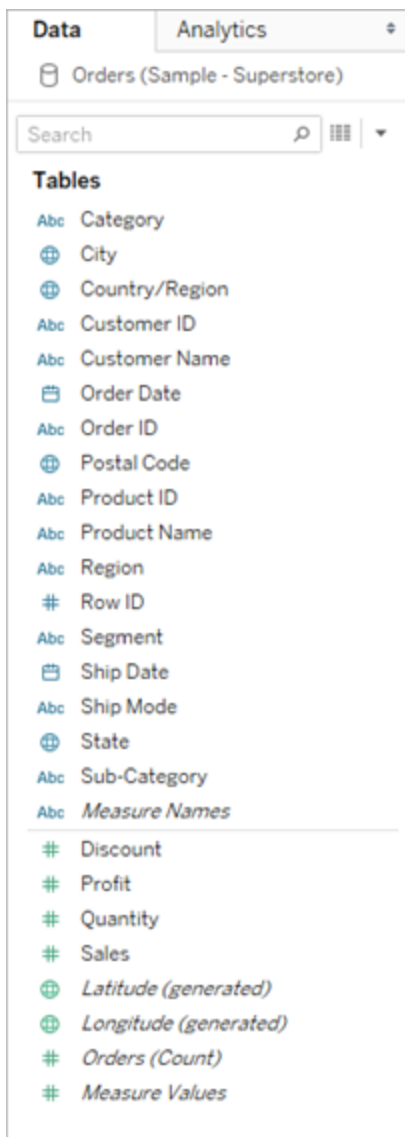

Current data source connections appear at the top of the **Data** pane. When you have more than one connection available, click a connection to select it and start working with that data.

You build visualizations by adding fields from the Data pane to the view. For details, see [Start Building a Visualization by Dragging Fields to the View](#) on page 1135.

Fields can be organized by table (**Group by Data Source Table**) or folder (**Group by Folder**). Dimensions are displayed above the gray line, and measures below the gray line for each table or folder. In some cases, a table or folder might contain only dimensions, or only measures to start with.

- Calculated fields are listed with their originating field, if all of their input fields come from the same table.
- Sets are listed with the table with their originating field.
- Parameters are global to the workbook and are displayed in the Parameters area.
- Fields that don't belong to a specific table are displayed in the general area below the tables. These include: aggregated calculations, calculations that use fields from multiple tables, Measure Names, and Measure Values.

Below the data source connections in the **Data** pane are the fields that are available in the currently selected data source. You can toggle between the **Data** and **Analytics** panes in a worksheet. For details on the Analytics pane, see [Apply Advanced Analysis to a View \(Analytics Pane\)](#) on page 48.

Fields from a single-table data source in the Data pane

The Data pane includes:

- **Dimension fields** – Fields that contain qualitative values (such as names, dates, or geographical data). You can use dimensions to categorize, segment, and reveal the details in your data. Dimensions affect the level of detail in the view. Examples of dimensions include dates, customer names, and customer segments.
- **Measure fields** – Fields that contain numeric, quantitative values can be measured. You can apply calculations to them and aggregate them. When you drag a measure into the view, Tableau applies an aggregation to that measure (by default). Examples of measures: sales, profit, number of employees, temperature, frequency.

- **Calculated fields** – If your underlying data doesn't include all of the fields you need to answer your questions, you can create new fields in Tableau using calculations and then save them as part of your data source. These fields are called calculated fields.
- **Sets** – Subsets of data that you define. Sets are custom fields based on existing dimensions and criteria that you specify. For more information, see [Create Sets on page 1040](#).

Named sets from an MS Analysis Services server or from a Teradata OLAP connector also appear in Tableau in this area of the Data pane. You can interact with these named sets in the same way you interact with other custom sets in Tableau.

- **Parameters** – Values that can be used as placeholders in formulas, or replace constant values in calculated fields and filters. For more information, see [Create Parameters on page 1070](#).

**Note:** For cube data sources, fields are explicitly defined as dimensions or measures when the database is created. For relational data sources, Tableau automatically organizes the fields. By default, fields containing text, date or boolean values are dimensions, while fields containing numerical values are measures.

By default the field names defined in the data source are displayed in the Data pane. You can rename fields and member names, create hierarchies, and organize the fields into groups and folders. For details, see [Edit Default Settings for Fields on page 1011](#), [Organize and Customize Fields in the Data Pane on page 999](#), and [Create Hierarchies on page 1024](#)

### Columns become measure and dimension fields in the view

Data sources contain fields. For relational data sources that you connect to, the fields are determined by the columns of a table or view. Each field contains a unique attribute of the data such as customer name, sales total, product type, and so on.

For cube (multidimensional) data sources, the fields are determined by the dimensions and measures of a cube. In Tableau, cube data sources are supported only in Windows.

Here's an example of fields from an Excel worksheet.

	A	B	C	D	E	F	G	H
1	Row ID	Order ID	Order Date	Ship Date	Ship Mode	Customer ID	Customer Na	Segment
2	1	CA-2013-152156	11/9/2014	11/12/2014	Second Class	CG-12520	Claire Gute	Consumer
3	2	CA-2013-152156	11/9/2014	11/12/2014	Second Class	CG-12520	Claire Gute	Consumer
4	3	CA-2013-138688	6/13/2014	6/17/2014	Second Class	DV-13045	Darrin Van H	Corporate
5	4	US-2012-108966	10/11/2013	10/18/2013	Standard Cla	SO-20335	Sean O'Donn	Consumer
6	5	US-2012-108966	10/11/2013	10/18/2013	Standard Cla	SO-20335	Sean O'Donn	Consumer
7	6	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
8	7	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
9	8	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
10	9	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
11	10	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
12	11	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
13	12	CA-2011-115812	6/9/2012	6/14/2012	Standard Cla	BH-11710	Brosina Hoffr	Consumer
14	13	CA-2014-114412	4/16/2015	4/21/2015	Standard Cla	AA-10480	Andrew Allen	Consumer
15	14	CA-2013-161389	12/6/2014	12/11/2014	Standard Cla	IM-15070	Irene Maddo	Consumer
16	15	US-2012-118983	11/22/2013	11/26/2013	Standard Cla	HP-14815	Harold Pawla	Home Office
17	16	US-2012-118983	11/22/2013	11/26/2013	Standard Cla	HP-14815	Harold Pawla	Home Office
18	17	CA-2011-105893	11/11/2012	11/18/2012	Standard Cla	PK-19075	Pete Kriz	Consumer
19	18	CA-2011-167164	5/13/2012	5/15/2012	Second Class	AG-10270	Alejandro Grc	Consumer
20	19	CA-2011-143336	8/27/2012	9/1/2012	Second Class	ZD-21925	Zuschuss Doi	Consumer
21	20	CA-2011-143336	8/27/2012	9/1/2012	Second Class	ZD-21925	Zuschuss Doi	Consumer
22	21	CA-2011-143336	8/27/2012	9/1/2012	Second Class	ZD-21925	Zuschuss Doi	Consumer

When you start building a visualization in a worksheet, these columns are available as fields in the Data pane. For details, see [Areas of the Data pane on page 37](#).

Each field has a data type (that you can change if needed), and a role: discrete dimension, continuous dimension, discrete measure, or continuous measure. For details, see [Data Types on page 158](#) and [Dimensions and Measures, Blue and Green on page 148](#).

Each field also includes some default settings, such as a default aggregation of SUM or AVG, depending on the structure of the current view. For details, see [Edit Default Settings for Fields on page 1011](#) and [Data Aggregation in Tableau on page 173](#).

### Fields that Tableau automatically creates

The Data pane can also contain a number of fields that do not come from your original data: Measure Names and Measure Values, Number of Records, Latitude and Longitude.

#### Measure Names and Measure Values

- The **Measure Values** field contains all the measures in your data, collected into a single field with continuous values. Drag individual measure fields out of the Measure Values card to remove them from the view.
- The **Measure Names** field contains the names of all measures in your data, collected into a single field with discrete values.

For more details about how to use Measure Values and Measure Names in visualizations, see [Measure Values and Measure Names](#) on page 1160.

## Count of Table

Starting with Tableau 2020.2, every table in a data source has a **Count** field, in the form of *NameofTable*(Count). The table count field is an automatically generated, calculated field.

COUNT of table = SUM of the number of records per table

To see the count for a table, drag its Count field into the view. To see the count for all tables, select the Count field for each table in the Data pane, and then click the Text Table in Show Me.

You can't build calculations on top of a table's Count field, and it is aggregate-only.

## Number of Records (before version 2020.2)

You might see a Number of Records field if it is being used in a visualization from a previous version of Tableau.

In versions of Tableau before 2020.2, the **Number of Records** field is an automatically generated, calculated field that is set to the number 1. That number gets associated with each row in the data source. If you add the Number of Records field to the view, you will see the summed count of all the rows in a data source (the number of records). You can use the Number of Records field to get quick counts of various dimensions' values. Viewing the Number of Records can help you to see if your data joins are working the way you expect them to.

## Latitude and Longitude (generated)

When Tableau interprets fields to be geographic fields that can be used with maps, it automatically geocodes the data and includes **Latitude (generated)** and **Longitude (generated)** fields. You can use these fields to overlay your data on live maps. For more information on how to use these fields, and best practices for building maps in Tableau, see [Maps and Geographic Data Analysis in Tableau](#) on page 1593 [Assign Geographic Roles](#) on page 1669, [Location Data that Tableau Supports for Building Map Views](#) on page 1633,

## Perform common tasks in the Data pane

**To select a data source connection for analysis**, click the data source connection name in the Data pane. For more details, see [Navigating Data Sources in the Data Pane](#) on page 45.

To view a context menu for the data source, click **Data** in the top menu and then click on the data source in the menu list. For more information, see [Edit Data Sources on page 904](#).

To search for fields in the **Data** pane, click the magnifying glass icon and then type in the text box.

To see the underlying data, click the **View Data** icon at the top of the **Data** pane.

For more information, see [View Underlying Data on page 2610](#)

View Data: Sample - Superstore

In cases where Tableau has misclassified a field as a dimension or a measure, possibly because of the data type, you can convert it and change its role.

**To convert a measure to a dimension**, drag the measure and drop it into the **Dimensions** area in the **Data** pane. For more details, see [Convert a Measure to a Dimension on page 1019](#).

## Change data fields to fit your needs

When you drag a field into the view, it will have certain default settings and characteristics. You can customize a field that is already in the view, just for that instance of the field. Or you can change its settings in the Data pane to make the field use those settings going forward.

You can control the definition of a field in the view, depending on how you want to work with that field data.

**Note:** To change the default settings for a field before you drag it into the view, right-click it (Control-click on a Mac). You can then edit its settings and default properties from its context menu.

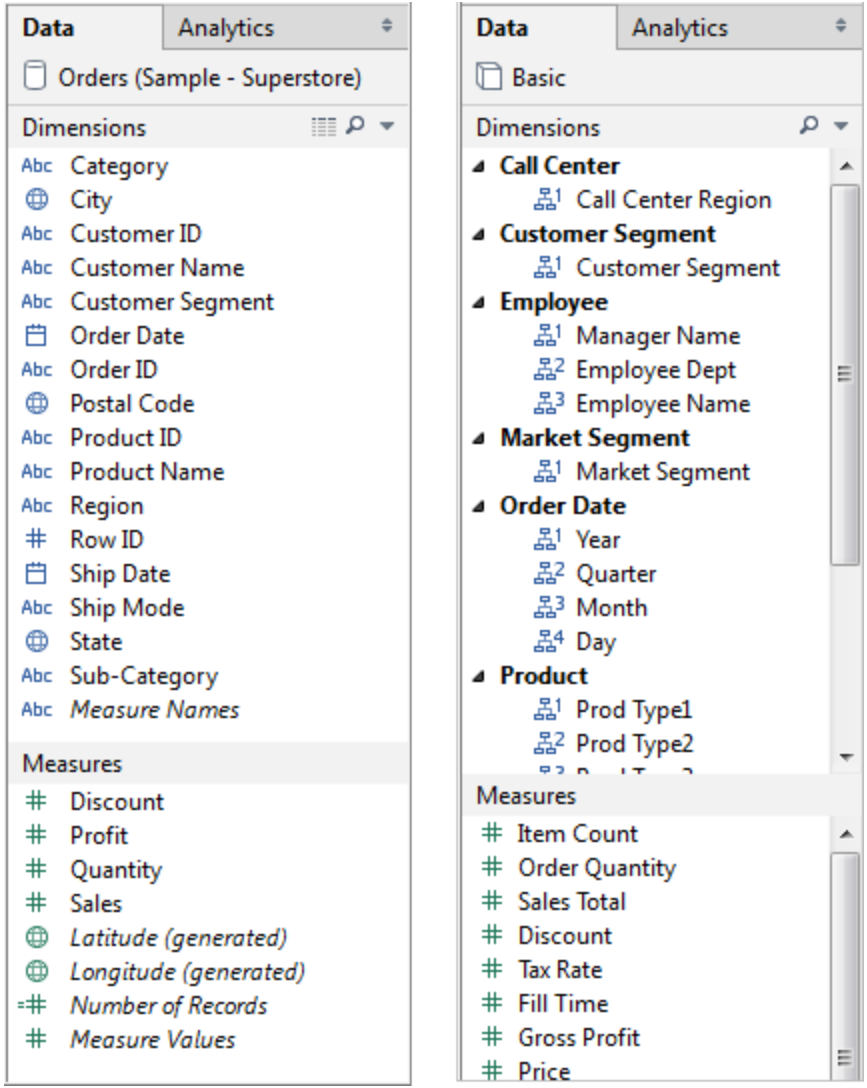

For details on the many ways you can customize the fields in the Data pane, see [Organize and Customize Fields in the Data Pane on page 999](#) and [Edit Default Settings for Fields on page 1011](#).

## Relational versus cube data

The Data pane for a relational and cube data source are shown below. Note that the panes look essentially the same for both data sources in that the fields are organized into dimensions and measures. However, the cube data source contains hierarchies for dimensions. For example, notice that the Employee dimension in the cube Data pane contains hierarchical members such as Manager Name and Employee Dept.

Relational data sources don't have built-in hierarchies. However, relational data sources often have related dimensions that have an inherent hierarchy. For example, a data source may have fields for Country, State, and City. These fields could be grouped into a hierarchy called Location. You can assemble relational hierarchies by dragging and dropping in the Data pane. For details, see [Create Hierarchies on page 1024](#).

**Note:** In Tableau, cube (multidimensional) data sources are supported only in Windows.

*Data pane with relational data (left image) versus cube data (right image)*

You can expand or collapse hierarchies in both relational and cube Data panes by clicking the arrow. You can hide the Data pane all together by clicking the minimize button  in the upper-right corner of the Data pane.

For information on cube data sources, see [Cube Data Sources](#) on page 929.

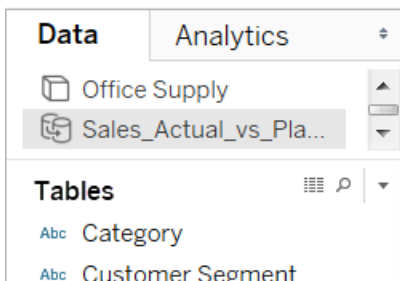

### Navigating Data Sources in the Data Pane

The top of the Data pane lists all of the data sources in a given workbook. Click the data source you want to use to select it. The Data pane updates to show the corresponding fields in that data source.

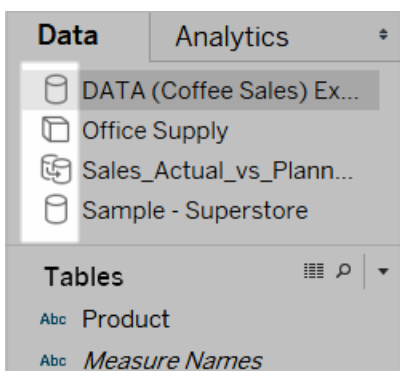

Note: images in this topic have not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

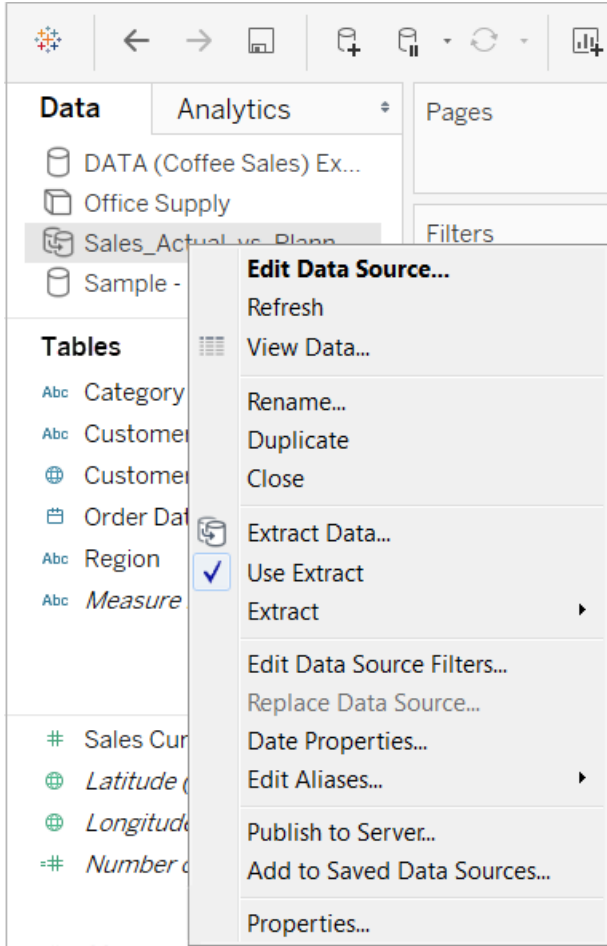

You can resize the data source list area in the Data pane to save space. When you resize to a limited vertical height, you can scroll down to a data source.

Each data source has an icon to indicate its type. For example, the icon can indicate whether the data source is relational, cube (multidimensional), or an extract. In Tableau, cube data sources are supported only in Windows.

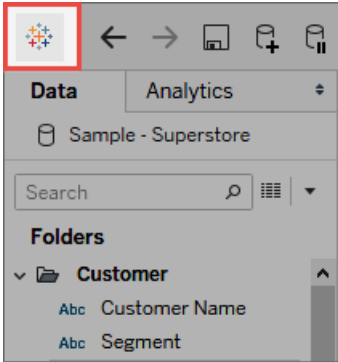

You can right-click (control-click on a Mac) the data source to access the commands that are on the Data menu. For example, you can right-click (control-click on a Mac) a data source and rename, export, or close it.

For details on the many ways you can customize and work with the fields in the Data pane, see [Organize and Customize Fields in the Data Pane](#) on page 999, [Edit Default Settings for Fields](#) on page 1011, and [Work with Data Fields in the Data Pane](#) on page 37.

## Navigate Between the Start Page and Workspace

When Tableau Desktop is already open, you can navigate to the start page by clicking the Tableau icon in the upper-left corner of the Tableau Desktop workspace.

To go back to the Tableau workspace, click the Tableau icon in the start page.

### Apply Advanced Analysis to a View (Analytics Pane)

Drag reference lines, box plots, trend lines forecasts, and other items into your view from the **Analytics** pane, which appears on the left side of the workspace. Toggle between the **Data** pane and the **Analytics** pane by clicking the tabs at the top of the side bar.

### *Tableau Desktop Analytics pane*

In Tableau Desktop, options for adding Analytics objects to the view are available the **Analytics** pane or menu, or in context in the view. For example, reference lines and bands are available when you edit an axis, and trend lines and forecasts are available from the Analysis menu.

The **Analytics** pane provides drag-and-drop access for the various options.

On the web, most Analytics objects are available from the Analytics pane.

### Add an analytics object to the view

To add an item from the **Analytics** pane, drag it into the view. When you drag an item from the **Analytics** pane, Tableau shows the possible destinations for that item. The range of choices varies depending on the type of item and the current view.

In a simple case, the drop target area would offer these three options:

The terms **Table**, **Pane** and **Cell** define the scope for the item:

Adds a reference line to the entire table across all panes.

Adds a reference line on a per pane basis. Computed reference lines are recalculated for each pane in the view.

Adds a reference line within each cell. Computed reference lines are recalculated for each cell in the view.

For a more complicated view—for example, if the view contained a line chart with multiple or dual axes—Tableau would show you a drop target area that looked like this:

If you dropped the item in one of the three larger boxes in the header at the top of the drop target area--for example, the Table box--a separate median with quartiles would be added for each axis:

But if you drop the item in any of the six lower boxes aligned with a specific measure, the median with quartiles would only be added on the corresponding axis, with the specified scope.

### Delete an analytics object from the view

You can delete an analytics object from the view by clicking Undo, or drag the object off the view to delete it.

You can also click on an item and choose **Remove** from the tooltip.

**Note:** Some **Analytics** pane items (**Median with Quartiles** and **Average with 95% CI**) add both a reference line and a reference distribution. Unless you are using Undo, you would need to delete these items separately.

### Edit an analytics object in the view

To edit an item you have added from the Analytics pane, click on the item and select **Edit** from the tooltip. For additional editing options, see the section for a particular item type under Analytics object definitions, below.

## Analytics object definitions

The following items can be dragged from the **Analytics** pane and dropped in the view. If an analytics object cannot be applied to the current configuration of fields in the view, it isn't available.

### Constant Line

Adds one or more constant lines to the view. You can add a constant line for a specific measure, for all measures, or for date dimensions. When you add a constant line, Tableau displays a Value prompt where you specify the value for the constant:

Value:

In Tableau Desktop, the Value prompt for a date value is a calendar control:

Value:  

January 2011						
S	M	T	W	T	F	S
26	27	28	29	30	31	1
2	3	4	5	6	7	8
9	10	11	12	13	14	15
16	17	18	19	20	21	22
23	24	25	26	27	28	29
30	31	1	2	3	4	5

Today: 1/9/2015

You can click on a resulting constant line and choose **Edit** or **Remove**. In Tableau Desktop there is a third option: **Format**. Choosing **Edit** opens the Edit Reference Line dialog box. For details, see [Edit Existing Reference Lines, Bands, and Distributions](#) on page 1941 in the **Reference Lines, Bands, Distributions, and Boxes** article. Another way to edit a line in Tableau Desktop is to right-click (control-click on Mac) the relevant axis and choose **Edit Reference Line**.

### Average Line

Adds one or more average lines to the view. You can add an average line for a specific measure or for all measures.

You can click on a resulting average line and choose a different aggregation, such as Total or Sum. You can also choose **Edit** or **Remove**. In Tableau Desktop there is a third option: **Format**.

Choosing **Edit** opens the Edit Reference Line dialog box. For details, see [Edit Existing Reference Lines, Bands, and Distributions](#) on page 1941 in the **Reference Lines, Bands, Distributions, and Boxes** article. Another way to edit a line in Tableau Desktop is to right-click (control-click on Mac) the relevant axis and choose **Edit Reference Line**.

### Median with Quartiles

Adds one or more sets of median lines and distribution bands to the view. You can add a median with quartiles for a specific measure or for all measures.

The distribution bands are computed as quartiles; the middle two quartiles are shaded.

You can click on a resulting median line or distribution and choose **Edit** or **Remove**. In Tableau Desktop there is a third option: **Format**. Median lines and distributions must be edited, formatted, or removed separately. Choosing **Edit** opens the Edit Reference Line dialog box. You must click on the outer edge of a distribution band to see the options--clicking in the middle of the band has no effect. For details, see [Edit Existing Reference Lines, Bands, and Distributions](#) on page 1941 in the **Reference Lines, Bands, Distributions, and Boxes** article. Another way to edit a line or distribution in Tableau Desktop is to right-click (control-click on Mac) the relevant axis and choose **Edit Reference Line**. A submenu will offer you two choices: **Quartiles** and **Median**.

For information on distribution types, including quartiles, see [Add Reference Distributions](#) on page 1932 in the **Reference Lines, Bands, Distributions, and Boxes** article.

### Box Plot

Adds one or more box plots to the view. You can add box plots for a specific measure or for all measures. The scope for a box plot is always **Cell** (and never **Table** or **Pane**).

Click or hover over any of the horizontal lines in the box plot to see statistical information about the whiskers, quartiles, and median.

You can also choose **Edit** or **Remove** when you click on a line. In Tableau Desktop there is a third option: **Format**. Choosing **Edit** opens the Edit Reference Line dialog box. Another way to edit a box plot in Tableau Desktop is to right-click (control-click on Mac) the relevant axis and choose **Edit Reference Line**.

**Note:** In Tableau Desktop, there are two items named **Box Plot** in the Analytics pane. For the Box Plot option in the Summarize section, Tableau will automatically add a box plot for the specified target. For the Box Plot option in the Custom section, Tableau will open the Edit Reference Line, Band, or Box dialog box after you specify a target.

## Totals

Adds totals to the view. When you add totals, the drop options are **Subtotals**, **Column Grand Totals**, and **Row Grand Totals**.

For details, see [Show Totals in a Visualization on page 1298](#).

To remove totals, click the relevant column or row header and choose **Remove**.

In Tableau Desktop, you can also click on a totals column or row header after adding totals and set the aggregation for that row or column from the tooltip:

## Average with 95% CI

Adds one or more sets of average lines with distribution bands; the distribution bands are configured at a 95% confidence interval. You can add these items for a specific measure or for all measures.

The confidence interval distribution bands shade the region in which the population average will fall 95% of the time.

You can click on a resulting average line or distribution and choose **Edit** or **Remove**. In Tableau Desktop there is a third option: **Format**. Choosing **Edit** opens the Edit Reference Line dialog box. The average lines and distributions must be edited, formatted, or removed separately. You must click on the outer edge of a distribution band to see the options--clicking in the middle of the band has no effect. Another way to edit a line or distribution in Tableau Desktop is to right-click (control-click on Mac) the relevant axis and choose **Edit Reference Line**. A submenu will offer you two choices: **Average** and **95% Confidence Interval**.

You can also remove lines and bands by dragging them off the view.

## Median with 95% CI

Adds one or more sets of median lines with distribution bands; the distribution bands are configured at a 95% confidence interval. You can add these items for a specific measure or for all measures.

The confidence interval distribution bands shade the region in which the population median will fall 95% of the time.

You can click on a resulting median line or distribution and choose **Edit**, **Format**, or **Remove**. In Tableau Desktop there is a third option: **Format**. Choosing **Edit** opens the Edit Reference Line dialog box. The median lines and distributions must be edited, formatted, or removed separately. You must click on the outer edge of a distribution band to see the options--clicking in the middle of the band has no effect. Another way to edit a line or distribution in Tableau Desktop is to right-click (control-click on Mac) the relevant axis and choose **Edit Reference Line**. A submenu will offer you two choices: **Median** and **95% Confidence Interval**.

You can also remove lines and bands by dragging them off the view.

## Trend Line

Adds one or more trend lines to the view. When you add trend lines, the drop options identify the trend line model types available in Tableau: **Linear**, **Logarithmic**, **Exponential**, and **Polynomial**. For some views, only a subset of these options is available.

For details, see [Trend Line Model Types](#) on page 1949

Click on a trend line to remove or edit it, or to see a statistical definition. You can also remove a trend line by dragging it off the view.

## Forecast

Adds a forecast to the view. This option is only available in Tableau Desktop—not when you edit a view on the web. Forecasting is only possible when there is at least one measure in the view.

Forecasting is not supported for views based on multidimensional data sources. In addition, the view cannot contain any of the following:

- Table calculations
- Disaggregated measures
- Percent calculations
- Grand Totals or Subtotals
- Date values with aggregation set to Exact Date

A time series containing null values also imposes constraints.

For details, see [Forecasting on page 1983](#).

To remove, edit, or read a description of the current forecast, go to the Analysis menu and choose **Forecast**.

### Custom Reference Line

You can add reference lines for a specific measure or for all measures in the view.

After you drag a reference line from the **Analytics** pane and drop it on a target, Tableau automatically opens an edit dialog box. See [Add a Reference Line on page 1920](#) in the **Reference Lines, Bands, Distributions, and Boxes** article for information on the available options. To return to this dialog box later, click on the line and choose **Edit**.

### Custom Reference Band

You can add reference bands for a specific measure or for all measures in the view.

After you drag a reference band from the **Analytics** pane and drop it on a target, Tableau automatically opens the Edit Reference Line, Band, or Box dialog box. See [Add Reference Bands on page 1927](#) in the **Reference Lines, Bands, Distributions, and Boxes** article for information on the available options. To return to this dialog box later, click on the band and choose **Edit**. You must click on the outer edge of a reference band to see the options--clicking in the middle of the band has no effect.

### Custom Distribution Band

You can add reference distributions for a specific measure or for all measures in the view.

After you drag a reference distribution from the **Analytics** pane and drop it on a target, Tableau automatically opens Edit Reference Line, Band, or Box dialog box. See [Add Reference Distributions on page 1932](#) in the **Reference Lines, Bands, Distributions, and Boxes** article for information on the available options. To return to this dialog box later, click on the band and choose **Edit**. You must click on the outer edge of a distribution band to see the options--clicking in the middle of the band has no effect.

### Custom Box Plot

In Tableau Desktop—but not when you edit a view on the web—you can drag a box plot from the Custom section of the **Analytics** pane and drop it on a target. (But keep in mind that on the web, you can add a box plot from the Summarize section on the Analytics pane.) When you drag Box Plot from the Custom section, Tableau automatically opens Edit Reference Line, Band, or Box

dialog box. See [Add a Box Plot on page 1937](#) in the **Reference Lines, Bands, Distributions, and Boxes** article for information on the available options. The scope for a box plot is always **Cell** (and never **Table** or **Pane**).

Click any of the horizontal lines in the box plot to see statistical information about the whiskers, quartiles, and median.

To return to this dialog box later, click on the band and choose **Edit**.

## Shelves and Cards Reference

Every worksheet in Tableau contains shelves and cards, such as Columns, Rows, Marks, Filters, Pages, Legends, and more.

By placing fields on shelves or cards, you:

- Build the structure of your visualization.
- Increase the level of detail and control the number of marks in the view by including or excluding data.
- Add context to the visualization by encoding marks with color, size, shape, text, and detail.

Experiment with placing fields on different shelves and cards to find the optimal way to look at your data.

### Options for starting a view

If you aren't sure where to place a field, you can get let Tableau help you determine the best way to display the data.

- You can drag fields from the **Data** pane and drop them onto the cards and shelves that are part of every Tableau worksheet.
- You can double-click one or more fields in the **Data** pane.
- You can select one or more fields in the **Data** pane and then choose a chart type from **Show Me**, which identifies the chart types that are appropriate for the fields you selected. For details, see [Use Show Me to Start a View on page 1173](#).
- You can drop a field on the **Drop field here** grid, to start creating a view from a tabular

perspective.

## Columns and Rows shelves

Drag fields from the Data pane to create the structure for your visualizations.

The **Columns** shelf creates the columns of a table, while the **Rows** shelf creates the rows of a table. You can place any number of fields on these shelves.

When you place a dimension on the **Rows** or **Columns** shelves, headers for the members of that dimension are created. When you place a measure on the **Rows** or **Columns** shelf, quantitative axes for that measure are created. As you add more fields to the view, additional headers and axes are included in the table and you get an increasingly detailed picture of your data.

In the view shown below, the members of the **Segment** dimension are displayed as column headers, while the **Profit** measure is displayed as a vertical axis.

Tableau displays data using marks, where every mark corresponds to a row (or a group of rows) in your data source. The inner fields on the **Rows** and **Columns** shelves determine the default mark type. For example, if the inner fields are a measure and a dimension, the default mark type is a bar. You can manually select a different mark type using the Marks card drop-down menu. For more information, see [Change the Type of Mark in the View on page 1182](#).

Adding more fields to the **Rows** and **Columns** shelves adds more rows, columns, and panes to the table.

## Hide rows and columns

Generally you will add dimensions and measures to create the rows and columns of the table and you'll either include all data or add filters to only show a subset. However, when you filter data it is also excluded from calculations and other computations performed on the summarized data in the table. Instead of filtering the data, you can hide the row or column so it doesn't display in the view but it is still included in calculations.

**Tip:** Hiding columns is especially useful when using table calculations that compare to a previous or next date value. In these cases, there will be a row or column that doesn't show data because there is no data to be compared to. Hide the empty column to keep the table calculation intact. For more details on table calculations, see [Table Calculation Types on page 2496](#).

For example, when calculating year-over-year growth, the first year wouldn't have a previous year to compare to, so the column is left blank. Filtering the first year would remove it from the view but it would also remove it from the calculation (the second year then doesn't have a previous year to compare to and is left blank). Instead of filtering, hiding the blank column keeps the calculation intact.

### To hide a row or column:

Right-click (control-click on Mac) the row or column you want to hide, and then select **Hide**.

**To show hidden data:**

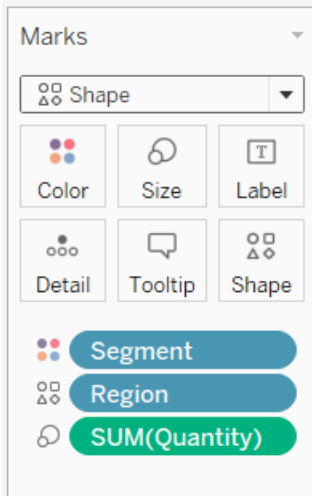

Open the field menu for a field that has hidden columns or rows and select **Show Hidden Data**.

## Marks card

The Marks card is a key element for visual analysis in Tableau. As you drag fields to different properties in the Marks card, you add context and detail to the marks in the view.

You use the Marks card to set the mark type (see [Change the Type of Mark in the View on page 1182](#)), and to encode your data with color, size, shape, text, and detail. To change the mark settings, see [Control the Appearance of Marks in the View on page 1205](#).

In this example, three different fields have been dragged to different properties in the Marks card. Segment is on Color, Region is on Shape, and Quantity is on Size.

After you add a field to the Marks card, you can click the icon next to the field to change the property it is using. You can also click the property buttons in the Marks card to change those settings.

Many properties can have multiple fields. For example, you can add multiple fields to Label, Detail, Tooltip, and Color. Size and Shape can only have one field at a time. For more details, see [Control the Appearance of Marks in the View on page 1205](#).

**Note:** By default, dragging a new field to **Color** replaces the existing fields. To add a new field to color without replacing the existing field, hold the SHIFT key on your keyboard while dragging a new field to **Color** on the Marks card.

## Filters shelf

The Filters shelf allows you to specify which data to include and exclude. For example, you might want to analyze the profit for each customer segment, but only for certain shipping containers and delivery times. By placing fields on the Filters shelf, you can create such a view.

**Note:** This section presents a brief overview of filtering. For more information on filtering, see [Filter Data from Your Views on page 1252](#).

You can filter data using measures, dimensions, or both at the same time. Additionally, you can filter data based on the fields that make up the columns and rows of the table. This is called an internal filter. You can also filter data using fields that don't contribute headers or axes to the table. This is called an external filter. All filtered fields display on the Filters shelf.

To illustrate the basic concepts of filtering, consider the following view.

Suppose you are not interested in the Home Office data. You can remove this column from the view by filtering the **Segment** dimension. To do so, select **Filter** on the field menu or drag the **Segment** dimension to the **Filters** shelf. The Filter dialog box opens. By default all members are selected. Clear the check box for **Home Office** to exclude it from the view. All selected members will be included.

As shown below, the view updates and the Home Office column is removed. The filter is indicated by the **Segment** field on the **Filters** shelf.

Suppose you want to only view profit for a category of the products. Even though the **Category** field is not used on the **Rows** and **Columns** shelves or on the Marks card, you can still add a filter. Drag the **Category** dimension to the **Filters** shelf. This is an example of an external filter because Category is not part of the view.

The Filter dialog box automatically opens. By default, none of the members are selected. Select the members you want to keep as part of the view. All cleared members are excluded. In this example, Office Supplies is selected.

The modified data view is shown below. The mark label shows that the sum of the profit for the Consumer segment has decreased to \$56,330. This number is derived by summing all the rows in the data source that are associated with the Corporate market and are part of the Office Supplies category.

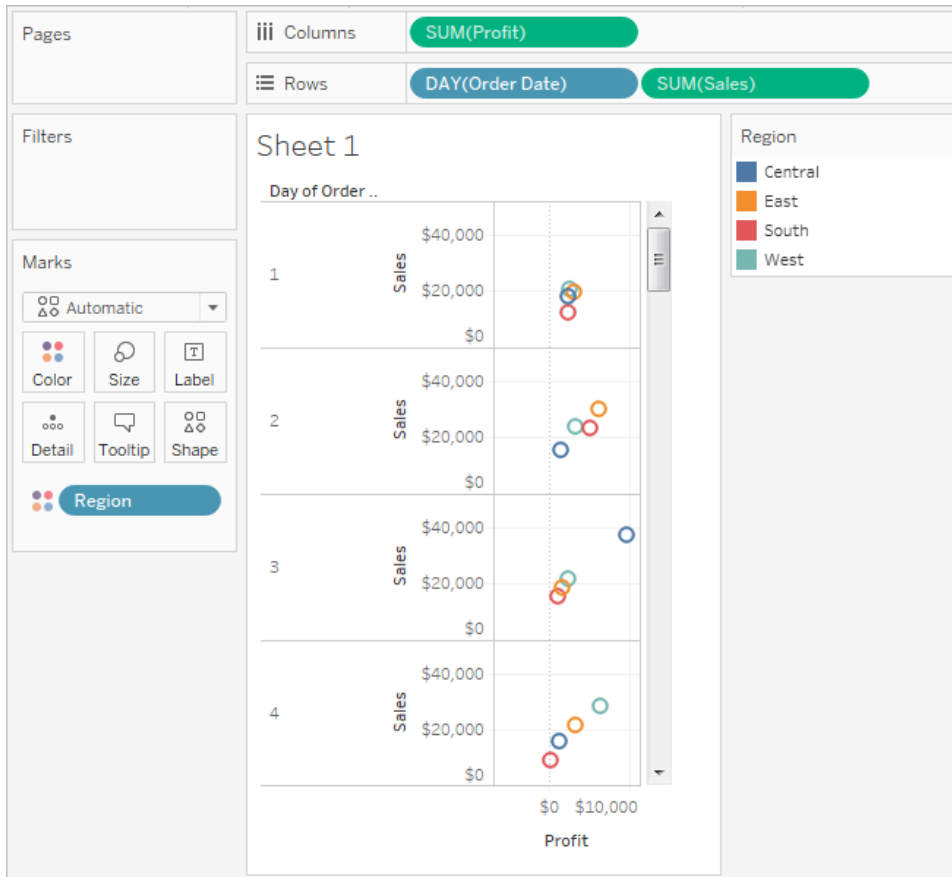

The order of fields placed on the Filters shelf does not affect the data view because the filters are independent. In other words, the result of filtering by customer segment, and then by container is the same as filtering by container and then by customer segment. For more information about the filtering order of operations, see [Filter Data from Your Views on page 1252](#).

## Pages shelf

The **Pages** shelf lets you break a view into a series of pages so you can better analyze how a specific field affects the rest of the data in a view. When you place a dimension on the **Pages** shelf you are adding a new row for each member in the dimension. When you place a measure on the **Pages** shelf, Tableau automatically converts the measure into a discrete measure.

The **Pages** shelf creates a set of pages, with a different view on each page. Each view is based on a member of the field you placed on the **Pages** shelf. You can easily flip through the views

and compare them on a common axis, using the controls that get added to the view when you move a field to the **Pages** shelf. For example, the view below shows the **Profit vs. Sales** by **Region** for each day throughout the month. The image below shows days 1, 2, 3, and 4. You would have to scroll down to see other days in the month.

To make this view more user-friendly, move **DAY(Order Date)** to the **Pages** shelf and use the associated control to flip through the pages (one for each day). You can quickly discover hidden insights. In this example, it is interesting that the 19th is an especially big day in terms of sales and profit in the Western region.

When you add a field to the **Pages** shelf, a page control is automatically added to the right of your view.

Use this control to navigate through the pages. There are three ways to navigate through the pages in a view:

- Jump to a specific page
- Manually advance through the pages
- Automatically advance through pages

### Jump to a specific page

Select the member or value you want to view from the drop-down list to display a specific page.

### Manually advance through the pages

You can manually advance through the sequence of pages by doing any of the following:

- Use the forward and back buttons on either side of the drop-down list to navigate through the pages one at a time.
- Use the Page Slider to quickly scroll forward and backward in the sequence of pages.
- Use any of the following keyboard shortcuts to scroll forward and backward in the sequence of pages.

F4	Starts and stops forward playback
SHIFT + F4	Starts and stops backward playback
CTRL + .	Skip forward one page
CTRL + ,	Skip backward one page

On a Mac, these are the equivalent keyboard shortcuts.

F4	Starts and stops forward playback
Shift-F4	Starts and stops backward playback
Command-period	Skip forward one page
Command-comma	Skip backward one page

### Automatically advance through pages

Use the playback controls to watch a slide show of the pages in the view. You can play forward or backward, and stop the playback at any time. You can control the speed of playback with the speed controls in the bottom right corner of the control. The smallest bar indicates the slowest playback speed.

### Show the Page history

Show page history using the Show History check box. With page history, marks from previous pages are shown on the current page.

*In Tableau Desktop only:* Open the drop-down control for history to specify what marks to show and when to show them.

The history drop-down control has the following options:

- **Marks to show history for** – select whether you want to show history for just selected marks, highlighted marks, marks that you’ve manually selected to show history for, or all marks. To manually show history for marks, right-click (control-click on Mac) the mark in the view and select an option on the Page History menu.
- **Length** – select the number of pages to show in the history.
- **Show** – specify whether to show the historical marks, a line tracing through the previous values (trails), or both.
- **Marks** – format the historical marks including the color and how much to fade them if the color is set to automatic, the marks will either use the default mark color or the color encoding on the Color shelf.
- **Trails** – format the lines that are drawn through the historical marks. This option is only available if Trails is selected in the Show options.

Page trails may not display if there are multiple marks per color on a page. Make sure that the level of detail for the view is less than or equal to the level of detail on the **Pages** shelf and on the

Color target. Also, trails are only supported for discrete mark types such as squares, circles, or shapes. They are not supported when the mark type is Automatic.

### Pages on dashboards (Tableau Desktop only)

When a dashboard contains multiple views that use the same field on the **Pages** shelf, you can control all of the views with a single page control by selecting the **Synchronized** option. This option is only available on the page control shown on a dashboard.

### Additional Shelves, Legends, Cards, and Controls

Some shelves, legends, cards, or controls are only displayed as a result of things that you do as you work with views. For example, the Color legend is only displayed when there is a field on Color.

Tableau provides controls for moving or otherwise customizing these elements of the view.

The following list describes each such shelf, legend, card, or control.

- **Measure Values Shelf**– Measure Values is a special field that always appears in the Data pane and contains all the measures of your data collected into one field. Tableau automatically adds Measure Values to the view when multiple measures are sharing the same axis. When Measure Values is in the view, Tableau displays a Measure Values shelf that shows which measures are being included. You can add measures to or remove measures from this card. For more information, see [Measure Values and Measure Names on page 1160](#).
- **Color Legend** – Shows how colors are allocated when there is a field on Color.
- **Shape Legend** – Shows how shapes are allocated when there is a field on Shape.
- **Size Legend** – Shows how sizes are allocated when there is a field on Size.
- **Map Legend** – Shows the legend for the symbols and patterns on a map. The map legend is not available for all map providers.
- **Parameter Controls** – A separate parameter control is available for every parameter in the workbook. For more information, see [Create Parameters on page 1070](#).
- **Title** – A title is displayed by default for every view. The default title is the sheet name. Double-click a title (Control-click on a Mac) to edit it.
- **Caption** – Choose **Show caption** from the Worksheet menu to display a caption for the view.
- **Summary Card** – Choose **Show summary** from the Worksheet menu to display a summary card for the view. For more information, see [Summary Card on page 2609](#).
- **Page Control** – Provides options for navigating through pages when there is a field on the Pages shelf.

## Parts of the View

This section describes the basic elements of views that you can create in Tableau. You can show or hide parts of the view as needed (described below). Every view has a table in some form, which may include rows, columns, headers, axes, panes, cells, and marks. Views can optionally include tooltips, titles, captions, field labels, and legends.

### The View area

Data views are displayed in a table on every worksheet. A table is a collection of rows and columns, and consists of the following components: Headers, Axes, Panes, Cells, and Marks. In addition to these, you can choose to show or hide Titles, Captions, Field Labels, and Legends.

**A. Field Labels on page 89** - The label of a discrete field added to the row or column shelf that describes the members of that field. For example, Category is a discrete field that contains three members; Furniture, Office Supplies and Technology.

**B. Titles on page 86** - The name that you give your worksheet, dashboard, or story. Titles display automatically for worksheets and stories and you can turn them on to display them in your dashboards.

**C. Marks on page 83** - The data that represents the intersection of the fields (dimensions and measures) included in your view. Marks can be represented using lines, bars, shapes, maps and so on.

**D. Legends on page 91** - A key that describes how the data is encoded in your view. For example if you use shapes or colors in your view, the legend describes what each shape or color represents.

**E. Axes on page 80** - Created when you add a measure (fields that contain quantitative, numerical information) to the view. By default, Tableau generates a continuous axis for this data.

**F. Headers below** - The member name of a field.

**G. Captions on page 88** - Text that describes the data in the view. Captions can be automatically generated and can be toggled on and off.

Also see information on **Cells on page 82** and **Panes on page 82**.

### Headers

Headers are created when you place a dimension or discrete field on the **Rows** shelf or the **Columns** shelves. The headers show the member names of each field on the shelves. For example, in the view below the column headers show the members of the **Order Date** field and the row headers show the members of the **Sub-Category** field.

Sheet 1

Sub-Category	Order Date			
	2012	2013	2014	2015
Accessories	\$25,014	\$40,524	\$41,896	\$59,946
Appliances	\$15,314	\$23,241	\$26,050	\$42,927
Art	\$6,058	\$6,237	\$5,910	\$8,914
Binders	\$43,488	\$37,453	\$49,485	\$72,986
Bookcases	\$20,037	\$38,544	\$26,275	\$30,024
Chairs	\$77,242	\$71,735	\$83,919	\$95,554
Copiers	\$10,850	\$26,179	\$49,599	\$62,899
Envelopes	\$3,856	\$4,512	\$4,730	\$3,379
Fasteners	\$661	\$545	\$960	\$858
Furnishings	\$13,826	\$21,090	\$27,874	\$28,915
Labels	\$2,841	\$2,956	\$2,827	\$3,861
Machines	\$62,023	\$27,764	\$55,907	\$43,545
Paper	\$14,835	\$15,288	\$20,638	\$27,718
Phones	\$77,391	\$68,314	\$78,660	\$105,643
Storage	\$50,329	\$45,048	\$58,632	\$69,834
Supplies	\$14,394	\$1,952	\$14,278	\$16,049
Tables	\$46,088	\$39,150	\$60,833	\$60,894

You can show and hide row and column headers at anytime.

**To hide headers:**

- Right-click (control-click on Mac) the headers in the view and select **Show Header**.

The screenshot shows a Tableau table with the following data:

Sub-Category	2012	2013
Accessories	\$25,014	\$40,524
Appliances	\$15,314	\$23,241
Art	\$6,058	\$6,237
Binders		
Bookcases		
Chairs		
Copiers		
Envelopes		
Fasteners		
Furniture		
Labels		
Machines		
Paper		
Phones		
Storage	\$50,329	\$45,048

A context menu is open over the 'Art' row, showing the following options: Keep only (checked), Exclude (X), Hide, Drill down (+), Format..., Rotate Label, Show Header (checked), Edit alias..., and Split.

**To show headers:**

- Select the field in the view whose headers you want to show and select **Show Header** on the field menu.

Hiding headers can be useful when you are working with multiple measures. For example, the view below shows both the sales and profit for each region along a single axis. You can see the view looks cluttered with the Measure Names headers showing. Because Measure Names is also indicated by the mark color, you can hide the excess headers to clean up the view.

Sheet 1

Axes

Axes are created when you place a measure or continuous field on the **Rows** or **Columns** shelves. By default, the values of the measure field are displayed along a continuous axis.

You can show and hide axes at any time.

**To hide axes:**

- Right-click (control-click on Mac) the axis in the view and select **Show Header** to clear the check mark next to this option.

**To show axes:**

- Right-click (control-click on Mac) the measure in the view whose axis you want to show and select **Show Header** on the field menu.

## Panes

A pane is defined by the intersection of fields on the rows and columns shelves.

In a table calculation, this is seen as one or more cells that belong to the same field, which are computed down or across according to the calculation, as in the example below:

		Order Date			
Quarter of Order..	Month of Order ..	2011	2012	2013	2014
Q1	January				
	February	-\$9,136	-\$5,963	\$4,325	-\$24,420
	March	\$50,880	\$26,256	\$28,319	\$33,625
Q2	April				
	May	-\$4,647	-\$4,064	\$17,442	\$5,539
	June	\$10,947	-\$5,334	-\$17,261	\$2,609
Q3	July				
	August	-\$6,037	\$8,133	-\$5,175	\$13,088
	September	\$53,868	\$27,698	\$39,643	\$28,973
Q4	October				
	November	\$47,175	\$44,568	\$25,729	\$34,533
	December	-\$9,083	-\$1,053	\$15,045	-\$21,852

For more information, see [Transform Values with Table Calculations](#) on page 2484.

## Cells

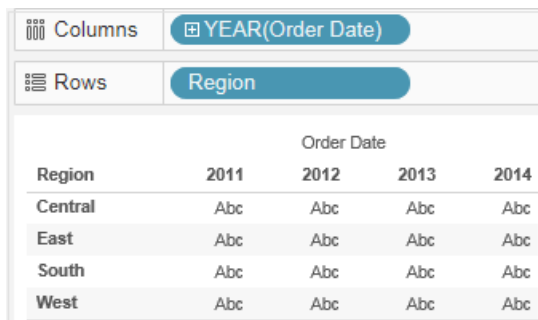

Cells are the basic components of any table you can create in Tableau, defined by the intersection of a row and a column. For example, in a text table, a cell is where the text is displayed, as shown in the view below:

## Marks

When you drag fields to the view, the data are displayed using marks. Each mark represents the intersection of all of the dimensions in the view.

For example, in a view with **Region** and **Year** dimensions, there is a mark for every combination of those two dimensions (East 2011, East 2012, West 2011, West 2012, etc.). In this case, the mark type is set to Text, so the **Abc** represents the location where the value for the text mark will appear—once a measure such as **Sales** is added to the view.

For details on creating and customizing marks, see [Marks card on page 62](#), [Control the Appearance of Marks in the View on page 1205](#), [Change the Type of Mark in the View on page 1182](#), [Stack Marks on page 1235](#)

Marks can be displayed in many different ways including lines, shapes, bars, maps, and so on. You can show additional information about the data using mark properties such as color, size, shape, labels, etc. The type of mark you use and the mark properties are controlled by the Marks card. Drag fields to the Marks card to show more data. For example, the same view above is shown again below but this time with **Profit** on Color. With this additional information, it is clear that the West region had the highest profit in 2014.

Control the marks in the view using the Marks card. Use the drop-down menu to specify the type of mark to show. Drag fields to the Marks card and use the drop-down controls to add more information to the view and control the color, shape, size, labels, and number of marks in the view.

## Tooltips

Tooltips are additional data details that display when you hover over one or more marks in the view. When you select one or more marks and hover, tooltips also include options to filter marks (exclude or keep only), display marks that have the same values, create groups, create sets, or display the underlying data. If you don't want users to be able to access tooltip commands, you can disable them.

For details on formatting tooltips and other tooltip settings, also see [Format Titles, Captions, Tooltips, and Legends](#) on page 2921, [Add tooltips to marks](#) on page 1215, and [Create Views in Tooltips \(Viz in Tooltip\)](#) on page 1315. For details on analysis options in tooltips, see [Explore and Inspect Data in a View](#) on page 2589

### Tooltip command buttons for exploring data in a viz

The top of the tooltip lists commands for filtering data, creating a group, sorting the selection, and view the underlying data. For example, you can use the tooltip to quickly remove an outlier in a scatter plot. Each of the commands are described below.

To see tooltip commands, hover over a mark and then keep the cursor still. The

- **Keep Only** - creates a filter that removes all other data. See [Select to keep or exclude data points in your view](#) on page 1253 to learn more.
- **Exclude** - creates a filter that removes the selected data. See [Select to keep or exclude data points in your view](#) on page 1253 to learn more.
- **Group Members** - creates a group based on the selection. If the selection contains multiple dimensions, you can group on one dimension or all dimensions. See [Correct Data Errors or Combine Dimension Members by Grouping Your Data](#) on page 1038 to learn more.
- **Create Set** (Tableau Desktop only) - creates a new set containing the selected members. You can create a new set or add members to an existing set. See [Create Sets](#) on page 1040 to learn more.
- **View Data** - opens a window displaying the data. You can view the summarized data or the underlying data. See [View Underlying Data](#) on page 2610 to learn more.

These commands are visible by default. You can disable the commands in the **Edit Tooltip** dialog box by deselecting **Include command buttons**. Doing so will also hide the aggregation summary if multiple marks are selected.

## Disable tooltip commands

If you don't want users to be able to access tooltip commands, you can disable them.

1. Click **Tooltip** on the Marks card or select **Worksheet > Tooltip**.
2. In the Edit Tooltip dialog box, clear the **Include command buttons** check box.

Tooltip settings apply to the active worksheet and can be different for each sheet in the workbook.

## Body text and markup in tooltips

The body of a tooltip contains details about a specific mark or a selection of multiple marks. For example, in a bar chart showing sales by region, the tooltip body may include the actual sales amount and the region name. The default tooltip is based on the fields used in the view. You can customize what is shown in the tooltip by dragging fields to **Tooltip** on the Marks card.

To customize a tooltip and its formatting, click **Tooltip** on the Marks card.

Alternatively, you can select **Worksheet > Tooltip**.

## Action links

If the sheet has any actions, the action links are listed below the body of the tooltip. An action adds context and interactivity to your data through filters, highlighting, and links to external resources. See [Actions on page 1331](#) to learn more about adding actions to your workbook.

## Titles

You can show titles on any worksheet, dashboard, or story. For worksheets and stories, a title is displayed by default, but you can remove it. For dashboards, you can add a title. By default, the title is the name of the sheet, but you can edit the title to change the text and include dynamic values such as page number and sheet name. For more information about how to format titles, see [Format Titles, Captions, Tooltips, and Legends on page 2921](#).

## Show and hide titles in worksheets

Titles are shown by default for worksheets and are included as part of the worksheet, shown at the top of the view. You can move the title to the sides or the bottom of the view. However, when you move the title from the top of the view, it becomes a **Title** card and displays like any other card in the view.

**Note:** If you move a title from the top position and then hide it; when you show the title again, it appears back at the top of the worksheet in its default position.

### To show or hide titles in a worksheet

- From the toolbar menu, click **Worksheet** > **Show Title**.
- On the toolbar, click the drop-down arrow on the **Show/Hide Cards** button and select **Title** from the context menu.

Toggle the check mark on or off to show or hide the title.

### Show and hide titles in dashboards

You can turn on titles for dashboards. The title appears as part of the dashboard.

To show or hide titles on a dashboard, from the toolbar menu, select **Dashboard** > **Show Title**.

When you add worksheets to the dashboard, the title of the worksheet automatically shows, even if you turned off the title on the worksheet itself. To turn off the title for the worksheet on the dashboard, do the following steps:

1. In the dashboard, select the worksheet to highlight it.
2. In the top right corner of the highlighted worksheet, click the drop-down arrow and select **Title** in the context menu to clear the check mark.

### Show and hide titles in stories

Story titles are displayed by default. To toggle story titles on or off, in the top menu, select **Story** > **Show Title** to add or remove the check mark.

### Captions

All views can have a caption that is either automatically generated or manually created. The caption is displayed on the Caption card.

To show a caption in a worksheet, select it on the **Show/Hide Cards** toolbar menu  or select **Worksheet** > **Show Caption**.

The caption is automatically generated by default.

To edit the caption, double-click the Caption area in the view. In the **Edit Caption** dialog box, you can use change the font, size, color, and alignment and style.

Click the **Insert** menu to add automatic text such as page number, sheet name, and field and parameter values.

The caption can optionally be included when printing, printing to PDF, and publishing to Tableau Server. When you export the view as an image to another application like Microsoft PowerPoint, you can optionally include the caption.

### Field Labels

Placing discrete fields on the rows and column shelves creates headers in the view that display the members of the field. For example, if you place a field containing products on the rows shelf, each product name is shown as row headers.

In addition to showing these headers, you can show field labels, which are labels for the headers. In this example, the rows are labeled **Category**, to indicate that the discrete category names are members of the **Category** field.

		Region / Order Date			
		East			
Category		2012	2013	2014	2015
Furniture		47,233	53,817	46,387	60,854
Office Supplies		35,969	42,655	61,645	65,247
Technology		45,479	59,859	72,497	87,138

Field labels apply only to discrete fields. When you add continuous fields to the view, Tableau creates an axis. The axis is labeled with a header.

By default, field labels are shown.

To hide or show field labels, select **Analysis > Table Layout > Show Field Labels for Rows** or **Show Field Labels for Columns**.

You can format the fonts, alignment, shading, and separators for field labels.

## Legends

When you add fields to Color, Size, and Shape on the Marks card, a legend displays to indicate how the view is encoded with relation to your data.

### Color Legend

### Size Legend

### Shape Legend

Not only do legends help you understand encodings, you can also use legends to sort, filter, and highlight specific sets of data. For more information, see [Legend Highlighting on page 1337](#).

## Measure values and color legends

If you include the **Measure Values** and **Measure names** fields in your views, you can create either a single combined color legend or separate color legends for your measures. If you drag the **Measure Values** field to Color on the Marks card, by default Tableau creates a single color legend that applies one color palette to all marks in the view. If you want to differentiate certain

measures in the view you can create separate color legends for the measures and assign a unique color palette to each legend.

For more information about Measure Values and Measure Names, see [Measure Values and Measure Names](#) on page 1160.

The following example shows how to create separate color legends. This example uses the Sample Superstore data set.

1. Connect to the Sample-Superstore data set.
2. From the Data pane:
  - Drag **Order Date** to the Columns shelf and **Category** and **Sub-Category** to the Rows shelf.
  - Drag **Measure Names** to the columns shelf and drop it to the right of **Order Date**.
  - Drag **Measure Values** to Color on the Marks card.
3. In the Measure Values card, drag measures off the card so that you keep **SUM(Sales)**, and **SUM(Profit)** only.
4. Click **Label** on the Marks card and select **Show mark labels** to show the measure values in the view.

When you drag **Measure Values** to Color on the Marks card, Tableau creates a single color legend and adds it to the view. Your view should look something like this.

Category	Sub-Cate..	Order Date							
		2012		2013		2014		2015	
		Profit	Sales	Profit	Sales	Profit	Sales	Profit	Sales

5. To create separate legends for each measure on the view, click the drop-down arrow on the **Measure Values** field in the Marks card and select **Use Separate Legends** from the context menu.

### Tableau Desktop version

### Web version

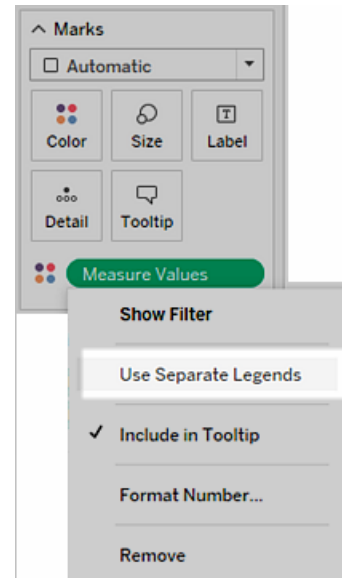

Tableau creates an individual color legend for each measure in the view using the default color palette.

The screenshot shows a Tableau dashboard with a pivot table. The columns are 'YEAR(Order Date)' and 'Measure Names'. The rows are 'Category' and 'Sub-Category'. The pivot table displays data for 2012, 2013, 2014, and 2015, with Profit and Sales values. A color legend for 'SUM(Profit)' is visible on the right, showing a gradient from blue to red.

Category	Sub-Catego..	Order Date							
		2012		2013		2014		2015	
		Profit	Sales	Profit	Sales	Profit	Sales	Profit	Sales
Furniture	Bookcases	-\$346	\$20,037	-\$2,755	\$38,544	\$212	\$26,275	-\$584	\$30,024
	Chairs	\$6,955	\$77,242	\$6,228	\$71,735	\$5,763	\$83,919	\$7,644	\$95,554
	Furnishings	\$1,973	\$13,826	\$3,052	\$21,090	\$3,935	\$27,874	\$4,099	\$28,915
	Tables	-\$3,124	\$46,088	-\$3,510	\$39,150	-\$2,951	\$60,833	-\$8,141	\$60,894
Office Supplies	Appliances	\$2,459	\$15,314	\$2,512	\$23,241	\$5,301	\$26,050	\$7,865	\$42,927

	Binders	\$4,740	\$43,488	\$7,597	\$37,453	\$10,148	\$49,485	\$7,737	\$72,988
	Envelopes	\$1,495	\$3,856	\$1,960	\$4,512	\$2,067	\$4,730	\$1,442	\$3,379
	Fasteners	\$179	\$661	\$172	\$545	\$294	\$960	\$305	\$858
	Labels	\$1,286	\$2,841	\$1,323	\$2,956	\$1,193	\$2,827	\$1,745	\$3,861
	Paper	\$6,371	\$14,835	\$6,570	\$15,288	\$9,063	\$20,638	\$12,049	\$27,718
	Storage	\$4,166	\$50,329	\$3,505	\$45,048	\$6,240	\$58,632	\$7,368	\$69,834
	Supplies	\$490	\$14,394	-\$25	\$1,952	-\$699	\$14,278	-\$955	\$16,049
Technology	Accessories	\$6,403	\$25,014	\$10,197	\$40,524	\$9,664	\$41,896	\$15,672	\$59,946
	Copiers	\$2,913	\$10,850	\$9,930	\$26,179	\$17,743	\$49,599	\$25,032	\$62,899
	Machines	\$369	\$62,023	\$2,977	\$27,764	\$2,907	\$55,907	-\$2,869	\$43,545
	Phones	\$11,808	\$77,391	\$10,399	\$68,314	\$9,437	\$78,660	\$12,872	\$105,643

To assign a different color palette to the color legend, do one of the following:

- In Tableau Desktop, click the drop-down arrow in the top right corner for each color legend and select **Edit Colors**. Then select a color from the Palette drop-down list.

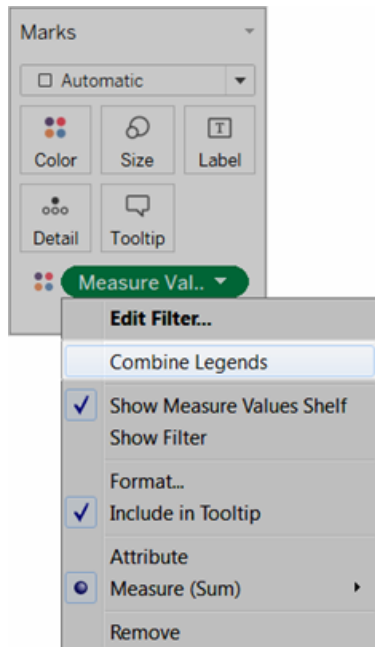

- In Tableau Server or Tableau Cloud, click the drop-down arrow in the top right corner for each color legend. Then select a color from the Palette drop-down list.

Your view might look something like the following example:

		Order Date							
		2012		2013		2014		2015	
Category	Sub-Cate...	Profit	Sales	Profit	Sales	Profit	Sales	Profit	Sales
Furniture	Bookcases	-\$346	\$20,037	-\$2,755	\$38,544	\$212	\$26,275	-\$584	\$30,024
	Chairs	\$6,955	\$77,242	\$6,228	\$71,735	\$5,763	\$83,919	\$7,644	\$95,554
	Furnishi...	\$1,973	\$13,826	\$3,052	\$21,090	\$3,935	\$27,874	\$4,099	\$28,915
	Tables	-\$3,124	\$46,088	-\$3,510	\$39,150	-\$2,951	\$60,833	-\$8,141	\$60,894

	Phones	\$11,808	\$77,391	\$10,399	\$68,314	\$9,437	\$78,660	\$12,872	\$105,643

- To combine the separate legends back to a single legend, click the drop-down arrow on the **Measure Values** field on the Marks card and select **Combine Legends** from the context menu.

### Tableau Desktop version

### Web version

## Workbooks and Sheets

Tableau uses a workbook and sheet file structure, much like Microsoft Excel. A workbook contains sheets. A sheet can be a worksheet, a dashboard, or a story.

- A **worksheet** contains a single view along with shelves, cards, legends, and the Data and Analytics panes in its side bar. For details on the worksheet workspace, see [The Tableau Workspace on page 27](#).
- A **dashboard** is a collection of views from multiple worksheets. The Dashboard and Layout panes are available in its side bar. For more details about creating dashboards, see [Dashboards on page 2627](#).
- A **story** contains a sequence of worksheets or dashboards that work together to convey information. The Story and Layout panes are available in its side bar. For more details about creating stories, see [Stories on page 2763](#).

For details on hiding or showing sheets in a workbook or Viz in Tooltip, see [Manage Sheets in Dashboards and Stories on page 2752](#) and [Hide or show a Viz in Tooltip worksheet on page 1323](#). For details on organizing sheets, see [Navigate and Organize Sheets on page 102](#). For details on creating and opening workbooks, see [Create or Open Workbooks on page 99](#).

### About sheets

Each workbook can contain different types of sheets: views (also known as worksheets), dashboards, and stories.

- A worksheet is where you build views of your data by dragging and dropping fields onto shelves.
- A dashboard is a combination of several views that you can arrange for presentation or to monitor.
- A story is a sequence of views or dashboards that work together to convey information.

The sheets display along the bottom of the workbook as tabs. In this section you'll learn how to create, open, duplicate, hide, and delete sheets. You'll also learn how to organize sheets in a workbook.

Within a workbook, you can create new sheets, clear an entire worksheet, duplicate sheets, hide or show a worksheet, and delete a sheet. Tableau has several ways to view and organize the sheets in your workbook.

## Create new worksheets, dashboards, or stories

There are several ways to create new sheets in a workbook, dashboard, or a story. You can create as many sheets in a workbook as you want.

**To create a new worksheet, dashboard, or story**, click the **New Worksheet**, **New Dashboard**, or **New Story** button at the bottom of the workbook.

The **New Worksheet** button.

**To rename a new worksheet, dashboard, or story**, right-click (Ctrl-click on a Mac) the tab and then select the **Rename** command.

## More ways to create new worksheets

Create a new worksheet by doing one of the following:

- Select **Worksheet > New Worksheet**.
- Right-click any open tab in the workbook, and select **New Worksheet** from the menu.
- On the toolbar, click the drop-down arrow on the **New Worksheet**  button and then select **New Worksheet**.
- Press Ctrl + M on your keyboard (Command-M on a Mac).

## More ways to create new dashboards

Create a new dashboard by doing one of the following:

- Select **Dashboard > New Dashboard**.
- Click the **New Dashboard** button at the bottom of the workbook.

- Right-click on any open tab in the workbook, and select **New Dashboard** from the menu.

- On the toolbar, click the drop-down arrow on the New Worksheet  button and then select **New Dashboard**.

### More ways to create new stories

Create a new story by doing one of the following:

- Select **Story > New Story**.
- Click the **New Story** button at the bottom of the workbook.

- Right-click on any open tab in the workbook, and select **New Story** from the menu.
- On the toolbar, click the drop-down arrow on the **New Worksheet**  button and then select **New Story**.

### Undo, redo, or clear sheets

Every Tableau workbook contains a history of steps you have performed on the worksheets, dashboards, and stories in that workbook for the current work session.

**To move backward through the history**, click **Undo**  on the toolbar or press Ctrl + Z on your keyboard (Command-Z on a Mac).

**To move forward through the history**, click **Redo**  on the toolbar or press Ctrl + Y (Command-Y on a Mac) on your keyboard.

**To remove all fields, formatting, sizing, axis ranges, filters, sorts, and context filters in**

**the sheet**, click **Clear Sheet**  on the toolbar.

**To clear specific aspects of the view**, use the Clear Sheet drop-down menu.

**Note:** Using the clear commands on the toolbar does not clear the history. If you decide that you didn't want to clear the sheet, click the **Undo** button.

## Duplicate a sheet

When you want to use an existing sheet as a jumping off point for more exploration, you can duplicate that sheet. The duplicated sheet contains all of the same fields and settings as a starting point for new analysis.

**Duplicate** creates a new version of a worksheet, dashboard, or story you can modify without effecting the original sheet.

To duplicate the active sheet, right-click the sheet tab (control-click on Mac) and select **Duplicate**.

**Note:** When you duplicate a dashboard, a new version of the dashboard is created, but it still references the original worksheets that were used to create the dashboard.

## Duplicate as Crosstab

A crosstab (sometimes referred to as a Pivot Table) is a table that summarizes data in rows and columns of text. It is a convenient way to display the numbers associated with the data view.

To create a new cross-tab sheet based on the data in the current sheet, right-click the sheet tab (control-click on Mac) and select **Duplicate as Crosstab**. Or select **Worksheet > Duplicate as Crosstab**.

This command inserts a new worksheet or worksheets into your workbook and populates the sheet with a cross-tab view of the data from the original worksheet. Dashboards and stories cannot be duplicated as crosstabs.

## Rename sheets

To rename the active sheet, right-click (control-click on Mac) the sheet in the sheet tab along the bottom of the workbook, and then click **Rename Sheet**.

Or, double-click the name of the sheet in a sheet tab, type a new name, and then click **Enter**.

## See the underlying data in a sheet

To see the numbers behind the marks in your view

Hover over or click a mark to display the associated data in a tooltip. With the tooltip open, click the **View Data** command at the top of the tooltip to view underlying data.

Right-click the view (with no marks selected), and then click View Data.

You can copy and paste the data into Excel or another application. To export the underlying data, click **Export All**.

## Delete sheets

Deleting a sheet removes it from the workbook. There must always be at least one worksheet in a workbook.

To delete the active sheet, right-click (control-click on Mac) the sheet in the sheet tab along the bottom of the workbook, and then click **Delete**.

Worksheets used in a dashboard or story cannot be deleted, but they can be hidden.

A worksheet used as Viz in Tooltip can be hidden or deleted.

## Create or Open Workbooks

A workbook contains one or more sheets, each of which can be a worksheet, dashboard, or story. You can use workbooks to organize, save, share, and publish your results.

- [Create or open a workbook below](#)
- [Open a workbook that has an unsupported data connection on the Mac below](#)
- [Open a published workbook from the server on the next page](#)

## Create or open a workbook

When you open Tableau, a new, blank workbook opens automatically.

**To create a new workbook**, select **File > New**

**To open an existing workbook**, click the thumbnail image of the workbook on the start page.

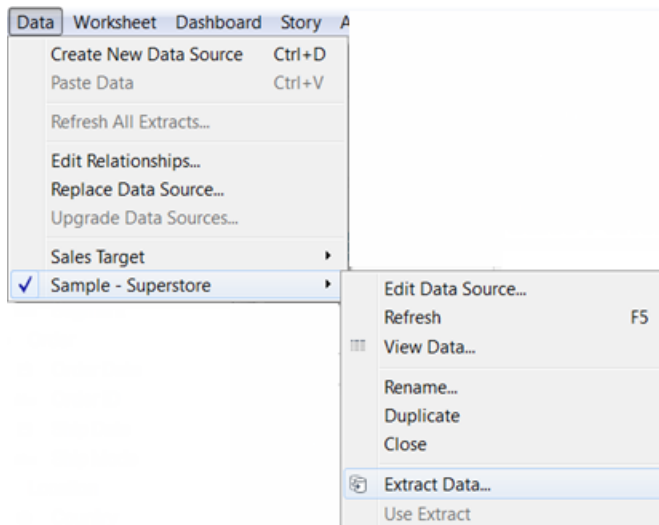

You can open multiple workbooks simultaneously. Each workbook appears in its own window.

**Note:** When you open multiple workbooks in Tableau Desktop on the Mac, multiple instances of the application are created, each with its own icon in the Dock. This differs from typical Mac application behavior, where one instance of the application handles all open documents.

## Open a workbook that has an unsupported data connection on the Mac

When working in Tableau Desktop on the Mac, you might need to open a Windows workbook that contains data sources that are not supported in Tableau Desktop on the Mac. To do so, follow the steps below:

1. In Tableau Desktop on Windows, save the workbook as an extract. To create and save an extract, on the **Data** menu, select a data source, and then select **Extract Data**.

2. Open the extract file (.hyper) you saved in Tableau Desktop on your Mac.

### Open a published workbook from the server

If you have been granted the **Download/Web Save As** permission for a published workbook, you can use Tableau Desktop to open the workbook from the server. When you open a workbook from the server and make changes, you can save it to your computer or, if you have been allowed the **Write/Web Save** permission, you can save the changes directly on the server.

### To open a workbook from the server

1. Select **Server > Open Workbook**.

2. If you are not already signed in to Tableau Server or Tableau Cloud, do so at the prompt.

If you're not sure how to sign in to the server you use, see [Sign in to Tableau Server or Tableau Cloud](#) on page 195.

3. In the Open Workbook from Tableau Server dialog box, select the workbook you want to open, and then click **Open**.

**Tip:** You can use the **Find** drop-down list or the Search box to browse or search for the workbook you want.

You can search all workbooks on the server or find by tags, publisher, project, or workbooks that you published.

## Navigate and Organize Sheets

You can navigate and organize sheets in a workbook using the sheet tabs, the filmstrips, or the sheet sorter.

### Options for navigating, viewing, and organizing sheets

There are three ways to navigate and view the sheets in a workbook:

- Tabs at the bottom of the workbook
- In the filmstrip view
- In the sheet sorter view

The tabs are useful when you want to quickly navigate between a small number of sheets. If your workbook has a large number of sheets, you can use the sheet sorter to easily navigate them all.

You can also drag and drop to do the following:

- Reorder the sheets
- Create new sheets
- Duplicate or delete existing sheets from any of the views

### Navigate with sheet tabs

Each sheet is represented as a tab along the bottom of the workbook. Select any tab to open the corresponding worksheet.

In the bottom right corner of the application window, there are several controls that you can use to advance through each sheet or quickly jump to the first or last sheet in the workbook. These controls are only available when there are too many sheet tabs to show across the bottom of the application window.

You can also navigate between sheets using the window menu or move through the multiple worksheets by pressing the left or right arrow keys on your keyboard.

To navigate through multiple worksheets, select a worksheet tab at the bottom of the workbook first.

**Note:** Navigating within a story is a different matter—there, you use the Navigator to move between story points. See [Create a Story on page 2770](#).

### Show thumbnails with the filmstrip

Similar to the sheet tabs, the filmstrip displays along the bottom of the workbook. However, instead of just sheet names, the filmstrip also shows a thumbnail image of each sheet. The filmstrip is useful when you are using Tableau to present your analysis and works well when you are working in Presentation mode.

Open the filmstrip by clicking the **Filmstrip**  button on the status bar (bottom right corner) of the workbook. Just like with the tabs, select the thumbnail image for the sheet you want to open. You can right-click the images to specify commands that apply to each sheet.

**Note:** When viewed from a Retina display, workbooks that are created on a standard resolution device will show only the first thumbnail in the filmstrip in high resolution. To display all thumbnails in the filmstrip in high resolution, resave the workbook on a computer with Retina display.

## Manage many sheets with sheet sorter

The sheet sorter shows all sheets in a workbook as thumbnail images on a single page. The sheet sorter is useful when you have a large number of sheets in a workbook. Open the sheet

sorter by clicking the sheet sorter  button on the status bar (bottom right corner of the workbook).

Right-click a sheet (Control-click on the Mac) to see these commands. You can also right-click (Control-click on the Mac) to refresh the thumbnail image of a particular sheet or **Refresh All Thumbnails** at once. If you have a large number of sheets, refreshing your view can take some time.

## Sheet commands

Use sheet commands to manage and organize your worksheets. For example you can create new sheets, duplicate sheets, copy formatting, apply color, or delete the sheet entirely.

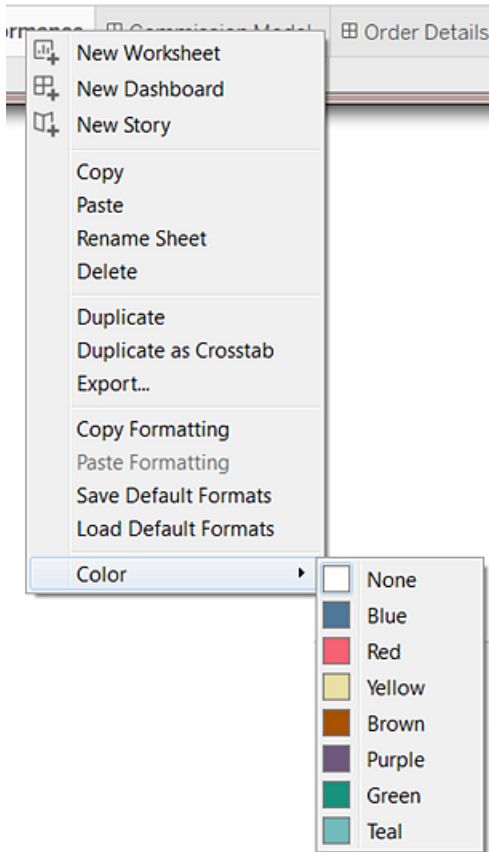

You can access sheet commands on the right-click menu (Control-click on a Mac) in the worksheet, sheet sorter, or the filmstrip view. To apply commands to multiple sheets at once, press the Ctrl key (Shift key on a Mac), and then select the sheets.

To make it easier to identify and group sheets, you can assign a color to sheets. You can select from seven different colors. Selecting **None** clears the color.

## Tableau Desktop and Web Authoring Help

To assign a color to sheets, select one or more sheets, right-click the sheets (Control-click on the Mac), select **Color**, and then pick a color.

The color strip appears on the bottom of the tab or sheet.

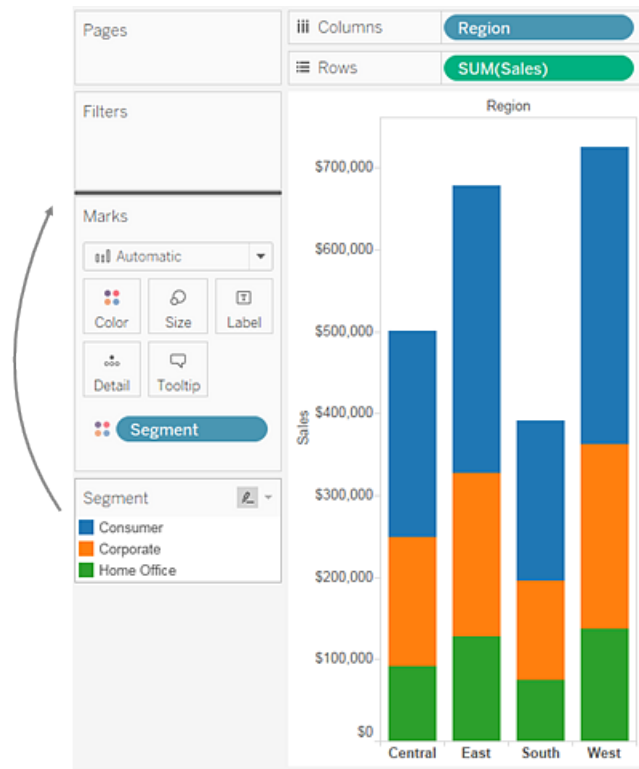

## Reorganizing the Workspace

Every worksheet contains a variety of cards, shelves, legends, and so on. You can reorganize the workspace by rearranging cards, hiding and showing specific parts of the workspace, and hiding everything but the view using Presentation Mode.

## Rearranging Cards

A worksheet contains several cards that contain shelves, legends, and other controls. Each card can be rearranged to create a custom workspace. To move a card, point the cursor at the title

area of the card you want to move. When the cursor becomes the move symbol , click and drag the card to a new position. As you drag the card around the worksheet, the possible positions for it are highlighted with a black bar.

You can restore the worksheet windows to their default state by selecting **Reset Cards** on the Show/Hide Cards toolbar control.

## Showing and Hiding Parts of the Workspace

Just about everything in the workspace can be turned on and off so you can avoid cluttering the worksheet with unnecessary cards, shelves, etc.

- To show and hide the toolbar or status bar, select **Window** and then select what you want to hide.
- To show and hide the window on the left side, which is either the Data pane (for worksheets), the Dashboard pane (for dashboards), or the Dashboards and Sheets pane (for stories); click the Minimize button  in the upper right corner of the pane. The pane is minimized to the bottom left corner of the workbook. Click the same button again to restore the pane.
- To show or hide a card click **Show/Hide Cards**  on the toolbar and then select the card you want to show or hide.

You can restore the worksheet windows to their default state by selecting **Reset Cards** on the **Show/Hide Cards** toolbar control.

## Presentation Mode

Sometimes you may want to use Tableau to present your findings. Rather than hiding each card or shelf one at a time, you can switch to presentation mode. Presentation mode hides everything on the sheet except for the view and its associated legends, filter cards, parameter controls, and worksheet tabs.

- To switch in and out of presentation mode, click the Presentation Mode  button on the toolbar or select **Window > Presentation Mode**.

Use the presentation mode controls in the bottom right corner to move between sheets and more. Each presentation mode control is described below.

	Show Filmstrip - shows the sheets as thumbnails at the bottom of the workspace.
	Show Tabs - shows the sheet tabs at the bottom of the workspace.
	Previous/Next Sheet - advances forward or backward through the sheets in a workbook.
	Enter/Exit Full Screen - switches between expanding the workbook to fill the entire screen and showing it in a window.

Exit Presentation Mode - returns the workbook to showing the entire workspace including the menus, toolbar, and the Data pane.

## Tableau File Types and Folders

You can save your work using several different Tableau specific file types: workbooks, bookmarks, packaged data files, data extracts, and data connection files. Each of these file types are described below. For related details, see [Save Your Work on page 3013](#).

- **Workbooks (.twb)** – Tableau workbook files have the .twb file extension. Workbooks hold one or more worksheets, plus zero or more dashboards and stories.
- **Bookmarks (.tbn)** – Tableau bookmark files have the .tbn file extension. Bookmarks contain a single worksheet and are an easy way to quickly share your work. For more information, see [Save a bookmark on page 3015](#).
- **Packaged Workbooks (.twbx)** – Tableau packaged workbooks have the .twbx file extension. A packaged workbook is a single zip file that contains a workbook along with any supporting local file data and background images. This format is the best way to package your work for sharing with others who don't have access to the original data. For more information, see [Packaged Workbooks on page 3018](#).
- **Extract (.hyper)** – Tableau extract files have the .hyper extension. Extract files are a local copy of a subset or entire data set that you can use to share data with others, when you need to work offline, and improve performance. For more information, see [Extract Your Data on page 867](#).
- **Data Source (.tds)** – Tableau data source files have the .tds file extension. Data source files are shortcuts for quickly connecting to the original data that you use often. Data source files do not contain the actual data but rather the information necessary to connect to the actual data as well as any modifications you've made on top of the actual data such as changing default properties, creating calculated fields, adding groups, and so on. For more information, see [Save Data Sources on page 919](#).
- **Packaged Data Source (.tdsx)** – Tableau packaged data source files have the .tdsx file extension. A packaged data source is a zip file that contains the data source file (.tds) described above as well as any local file data such as extract files (.hyper), text files, Excel files, Access files, and local cube files. Use this format to create a single file that you can then share with others who may not have access to the original data stored locally on your computer. For more information, see [Save Data Sources on page 919](#).

These files can be saved in the associated folders in the My Tableau Repository directory, which is automatically created in your My Documents folder when you install Tableau. Your work files can also be saved in other locations, such as your desktop or a network directory.

### Changing the Repository Location

You can specify a new location for the Tableau repository if you are not using the default location in your Documents folder. For instance, if you are required to have your data on a network server instead of on your local machine, you can point Tableau at the remote repository.

1. Select **File > Repository Location**.
2. Select a new folder that will act as the new repository location in the Select a Repository dialog box.
3. Restart Tableau so that it uses the new repository.

Changing the repository location does not move the files contained in the original repository. Instead, Tableau creates a new repository where you can store your files.

### Language and Locale

Tableau Desktop is localized into several languages.

When you first run Tableau, it recognizes your computer locale and uses the appropriate language if it's supported. If you're using an unsupported language, the application defaults to English.

#### Set a language

You can configure Tableau to display the user interface (menus, messages, etc.) by choosing **Help > Choose Language**. After you change this setting, you must restart the application for the changes to take effect. You don't need to change this setting for every workbook.

## Set a locale

To configure date and number formatting, choose **File > Workbook Locale**. By default, the locale is set to **Automatic**, which means the locale matches the locale when the workbook is opened. This can be useful if you're authoring a workbook that will be viewed in many different languages and you want the dates and numbers to update accordingly. When you select a specific locale, the workbook doesn't change regardless of who opens it.

Tableau checks the following, in order, to determine the workbook locale:

1. Workbook Locale (explicit setting)
2. Windows Locale or Mac language
3. Tableau Language

If none of the above are set, then the workbook locale defaults to English.

## Day of the Week Sorting

You should set your workbook locale so Tableau can sort the days of the week in the correct chronological order. Otherwise, Tableau sorts the names of the days alphabetically. If locales are appropriate, you can sort the days of the week manually. See [Sort Data in a Visualization on page 1289](#).

## Visual Cues and Icons in Tableau Desktop

Tableau provides many visual cues to help you evaluate the type of data that's displayed in the Data pane and the state of a data view.

### Data sources in the Data pane

The following table explains each of the icons used to describe the type of data sources in the Data pane. Each icon in the table can be modified by one of two indicators.

- A blue check mark indicates that the data source is the primary data source in the workbook. 
- An orange check mark indicates that the data source is the secondary data source in the workbook. 

Visual Cue	Description
	The workbook is directly connected to a relational data source or file.
	The workbook is connected to a cube (multidimensional) data source. In Tableau, cube data sources are supported only in Windows.

Visual Cue	Description
	The workbook is connected to an extract that still references the underlying data.
	The workbook is connected to an Excel table, sub-table, or named range.
	The workbook is connected to a data source that has been published to Tableau Server.

## Fields in the Data Pane

The following table explains each of the icons displayed in the Data pane. Each icon in the table can be modified by one of four indicators.

- Blue icons indicate that the field is discrete. `Abc`
- Green icons indicate that the field is continuous. `#`
- Icons preceded by the equal sign (=) indicate that the field is a user-defined calculation or a copy of another field. `=Abc`

Visual Cue	Description
	The field contains text values.
	The field contains numeric values.

Visual Cue	Description
	The field is a calculation defined on the server.
	The field contains only date values.
	The field contains both date and time values.
	The field contains geographical data and has been assigned a geographic role. Use these fields when building map views. See <a href="#">Maps and Geographic Data Analysis in Tableau on page 1593</a> .
	The field contains geographical data from an active custom geocoding file. See <a href="#">Geocode Locations Tableau Does Not Recognize and Plot Them on a Map on page 1653</a> .
T F =T F	The field contains boolean (true or false) values.
	The field is a calculation that is defined in the database by an administrator. These fields are marked with a cylinder icon and are not available for all data sources.
	The field is a user-defined set. See <a href="#">Create Sets on page 1040</a> .
	The field is a server named set.
	The field is a set that was automatically created as a result of an action.
	The field is a user filter, used when publishing to the web. See <a href="#">Restrict Access at the Data Row Level on page 3095</a> .

Visual Cue	Description
	The field is a numeric bin. See <a href="#">Create Bins from a Continuous Measure</a> on page 1541.
	The field is a group. See <a href="#">Correct Data Errors or Combine Dimension Members by Grouping Your Data</a> on page 1038.
	The field is a cluster group. See <a href="#">Find Clusters in Data</a> on page 1959.
	The field is a relational hierarchy. See <a href="#">Create Hierarchies</a> on page 1024.
	A folder that contains one or more fields. Folders are used to organize fields in the Data pane. See <a href="#">Organize the Data Pane</a> on page 999.
	The field is an attribute of a cube (multidimensional) data source. In Tableau, cube data sources are supported only in Windows.
	The field is a varying attribute of a cube (multidimensional) data source.
	The field is a level in a multidimensional hierarchy. Levels greater than five are shown without numbers.
	The field is blended with a field from another data source. See <a href="#">Blend Your Data</a> on page 764
	The field is not blended with a field from another data source. See <a href="#">Blend Your Data</a> on page 764

## Fields on Shelves

Fields placed on shelves use a combination of icons, colors, and text styles as visual cues.

Visual Cue	Description
	<p>A blue field on a shelf indicates a discrete field. In most cases, adding a dimension to a shelf results in a blue field. Blue fields are discrete—they contain a finite number of values. Adding a blue field to a shelf creates headers. For details, see <a href="#">Headers on page 77</a>.</p>
	<p>A green field on a shelf indicates a continuous field. In most cases, adding a measure to a shelf results in a green field. Green fields are continuous—they contain an infinite number of values. Adding a green field to a shelf creates an axis. For details, see <a href="#">Axes on page 80</a>.</p>
	<p>The Sort icon indicates a field that has either a computed or manual sort order applied. See <a href="#">Sort Data in a Visualization on page 1289</a>.</p>
	<p>The sigma icon indicates a slicing filter in a multidimensional (cube) data source. See <a href="#">Create Slicing Filters on page 935</a>.</p>
	<p>The Venn diagram icon indicates a set. See <a href="#">Create Sets on page 1040</a>.</p>
	<p>A field name shown in italics indicates a filtered set.</p>
	<p>A gray field on the Filters shelf indicates a context filter. See <a href="#">Use Context Filters on page 1281</a>.</p>
	<p>The delta icon indicates that the field is a table calculation. See <a href="#">Transform Values with Table Calculations on page 2484</a>.</p>
	<p>The plus and minus controls appear when the field is part of a hierarchy that you can traverse.</p>

Visual Cue	Description
	The arrow icon indicates that a forecast is being displayed for the field. This icon is also used on the Forecast Indicator field, which is an automatic field used to distinguish between actual and forecast values. See <a href="#">Forecasting on page 1983</a> .
	The field is from a secondary data source. See <a href="#">Blend Your Data on page 764</a> .
	The field is assigned to a specific worksheet.
	The field is assigned to all worksheets with the same data source.
	The field is incompatible with one or more other fields in the view.

## Fields on the Marks card

Fields placed on the Marks card use specific icons to describe how they appear in the view. For more details, see [Control the Appearance of Marks in the View on page 1205](#).

Visual Cue	Description
	The field is applied to Color on the Marks card.
	The field is applied to Size on the Marks card.
	The field is applied to Label on the Marks card.

Visual Cue	Description
	The field is applied to Shape on the Marks card.
	The field is applied to Detail on the Marks card.
	The field is applied to Tooltip on the Marks card.
	The field is applied to Path on the Marks card. Path is only available when the Line or Polygon mark type is selected from the Marks drop-down menu.

### Sheets in the Dashboards and Worksheets pane

The following table explains each of the icons used to describe the type of sheet that can be placed in a story. A blue check mark indicates that a sheet is being used in one or more story points. ✓

Visual Cue	Description
	The sheet is a worksheet.
	The sheet is a dashboard.

### Fields in the Calculation editor

Fields in the calculation editor are color coded by field type.

Visual Cue	Description
[ORANGE]	The field is a dimension, set, or measure.
[Parameters]. [PURPLE]	The field is a parameter. Tableau appends [Parameters] to avoid ambiguity when a parameter has the same name as another field
[ORANGE]. [ORANGE]	The field is from a secondary data source.
BLUE()	The field is a calculation function.

## Tableau Concepts

What are dimensions and measures? Why are some fields dimensions and others measures?

Why is the background color blue for some fields, and green for others?

How does adding a filter affect my viz?

How does Tableau aggregate data in a view?

The topics in this section cover concepts that answer these questions to help you understand why Tableau does what it does.

If you're new to Tableau Desktop, also see other topics in [Get Started on page 3](#).

If you're new to Tableau Public, also see Tableau Public [Resources](#).

## Structure Data for Analysis

There are certain concepts that are fundamental to understanding data prep and how to structure data for analysis. Data can be generated, captured, and stored in a dizzying variety of formats, but when it comes to analysis, not all data formats are created equal.

Data preparation is the process of getting well formatted data into a single table or multiple related tables so it can be analyzed in Tableau. This includes both the structure, i.e. rows and columns, as well as aspects of data cleanliness, such correct data types and correct data values.

**Tip:** It may help to go through the following topic with a data set of your own. If you do not already have a data set you can use, see our tips for [finding good data sets](#).

## How structure impacts analysis

The structure of your data may not be something you can control. The rest of this topic assumes you have access to the raw data and the tools needed to shape it, such as Tableau Prep Builder. However, there may be situations when you can't pivot or aggregate your data as desired. It is often still possible to perform the analysis but you may need to change your calculations or how you approach the data. For an example of how to perform the same analysis with different data structures, see Tableau Prep Day in the Life Scenarios: [Analysis with the Second Date in Tableau Desktop](#). But if you can optimize the data structure it will likely make your analysis much easier.

## Data Structure

Tableau Desktop works best with data that is in tables formatted like a spreadsheet. That is, data stored in rows and columns, with column headers in the first row. So what should be a row or column?

### What is a row?

A row, or record, can be anything from information around a transaction at a retail store, to weather measurements at a specific location, or stats about a social media post.

It's important to know what a record (row) in the data represents. This is the *granularity* of the data.

Here, each record is a day

Here, each record is a month

Date	Max TemperatureF	Mean TemperatureF	Date	Max TemperatureF	Mean TemperatureF	Min TemperatureF
1/1/2015	42		January	63	45	26
1/2/2015	42		February	62	49	33
1/3/2015	41		March	69	51	31
1/4/2015	51		April	77	52	37
1/5/2015	54		May	82	59	43
1/6/2015	54		June	92	68	49
1/7/2015	46		July	95	71	54
1/8/2015	46		August	92	69	54
1/9/2015	50		September	81	61	45
1/10/2015	46		October	74	58	45
			November	60	44	25

**Tip:** A best practice is to have a unique identifier (UID), a value that identifies each row as a unique piece of data. Think of it like the social security number or URL of each record. In Superstore, that would be Row ID. Note that not all data sets have a UID but it can't hurt to have one.

Try to make sure you can answer the question "What does a row in the data set represent?". This is the same as answering "What does the TableName(Count) field represent?". If you can't articulate that, the data might be structured poorly for analysis.

## Aggregation and Granularity

A concept related to what makes up a row is the idea of aggregation and granularity, which are opposite ends of a spectrum.

### Aggregation

- refers to how multiple data values are brought together into a single value, such as counting all the Google searches for Pumpkin Spice or taking the average of all the temperature readings around Seattle on a given day.
- By default, measures in Tableau are always aggregated. The default aggregation is SUM. You can change the aggregation to options like Average, Median, Count Distinct, Minimum, etc.

### Granularity

- refers to how detailed the data is. What does a row or record in the data set represent? A person with malaria? A provinces' total cases of malaria for the month? That's the granularity.
- Knowing the granularity of the data is crucial to working with level of detail (LOD) expressions.

Understanding aggregation and granularity is a critical concept for many reasons; it impacts things like finding useful data sets, building the visualization you want, relating or joining data correctly, and using LOD expressions.

**Tip:** For more information, see [Data Aggregation in Tableau](#).

### What is a field or column?

A *column* of data in a table comes into Tableau Desktop as a *field* in the data pane, but they are essentially interchangeable terms. (We save the term *column* in Tableau Desktop for use in the

columns and rows shelf and to describe certain visualizations.) A field of data should contain items that can be grouped into a larger relationship. The items themselves are called *values* or *members* (only discrete dimensions contain members).

What values are allowed in a given field are determined by the *domain* of the field (see the note below). For example, a column for "grocery store departments" might contain the members "deli", "bakery", "produce", etc., but it wouldn't include "bread" or "salami" because those are items, not departments. Phrased another way, the domain of the department field is limited to just the possible grocery store departments.

Additionally, a well-structured data set would have a column for "Sales" and a column for "Profit", not a single column for "Money", because profit is a separate concept from sales.

- The domain of the Sales field would be values  $\geq 0$ , since sales cannot be negative.
- The domain of the Profit field, however, would be all values, since profit can be negative.

**Note:** *Domain* can also mean the values present in the data. If the column "grocery store department" erroneously contained "salami", by this definition, that value would be in the domain of the column. The definitions are slightly contradictory. One is the values that could or should be there, the other is values that actually are there

## Categorizing fields

Each column in the data table comes into Tableau Desktop as a field, which appears in the **Data** pane. Fields in Tableau Desktop must be either a dimension or measure (separated by a line within tables in the **Data** pane) and either discrete or continuous (color coded: blue fields are discrete and green fields are continuous).

- *Dimensions* are qualitative, meaning they can't be measured but are instead described. Dimensions are often things like city or country, eye color, category, team name, etc. Dimensions are usually discrete.
- *Measures* are quantitative, meaning they can be measured and recorded with numbers. Measures can be things like sales, height, clicks, etc. In Tableau Desktop, measures are automatically aggregated; the default aggregation is SUM. Measures are usually continuous.
- *Discrete* means individually separate or distinct. Toyota is distinct from Mazda. In Tableau Desktop, discrete values come into the view as a label and they create panes.

- *Continuous* means forming an unbroken, continuous whole. 7 is followed by 8 and then it's the same distance to 9, and 7.5 would fall midway between 7 and 8. In Tableau Desktop, continuous values come into the view as an axis.
- Dimensions are usually discrete, and measures are usually continuous. However, this is not always the case. Dates can be either discrete or continuous.
  - Dates are dimensions and automatically come into the view as discrete (aka date parts, such as "August", which considers the month of August without considering other information like the year). A trend line applied to a timeline with discrete dates will be broken into multiple trend lines, one per pane.
  - We can choose to use continuous dates if preferred (aka date truncations, such as "August 2024", which is different than "August 2025"). A trend line applied to a timeline with continuous dates will have a single trend line for the entire date axis.

**Tip:** For more information, see [Dimensions and Measures, Blue and Green](#).

In Tableau Prep, no distinction is made for dimensions or measures. Understanding the concepts behind discrete or continuous are important, however, for things like understanding the detail versus summary presentation of data in the profile pane.

- Detail: the detail view shows every domain element as a discrete label and has a visual scrollbar to provide a visual overview of all the data.
- Summary: the summary view shows the values as binned on a continuous axis as a histogram.

## Binning & Histograms

A field like age or salary is considered continuous. There is a relationship between the age 34 and 35, and 34 is as far from 35 as 35 is from 36. However, once we're past age 10 or so, we usually stop saying things like we're "9 and a half" or "7 and  $\frac{3}{4}$ ". We're already binning our age to neat year-sized increments. Someone who is 12,850 days old is older than someone who is 12,790 days old, but we draw a line and say they're both 35. Similarly, age groupings are often used in place of actual ages. Child prices for movie tickets might be for kids 12 and under, or a survey may ask you to select your age group, such as 20-24, 25-30, etc.

Histograms are used to visualize the distribution of numerical data using binning. A histogram is similar to a bar chart, but rather than being discrete categories per bar, the rectangles making up the histogram span a *bin* of a continuous axis, such as range of the number of blossoms (0-4, 5-9, 10-14, etc.). The height of the rectangles is determined by frequency or count of those values.

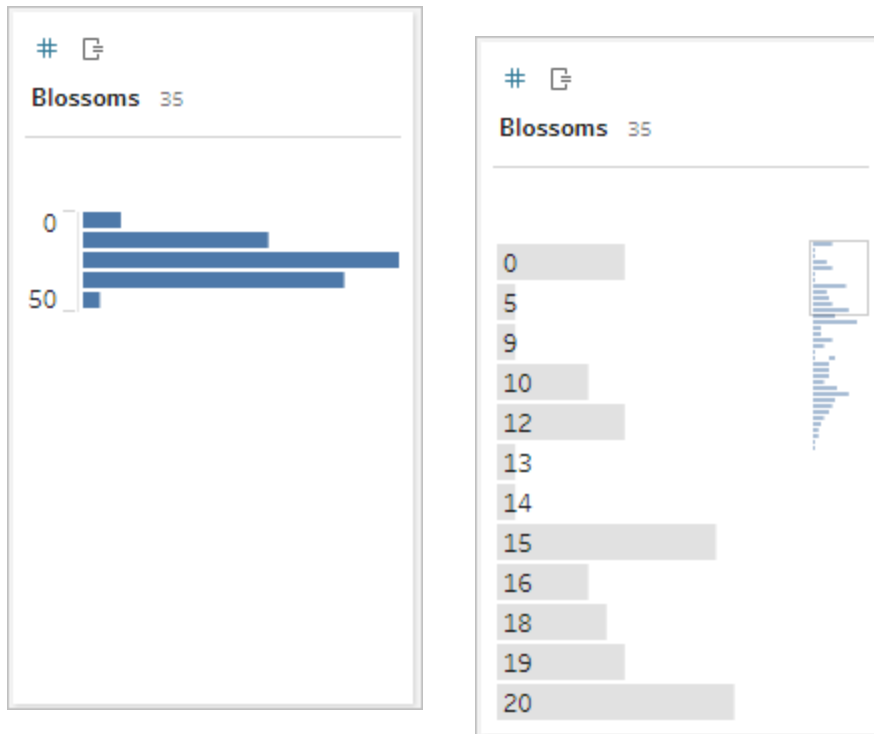

Here, the y-axis is the count of plants that fall into each bin. Seven plants have 0-4 blossoms, two plants have 5-9 blossoms, and 43 plants have 20-24 blossoms.

In Tableau Prep, the summary view is a histogram of binned values. The detail view shows the frequency for every value and has a visual scrollbar off to the side that shows the overall distribution of the data.

Summary view

Detail view

## Distributions and outliers

Seeing the distribution of a data set can help with outlier detection.

- *Distribution*: the shape of the data in a histogram, though this depends on the size of the bins. Being able to see all your data in a histogram view can help identify if the data seems correct and complete. The shape of the distribution will only be of use if you know the data and can interpret whether or not the distribution makes sense.
  - For example, if we were to look at a data set of the number of homes with broadband internet from 1940-2017, we'd expect to see a very skewed distribution. However, if we were to look at the number of homes with broadband internet from January 2017 to December 2017 we'd expect a fairly uniform distribution.
  - If we were to look at a data set of Google searches for "Pumpkin Spice Latte", we'd expect to see a fairly sharp peak in the fall, whereas searches for ""convert Celsius to Fahrenheit" would likely be fairly stable.
- *Outlier*: a value that is extreme compared to other values. Outliers may be correct values or they may be indicative of an error.

- Some outliers are correct and indicate actual anomalies; these should not be removed or modified.
- Some outliers indicate issues with data cleanliness, such as a salary of \$50 instead of \$50,000 because a period was typed instead of the comma.

## Visual outlier detection with distributions

If you were to see a list like this:

at first glance it doesn't look odd. But if, instead of a list of labels, this was plotted on a continuous binned axis, it would look like this:

And it's much more obvious that the last observation is farther away from the first and may be an outlier due to error.

## Data Types

Databases, unlike spreadsheets, usually enforce strict rules on data types. Data types classify the data in a given field and provide information about how the data should be formatted, interpreted, and what operations can be done to that data. For example, numerical fields can have mathematical operations applied to them and geographic fields can be mapped.

Tableau Desktop assigns whether a field is a dimension or measure, but fields have other characteristics that depend on their data type. These are indicated by the icon each field has (though some types share an icon). Tableau Prep uses the same data types. If data type is enforced on a column and an existing value doesn't match its assigned data type, it may be displayed as null (because "purple" doesn't mean anything as a number).

Some functions require specific data types. For example, you cannot use CONTAINS with a numerical field. Type functions are used to change the data type of a field. For example, DATEPARSE can take a text date in a specific format and make it a date, thus enabling things like automatic drill down in the view.

Icon	Data type
	Text (string) values
	Date values
	Date & Time values
	Numerical values
	Boolean values (relational only)
	Geographic values (used with maps)

**Tip:** For more information, refer to the Help article on [Data Types](#).

## Pivot and Unpivot Data

People-friendly data is often captured and recorded in a wide format, with many columns. Machine-readable data, like Tableau prefers, is better in a tall format, with fewer columns and more rows.

**Note:** Traditionally, pivoting data means going from tall to wide (rows to columns), and unpivoting means going from wide to tall (columns to rows). However, Tableau uses the word *pivot* to mean going from wide (people-friendly) to tall (machine-readable) by turning columns into rows. In this document, *pivot* will refer to the Tableau sense of the word. For clarity, it can help to specify "pivot columns to rows" or "pivot rows to columns".

For more information, refer to the Help articles [Pivot Your Data](#) and [Tips for Working with your Data](#).

### Wide data

In the WHO malaria data set, there is a column for country, then a column per year. Each cell represents the number of cases of malaria for that country and year. In this format we have 108

rows and 16 columns.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P
1	Country	2014	2013	2012	2011	2010	2009	2008	2007	2006	2005	2004	2003	2002	2001	2000
2	Afghanistan	61362	39263	54840	77549	69397	64880	81574	92202	86129	116444	242022	360940	415356		94475
3	Algeria	0	0	55	1	1	0	3	27	1	2	3	6	8	8	35
4	Angola	2298979	1999868	1496834	1632282	1682870	1573422	1377992	1533485	1082398	889572					
5	Argentina	0	0	0	0	14	86	130	387	212	252	115	122	125	215	440
6	Armenia					0	0	0	0	0	7	47	29	52	79	141
7	Azerbaijan	0	0	3	4	50	78	72	108	143	242	386	482	506	1058	1526
8	Bahamas				6	1		14	6	49	1	2	3	1	4	2
9	Bangladesh	10216	3864	9901	51773	55873	63873	84690	59866	32857	48121	58894	54654	62269	54216	55599
10	Belize	19	20	33	72	150	256	540	845	844	1549	1066	1084	1134	1162	1486
11	Benin	1044235	1078834	705839	422968		889597									
12	Bhutan	19	15	0	194	436	972	329	793	1868	1825	2670	3806	6511	5982	5935
13	Bolivia (Plurinatic	7401	7342	7415	7143	13769	9743	9748	14610	19725	21442	14910	20343	14276	15765	31469
14	Botswana	1346	456	193	432	1046	1024	927	390		670	198	591	1640	3720	10510
15	Brazil	143415	177767	242758	267146	334667	309316	315746	458652	549469	606067	465004	408886	348259	388303	613241
16	Burkina Faso	5428655	3769051	3858046	428113	804539	182527	36514	44246	44265	21335	18256				
17	Burundi	4506732	4141207	3161026	1671874	1762447	1106673	876781	1101644	701721	237464	262206	262460	237120	213016	200006

It's easy for a person to read and understand this format. However, if we were to bring this data into Tableau Desktop, we get a field per column. We have a field for 2000, a field for 2001, a field for 2002, etc.

To think of it another way, there are 15 fields that all represent the same basic thing—number of reported cases of malaria—and no single field for time. This makes it very hard to do analysis across time as the data is stored in separate fields.

## Example: working with wide data

Q: How would we create a map that shows the total number of malaria cases per country from 2000 to 2014?

A: Create a calculated field to sum all the years.

Note: this image has not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

Another indication that this format isn't ideal for analysis can be seen in the fact that nowhere do we have information about what the actual values mean. For Algeria in 2012, we have the value 55. Fifty five what? It's not clear from the structure of the data.

	A	B	C	D	E
1	<b>Country</b>	<b>2014</b>	<b>2013</b>	<b>2012</b>	<b>2011</b>
2	<b>Afghanistan</b>	61362	39263	54840	77549
3	<b>Algeria</b>	0	0	55	1
4	<b>Angola</b>	2298979	1999868	1496834	1632282

If the name of the column isn't describing what the values are but rather conveys additional information, this is a sign the data needs to be pivoted.

### Tall data

If we pivot the data, we reshape the data from wide to tall. Now, rather than having a column for each year, we have a single column, Year, and a new column, Reported Cases. In this format we have 1,606 rows and 3 columns. This data format is taller rather than wider.

	A	B	C
1	Country	Year	Reported Cases
2	Afghanistan	2000	94,475
3	Afghanistan	2001	
4	Afghanistan	2002	415,356
5	Afghanistan	2003	360,940
6	Afghanistan	2004	242,022
7	Afghanistan	2005	116,444
8	Afghanistan	2006	86,129
9	Afghanistan	2007	92,202
10	Afghanistan	2008	81,574
11	Afghanistan	2009	64,880
12	Afghanistan	2010	69,397
13	Afghanistan	2011	77,549
14	Afghanistan	2012	54,840
15	Afghanistan	2013	39,263
16	Afghanistan	2014	51,263

Now in Tableau Desktop, we have a field for Year and a field for Reported Cases as well as the original Country field. It's much easier to do analysis because each field represents a unique quality about the data set—location, time, and value.

Note: this image has not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

## Example: working with tall data

Q: How would we create a map that shows the total number of malaria cases per country from 2000 to 2014?

A: Use the Reported Cases field.

Note: this image has not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

Now it's easy to see that for Algeria in 2012, the 55 refers to the number of reported cases (because we could label this new column).

	A	B	C
1	Country	Year	Reported Cases
28	Algeria	2011	1
29	Algeria	2012	55
30	Algeria	2013	0

**Note:** In this example, the wide data consisted of a single record per country. With the tall data format, there are now 15 rows for each country (one for each of the 15 years in the data). It's important to keep in mind that there are now multiple rows per country.

If there was a column for Land Area, that value would be repeated for each of the 15 rows for each country in a tall data structure. If you created a bar chart by bringing out **Country** to **Rows** and **Land Area** to **Columns**, by default the view would sum the land area for all 15 rows per country.

For some fields it may be necessary to compensate for double counting values by aggregating with an average or minimum rather than sum or filtering.

## Normalization

Relational databases are made up of multiple tables that can be related or linked together in some way. Each table contains a unique identifier, or key, per record. By relating or joining on the keys, records can be linked to provide more information than is contained in a single table. What information goes into each table is dependent on the data model used, but the general principle is around reducing duplication.

For example, consider event planning for an event like a wedding. We need to keep track of information at the level of groups (such as families or couples) as well as the level of individuals.

A table could be created that combines all the information together:

ID	Name	Group	Dietary	Seating	Attending	Address	Invitation	Gift	Bride
10	Cedar	Tree	Omnivore	1	yes	87 Forest Ave	sent	pebble	yes
11	Redwood	Tree	Omnivore	1	yes	87 Forest Ave	sent	pebble	yes
12	Fir	Tree	Vegan	1	yes	87 Forest Ave	sent	pebble	yes
13	Madrona	Tree	Omnivore		no	87 Forest Ave	sent	pebble	yes
14	Chanterelle	Mushroom	Omnivore	2	yes	3 Troll St	sent	leaf	no
15	Cremini	Mushroom	Kosher	2	yes	3 Troll St	sent	leaf	no
16	Portobello	Mushroom	Omnivore	2	yes	3 Troll St	sent	leaf	no
17	Hydrangea	Flower				652 Meadow Ln	undeliverable		yes
18	Dahlia	Flower				652 Meadow Ln	undeliverable		yes

However, if an address is incorrect and needs to be fixed, it must be fixed across multiple rows, potentially leading to errors or conflicts. A better structure is to create two tables, one for information that pertains to the group (such as address and if the invitation was sent) and one for information pertaining to the individuals (for things like seating assignments and dietary restrictions).

Group table

Individual table

ID	Group	Address	Invitation	Gift	Bride
34	Tree	87 Forest Ave	sent		
35	Mushroom	3 Troll St	sent		
36	Flower	652 Meadow Ln	undeliverable		

ID	Name	Group	Dietary	Seating	Attending
10	Cedar	Tree	Omnivore	1	yes
11	Redwood	Tree	Omnivore	1	yes
12	Fir	Tree	Vegan	1	yes
13	Madrona	Tree	Omnivore		no
14	Chanterelle	Mushroom	Omnivore	2	yes
15	Cremini	Mushroom	Kosher	2	yes
16	Portobello	Mushroom	Omnivore	2	yes
17	Hydrangea	Flower			
18	Dahlia	Flower			

It's much easier to track and analyze group-level information in the group table and individual-level information in the individual table. For example, the number of chairs needed can be obtained from the number of Attending = Yes records in the individual table, and the number of stamps needed for thank-yous can be obtained from the number of records in the group table where Gift isn't null.

The process of breaking up all the data into multiple tables—and figuring out which table contains which columns—is called *normalization*. Normalization helps reduce redundant data and simplifies the organization of the database.

However, there may be times when information is needed that spans multiple tables. For example, what if we wanted to balance seating arrangements (individuals) such that groups from the bride's side are intermingled with groups from the groom's side? (The bride or groom affiliation is tracked at the group level.) To achieve this, we need to relate the tables back together so the individuals are associated with information about their group. Proper normalization isn't just breaking up tables, it also requires the presence of a shared, related field or unique identifier that can be used to combine the data back together again. Here, that related field is Group. That field is present in both tables, so we can join on this field and return to our original, single table format. This is a *denormalized* structure.

So why didn't we just keep the original denormalized table? It is harder to maintain and was storing redundant information. At scale, the level of data duplication can become massive. Storing the same information over and over isn't efficient.

Normalized tables have a few key properties:

- Each row needs a unique identifier
- Each table needs a column or columns that can be used to connect it back to other tables (key).

These shared (key) columns are used for relating or joining tables back together. For our data, the relationship or join clause would be on the Group field in each table.

### Join Types

Although the default method for combing data in Tableau Desktop is relating, there are cases when you may want to join tables in Tableau Desktop or Tableau Prep Builder. For a basic overview of joins and join types, see [Join Your Data](#).

Name	# of Siblings
Taylor	2
Alex	3
Shannon	0
Tracy	1

Name	Eye Color
Taylor	Blue
Alex	Brown
Morgan	Brown

**Inner Join**

Name	# of Siblings	Eye Color
Taylor	2	Blue
Alex	3	Brown

**Left Join**

Name	# of Siblings	Eye Color
Taylor	2	Blue
Alex	3	Brown
Shannon	0	<i>null</i>
Tracy	1	<i>null</i>

**Right Join**

Name	Eye Color	# of Siblings
Taylor	Blue	2
Alex	Brown	3
Morgan	Brown	<i>null</i>

**Outer Join**

Name	# of Siblings	Eye Color
Taylor	2	Blue
Alex	3	Brown
Shannon	0	<i>null</i>
Tracy	1	<i>null</i>
Morgan	<i>null</i>	Brown

## "Tidy" Data

Hadley Wickham published an article in 2014 in the Journal of Statistical Software called "Tidy Data" (August 2014, Volume 59, Issue 10). This article does an excellent job of laying out a framework for data that is well-structured for analysis. The article can be found [here \(Hadley Wickham's Academic Portfolio\)](#) or [here \(hosted by r-project.org\)](#).

**Note:** The article is hosted on external websites. Tableau cannot take responsibility for the accuracy or freshness of pages maintained by external providers. Contact the owners if you have questions regarding their content.

## Find Good Data Sets

A good way to learn how to use Tableau Desktop (or build sample or proof-of-concept content) is to find a data set you find interesting. When you have real questions you want to answer with data, the steps of the analysis become easier and more meaningful.

### The reality of data sets

There are two unavoidable facts about trying to find a data set that's not official, business-sanctioned data.

#### **You won't find what you're looking for.**

- Try to avoid strict expectations of what you need.
- Stay flexible and open minded about what you can use for a given project.
- Sometimes the data you want is behind a paywall—decide if it's worth it or not.

#### **You'll have to clean up the data.**

- Be prepared for basic [cleaning and shaping](#) to make sure the data is [well structured for analysis](#).
- You may need to [bring in other data sets](#).
- Having a data dictionary or metadata can be vital.
- [Calculations](#) may be necessary.

### What makes a good data set

A good data set is one that suits your purpose. As long as that need is met, it's a good data set. However, there are some considerations that can help you weed out data sets that are unlikely to suit your purpose. On the whole, look for data sets that meet the following conditions:

1. Contain the elements you need
2. Are disaggregated data
3. Have at least a couple dimensions and a couple measures
4. Have good metadata or a data dictionary
5. Are useable (not in a proprietary format, too messy, or too cumbersome)

## What makes Superstore super?

Superstore is one of the sample data sources that come with Tableau Desktop. Why is it such a good data set?

- **Necessary elements:** Superstore has dates, geographic data, fields with a hierarchy relationship (Category, Sub-Category, Product), measures that are positive and negative (Profit), etc. There are very few chart types you can't make with Superstore alone, and few features it can't be used to demonstrate.
- **Disaggregated:** The row-level data is each item in a transaction. Those items can be rolled up to the order level (via Order ID) or by any of the dimensions (such as date, customer, region, etc.)
- **Dimensions and measures:** Superstore has several dimensions allowing us to "slice and dice" by things like category or city. There are also multiple measures and dates, which open the possibilities for chart types and calculations.
- **Metadata:** Superstore has well-named fields and values. You don't need to look up what any values mean.
- **Small and clean:** Superstore is only a few megabytes so it takes up little room in the Tableau installer. It's also clean data, with only the correct values in each field and a good data structure.

### 1. A good data set has the elements you need for your purposes

If you're looking for a data set to build a specific visualization or to showcase specific functionalities, make sure the data set has the types of fields you need. For example, maps are a great visual but require geographic data. Basic demos often involve drilling down into dates, so the data would need at least one date field (and it would need to be more granular than just year to show drill down). Not all data sets need all these elements—know what you need for your purpose and don't waste time with data sets that are missing key elements.

Common elements for analysis:

- Dates
- Geographic data
- Hierarchical data
- "Interesting" measures—either substantial variation in magnitude or positive and negative values

Some features or viz types may require specific characteristics of the data such as:

- Clusters
- Forecasting
- Trend lines
- User filters
- **Spatial calculations**
- Certain calculations
- Bullet charts
- Control charts

## 2. A good data set is disaggregated (raw) data

If the data is too aggregated, there isn't much you can do for analysis. For example, if you want to look at trends in people Googling "Pumpkin Spice" but have yearly data, you can only look at a very high level overview. Ideally you want to get your hands on daily data, so you could see the huge spike when Starbucks starts offering #PSL.

What counts as disaggregated can vary by analysis. Note that due to privacy or practicality, some data sets will never be fully granular. For example, you would be unlikely to find a data set with case-by-case reporting of malaria by address, so monthly totals by region might be granular enough.

## Aggregation and granularity

Understanding aggregation and granularity is a critical concept for many reasons; it impacts things like finding useful data sets, building the visualization you want, combining data correctly, and using LOD expressions. Aggregation and granularity are opposite ends of a spectrum.

**Aggregation** refers to how the data is combined together, such as summing all the searches for Pumpkin Spice or taking the average of all the temperature readings around Seattle on a given day.

- By default, measures in Tableau are aggregated. The default aggregation is SUM. You can change the aggregation to things like average, median, count distinct, minimum, etc.

**Granularity** refers to how detailed the data is. What does a row (aka record) in the data set represent? A person with malaria? A provinces' total cases of malaria for the month? That's the granularity. Knowing the granularity of the data is crucial.

For more information, see [Data Aggregation in Tableau](#) on page 173.

### 3. A good data set has dimensions and measures

Many visualization types require **dimensions** and **measures**

- If you only have dimensions, you're mostly limited to counting, calculating percentages, or using the [Count of Table](#) field.
- If you only have measures, you can't break out the values by anything. You can dis-aggregate the data entirely or work with the overall SUM or AVG, etc.

Which isn't to say a data set with only dimensions can't be useful. Demographic data is an example of dimension-heavy data, and much analysis around demographics is counting or percentage-based. But for a more analytically rich data set, you want at least a few dimensions and measures.

## Dimensions and Measures, Discrete and Continuous

In the image above, note that the **Numeric dimension** doesn't have an aggregation on the Marks card, unlike both the **Continuous measure** and **Discrete measure**.

## Dimensions and Measures

Fields are broken out into dimensions and measures with a horizontal line in the data pane. In Tableau, dimensions come out into the view as themselves, whereas measures are automatically aggregated; the default aggregation for a measure is SUM.

- **Dimensions** are qualitative, meaning they are described, not measured.
  - Dimensions are often things like city or country, eye color, category, team name, etc.
  - Dimensions are usually discrete.
- **Measures** are quantitative, meaning they can be measured and recorded (numeric).
  - Measures are often things like sales, height, number of clicks, etc.
  - Measures are usually continuous.

If you could do math with a field, it should be a measure. If you're ever not sure if a field should be a measure or a dimension, think about if you can do meaningful math with the values. Is there any meaning to  $AVG(\text{RowID})$ , the sum of two Social Security numbers, or dividing a postal code

by 10? No. Those are dimensions that happen to be written as numbers. Think about how many countries have alphanumeric postal codes—they're just labels, even though in the US they're only numeric. Tableau can recognize many field names that indicate a numeric field is actually an ID or a postal code and tries to make those dimensions, but it's not perfect. Use the "could I do math with this?" test to decide if a numeric field should be a measure or dimension and rearrange the data pane as necessary.

**Note:** Although you can do math with dates (such as the DATEDIFF calculation), the standard convention is to categorize dates as dimensions.

## Discrete and Continuous

Discrete or Continuous fields are somewhat aligned with the concepts of dimension and measure, but they're not identical.

- **Discrete** fields contain distinct values. They make headers or labels in the view and the pills are blue
- **Continuous** fields "form an unbroken whole". They make an axis in the view and the pills are green

A good way of understanding discrete and continuous is to look at a date field. Dates can be either discrete OR continuous.

- Looking at average temperatures in August across a decade or century means "August" is being used as a discrete, qualitative date part.
- Looking at the overall trend in reported malaria cases since 1960 would take a single, unbroken axis, meaning the date is being used as a continuous, quantitative value.

For more information, see [Dimensions and Measures, Blue and Green](#) on page 148.

## Fields Created by Tableau

Tableau creates at least three fields, no matter what the data set is:

- *Measure Names* (a dimension)
- *Measure Values* (a measure)
- *TableName(Count)* (a measure)

And if there are geographic fields in the data set, Tableau also creates *Latitude (generated)* and *Longitude (generated)* fields.

**Measure Names** and **Measure Values** are two useful fields. For more information, see [Measure Values and Measure Names](#) on page 1160.

**Count of Table** provides the number of records for the table by counting the rows. This enables you to have at least one measure in your data set and can help with some analysis. You must understand the granularity of your data (what a row represents) to be able to define what the number of rows means.

Here, each row is a day, so the Count of Table would be the number of days:

Date	Max TemperatureF	Mean TemperatureF	Min TemperatureF
1/1/2015	42	34	26
1/2/2015	42	37	32
1/3/2015	41	38	35
1/4/2015	51	45	38
1/5/2015	54	52	49
1/6/2015	54	49	43
1/7/2015	46	44	42
1/8/2015	46	41	35
1/9/2015	50	44	38
1/10/2015	46	45	43

Here, each row is a month, so the Count of Table would be the number of months:

Date	Max TemperatureF	Mean TemperatureF	Min TemperatureF
January	63	45	26
February	62	49	33
March	69	51	31
April	77	52	37
May	82	59	43
June	92	68	49
July	95	71	54
August	92	69	54
September	81	61	45
October	74	58	45
November	60	44	25

#### 4. A good data set has metadata or a data dictionary

A data set can only be useful if you know what the data *is*. There are few things more frustrating in the hunt for good data than opening a file that looks like this:

Diet	Source	Donor	Collection	Sex	OTU0	OTU1	OTU2	OTU3	OTU4
0	4	0	0	0	7.38E-14	9.05E-11	8.22E-11	3.86E-11	8.25E-11
1	12	1	0	0	1.54E-13	5.67E-11	3.12E-11	8.52E-11	1.73E-11
1	4	3	0	0	5.52E-13	3.46E-11	0.00077	4.76E-11	9.80E-11
0	4	0	0	1	5.69E-13	2.75E-11	8.08E-11	9.94E-11	5.90E-12
1	4	3	0	0	8.97E-13	8.33E-11	0.000274	8.49E-11	5.38E-11
0	4	0	0	0	9.43E-13	6.21E-11	1.41E-11	6.32E-11	9.17E-11
1	11	0	0	0	1.13E-12	1.85E-11	9.04E-11	4.09E-11	5.31E-11
1	4	0	0	0	1.49E-12	7.86E-12	8.87E-11	3.48E-11	8.16E-11
1	6	0	1	0	1.63E-12	4.42E-11	9.12E-11	8.53E-11	9.40E-12

What does a Source of 4 or 12 mean? And what information is in the fields OTU0-OTU4?

A good data set is one that has either well-labeled fields and members or a data dictionary so you can relabel the data yourself. Think of Superstore—it's immediately obvious what the fields and their values are, such as Category and its members Technology, Furniture, and Office Supplies. Or, for the microbiome data set in the image above, there is a **data dictionary** which explains each Source (4 is feces and 12 is stomach) and the taxonomy of each OTU (OTU3 is a bacterium of the genus *Parabacteroides*).

Data dictionaries can also be called metadata, indicators, variable definitions, glossaries, or any number of other things. At the end of the day, a data dictionary provides information about column names and members in a column. That information can be brought into the data source or viz in several ways, including:

- Rename the columns so they are easier to understand (this can be done in the data set itself or in Tableau).
- Re-alias the members of the field (this can be done in the data set itself or in Tableau).
- Create calculations to add the data dictionary information.
- Comment on the field in Tableau (comments do not appear on published vizzes, only in the authoring environment).
- Use the data dictionary as another data source and combine the two data sources.

Losing a data dictionary can render a data set useless. If you're bookmarking a data set, bookmark the data dictionary, too. If you're downloading, download both and keep them in the same place.

### 5. A good data set is one you can use

As long as you can understand the data set and it has the information you need, even a small data set can pack a punch for analysis. Smaller data sets are also easy to store, share, and publish, and are likely to perform well.

Similarly, even if you find the "perfect" data set for your needs, if it requires an unrealistic amount of effort to clean up, it's not perfect after all. Knowing when to walk away from a data set that is too messy is important.

For example, this data set is from a Wikipedia article on relative letter frequencies. It started as 84 rows and 16 columns (pivoted to be 1,245 rows and 3 columns). The Excel file is 16KB. But with some groups, sets, calculations, and other manipulations, it enables robust analysis and interesting visuals.

[Click the image to download the workbook.](#)

## Relabel your data

Once you find a good data set, you'll often need to relabel it. Relabeling data can be useful to either create fake data for samples or proof-of-concepts, or to make the data more readable.

**Renaming** a field changes how that field appears in Tableau, such as renaming "Sales" to "Pipeline Sales" or "State" to "Province".

**Re-aliasing** changes how the members of a field are displayed, such as re-aliasing values in a Country field so that CHN becomes China and RUS becomes Russia.

- The values in a discrete dimension field are called **members**. Only members can be re-aliased. Consider a measure field for temperature. A value of 54°F can't be changed without changing data itself. But re-aliasing the member "CHN" as "China" in a Country field is the same information, just labeled in another way.

Renaming and re-aliasing mean almost the same thing. It's the convention in Tableau that fields are named and members are aliased. For more information, see [Organize and Customize](#)

[Fields in the Data Pane](#) on page 999 and [Create Aliases to Rename Members in the View](#) on page 1015.

**Note:** Renaming or re-aliasing only changes the appearance in Tableau Desktop; no changes are written back to the underlying data.

## Relabel to make fake data

Relabeling existing data sets is a great way to make samples or proof-of-concept content more compelling.

1. Use an easy data set (like Superstore) to build what you want (a specific chart type, showing off certain functionality, etc.)
2. Rename the relevant fields, change tooltips, and otherwise change the textual aspects to mask what the data actually represents.

**Important:** Only do this when it's clear the information is fake. Be careful that people don't think it's real data and try to use it for analysis. For example, use silly names or meaningless field names like colors or animals.

## Re-alias to make the data easier to use

It's more efficient to store the data as numeric values rather than string values, though numeric encoding can make the data harder to understand. For small data sets it probably won't make a performance impact, so prioritize being able to understand the data easily.

A downside to re-aliasing is that you no longer have access to those numeric values (making it harder to do things like sort, assign color gradients, etc.). Consider duplicating the field and re-aliasing the copy. Alternatively, a calculation in Tableau can be a good way to preserve the original information while also making it more easily understandable.

## Re-alias with the CASE function

Calculations can be very powerful for re-aliasing. For example, CASE functions allow you to say, essentially, "when this field has a value of A, give me X. When the value is B, give me Y".

Here, the CASE function looks at the F-scale in a tornado data set and provides the written description associated with each numeric value:

```
CASE [F-scale]
WHEN "0" THEN "Some damage to chimneys; branches broken off trees;
```

```

shallow-rooted trees pushed over; sign boards damaged."
WHEN "1" THEN "The lower limit is the beginning of hurricane wind
speed; peels surface off roofs; mobile homes pushed off foundations
or overturned; moving autos pushed off the roads..."
WHEN "2" THEN "Roofs torn off frame houses; mobile homes demolished;
boxcars overturned; large trees snapped or uprooted; highrise windows
broken and blown in; light-object missiles generated."
WHEN "3" THEN "Roofs and some walls torn off well-constructed houses;
trains overturned; most trees in forest uprooted; heavy cars lifted
off the ground and thrown."
WHEN "4" THEN "Well-constructed houses leveled; structures with weak
foundations blown away some distance; cars thrown and large missiles
generated."
WHEN "5" THEN "Strong frame houses lifted off foundations and carried
considerable distances to disintegrate; ... trees debarked; steel
reinforced concrete structures badly damaged."
END

```

Now we can chose to use either the original "F-scale" field (0-5) or the "F-scale damage description" field in the viz.

### Tips when looking for data sets

**Note:** Try to make sure you can answer the question "What does a row (aka record) in the data set represent?" If you can't articulate that, you might not understand the data well enough to be able to use it or it might be structured poorly for analysis.

- Keep track of where the data came from.
- Keep the data dictionary information with the data itself.
- Avoid stale data if you need the content to stay evergreen. Look for:
  - updatable data (stocks, weather, regularly published reports, etc.)
  - timeless data (the average mass of various animals isn't going to change from year to year)
  - data you can future-proof by artificially changing to historical or future dates
- Try simply Googling what you're looking for, you might be surprised.
- Don't be afraid to give up on a data set if it's too much work to prep.

## Places to look for data

Where can you look for data? There are a potentially overwhelming number of places to find data sets. Here are some options to get you started. Note that the reality of data sets does apply to these sites—you probably won't find what you're thinking of right now, and you will most likely need to do some cleaning to get the data ready for analysis.

**Disclaimer:** Although we make every effort to ensure these links to external websites are accurate, up to date, and relevant, Tableau cannot take responsibility for the accuracy or freshness of pages maintained by external providers. Listing a site here is not an endorsement of any content or organization. Contact the external site for answers to questions regarding its content.

**Tableau Public:** Tableau Public is an amazing resource for Tableau-friendly data sets. Search for workbooks that are on a topic you're interested in, browse for inspiration, then download the workbook to access the data. Or check out the curated [Sample Data](#).

**Wikipedia tables:** Get data out of Wikipedia tables by: copying and pasting into a spreadsheet, [copying and pasting directly into Tableau](#), or using [Google sheets and the IMPORTHTML function](#) to create a Google spreadsheet of the data.

**Google Dataset Search:** "A search engine to unite the fragmented world of online datasets."

**Data is Plural :** Subscribe for a weekly newsletter with data sets, or browse the [archive](#).

**Makeover Monday:** "Join us every Monday to work with a given data set and create better, more effective visualizations and help us make information more accessible." You can see what other people have done with the same data set, kickstarting your analysis or giving inspiration. Use [#makeovermonday](#) on Twitter to participate.

## Dimensions and Measures, Blue and Green

Tableau identifies each field as a dimension or measure in the **Data** pane, depending on the type of data the field contains. You use these fields to build your analysis.

### About data field roles and types

Data fields are made from the columns in your data source. Each field is automatically assigned a data type such as integer, string, or date, and a role: a discrete dimension or continuous measure (or less commonly, a continuous dimension or discrete measure).

- *Dimensions* contain qualitative values (such as names, dates, or geographical data). You can use dimensions to categorize, segment, and reveal the details in your data. Dimensions affect the level of detail in the view.
- *Measures* contain numeric, quantitative values that you can measure. Measures are aggregated by default. When you drag a measure into the view, Tableau applies an aggregation on the pill.

### Blue versus green fields

Tableau represents data differently in the view depending on whether the field is discrete or continuous). *Continuous* and *discrete* are mathematical terms.

- *Continuous* means "forming an unbroken whole, without interruption". These fields are colored green. When a continuous field is put on the Rows or Columns shelf, an axis is created in the view.
- *Discrete* means "individually separate and distinct." These fields are colored blue. When a discrete field is put on the Rows or Columns shelf, a header is created in the view.

### Possible combinations of fields in Tableau

This table shows examples of what the different fields look like in the view. An instance of a field in the view (on the Rows shelf, for example) is sometimes referred to as a "pill".

#### Discrete Dimensions

Product Name

<b>Continuous Dimensions</b> (dimensions with a data type of String or Boolean can't be continuous)	YEAR(Order Date)
<b>Discrete Measures</b>	SUM(Profit)
<b>Continuous Measures</b>	SUM(Profit)

**Note:** With a cube (multidimensional) data source, the options for changing data roles are limited. In Tableau Desktop, cubes are supported only on Windows.) You can change some measures from continuous to discrete, but in general, you can't change data roles for fields in cube data sources. For related details, see [Cube Data Sources on page 929](#).

A visual cue when a field is a measure is that the pill is aggregated with a function, indicated

before the field name, such as: **SUM(Profit)**. To learn more about aggregation, see [List of Predefined Aggregations in Tableau on page 177](#) and [Aggregate Functions in Tableau on page 2240](#).

But there are exceptions:

- If the entire view is disaggregated, then by definition no field in the view is aggregated. For details, see [How to Disaggregate Data on page 182](#).
- If you're using a multidimensional data source, fields are aggregated in the data source and measures fields in the view don't show that aggregation.
- And dimensions can sometimes be aggregated with specific aggregations such as MAX or ATTR.

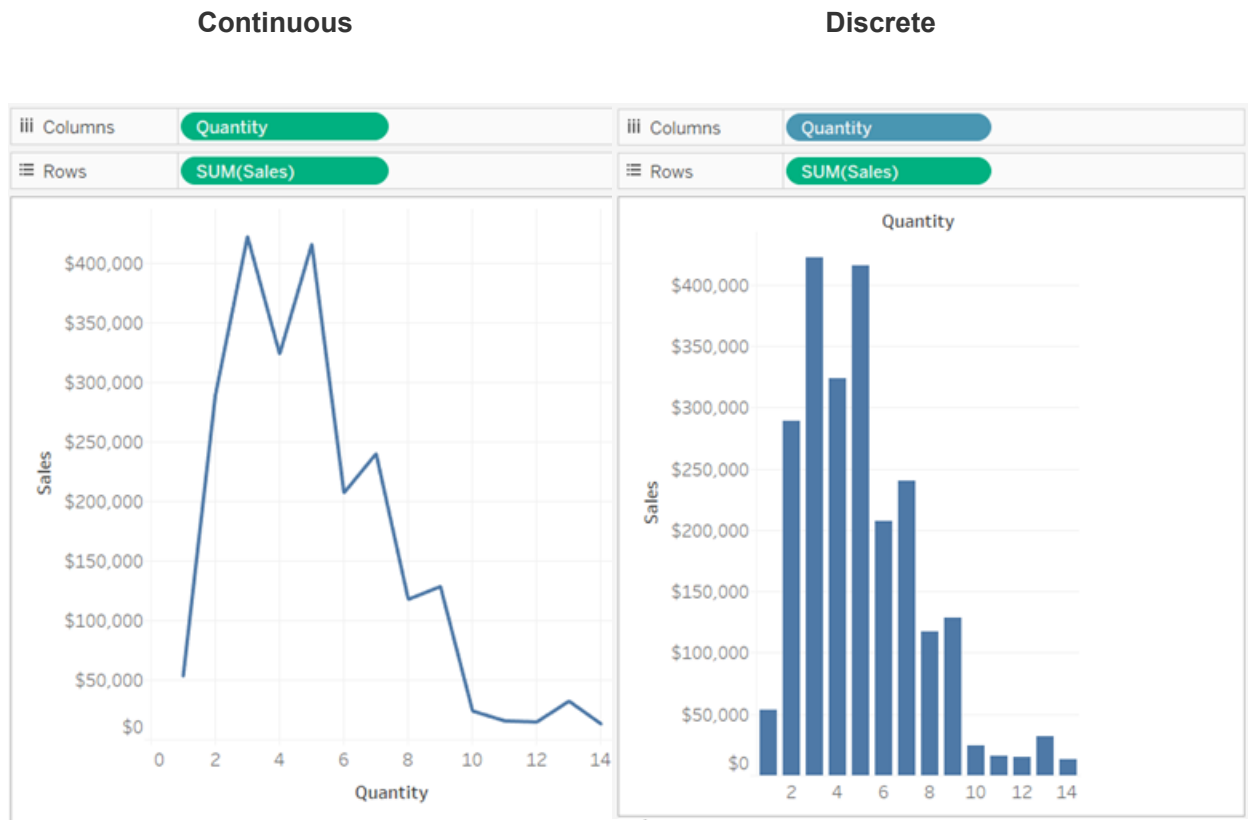

**Note:** You can set the default aggregation and other properties and settings for fields. For details on customizing the fields in the Data pane, see: [Organize and Customize Fields in the Data Pane on page 999](#), [Edit Default Settings for Fields on page 1011](#) and [Work with Data Fields in the Data Pane on page 37](#).

### Examples of continuous and discrete fields used in a view

In the example on the left, because the **Quantity** field is **Continuous**, it creates a horizontal axis along the bottom of the view. The green pill and the axis help you to see that it's a continuous

field.

In the example on the right, the **Quantity** field is **Discrete**. It creates a horizontal headers instead of an axis. The blue pill and the horizontal headers help you to see that it's discrete.

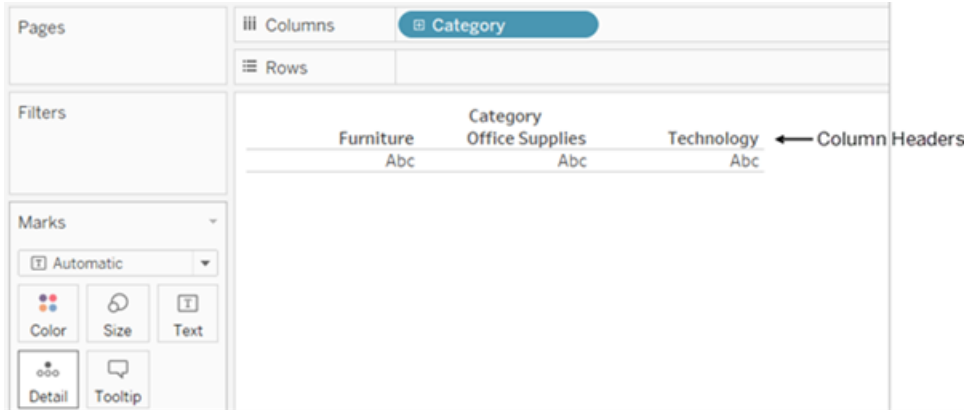

In both examples, the **Sales** field is set to **Continuous**. It creates a vertical axis because it's continuous and on the Rows shelf. If it was on the Columns shelf the axis would be horizontal. The SUM aggregation indicates that it's a measure.

The absence of an aggregation function in the **Quantity** field name indicates that it's a dimension.

### Dimension fields in the view

When you drag a discrete dimension field to **Rows** or **Columns**, Tableau creates column or row headers.

Often, fields from the **Dimension** area are discrete when you add them to a view, with a blue background. Date dimensions and numeric dimensions can be discrete or continuous, and all measures can be discrete or continuous.

After you drag a dimension to **Rows** or **Columns**, you can change the field to a measure by clicking the field and choosing **Measure**. Now the view contains a continuous axis instead of column or row headers, and the pill is green:

Date dimensions can be discrete or continuous. Dimensions containing strings or Boolean values can't be continuous.

Tableau doesn't aggregate dimensions. For a discussion of the different types of aggregation Tableau can perform, see [List of Predefined Aggregations in Tableau on page 177](#).

In Tableau queries, dimensions in the view are expressed in SQL as "Group By" clauses.

For details on converting fields between continuous and discrete, see [Convert Fields between Discrete and Continuous on page 1018](#).

## How dimensions affect the level of detail in the view

The level of detail in a view refers to how granular the data is given the dimension and measure data in the view.

As you add dimensions to **Rows** or **Columns**, the number of marks in the view increases.

To understand why adding dimensions increases the number of marks in the view, do the following:

1. Drag **Segment** to **Columns**.

The status bar at the bottom of the Tableau window shows you that there are now three marks in the view:

Those marks contain placeholder text, *Abc*, because you're only building the view's structure at this point.

2. Drag **Region** to **Columns**.

Now there are 12 marks. Three values in **Segment** multiplied by four values in **Region** is 12.

3. Drag [**Ship Date**] to **Rows**.

The total is now 57 marks (three segments by four regions by five years is 60, but three possible combinations have no data).

We could continue adding dimensions to **Rows** and **Columns** to see the number of total marks continues to increase. Encoding a dimension by a property on the Marks card (such as Color or Size) increases the number of marks without adding headers. This use of dimensions to determine the breakdown of marks is known as setting the *level of detail*.

Adding a dimension to any of the following locations in Tableau affects the level of detail:

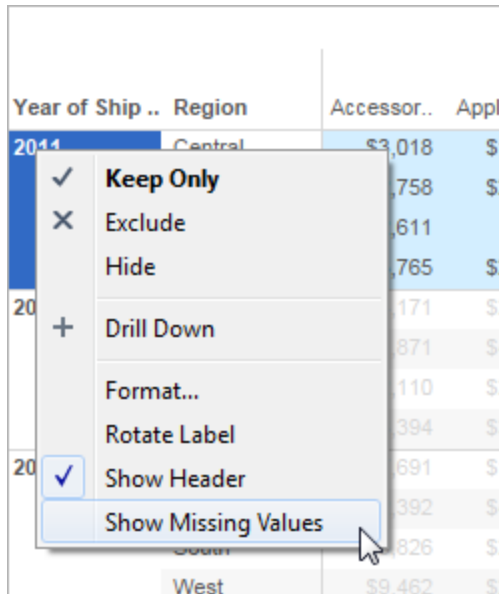

- The view now contains 57 separate instances of `abc`—the view is all structure and no content. Drag **Sales** to Text to see the values. The view can now be considered complete:

Year of S...	Segment / Region							
	Consumer				Corporate			
	Central	East	South	West	Central	East	South	West
2012	\$67,133	\$75,825	\$32,272	\$88,207	\$19,156	\$32,654	\$34,163	\$34,291
2013	\$49,640	\$85,683	\$49,245	\$80,654	\$29,454	\$49,703	\$18,033	\$38,771
2014	\$65,971	\$90,947	\$52,958	\$86,452	\$60,234	\$53,018	\$27,250	\$64,290
2015	\$68,976	\$97,846	\$59,291	\$105,655	\$48,801	\$65,034	\$42,440	\$87,293
2016	\$311	\$607	\$1,815	\$1,913	\$352			\$1,211

### Notes

- Sometimes, adding a measure to the view can increase the number of marks in the view. For example, with **Sales** on **Rows**, the number of marks is 57. But if **Profit** is also put on **Rows**, the number of marks increases to 114. But this isn't the same as changing the view's level of detail.

- The number of marks in the view isn't always the same as multiplying the number of members of each dimension. There are multiple reasons why the number of marks could be lower. To force a mark to show for every possible combination you can **Show Missing Values**. For more information about how to show missing values, see [Show or Hide Missing Values or Empty Rows and Columns](#) on page 1171.

## Measure fields in the view

When you drag a measure to the view, it's aggregated by default. The type of aggregation varies depending on the type of view. Always check the aggregation and change it if necessary. For details, see "Change the default aggregation" in [Edit Default Settings for Fields](#) on page 1011. For more details about aggregation, see [Data Aggregation in Tableau](#) on page 173.

When you drag a continuous field from the **Data** pane to **Rows** or **Columns**, Tableau creates a continuous axis for that field.

If you click the field and change it to **Discrete**, the values become column headers.

The screenshot shows the Tableau interface with a pivot table. The Columns shelf contains 'SUM(Sales)' and the Rows shelf contains 'Category'. The pivot table displays sales for Furniture, Office Supplies, and Technology. The column headers are 'Sales', 'Furniture', 'Office Supplies', and 'Technology'. An arrow points to the column headers with the text 'Column headers'.

Category	Sales	Furniture	Office Supplies	Technology
Furniture	\$719,047	\$742,000	\$836,154	
Office Supplies	\$719,047			
Technology				\$836,154

Tableau continues to aggregate values for the field, because even though the field is now discrete, it's still a measure, and Tableau aggregates measures by default.

In cases where Tableau has misclassified a field as a dimension or a measure, possibly because of the data type, you can convert it and change its role. If a measure doesn't need to be aggregated (such as numeric IDs), convert the field to a dimension.

For related details, see [Convert a Measure to a Dimension](#) on page 1019.

For details on converting fields between continuous and discrete, see [Convert Fields between Discrete and Continuous](#) on page 1018.

## How continuous and discrete fields change the view

*Continuous* and *discrete* are mathematical terms. Continuous means "forming an unbroken whole, without interruption"; discrete means "individually separate and distinct."

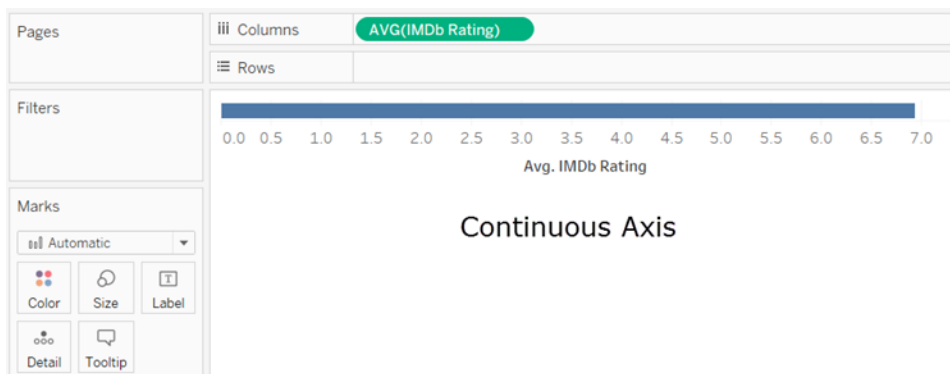

In Tableau, fields can be either continuous or discrete. When you drag a field from the **Data** pane to **Columns** or **Rows**, the values are continuous by default and Tableau creates an axis. When you drag a field from the **Data** pane to **Columns** or **Rows**, the values are discrete by default and Tableau creates column or row headers.

### Continuous fields produce axes

If a field has values that are numbers that can be added, averaged, or otherwise aggregated, it's added as a measure field in the **Data** pane when you first connect to a data source. Tableau is assuming that the values are continuous.

Tableau displays an axis when you drag a continuous field to **Rows** or **Columns**. An axis is a measuring line that shows values between a minimum and a maximum. Rulers and analog thermometers are examples of physical objects that display axes.

While there are value labels on a continuous axis (0, 0.5, ... 3.0 in the following image), actual marks don't have to align with these tick marks. For example, in the following image, the blue bar actually extends to a value of 6.940 on the horizontal axis, not 7.0 exactly.

The number of potential values for continuous fields is impossible to anticipate. For example, if you have a field named **Ratings** and the initial values are 1, 3, 3.5, 3.6, and 4, that's five distinct values. But if you bring **Ratings** to **Rows**, the aggregated value is a sixth value (3.02) that didn't exist until you added the field to the view. And if you then applied a filter that eliminated two of the initial values, the average changes to a different value. And then if you changed the aggregation, ... You get the idea. The number of potential values is, if not infinite, then immense.

The fact that a field contains numbers doesn't automatically indicate that those values are continuous. Postal codes are the classic example: though they're often composed entirely of numbers, they're actually string values that shouldn't be added or averaged. If Tableau assigns such a field as a measure to the **Data** pane, drag it to a dimensions area to change it to a dimension.

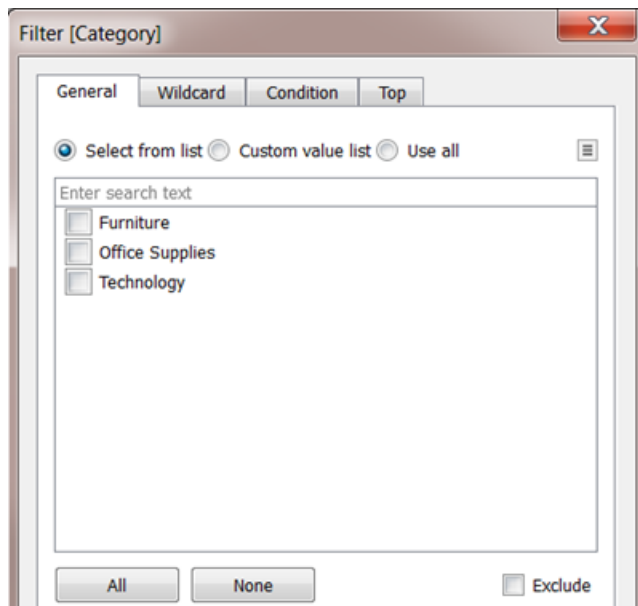

### Discrete fields create headers

If a field contains values that aren't numbers, it's identified as a dimension in the **Data** pane. Tableau treats the values as discrete.

Tableau creates headers when you drag a discrete field to **Columns** or **Rows**. The individual values for a discrete field become the row or column headings.

### Discrete versus continuous fields on filters

- When you drop a discrete dimension field on the **Filters** shelf, Tableau prompts you to choose which members of the discrete field to include in the view.

- When you drop a Date field on Filters, the result can be a discrete filter or a continuous filter. For more information, see [Filter dates](#) on page 1259.
- When you drop a continuous measure on Filters, Tableau first prompts you to choose an aggregation for the filter.
- When you drop a continuous dimension on Filters (other than a Date), Tableau prompts you to specify how to filter the continuous range of values.

For more on filtering various types of fields, see [Drag dimensions, measures, and date fields to the Filters shelf](#) on page 1255.

### Discrete versus continuous fields on color

When you drop a discrete field on Color in the Marks card, Tableau displays a categorical palette and assigns a color to each value of the field.

When you drop a continuous field on Color, Tableau displays a quantitative legend with a continuous range of colors.

For more information about color palettes, see [Color Palettes and Effects](#) on page 1237.

## Data Types

All fields in a data source have a data type. The data type reflects the kind of information stored in that field, for example integers (410), dates (1/23/2025) and strings ("Belgium"). The data type of a field is identified in the **Data** pane by one of the icons shown below.

### Data type icons in Tableau

Icon	Data type
	Text (string) values
	Date values
	Date & Time values
	Numerical values
	Boolean values (relational only)
	Geographic values (used with maps)
	Image role (used with image link URLs)

Icon	Data type
	Cluster Group (used with <a href="#">Find Clusters in Data</a> on page 1959)

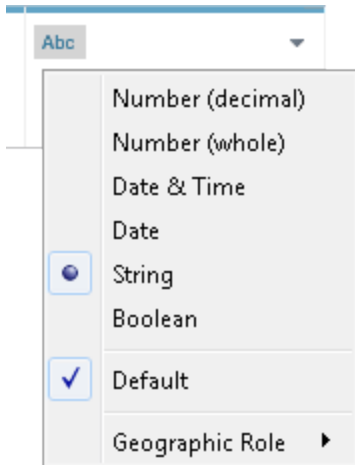

You can change the data type for a field either on the **Data Source** page or in the **Data** pane.

### Change the data type for a field in the Data Source page

Sometimes Tableau incorrectly interprets the data type of a field. For example, Tableau might interpret a field that contains dates as an integer data type, rather than a date data type.

You can change the data type for a field that was part of the original data source (as opposed to a calculated field created in Tableau) on the **Data Source** page.

1. Click the data type icon for the field (as shown in the table above).
2. Choose a new data type from the drop-down list:

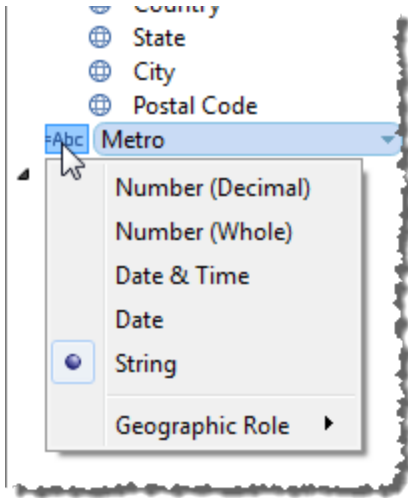

**Tip:** Be sure to change data types before you create an extract. Otherwise, your data may not be accurate. For example, if a floating-point field in the original data source is interpreted as an integer by Tableau, and you create your extract before you change the field's data type, the resulting floating-point field in Tableau will have some of its precision truncated.

For information on changing data types on the **Data Source** page, see [Data Source Page](#) on page 24.

## Change the data type for a field in the Data pane

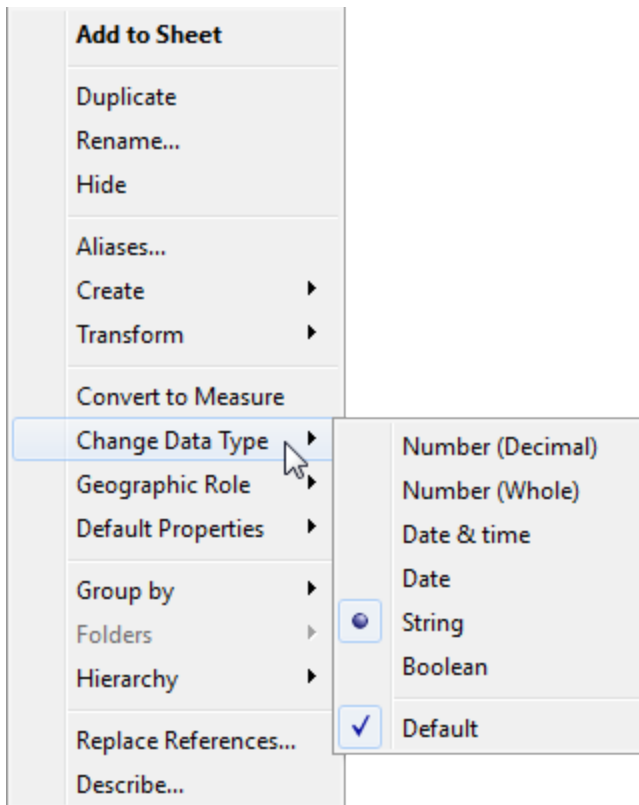

To change the data type of a field in the **Data** pane, click the icon to the left of the field name, and then choose a new data type from the drop-down list.

## Change the data type for a field in the view

To change a field's data type in a view, right-click (control-click on a Mac) the field in the **Data** pane, choose **Change Data Type**, and then select the appropriate data type from the drop-down list.

**Note:** Sometimes the data in your database is more precise than Tableau can model. When you add these values to the view, a precision warning appears in the right corner of the status bar. See [Status Bar Information](#) on page 35.

## Mixed data types in data from files

Most columns in a Microsoft Excel, Microsoft Access, or CSV (comma-separated value) file contain values that are all of the same data type (Booleans, dates, numbers, or text). When you connect to the file, Tableau creates a field in the appropriate area of the **Data** pane for each column. Dates and text values are dimensions, and numbers are measures.

However, files that you connect to might include columns that have a mixture of data types, such as numbers and text, or numbers and dates. When you connect to the file, the mixed-value column is mapped to a field with a single data type in Tableau. Therefore, a column that contains numbers and dates might be mapped as a number data type (making it a measure) or it might be mapped as a date data type (in which case Tableau treats it as a dimension.)

Tableau determines how to map mixed-value columns to data types by the data types of the first 10,000 rows in an Excel data source, and the first 1,024 rows in a CSV data source. For example,

if most of the first 10,000 rows are text values, the entire column is mapped to use the text data type.

**Note:** Empty cells also create mixed-value columns because their formatting is different from text, dates, or numbers.

When Tableau determines a data type for each field, if the values in a field don't match that data type, Tableau handles the field in one of several different ways, depending on the data type. For example, sometimes Tableau populates those fields with Null values, as shown in the following table:

Mapped data type	Treatment of other data types in the field.
Text	Dates and numbers are treated as text. Nulls are not created.
Dates	Text is treated as Null. A number is treated as the day in numeric order from 1/1/1900.
Numbers	Text is treated as Null. A date is treated as the number of days since 1/1/1900.
Boolean	Text, dates, and numbers are treated as Null.

If using fields that are based on mixed-value columns introduces difficulties when analyzing your data, you can do one of the following:

- Format empty cells in your underlying data source so that they match the data type of the column.
- Create a new column that does not contain the mixed values.

## Tableau's Order of Operations

The order of operations in Tableau, sometimes called the query pipeline, is the order in which Tableau performs various actions. Actions are also known as operations. Many operations apply filters, which means that as you build a view and add filters, those filters always execute in the order established by the order of operations.

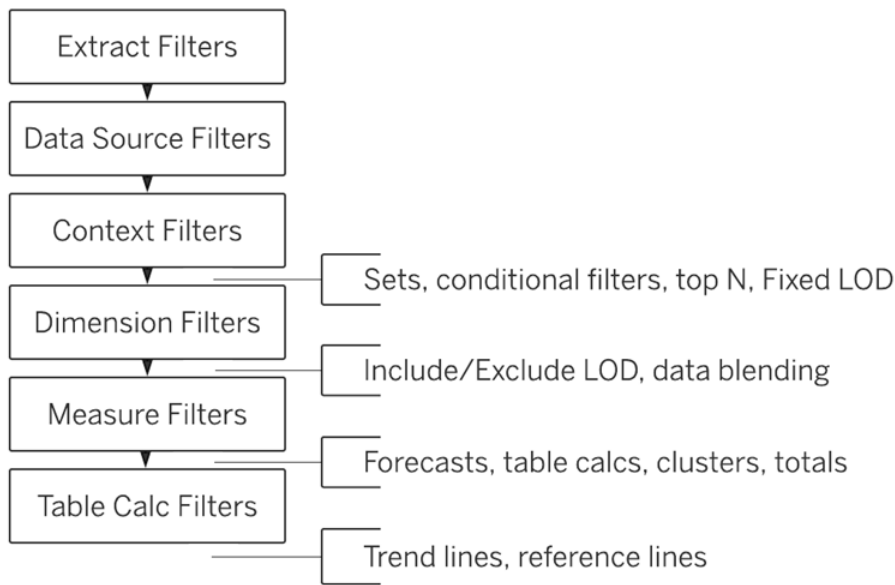

**Watch a Video:** To see related concepts demonstrated in Tableau, watch [Understanding Tableau's Order of Operations](#), a 1-hour, free video presentation.

This article includes two scenarios for updating a view to correct problems resulting from the order of operations: converting a dimension filter to a context filter, and converting a table calculation to a FIXED level of detail expression.

### About the order of operations (aka query pipeline)

Sometimes, you might expect Tableau to execute filters in one order, but the order of operations dictates that they be executed in a different order, which gives you unexpected results. When this happens, you can sometimes change the order in which operations are executed in the pipeline.

The Tableau order of operations includes the following, from top to bottom.

**Note:** In the order of operations, the **latest date filter** is global to the workbook, while context filters apply per worksheet. The latest date is determined just after the workbook opens for first use, after data source filters, but before context filters. At that point the date is set, and the latest date preset is used as a dimension filter.

## Example 1: Convert a Dimension Filter to a Context Filter

This and the following example use the **Sample – Superstore** data source provided with Tableau Desktop.

In this example, the view addresses the following question: Who are the top 10 customers, by total sales, in New York City?

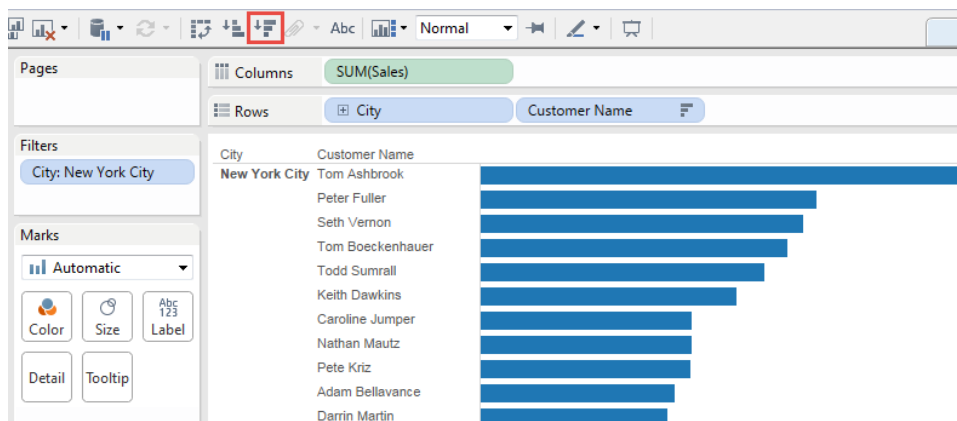

The view contains two dimension filters, one that you create on the **General** tab in the Filters dialog box, and the other on the **Top N** tab. The problem is that these filters are executing simultaneously, whereas you would like the general filter to be applied before the top n filter, so that the top n filter can act on the results as previously filtered by the general filter. The solution is to redefine one of the filters as a context filter so that a clear order of precedence is established.

Here are the steps for building this view.

1. Drag **Sales** to **Columns**.
2. Drag **City** and **[Customer Name]** to **Rows**.
3. Drag **City** from the **Data** pane again, this time to **Filters**. On the **General** tab in the Filter dialog box, set the filter to show just a single value: New York City. Do this by clicking **None** and then choosing **New York City**.

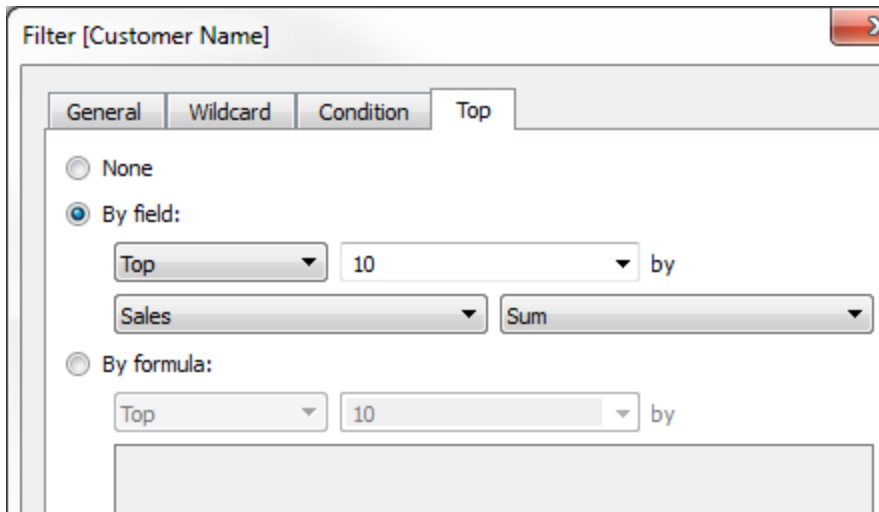

This creates a general dimension filter.

4. Click the **Sort Descending** button (  ) on the toolbar. Your view now looks like this:

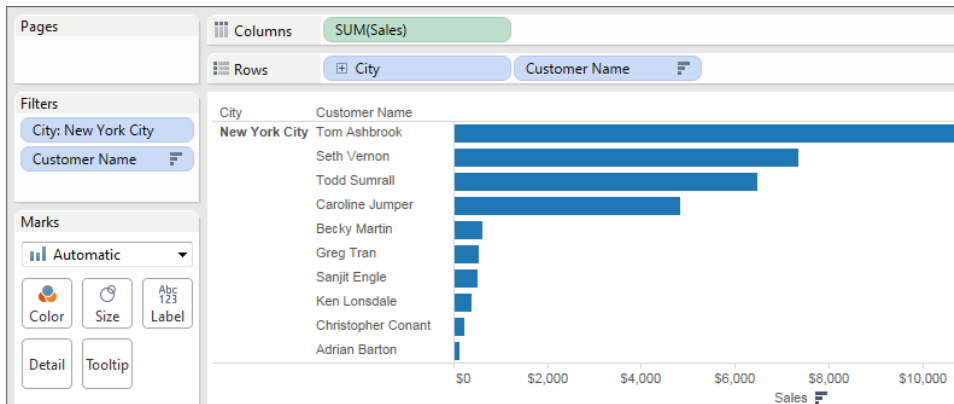

Note the first few names in the list: Ashbrook, Fuller, Vernon, etc.

- Now drag **[Customer Name]** from the **Data** pane to **Filters**, and create a Top 10 Filter, to show only the top 10 customers by total sales:

After you apply this second filter, the view looks right, but notice that the names shown are no longer the same as before:

What happened to Peter Fuller, formerly in second place? The goal was to show the top 10 customers in New York City, but now the view is actually showing the top 10 customers overall.

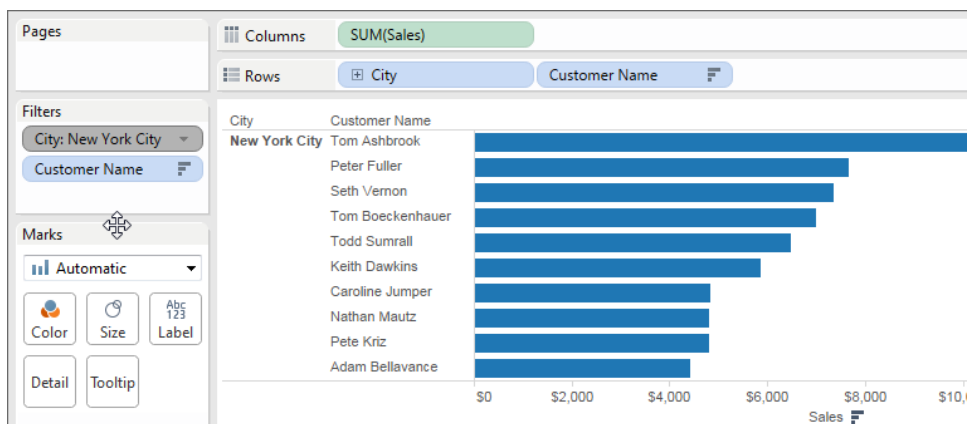

The problem is that top and general dimension filters are applied simultaneously—they are both dimension filters, and they appear in the same place in the Tableau order of operations:

The solution is to add the general dimension filter (on **City**) to context—that is, by turning it into a context filter, which is executed before any other filter that you create in a worksheet.

For details, see [Use Context Filters](#) on page 1281.

- Right-click **City** on the **Filters** shelf (Control-click on a Mac) and choose **Add to Context**. As a context filter, this filter now takes precedence over the dimension filter, and so the view now shows what it's supposed to:

## Example 2: Convert a Table Calculation to a FIXED Level of Detail Expression

In this example, the view addresses the following question: What is the percent of total sales by product sub-category?

The view contains a dimension filter and a table calculation. Tableau applies the dimension filter before executing the table calculation. To invert the order of these operations, use a FIXED level of detail expression instead of a table calculation.

Here are the steps for building this view.

1. In a new worksheet, drag **Sales** to **Columns**.
2. Drag **Sub-Category** to **Rows**.
3. Right-click **SUM(Sales)** on **Columns** and select a quick table calculation – **Percent of Total**.
4. Click the **Sort Descending** button (  ) on the toolbar to sort the categories from most to least.
5. Click the **Show Mark Labels** button (  ) on the toolbar to display measure values in the view.

Your view now looks like this:

Note the percentages for the first few items: 14.37%, 14.30%, etc.

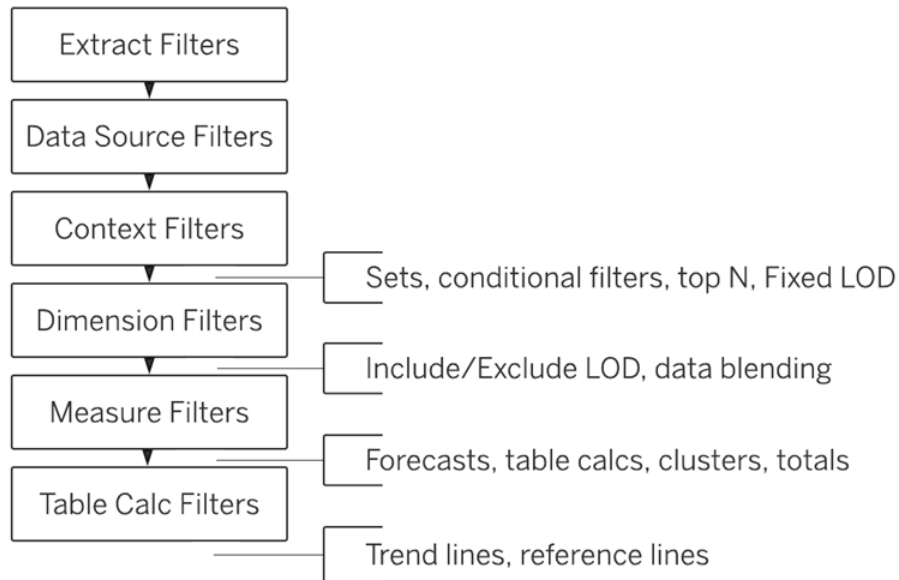

6. Right-click **Sub-Category** on **Rows** and choose **Show Filter**.
7. Clear the check mark for **Chairs** in the filter.

In the view, the percentages are now different—the highest percentage is now over 16%. In some cases, this may be just the result that you want (that is, for percentages to be recalculated as you work with the quick filter). But in other cases you may want the percentages to hold steady even as you filter items in or out. That’s what we want in this case.

In the order of operations, a dimension filter is applied before a table calculation:

To have Tableau calculate the percentages before it acts on the quick filter, you create a FIXED level of detail expression, and then use that instead of the table calculation.

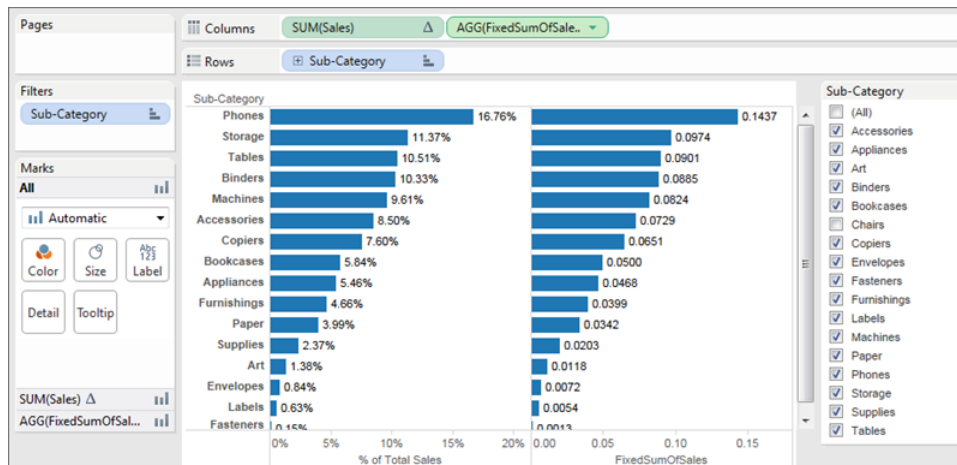

FIXED level of detail expressions compute a value using the specified dimensions, without reference to the dimensions in the view. In this case you’ll use it to establish percentages for the various sub-categories—percentages that won’t be affected by your general dimension filter. Why? Because FIXED level of detail expressions are computed before dimension filters are applied.

For details, see [Create Level of Detail Expressions in Tableau](#) on page 2525.

8. The FIXED level of detail expression must divide the sum of **Sales** (for a particular measure value) by the total sum of **Sales** for the view. Because the numerator is aggregated, the denominator must be as well, so the expression you write is:

```
SUM([Sales])/SUM({FIXED : SUM([Sales])})
```

9. Save that expression as **FixedSumOfSales** and then drag it from the **Data pane** to **Columns**, dropping it to the right of the existing **SUM(Sales)** field that uses the table calculation. (Keep them both in the view for comparison.) Here is what your view now looks like:

The percentage numbers in the chart on the right are now consistent, regardless of which fields you select or don't select with the quick filter. All that remains is to format the values for **FixedSumOfSales** so that they show as percentages.

10. Right-click **FixedSumOfSales** on **Columns** and choose **Format**. In the **Format** pane, choose **Numbers** and then **Percentage**:

# Tableau Desktop and Web Authoring Help

This gives you the final view:

As you select or clear items in the **Sub-Category** quick filter, the percentages in the bar chart on the left change, but the percentages in the bar chart on the right do not.

## Data Aggregation in Tableau

In Tableau, you can aggregate measures or dimensions, though it's more common to aggregate measures. Whenever you add a measure to your view, an aggregation is applied to that measure by default. The type of aggregation applied varies depending on the context of the view.

### Change the Aggregation of a Measure in the View

When you add a measure to the view, Tableau automatically aggregates its values. Sum, average, and median are common aggregations; for a complete list, see [List of Predefined Aggregations in Tableau](#) on page 177.

The current aggregation appears as part of the measure's name in the view. For example, **Sales** becomes **SUM(Sales)**. Every measure has a default aggregation that is set by Tableau when you connect to a data source. You can view or change the default aggregation for a measure—see [Set the Default Aggregation for a Measure](#) on page 180.

You can aggregate measures using Tableau only for relational data sources. Multidimensional data sources contain data that is already aggregated. In Tableau, multidimensional data sources are supported only in Windows.

You can change the aggregation for a measure in the view from its context menu:

## Aggregating Dimensions

You can aggregate a dimension in the view as **Minimum**, **Maximum**, **Count**, or **Count (Distinct)**. When you aggregate a dimension, you create a new temporary measure column, so the dimension actually takes on the characteristics of a measure.

Another way to view a dimension is to treat it as an Attribute by choosing **Attribute** from the context menu for the dimension. The **Attribute** aggregation has several uses:

- It can ensure a consistent level of detail when blending multiple data sources.
- It can provide a way to aggregate dimensions when computing table calculations, which require an aggregate expression.
- It can improve query performance because it's computed

Tableau computes Attribute using the following formula:

```
IF MIN([dimension]) = MAX([dimension]) THEN MIN([dimension]) ELSE "*"
END
```

The formula is computed in Tableau after the data is retrieved from the initial query. The asterisk (\*) is actually a visual indicator of a special type of Null value that occurs when there are multiple values. See [Troubleshoot Data Blending on page 784](#) to learn more about the asterisk.

Here is an example of using Attribute in a table calculation. The table shows sales by market, market size, and state. Suppose you wanted to compute the percent of total sales each state contributed to the market. When you add a Percent of Total quick table calc (see [Quick Table Calculations on page 2517](#)) that computes along State, the calculation computes within the red area. This is because the Market Size dimension is partitioning the data.

Columns		Measure Names		
Rows		Market	Market Size	State
Market	Market Size	State	Sales	% of Total Sales along State
Central	Major Market	Colorado	\$48,179	31.58%
		Illinois	\$69,883	45.80%
		Ohio	\$34,517	22.62%
	Small Market	Iowa	\$54,750	48.68%
		Missouri	\$24,647	21.92%
		Wisconsin	\$33,069	29.40%
East	Major Market	Florida	\$37,443	27.08%
		Massachusetts	\$29,965	21.67%
		New York	\$70,852	51.25%
	Small Market	Connecticut	\$25,429	63.07%
		New Hampshire	\$14,887	36.93%
South	Major Market	Texas	\$37,410	100.00%
	Small Market	Louisiana	\$23,161	34.82%
		New Mexico	\$15,892	23.89%

When you aggregate Market Size as an Attribute, the calculation is computed within the Market (East, in the following image), and Market Size is purely as a label.

Columns		Measure Names		
Rows		Market	ATTR(Market Size)	State
Market	Market Size	State	Sales	% of Total Sales along State
Central	Major Market	Colorado	\$48,179	18.18%
		Illinois	\$69,883	26.37%
		Ohio	\$34,517	13.02%
	Small Market	Iowa	\$54,750	20.66%
		Missouri	\$24,647	9.30%
		Wisconsin	\$33,069	12.48%
East	Major Market	Florida	\$37,443	20.97%
		Massachusetts	\$29,965	16.78%
		New York	\$70,852	39.68%
	Small Market	Connecticut	\$25,429	14.24%
		New Hampshire	\$14,887	8.34%
South	Major Market	Texas	\$37,410	36.00%
	Small Market	Louisiana	\$23,161	22.29%
		New Mexico	\$15,892	15.29%

## List of Predefined Aggregations in Tableau

Sometimes it's useful to look at numerical data in an aggregated form such as a sum or an average. The mathematical functions that produce aggregated data are called aggregation functions. Aggregation functions perform a calculation on a set of values and return a single value. For example, a measure that contains the values 1, 2, 3, 3, 4 aggregated as a sum returns a single value: 13. Or if you have 3,000 sales transactions from 50 products, you might want to view the sum of sales per product to determine which products have the highest revenue.

**Note:** Using floating-point values with aggregations can sometimes lead to unexpected results. For details, see [Understanding data types in calculations](#) on page 2169.

Tableau provides a set of predefined aggregations that are shown in the table. You can set the default aggregation for any measure that isn't a calculated field that itself contains an aggregation, such as `AVG([Discount])`. See [Set the Default Aggregation for a Measure](#) on page 180. You can also set the aggregation for a field already in the view. For details, see [Change the Aggregation of a Measure in the View](#) on page 173.

Aggregation	Description	Result for measure that contains 1, 2, 2, 3
Attribute	Returns the value of the given expression if it only has a single value for all rows in the group, otherwise it displays an asterisk (*) character. Null values are ignored. This aggregation is useful when aggregating a dimension. To set a measure in the view to this aggregation, right-click (control-click on Mac) the measure and choose <b>Attribute</b> . The field then changes to show the text ATTR:  	*
Dimension	Returns all unique values in a measure or dimension.	3 values (1, 2, 3)
Sum	Returns the sum of the numbers in a measure. Null values are ignored.	1 value (8)
Average	Returns the arithmetic mean of the numbers in a	1 value (2)

Aggregation	Description	Result for measure that contains 1, 2, 2, 3
	measure. Null values are ignored.	
Count (Distinct)	<p>Returns the number of unique values in a measure or dimension. When applied to a dimension, Tableau creates a new temporary column that is a measure because the result of a count is a number. You can count numbers, dates, booleans, and strings. Null values are ignored in all cases.</p> <p>This aggregation isn't available for the following types of workbooks:</p> <ul style="list-style-type: none"> <li>• Workbooks created before Tableau Desktop 8.2 and that use Microsoft Excel or Text File data sources.</li> <li>• Workbooks that use legacy connections.</li> <li>• Workbooks that use Microsoft Access data sources.</li> </ul> <p>If you're connected to a workbook that uses one of these types, Count (Distinct) is unavailable and Tableau shows the message "Requires extract." To use this aggregation, extract your data. See <a href="#">Extract Your Data on page 867</a>.</p>	1 value (3)
Minimum	Returns the smallest number in a measure or continuous dimension. Null values are ignored.	1 value (1)
Maximum	Returns the largest number in a measure or in the given expression based on a sample population. Null values are ignored. Returns a Null if there are fewer than 2 members in the sample that aren't Null. Use this function if your data represents a sample of the population.	1 value (3)
Std. Dev (Pop.)	Returns the standard deviation of all values in the given expression based on a biased population. Assumes that	1 value (0.7071)

Aggregation	Description	Result for measure that contains 1, 2, 2, 3
	its arguments consist of the entire population. Use this function for large sample sizes.	
Variance	Returns the variance of all values in the given expression based on a sample. Null values are ignored. Returns a Null if there are fewer than 2 members in the sample that are not Null. Use this function if your data represents a sample of the population.	1 value (0.6667)
Variance (Pop.)	Returns the variance of all values in the given expression based on a biased population. Assumes that its arguments consist of the entire population. Use this function for large sample sizes.	1 value (0.5000)
Disaggregate	<p>Returns all records in the underlying data source. To disaggregate all measures in the view, select <b>Aggregate Measures</b> from the Analysis menu (to clear the check mark).</p> <p>Tableau allows you to view data in disaggregated form (relational databases only). When data are disaggregated, you can view the individual rows of your data source. For example, after discovering that the sum of sales for rubber bands is \$14,600, you might want to see the distribution of individual sales transactions. To answer this question, you must create a view that shows individual rows of data. That is, you must disaggregate the data (see <a href="#">How to Disaggregate Data on page 182</a>). Another way to look at disaggregated data is to view the underlying data for all or part of a view. For more details, see <a href="#">View Underlying Data on page 2610</a>.</p>	4 values (1, 2, 2, 3)

You can also define custom aggregations as described in [Aggregate Functions in Tableau on page 2240](#). Depending on the type of data view you create, Tableau applies these aggregations at the appropriate level of detail. For example, Tableau applies the aggregation to individual

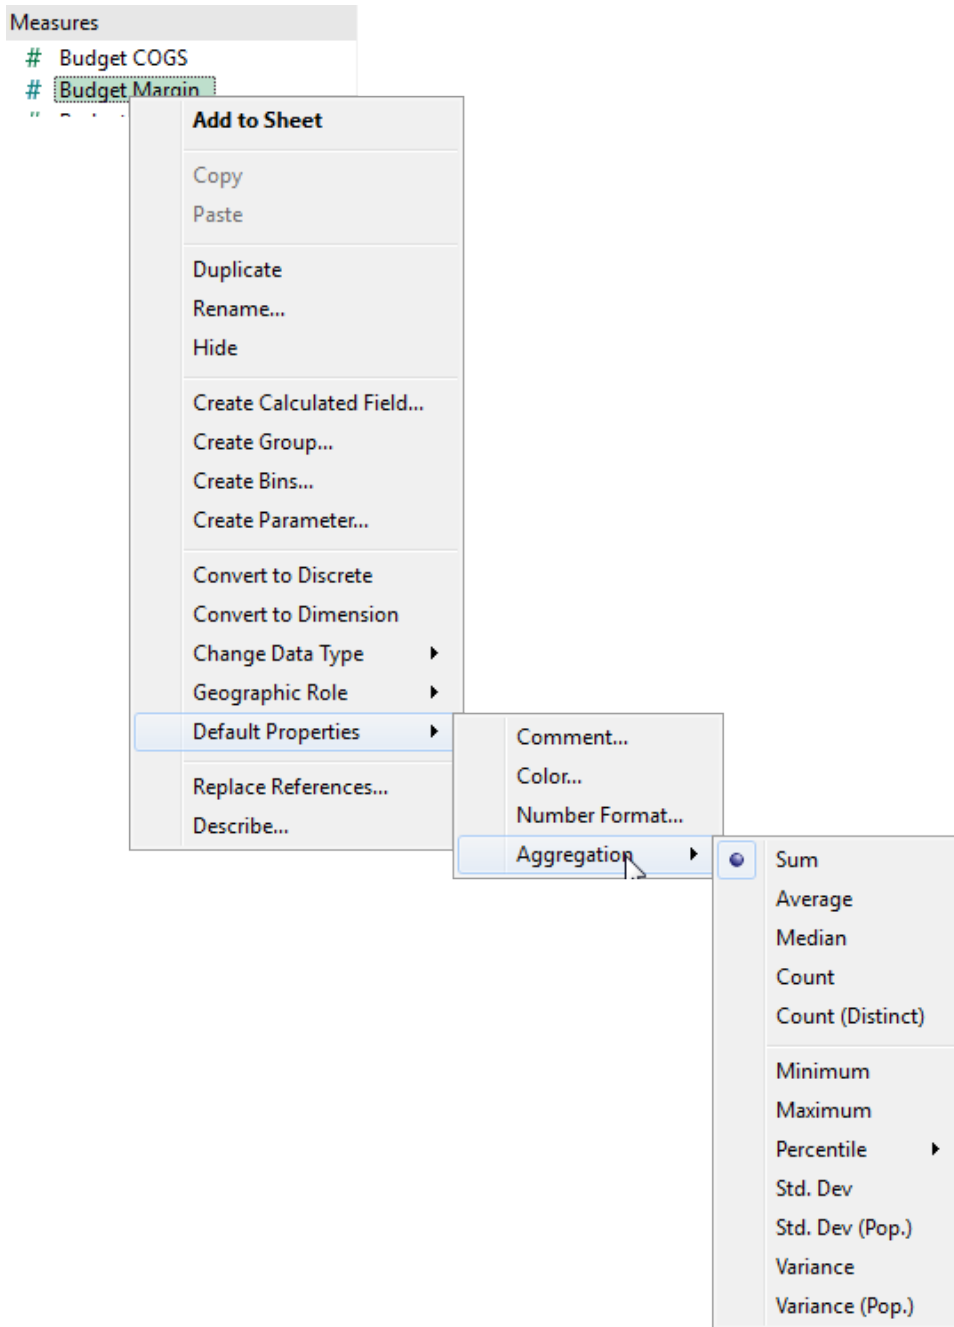

dimension members (the average delivery time in the East region), all members in a given dimension (the average delivery time in the East, West, and Central regions), or groups of dimensions (the sum of sales for all regions and for all markets).

## Set the Default Aggregation for a Measure

You can set the default aggregation for any measure that isn't a calculated field that itself contains an aggregation, such as `AVG([Discount])`. A default aggregation is a preferred calculation for summarizing a continuous or discrete field. The default aggregation is automatically used when you drag a measure to a view.

### To change the default aggregation:

Right-click (control-click on Mac) a measure in the Data pane and select **Default Properties > Aggregation**, and then select one of the aggregation options.

**Note:** You can use Tableau to aggregate measures only with relational data sources. Multidimensional data sources contain aggregated data only.

You can't set default aggregations for published data sources. The default aggregation is

set when the data source is initially published. [Create a Local Copy](#) of the published data source to adjust the default aggregation.

## How to Disaggregate Data

Whenever you add a measure to your view, an aggregation is applied to that measure by default. This default is controlled by the **Aggregate Measures** setting in the **Analysis** menu.

If you decide you want to see all the marks in the view at the most detailed level of granularity, you can disaggregate the view. Disaggregating your data means that Tableau displays a separate mark for every data value in every row of your data source.

### To disaggregate all measures in the view:

- Clear the **Analysis >Aggregate Measures** option. If it's already selected, click **Aggregate Measures** one time to deselect it.

When **Aggregate Measures** is selected, Tableau attempts to aggregate measures in the view by default. Individual row values from your data source are aggregated into a single value (a single mark) at the level of detail in your view.

The different aggregations available for a measure determine how the individual values are collected: they can be added (SUM), averaged (AVG), or set to the maximum (MAX) or minimum (MIN) value from the individual row values.

For a complete list of the available aggregations, [List of Predefined Aggregations in Tableau on page 177](#).

The level of detail is determined by the dimensions in your view—for information about the concept of level of detail, see [How dimensions affect the level of detail in the view on page 152](#).

Disaggregating your data can be useful for analyzing measures that you may want to use both independently and dependently in the view. For example, you may be analyzing the results from a product satisfaction survey with the Age of participants along one axis. You can aggregate the **Age** field to determine the average age of participants or disaggregate the data to determine at what age participants were most satisfied with the product.

Disaggregating data can be useful when you're viewing data as a scatter plot. See [Example: Scatter Plots, Aggregation, and Granularity](#) below.

**Note:** If your data source is very large, disaggregating the data can result in a significant performance degradation.

## Example: Scatter Plots, Aggregation, and Granularity

If you place one measure on the **Rows** shelf and another measure on the **Columns** shelf, you're asking Tableau to compare two numerical values. Typically, Tableau chooses a scatter plot as the default visualization in such cases. The initial view will most likely be a single mark, showing the sum for all values for the two measures. This is because you must increase the level of detail in the view.

[Start building the scatter plot](#) below  
[Use dimensions to add detail](#) on the next page  
[Try adding more fields to the rows and columns shelves](#)  
on page 186  
[Try disaggregating the data](#) on page 188

### Start building the scatter plot

There are various ways to add detail to a basic scatter plot: **you can use dimensions to add detail**, you can add more fields to the Rows and Columns shelves, or you can **disaggregate the data**. You can also use any combination of these options. This topic looks at these alternatives using the **Sample-Superstore** data source.

To create the initial view, follow these steps:

1. Place the **Sales** measure on the **Columns** shelf.
2. Place the **Profit** measure on the **Rows** shelf.

The measures are automatically aggregated as sums. The default aggregation (SUM) is indicated in the field names. The values shown in the tooltip show the sum of sales and profit values across every row in the data source.

Follow these steps to use dimensions to add detail to the view and to disaggregate data.

### Use dimensions to add detail

Follow these steps to develop the scatter plot view you created by adding dimensions to show more levels of detail.

1. Drag the **Category** dimension to **Color** on the Marks card.

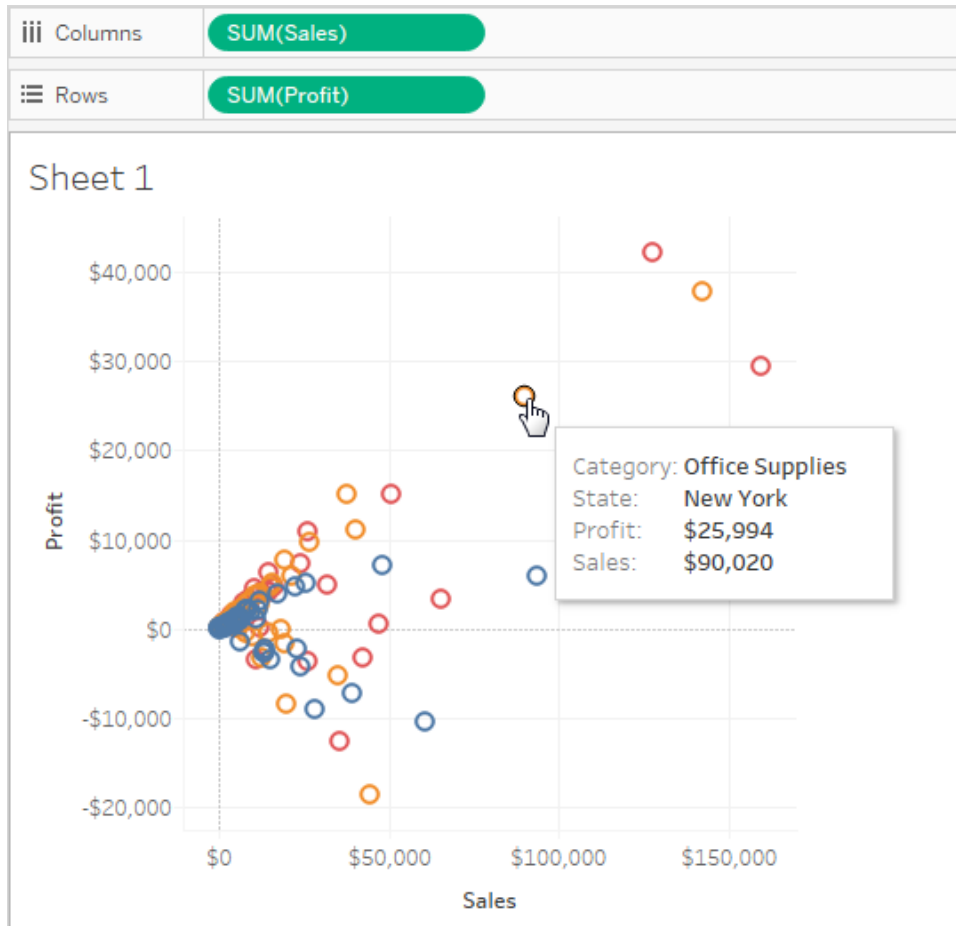

This separates the data into three marks—one for each dimension member—and encodes the marks using color.

2. Drag the **State** dimension to **Detail** on the Marks card.

Now there are many more marks in the view. The number of marks is equal to the number of distinct states in the data source multiplied by the number of categories.

Although more marks are now displayed, the measures are still aggregated. So regardless of whether there's one row in the data source where State = North Dakota and Category = Furniture, or 100 such rows, the result is always a single mark.

Maybe this process is developing the view in a direction you find useful, or maybe you prefer to go in a different direction. You decide what questions to ask.

### Try adding more fields to the rows and columns shelves

Revert to the original one-mark view and follow these steps to develop the scatter plot view by adding fields to the **Rows** and **Columns** shelves.

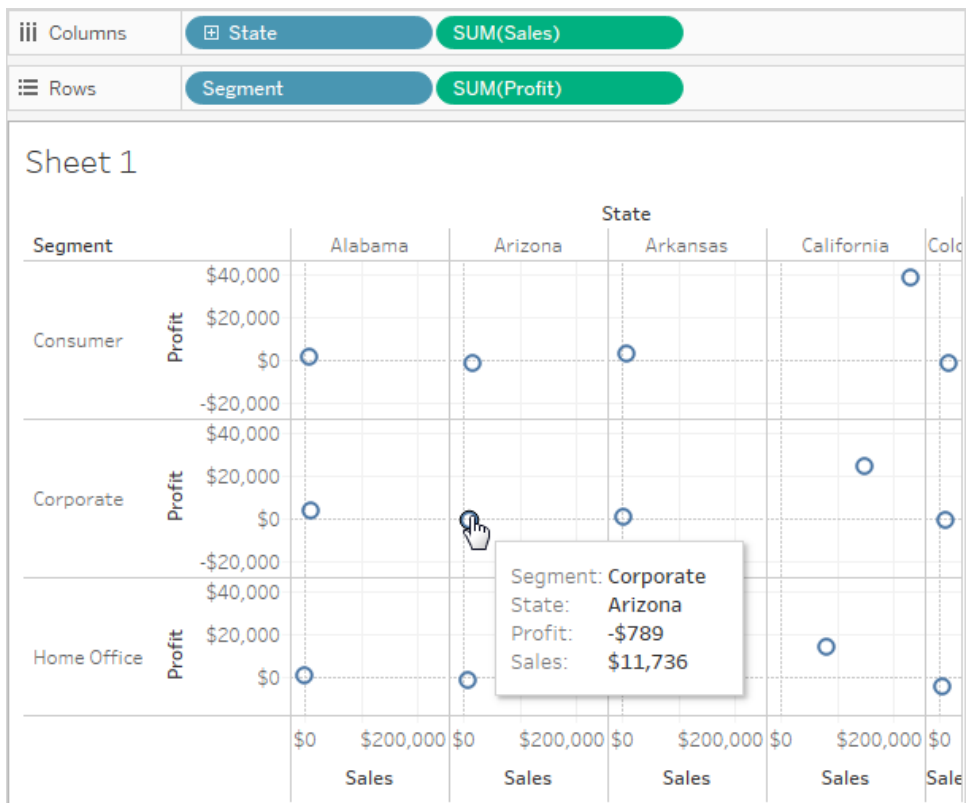

1. Drag the **State** dimension to the **Columns** shelf.

Even if you drop **Continent** to the right of **SUM(Sales)**, Tableau moves it to the left of **SUM(Sales)**. This is because you can't insert a dimension within a continuous axis. Instead, your view shows a separate axis for each member of the dimension.

2. Drag the **Segment** dimension to the **Rows** shelf.

You now have a view that provides an overview of Sales and Profit across states and customer segments. It can be interesting to hover over the marks in the view to see tooltip data for various segments:

## Try disaggregating the data

Another way to modify your original one-mark scatter plot to display more marks is by disaggregating the data.

Clear the **Analysis >Aggregate Measures** option. If it's already selected, click **Aggregate Measures** one time to deselect it.

What you have done is to dis-aggregate the data, because this command is a switch that was originally selected (check mark present). Tableau aggregates data in your view by default.

Now you see many marks—one for each row in your original data source:

When you disaggregate measures, you no longer are looking at the average or sum for the values in the rows in the data source. Instead, the view shows a mark for every row in the data source. Disaggregating data is a way to look at the entire surface area of the data. It's a quick way to understand the shape of your data and to identify outliers. In this case, the view shows there's a consistent relationship between sales and profit, indicated by the line of marks aligned at a forty-five degree angle.

## The Bookshop data set

The Bookshop data set was created for Tableau Desktop 2020.2 to showcase relationships—the new data modeling capabilities for combining data.

## Download the files

You can choose to download the raw data and start from scratch building your own data model, or download one of the pre-built data sources to jump right into analysis with relationships.

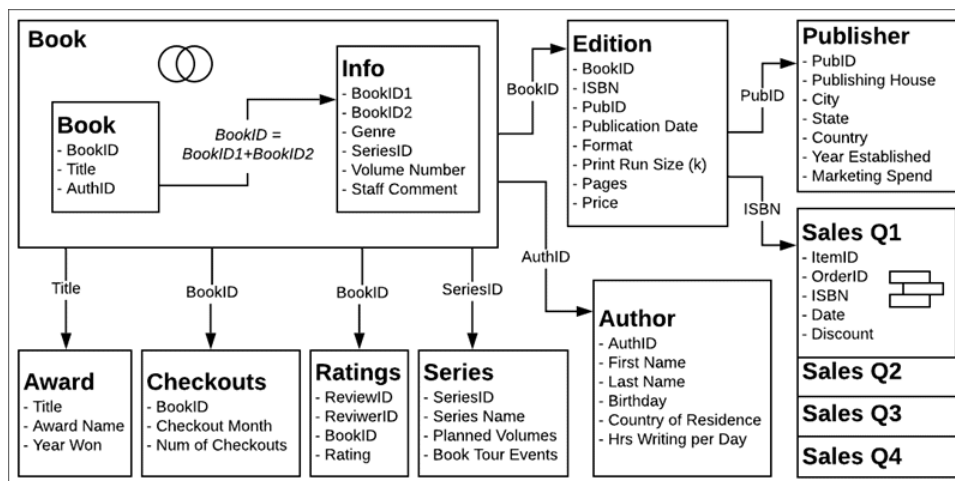

- Raw data (xlsx)
  - [Bookshop.xlsx](#) - the raw data as an .xlsx file
  - [BookshopLibraries.xlsx](#) - additional library tables that introduce many-to-many relationships (contains only the additional library tables)
- Packaged data source (tdsx) files
  - [Bookshop.tdsx](#) - a packaged .tdsx file with the related data source already built and some metadata customizations added
  - [MinimalBookshop.tdsx](#) - the same tables as Bookshop.tdsx but without any metadata or cleanup
  - [Bookshop\\_libraries.tdsx](#) - a packaged .tdsx file that adds the library tables to Bookshop.tdsx (includes all tables).

To connect to a downloaded .tdsx

1. Open Tableau Desktop.
2. In the Connect pane on the left, choose the **More...** option under the **To a File** heading.
3. Navigate to where you downloaded the .tdsx and double click it (or select it then click Open).

## About the data set

Bookshop consists of 13 tables, combined in the following manner:

**Note:** A central concept for this data set is the idea of a *book* versus an *edition*. A book is a concept with attributes such as author, title, and genre. An edition is a physical version of the book, with attributes such as format (hardcover, paperback), publication date, and page count.

## Data Dictionary

Some fields may need a little explanation.

- The **Rating** field in the Ratings table is on a scale of 1-5 with 5 being high.
- The **Format** field is a detailed breakdown of the format. Everything other than “Hardcover” could be considered “Paperback”.
- **ISBN** stands for International Standard Book Number and is a unique 13 digit identifier given to each edition of a book. The ISBN is represented in the barcode and is tied to the price.
- The **ItemID** and **OrderID** fields are hierarchical. An order may contain multiple items.
- The **Staff Comment** field contains summaries and reviews for some of the books.

## If you build your own data source

1. The **Publisher** and **Sales** tables must be related to the **Edition** table.
2. The **Book** and **Info** tables can be related or joined, but it must be on the calculation  $BookID = [BookID1] + [BookID2]$ .
  - An inner join is suggested.
  - The **Series** table can only be used once the Info table is part of the data source.

*optional:*

3. We recommend renaming the logical table of Book joined with Info “Book” or something similar.
4. The four Sales tables can be analyzed independently, but if they are unioned, we recommend renaming the union “Sales” or something similar.
5. Most of the fields used to form relationships aren’t needed for analysis and can be hidden once the data model has been built
  - Any field ending with ID can be hidden (the only “ID” fields that do are ReviewID and ReviewerID from Ratings and ItemID and OrderID from Sales).
  - ISBN should be kept, ideally from the Edition table, as the identifier of each edition. The ISBN field in the unioned Sales table can be hidden.
  - The Title field in the Award table can be hidden.

- The sheet and table fields from the Union also don't contain unique information and can be hidden.
6. To simplify the data model, the core tables are **Book**, **Author**, and **Edition**. The easiest tables to leave out with minimal impact would be **Checkouts** and **Ratings**, followed by **Award**, **Publisher**, **Sales**, or **Info** and **Series**.

## Bookshop Libraries

The BookshopLibraries.xlsx file introduces new tables around libraries for the purpose of supporting many-to-many relationships. The Catalog table relates to the Editions table on ISBN. The Library Profiles table relates to the Catalog table as a many-to-many (n:n) relationship on LibraryID.

## Data Dictionary

### Library Profile

- The **Library** field is the name of the library.
- The **Library ID** field is an ID also used in the Catalog table.
- The **Consortium Member** field is a yes/no field that indicates if the library is part of the larger network of libraries that offer inter-library loans and share other services.
- The **Private** field is a yes/no field that indicates if this is a members-only library or a public institution.
- **Staff Type** and **Number of Staff** together describe how many Librarians, Library Assistants, and Library Technicians work for each library.

### Catalog

- **LoanID** is a unique identifier for the combination of ISBN and library that is used to track the **Number of Copies** a library has. For example, if the Idle Hour Library has two paperback copies and one hardcover copy of a title, there will be two Loan IDs.
- The **Library ID** field is an ID also used in the Library Profile table.

## Structure of the Library Profile table

The Library Profile table was originally formatted as an unpivoted table with a column for each staff type, below.

Library	LibraryID	Consortium Member	Private	Librarians	Library Technicians	Library Assistants
Idle Hour Library	L-IHL	Yes	No	53	61	16
The Bibliophile's Shelves	L-BS	Yes	Yes	4	3	0
Armchair Athanaeum	L-AA	No	Yes	6	0	0
Old Friend Library	L-OFL	Yes	No	3	5	17
Bide Awhile	L-BA	Yes	No	9	20	6
IndieUnBound	L-IUB	Yes	No	7	2	47
Page Station Book Exchange	L-PS	No	Yes	3	1	4

The table was pivoted across the Librarians, Library Technicians, and Library Assistants columns. The final format has a column for Staff Type and a column for Number of Staff. However, this means that there is more than one row for each library. The Library ID values are therefore not unique, and the pivoted version of the table must be related many-to-many to the Catalog table.

While this has the benefit of allowing a many-to-one relationship between Catalog and Profile, it isn't an ideal [structure for data analysis](#).

## Explore

This data set, while fictional, supports various analytical scenarios and plenty of exploration. Some suggestions include:

- What books are the most popular? The least popular? Is that based on sales, reviews, checkouts, or another metric?
- Who was the youngest debut author? Who was the oldest?
- Do some publishing houses seem to specialize in any way?
- What was the longest time between editions of the same book?
- Are there any seasonal trends for sales? What about checkouts? Do any titles or genres have seasonal fluctuations?
- Are there any correlations between checkouts, print run size, book review ratings, and sales volume?
- Do the authors who spend the most time writing have the most successful books? Do they have the highest page count?
- When are most books published? Are there any anomalies?
- Are there any trends for genre, format, and price?
- What sort of distributions do the ratings have? Do those distributions vary by book? By genre? Do they seem to align with awards?
- How would you calculate the sales price, given that there is sometimes—but not always—a discount given at the time of sale?
- Do sales approximate the Pareto principle?
- Are there any patterns in the discounts?
- Do any tables in particular appear to have dirty data?

## Bookshop Data Set Easter Eggs

- *Etaoin Shrdlu* is a reference to linotype hot type machines. *Palimpsest* is a manuscript-making reference.
- Author names were derived from a list of famous American authors with their first and last names shuffled.
- Publication dates today are usually on Tuesdays. This was reflected in the data, which assumes this industry standard holds into the year 2178.
- One book has no reviews, checkouts, or sales.
- The Checkouts data is based actual library data, with BookIDs mapped to titles, so the checkout trends are real-world.

- The Ratings data is based on actual book rating data, with BookIDs mapped to titles, so the distribution of ratings for a given book is real.
- The proportion of sales that are for a single book versus multiple books is based on real-world data from an independent bookstore.
- The Sales data is completely generated, but is based on actual seasonal and weekday trends for a resort town with a tourism-based economy (proportionally by month and day of the week, and for spring break and the winter holidays).
  - Sales spike over long weekends and spring break.
  - Sales are much higher on weekends and at their lowest on Tuesdays and Thursdays.
  - Peak season is the summer between the 4th of July and Labor Day.
  - Sales spike immediately after Thanksgiving and in the weeks leading up to Christmas.
- The ISBNs in the data set are fictitious but constructed following ISBN-13 principles:
  - EAN—989 (not actually in use)
  - Group number—28
  - Publisher registrant element—varying length (2-4 digits)
  - Title element, varying length (3-5 digits, depending on the registrant element length)
  - Check digit, created with the ISBN-13 check digit modular arithmetic calculation
- One of the developers working on this feature suggested a book with no editions, and the title *The Deep Grey*, so its BookID ends with the last three digits of his work phone number.
- There is an (intentional) error in the Edition table where two editions of BookID PA169 were labeled as Palimpsest Printing, but the ISBN indicates they were actually printed by Etaoin Shrdlu Press.

The person who created this data set had way too much fun making it, and clearly has a deep obsession with books. She hopes you enjoy the data set and it helps you appreciate the power, elegance, and beauty of relationships in Tableau.

## Sign in to Tableau Server or Tableau Cloud

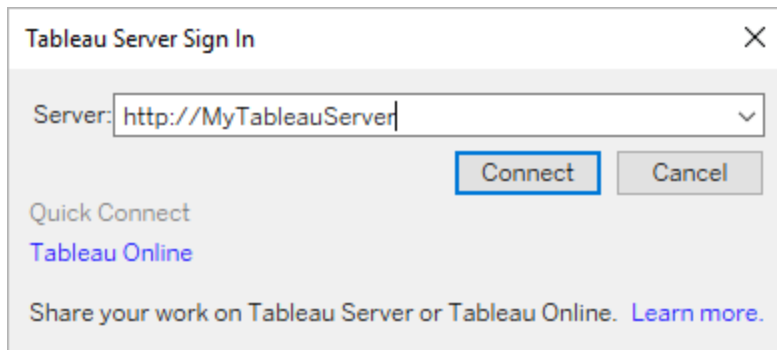

To access content on Tableau Server or Tableau Cloud, sign in via Tableau Desktop or a web browser.

**Note:** If you sign in via a web browser, it must be configured to allow first-party cookies.

## Sign in from Tableau Desktop

### Tableau Server

1. In Tableau Desktop, select **Server > Sign In**. Enter the name or address of your Tableau server, and then click **Connect**.

2. Do one of the following, which depends on if your Tableau Server is configured for **identity pools**:
  - Enter your user name and password, and then click **Sign In**. If you have access to multiple sites, select the one you want to use. You can also enter the name of the site and search for it.

- On the Tableau Server landing page, select the sign-in option that applies to you,

enter your user name and password, and then click **Sign In**.

## Tableau Cloud

1. In Tableau Desktop, select **Server > Sign In**. Click **Tableau Cloud** in the bottom left corner.

2. If your site is set up to use Tableau authentication, enter your user name (email address) and password you use for Tableau Cloud, and then click **Sign In**.

If multi-factor authentication (MFA) is enabled with Tableau authentication, you are prompted to verify your identity using the verification you selected during the MFA registration process. After verifying your identity, you are redirected to your site.

**Notes:**

- If you are signing in to Tableau Cloud or registering for MFA for the first time, see [Register for multi-factor authentication](#).
- You must be running Tableau Desktop 2021.1 and later to use MFA with Tableau authentication.

3. If you have access to multiple sites, select the one you want to use.

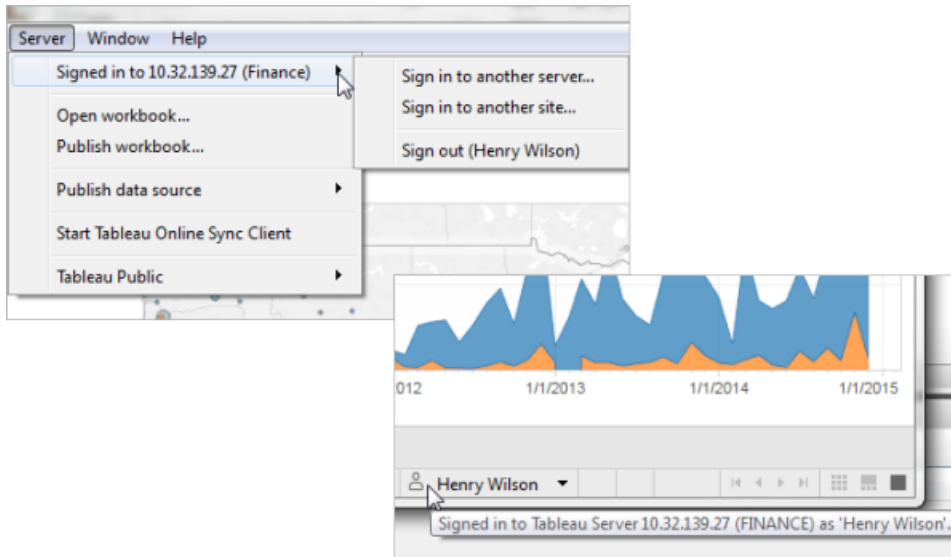

## Automatically keep Tableau Desktop connected to Tableau Server or Online

When you connect to Tableau Server or Tableau Cloud, Tableau Desktop keeps you signed in from session to session, if you don't sign out. Next time you launch Tableau Desktop, you are automatically signed in to your most recent server connection. You can easily switch to other available server and site connections.

You can see the server and site you are signed into, as well as who you are signed in as, in two places:

- The **Server** menu shows the server and site that you are signed in to. **Sign out** shows you are signed in as.

- The status bar also provides this information. Hover over the username to see the current server and site.

## Switch servers, switch sites

To switch servers, on the **Server** menu, click **Sign in to another server**, and then enter the server name and your sign-in credentials.

If you have access to multiple sites, on the **Server** menu, click **Sign in to another site**. This option is only available for Tableau Server sites.

## Sign out or clear all saved connections

When you sign in to a server and site, Tableau Desktop stores your credentials in a secure token that remembers your connection. After this token is in place, you can access the server directly, without having to sign in.

Click **Server > Sign out** to clear your sign-in credentials for the current connection. To remove all of your existing server connections, click **Help > Settings and performance > Clear saved server sign-ins**.

If you never want server sign-ins to be saved, a Tableau Server administrator can change the server settings to disallow connected clients. Be aware that this setting also affects other Tableau clients like Tableau Mobile. For more information, see [Authentication for Connected Devices](#) in the Tableau Server Help.

## Switch user accounts from Tableau Desktop (Kerberos authentication only)

If your organization uses Tableau Desktop with Kerberos authentication and it doesn't succeed, you're prompted to provide a user name and password. To sign in as a different user for testing purposes, complete these steps:

1. On the Server menu, select **Switch User**.

2. In the Tableau Server Sign In dialog box, provide the new user name and password.

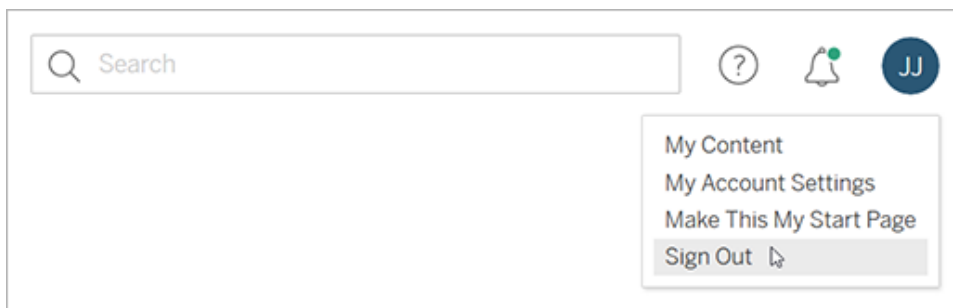

To later sign in using your normal credentials, select **Server > Switch to Self**.

## Sign in with another user account in a browser

If you are signed in to the wrong account, you can switch to another one.

1. Click **Sign Out** on the user menu in the upper-right corner of the page.

**Note:** If you do not see a **Sign Out** command on the Tableau Server user menu, you must use the sign-out interface provided by your organization's external identity provider (IdP). For more information, contact your administrator.

2. Type your user name and password, and then click **Sign In**

The image shows the Tableau sign-in interface. At the top is the Tableau logo, which consists of a cluster of plus signs followed by the word "tableau" in a lowercase, sans-serif font. Below the logo are two input fields: the first contains the text "jjohnson" and the second contains seven asterisks. Below these fields is a prominent orange button with the text "Sign In" in white.

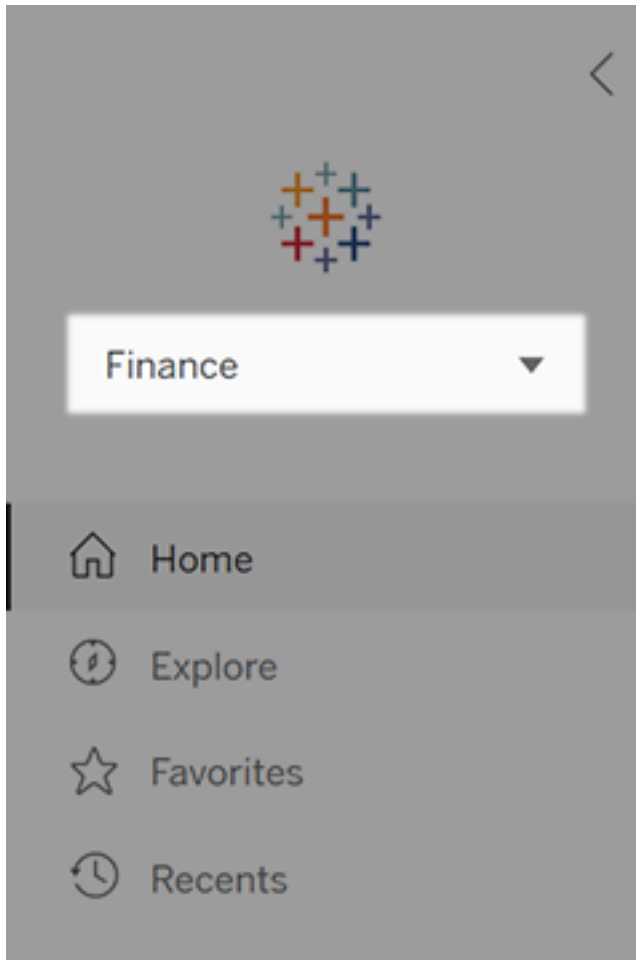

## Sign in to a specific site in a browser (Tableau Server only)

If you are a member of multiple sites, you're prompted to select one when you sign in to the server. Either click a visible site name or search for a name to select from a list of matching sites.

The image shows the Tableau site selection interface. At the top is the Tableau logo. Below it is the heading "Select a Site". Underneath is a search input field with the placeholder text "Search for a site" and a magnifying glass icon. Below the search field is a list of site names: "Default" and "Finance". The "Default" site is highlighted with a light gray background.

The name of the current site is displayed on the site picker.

## Choose the Right Chart Type for Your Data

What chart or graph works best for your data? In Tableau, form follows function. The visualization (or viz) you create depends on:

- The questions you are trying to ask
- The properties of your data
- How you want to present and communicate your insights to others

For example, showing the growth in sales each year requires a different visualization than showing the connection between discounted items and their profitability. Knowing what you need to show will help determine how you want to show it.

This topic presents nine different types of information that you can display with a visualization. This isn't a comprehensive list, and there are bound to be exceptions to these categories. With experience you will be able to more quickly assess what chart type you want to create. Because

Tableau is flexible, we encourage you to think outside the box. However, before you think outside the box, it's helpful to start with some common chart types.

## Change over time

### Related topics

- [Building Line Charts](#) on page 1470
- [Dates and Times](#) on page 1097
- [Continuous Dates](#) on page 1134

Showing a change over time for a measure is one of the fundamental categories of visualizations. There are many options for exploring change over time, including line charts, slope charts, and highlight tables.

To show change over time, you need to know the value you expect to change, and how to work with Date fields in Tableau.

What kind of question does this chart answer?

- How has this measure

changed in  
the past  
year?

- When did this measure change?
- How quickly has this measure changed?

### More inspiration

## Correlation

Sometimes you have two variables and are looking for the relationship

### Related topics

- [Build a Scatter Plot](#) on page 1488
- [Create Heatmaps that Show Trends or Density in Tableau](#) on page 1742
- [Add Trend Lines to a Visualization](#) on page 1942

between them. For example, you may be looking for the relationship between classroom size and school graduation rate, or how much lung capacity relates to endurance. (But remember, correlation does not always equal causation.)

Correlation can be shown with scatter plots or highlight tables, and you can use Tableau's [analytics objects](#) to show the strength of the correlation.

What types of question can this chart answer?

- Are these two measures related?  
How strongly?

- Are some measures more related than others?
- How strongly related are these measures?

## Magnitude

### Related topics

- [Build a Bar Chart](#) on page 1419
- [Build a Packed Bubble Chart](#) on page 1478
- [Building Line Charts](#) on page 1470

Magnitude shows the relative size or value of two or more discrete items. If you are comparing sales for different regions, you are looking at magnitude.

Magnitude charts include bar charts, packed bubble charts, and line charts.

What types of question can this chart answer?

- Which of these dimen-

- sion members has the highest measure?
- Are there any exceptional dimensions?
  - How large of a gap is there between the lowest and highest measure between these dimensions?

## Deviation

### Related topics

- [Build a Bar Chart](#) on page 1419
- [Build a Bullet Graph](#) on page 1436

Deviation charts show how far a value varies from some baseline, such as the average or median. If you wanted to know which items had unusually high or low profit margins, you would use a deviation chart.

You can use bullet

- [Calculate Z-scores](#) on page 1519

charts, bar charts, and combination charts to show deviation. You can also find the statistical significance of the deviation using a Z-score.

What types of question can this chart answer?

- How far from the norm does this measure stray?
- How important are the deviations in this measure?
- Is there a pattern to the deviations?

## Distribution

When you are trying to find the frequency of events within a

### Related topics

- [Build a Box Plot](#) on page 1429
- [Create a Pareto Chart](#) on page 1525
- [Create a Population Pyramid](#) on page 1531

population, you are looking at the distribution. If you are showing the number of respondents to a survey by age, or the frequency of incoming calls by day, a distribution chart might be the best choice.

Distribution charts include histograms, population pyramids, Pareto charts, and box plots.

What types of question can this chart answer?

- Are events clustered around a certain probability?
- Which population group buys the most items?
- When are

the busiest  
times in our  
work day?

## Ranking

### Related topics

- [Build a Bar Chart](#) on page 1419
- [Table Calculation Types](#) on page 2496
- [Sets for Top N and Others](#) on page 1061
- [Visualize Key Progress Indicators](#) on page 1521

Sometimes you not only want to depict the magnitude of some value, but also the relative ranking of all the members of your dimension. Showing the top ten sales people or demonstrating the under-performing states use a ranking chart.

Ranking charts are usually bar charts that integrate rank calculations, top n sets, or key progress indicators.

What types of question can this chart answer?

- How many people are

under-performing in the company?

- How much revenue is generated by our top ten customers?
- What is the value of our ten lowest revenue properties?

## Part-to-Whole

Part-to-Whole charts show how much of a whole an individual part takes up. For example, if you are showing how much each region contributes to overall sales, or how expensive each different shipping mode is for an individual product, you would use a part to whole chart.

### Related topics

- [Build a Pie Chart](#) on page 1484
- [Build a Treemap](#) on page 1501
- [Create an Area Chart](#) on page 1417
- [Stack Marks](#) on page 1235

Part-to-Whole charts can be pie charts, area charts, stacked bar charts, or treemaps.

What types of question can this chart answer?

- How much does this value contribute to the total?
- How does the distribution of costs change each year?
- Do different items contribute different amounts to sales by region?

## Spatial

Spatial charts can precise locations and geographical

### Related topics

- [Create Maps that Show Quantitative Values in Tableau](#) on page 1715
- [Create Maps that Highlight Visual Clusters of Data in Tableau](#) on page 1721

patterns in your data. Showing the airport terminals with the most foot traffic or a map of all sales across the country are examples of spatial maps.

Spatial maps include filled maps, point distribution maps, symbol maps, and density maps.

What types of question can this chart answer?

- Which city has the highest sales?
- How far from distribution centers are our customers?
- How many people arrive at which gate?

## Flow

Flow charts can be maps that convey movement over time, such as Sankey diagrams. Flow maps include path over time and path between origin and destination charts.

What types of question can this chart answer?

### Related topics

- [Create Maps that Show Paths Between Origins and Destinations in Tableau](#) on page 1748
- [Create Maps that Show a Path Over Time in Tableau](#) on page 1734

- What is the longest shipping route?
- How long are people lingering around gates?
- What are the bottlenecks to traffic in the city?

## Configure a forward proxy for OAuth authentication

You can configure a forward proxy in Tableau Server and Tableau Desktop to enable OAuth authentication. Forward proxies can help you manage traffic out to the internet for tasks such as load balancing.

### Use Windows to connect to Tableau Desktop through a forward proxy

Complete the following steps to configure the proxy server in Windows LAN Settings.

**1. Open the Local Area Network (LAN) Settings dialog box.**

**Tip:** A quick way to get to this dialog box is to search for Internet Options in the Windows Start menu.

**2. In the Internet Properties dialog box, select the Connections tab.**

**3. Select LAN settings.**

**4. Under Proxy server, select Use a proxy server for your LAN.**

**5. Enter the proxy server address.**

**6. Enter the server port.**

**7. Select Bypass proxy server for local addresses.**

**Note:** If you've already followed the steps in [Configuring Proxies for Tableau Server](#) and OAuth requests through your proxy aren't working then follow option 2.

### Windows configuration option 1: Use system environment variables

You can edit the system-wide environment variables and set `http_proxy` and `https_proxy` to your proxy to enable OAuth authentication.

1. In your Windows computer search box, enter **Advanced system settings**.
2. Tap **Enter** to open the **System Properties** box.
3. On the **Advanced** tab, select **Environment Variables**.
4. Scroll through the **System variables** field.
  - If the field has `http_proxy` or `https_proxy`, verify that the values don't conflict with the proxy server address that you configured in the previous step.
  - If they aren't set, then set them to the values that match the proxy server address configured in the previous step.
5. Restart Tableau Desktop.
6. Attempt to connect to an OAuth connector, and validate it works as expected.

**Note:** If you see a **OAuth-Client can't be empty** or **SSLHandshake Exception** or **Connection Refused** exception continue to option 2.

### Windows configuration option 2: Configure Java net.properties proxy settings

1. In your file directory, locate the version of Java you're using to run Tableau Desktop.

```
C:/Program Files/Tableau/Tableau <Version>/bin/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.
3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

**Warning:** Make sure to only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. Restart Tableau Desktop, and try to connect through OAuth.

## Use Mac to connect to Tableau Desktop through a forward proxy

To use Mac to connect Tableau Desktop through a forward proxy you must configure Java `net.properties` proxy settings.

1. In your file directory, locate the version of Java you're using to run Tableau Desktop.

```
/Applications/Tableau <Version>/Plugins/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

**Warning:** Make sure to only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. Restart Tableau Desktop, and try to connect through OAuth.

## Use Windows to connect through a proxy that requires OAuth authorization

If your proxy requires you to sign in with a username and password, then complete the following steps so OAuth requests connect through the proxy.

1. In your file directory, locate the version of Java that you're using to run Tableau Desktop.

```
C:/Program Files/Tableau/Tableau <Version>/bin/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Desktop, and try to connect through OAuth.

## Use Mac to connect through a proxy that requires OAuth authorization

If your proxy requires you to sign in with a username and password, then complete the following steps so OAuth requests connect through the proxy.

1. In your file directory, locate the version of Java that you're using to run Tableau Desktop.

```
/Applications/Tableau <Version>/Plugins/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Desktop, and try to connect through OAuth.

## Use Windows to connect to Tableau Server through a forward proxy

You can launch Tableau Server from behind a forward proxy to allow internet access. You can configure the proxy server in Windows LAN Settings to connect to Tableau Server through a forward proxy.

### Configure the proxy

Complete the following steps to configure the proxy server.

1. Open the **Local Area Network (LAN) Settings** dialog box.

**Tip:** A quick way to get to this dialog box is to search for Internet Options in the Windows Start menu.

2. In the **Internet Properties** dialog box, select the **Connections** tab.

3. Select **LAN settings**.

4. Under **Proxy server**, select **Use a proxy server for your LAN**.

5. Enter the proxy server address.

6. Enter the proxy server port.

7. Select **Bypass proxy server for local addresses**.

### Add exceptions

You can add exceptions to guarantee that all communications within a local Tableau Server cluster don't route to the proxy server. Complete the following steps to add exceptions.

1. In the **LAN settings** dialog box, select **Advanced**.

**Note:** This button is available only if you've selected the option to use a proxy server for your LAN.

2. In the **Proxy Settings** dialog box, in the **Exceptions** field, enter the following values.

- localhost
- Server host names
- IP addresses of other Tableau Server computers in the same cluster.

**Note:** Use semicolons to separate items.

3. Close the **Proxy settings** dialog box.
4. Close the **Local Area Network (LAN) Settings** dialog box.
5. In the **Internet Properties** dialog box, select **OK** to apply the settings.

**Note:** If you've completed the steps in [Configuring Proxies for Tableau Server](#) and OAuth requests through your proxy aren't working then follow option 2.

### Windows configuration option 1: Use system environment variables

You can edit system-wide environment variables and set `http_proxy` and `https_proxy` to your proxy.

1. In the Windows computer search box, enter **Advanced system settings**
2. Tap **Enter** to open the **System Properties** box.
3. On the **Advanced** tab, select **Environment Variables**.
4. Scroll through the **System variables** field.
  - If the field has `http_proxy` or `https_proxy`, verify that the values don't conflict with the proxy server address that you configured in the previous step.
  - If they aren't set, then set them to the values that match the proxy server address configured in the previous step.
5. Restart Tableau Server.
6. Attempt to connect to an OAuth connector, and validate it works as expected.

**Note:** If you see a **OAuth-Client can't be empty, SSLHandshake, or Connection Refused** exception continue on to option 2.

### Windows configuration option 2: Configure Java net.properties proxy settings

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
C:\Program Files\Tableau\Tableau Server\packages\Repository*\jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

**Warning:** Make sure to only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. The proxy host default value is `http.nonProxyHosts =localhost|127.*|[::1]`. If the default value matches the list of exceptions, bypass the proxy server, and then continue to step

6. If they don't match make sure that it has the following values.

- `localhost`
- Server host names and IP addresses of other Tableau Server computers in the same cluster.
- Each item is separated by “|”

6. Restart Tableau Server and try to connect through OAuth.

## Use Linux to connect to Tableau Server through a forward proxy

You can configure Java `net.properties` proxy settings to use Linux to connect Tableau Server through a forward proxy.

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
opt/tableau/tableau_server/packages/repository*/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyPort=<your proxy port>`
- `http.proxyHost=<your proxy host address>`
- `https.proxyPort=<your proxy port>`
- `https.proxyHost=<your proxy host address>`

**Warning:** Make sure to only include the host. If your proxy address is `http://myproxy:8888`, then set it to: `http.proxyHost=myproxy`

5. The proxy host default value is `http.nonProxyHosts =localhost|127.*|[::1]`. If the default value matches the list of exceptions, bypass the proxy server, and then continue to step 6. If they don't match make sure that it has the following values.

- localhost
- Server host names and IP addresses of other Tableau Server computers in the same cluster.
- Each item is separated by “|”

6. Restart Tableau Server and try to connect through OAuth.

## Use Windows to connect to Tableau Server through a proxy that requires OAuth authorization.

If your proxy requires that you sign in with a username and password, then complete the following steps to allow OAuth requests to connect through the proxy.

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
C:\Program Files\Tableau\Tableau Server\packages\repository*\jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Server, and try to connect through OAuth.

## Use Linux to connect to Tableau Server through a proxy that requires OAuth authorization.

If your proxy requires that you sign in with a username and password, then complete the following steps to allow OAuth requests to connect through the proxy.

1. In your file directory, locate the version of Java you're using to run Tableau Server.

```
opt/tableau/tableau_server/packages/repository*/jre
```

2. In the Java locations directory, select the `conf` folder. If this directory doesn't exist, then create one.

3. In the `conf` folder, locate the `net.properties` file, and open it in an editor. If this file doesn't exist, then create one by the same name.

**Note:** If you don't have write permissions on this file, use the system file settings to enable them.

4. Modify or create the following values:

- `http.proxyUser=<your proxy username>`
- `http.proxyPassword=<your proxy password>`

5. Restart Tableau Server, and try to connect through OAuth.

## SSL handshake errors

If you're getting errors, then check to ensure you have put your SSL cert into the correct keystore. On Windows, the keystore is under the system Trusted Certs store. If the keystore is correct, and you're still getting errors, then import your cert directly into the Java keystore. Complete the following steps to import your certificate into the Java keystore.

Export the SSL certificate for your proxy to a file.

**Tip:** You can find your certificate under Applications, Utilities, Keychain Access, System, Category, Certificates.

1. Locate the version of Java you're using to run Tableau.
2. Open the terminal command prompt.
3. Run the following command from the directory that contains the version of Java you're using to run Tableau.

```
Keytool -import -trustcacerts -file /Users/tableau_  
user/Desktop/SSL.cer -keystore Tableau  
<version>/Plugins/jre/lib/security/cacerts -storepass changeit
```

4. Restart Tableau Server or Tableau Desktop.

**Note:** If you get a **FileNotFoundException** (Access denied) when running the keytool command, try running the command with elevated permissions.

```
sudo keytool -import -trustcacerts -file /Users/tableau_  
user/Desktop/SSL.cer -keystore Tableau  
2021.3.1/Plugins/jre/lib/security/cacerts -storepass changeit
```

## OAuth Overview

OAuth (Open Authorization) is an authentication protocol that allows users to grant limited access to their resources on one website or application to another website or application, without sharing their actual login credentials.

OAuth acts like a trusted middleman that enables you to give permission for one service to access your data from another service without revealing your username and password. This document includes a technical explanation of the OAuth workflow and a practical OAuth analogy.

### OAuth workflow

OAuth provides a secure and standardized way for users to grant access to their data across different websites and applications without sharing their login credentials. It ensures that you have control over which services can access your data and allows you to revoke access at any time.

The following list is a step-by-step explanation of how OAuth works.

You (the user) want to use a website or application (called the "client") that requires access to your data on another website or application (called the "resource server").

The client requests permission to access your data from the resource server. It typically does this by redirecting you to the resource server's login page.

You enter your login credentials on the resource server's login page directly. This step is crucial because your username and password are never shared with the client.

The resource server verifies your credentials and authenticates you. Once authenticated, it generates a unique access token for the client.

The resource server redirects you back to the client application, providing the access token along with the redirection.

The client receives the access token and sends it to the resource server whenever it needs to access your data.

The resource server checks the validity of the access token. If the token is valid, it grants the client access to the requested resources for a limited period.

The client can use the granted access to retrieve or modify your data on the resource server, but only within the scope defined by the access token. The scope determines what actions and data the client can access.

If the access token expires or if the client needs additional permissions, the client can request a new access token by going through the authentication process again.

## Practical OAuth analogy

The following is an analogy of how OAuth works using a practical scenario.

Imagine you are throwing a party, and you want to hire a caterer (the client) to handle the food. However, you don't want to give the caterer the keys to your house (your login credentials) because that would give them access to all your personal belongings. So, you use a trusted party organizer (OAuth) to manage the access.

You tell the party organizer that you want to hire a caterer. The party organizer knows how to handle access to your house and the caterer's services.

The party organizer contacts the caterer and sends them to your house for a meeting. You're not home at this point.

The caterer arrives at your house but realizes they can't enter without your permission (access token). They call you to ask for access.

You, as the homeowner, want to verify the caterer's credibility before granting access. So, you ask the caterer some questions to confirm their identity (authentication).

Once you're satisfied with the caterer's credentials, you give them a temporary access code (access token) through the phone. This code allows them to enter your house and prepare the food but only within the scope of their catering duties.

The caterer enters your house using the access code and starts setting up the food. They can access the kitchen and dining area but are restricted from entering other rooms.

After a specified period or when the party ends, the access code expires, ensuring that the caterer can't re-enter your house without your permission.

In this scenario, you (the homeowner) are the user, the caterer is the client application, your house represents your personal data on the resource server, and the party organizer is OAuth.

The access code serves as the access token, allowing the client (caterer) limited access to your resources (house) without compromising your login credentials (house keys).

OAuth acts as a trusted intermediary, facilitating the secure sharing of your data between services while maintaining control over access permissions.

## Tableau Workbook Performance Checklist

Before you start building your visualizations and dashboards, you will want to be aware of what choices might impact performance in your workbooks on Tableau Desktop, Tableau Cloud, and Tableau Server.

This checklist is intended to make you aware of things you will want to consider related to workbook performance. Remember that all environments are different and there is no simple cure for workbook performance. The items below are areas to explore. Any given item may not apply to your situation or be the cause of poor performance. Always test what helps in your specific case.

**Learn more:** For more in-depth and related information beyond this topic, see:

[Optimize Workbook Performance](#) on page 2977 topics in Tableau help

[Designing Efficient Workbooks](#) whitepaper on tableau.com

[Designing Efficient Workbooks](#) (1 hour) and [Best Practices for Dashboard Performance](#) (50 minutes) free, video presentations

[The Tableau Performance Optimization Flowchart](#) and [The Tableau Performance Checklist](#) in the [InterWorks blog](#).

## General tips

This general list of considerations is a start in learning how to approach optimizing workbooks. It comes from the TL;DR page in the [Designing Efficient Workbooks](#) whitepaper.

- The cleaner your data is and the better it matches the structure of your questions, the faster your workbooks will run and the happier your life will be. Only connect to the data that you need for analysis.
- Extracts are a quick and easy way to make most workbooks run faster. If you don't need real-time data and aren't working over billions of rows of data, you should try them.
- The majority of slow dashboards are caused by poor design—in particular, too many charts on a single dashboard, or trying to show too much data at once. Keep it simple. Allow your users to incrementally drill down to details, rather than trying to show everything then filter (guided analysis).
- Don't work with data you don't need—both in terms of the fields you reference as well as the granularity of the records you return. Use filters, hide unused fields and aggregate.
- While reducing the data, make sure you use filters efficiently.
- Strings and dates are slow, numbers and Booleans are fast.
- There is no silver bullet for inefficient workbooks. Start by looking at the performance recorder to understand where the time is going. Long-running queries? Lots of queries? Slow calculations? Complex rendering? Use insights to focus your efforts in the right direction.
- Upgrading to the newest version may boost performance without needing anything else.
- If it is slow in the data source, it will be slow in Tableau Desktop. If it is slow in Tableau Desktop, it will (almost always) be slow in Tableau Server.
- Performance tuning is highly individualized to the context of your environment, data, analysis, and workbook. What works in one situation may not work in another--test and iterate to see what works in your specific case.

## Data source and structure

- Prepare your data to match the structure of your analysis before you connect to it in Tableau Desktop. [Tableau Prep](#) is a helpful tool for getting your data ready.
- Enable support for [referential integrity](#).

- Index the tables in your relational database.
- Make sure database permissions support creating temp tables.
- Connect with native database drivers.
- Whenever possible, connect to an extract rather than a live data source.
- Limit the amount of data that you bring into Tableau to what is necessary for your analysis.
- Consider using aggregated extracts and extract filters.
- Optimize extracts and hide unused fields before creating an extract.
- Avoid using custom SQL.
- Identify when you should be joining, blending, or using a cross-database join.
- Keep joins as limited as possible. Consider using multiple data sources so each type of analysis is built off a well-designed join.
- Consider aggregating before blending.

### Related topics and resources

- [Know Your Data at the Database Level](#) on page 2994
- [Test Your Data and Use Extracts](#) on page 2995
- [Designing Efficient Workbooks](#)

### Building views and dashboards

- Keep it simple. Break massive workbooks up into separate files, and consider using fewer sheets on a dashboard.
- Reduce the number of marks in the view—only add the fields you need, and use filters judiciously.
- Turn off automatic updates when building a view. Set up multiple steps before asking Tableau to perform the actions.
- When possible, try to use the same level of detail on multiple sheets on a dashboard to enable query batching.
- Limit the number of filters used—use guided analytics and filter actions when possible.

- Use fixed-size dashboards. They don't have to be re-rendered for different window sizes.
- Custom geocoding can massively inflate the size of a workbook.

## Related topics and resources

- [Design for Performance While You Build a View](#) on page 2998
- [Make Visualizations Faster](#) on page 3002
- [Turn off Automatic Updates to Boost Performance](#) on page 3010
- [Designing Efficient Workbooks](#)

## Filtering

- Filtering is one of the most common causes of poorly performing workbooks and dashboards.
- Use Extract and Data Source filters to limit the amount of data being brought into Tableau.
- Filters are more efficient when the data source is indexed.
- Context filters are evaluated before other filters in the view and should be used to help force an order of operations, but they no longer help improve query performance.
- Be aware that using **Keep only** and **Exclude** to filter out discrete items can be performance heavy.
- Filtering on a categorical dimension value that summarizes many points—such as filtering a state instead of all the cities in that state—is more efficient.
- Filtering on a range of values is often faster than filtering on large itemized lists of discrete values.
- Cross-database filters can require multiple queries when values are updated. Enable the **Show Apply Button** option on filters to let users apply the filter after making their selections.
- The **Only Relevant Values** filter option creates a query each time the other filters are changed. For dashboards that use guided analytics, try using [Filter Actions on page 1331](#) instead.
- Applying filters to multiple worksheets creates multiple queries.

- Enable the **Show Apply Button** option on filters. This lets you and your users click **Apply** to run a single query for multi-select filters.

## Calculations

- Booleans and integers are faster than strings and dates.
- MIN and MAX functions perform better than AVG and ATTR.
- When possible, use native Tableau features—groups, sets, bins, custom date fields, combined fields, and aliases—instead of calculations.
- Use optimized functions like CONTAINS and DATEPARSE or MAKEDATE when possible, rather than more complicated manual calculations, especially with dates.
- COUNTD is one of the slowest functions types, avoid when possible.
- If a table calculation is performing badly, see if it can be expressed via a LOD expression, and vice versa.

## Related topics and resources

- [Create Efficient Calculations](#) on page 2999
- [Designing Efficient Workbooks](#)

## Other Suggestions

- Publishing to Tableau Server will not improve performance. Tune your workbook in Tableau Desktop first.
- Use the performance recorder to identify where to focus tuning efforts.
- Upgrade to the latest version of your Tableau product.

# Connect to and Prepare Data

Before you begin your analysis, you must connect to your data and then set up the data source. There are many optional configurations that you can make on the Data Source page that Tableau uses to interpret and interact with your data.

The topics in this section describe how to connect to your data and use these configurations in order to optimize your data source for analysis.

## Connect to Your Data

Before you can build a view and analyze your data, you must first connect Tableau to your data. Tableau supports connecting to a wide variety of data, stored in a variety of places. For example, your data might be stored on your computer in a spreadsheet or a text file, or in a big data, relational, or cube (multidimensional) database on a server in your enterprise. Or, you might connect to public domain data available on the web such as U.S. Census Bureau information, or to a cloud database source, such as Google Analytics, Amazon Redshift, or Salesforce.

Starting in 2019.3, Tableau Catalog is available as part of the Data Management offering for Tableau Server and Tableau Cloud. When Tableau Catalog is enabled in your environment, in addition to connecting to published data sources, you can connect to databases and tables from **Tableau Server** on the **Connect** pane in Tableau Desktop. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help. Starting in 2021.4, Data Management includes virtual connections, a central access point to data. For more information, see "About Virtual Connections and Data Policies" in the [Tableau Server](#) or [Tableau Cloud](#) help.

## Tableau Desktop

When you launch Tableau Desktop, the data connectors that are available to you are listed on the **Connect** pane, which is the left pane on the **Start** page. Under **Search for Data**, select **Tableau Server** to find data using Tableau Server or Tableau Cloud. File types are listed next, then common server types, or servers that you've recently connected to. Click **More** to see the complete list of data connectors you can use.

For supported files and databases, Tableau provides native connectors that are built for and optimized for those types of data. If your file or database type is listed under **Connect**, use this native connector to connect to your data. If your file or database type isn't listed, you might have

the option of creating your own connection using **Other Databases (JDBC)**, **Other Databases (ODBC)**, a **Web Data Connector**, or a **Connector Plugin** built using the Tableau Connector SDK. Tableau provides limited support for connections that you create using these options.

The data connectors supported by your copy of Tableau Desktop are determined by the version you purchased. For more information, see the list of [data connectors](#) on the Tableau website. After you've connected to data, you can save the connections to have them show up under the **Saved data sources** section on the **Connect** pane.

You supply different information for each data connection that you want to make. For example, for most data connections, you'll need to supply a server name and your sign-in information. With some data connections, you can [Run Initial SQL on page 591](#) statements, and SSL-enabled servers require that you select the **Require SSL** check box when you connect. The following sections discuss the specific information you must provide for each type of data you want to connect to.

**Tip:** You can quickly create a data source in Tableau by copying and pasting data using the clipboard. For more information, see [Create a Data Source or Add a New Connection with Clipboard Data](#) on page 810.

## Tableau Server and Tableau Cloud web authoring

Sign in to your Tableau site and select **New > Create Workbook** on the Home page to open the **Connect to Data** page. The tabs that you see on the pages depend on the product you have.

### Tableau Server

On Tableau Server, select from the following tabs to connect to data:

- **On this site.** Browse to or search for published data sources. If you have Data Management, you can also connect to data using a virtual connection. If you have Data Management with Tableau Catalog enabled, you can additionally connect to external assets like databases, files, and tables.
- **Files.** Upload Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser.
- **Connectors.** Connect to data housed in a cloud database or on a server in your enterprise.

For more information about connecting to data, see [Creators: Connect to Data on the Web](#) on page 3142.

## Tableau Cloud

On Tableau Cloud, select from the following tabs to connect to data:

- **On this site.** Browse to or search for published data sources. If you have Data Management, you can also connect to data using a virtual connection. If you have Data Management with Tableau Catalog enabled, you can additionally connect to external assets like databases, files, and tables.
- **Files.** Upload Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser.
- **Connectors.** Connect to data housed in a cloud database or on a server in your enterprise.
- **Dashboard Starters.** Use to author and analyze data from Oracle Eloqua, Salesforce, ServiceNow ITSM, and QuickBooks Online.

For more information about connecting to data, see [Creators: Connect to Data on the Web](#) on page 3142.

The data connectors supported by your Tableau site are determined by your site's server and your license level. For more information, see [What Can I Do with a Tableau Site?](#) on page 3107

After you've connected to data, you can save the connections to have them show up in the **Data Sources** section of your site.

## Request a new connector

If Tableau doesn't have a native (built-in) connector for your data, consider requesting one on Tableau Community. Use [Ideas](#) on Community to search for your connector to see if it's been requested, and if it has been, vote for it. If it's not listed, add it. Tableau regularly reviews Ideas on Community to help determine what features should be added to the product.

## Supported Connectors

Follow the link below for information on how to connect to your specific data. Connectors are listed in the order that they appear on the **Connect** pane.

### Excel

This article describes how to connect Tableau to Microsoft Excel file data and set up the data source. Tableau connects to .xls and .xlsx files.

To connect to a .csv file, use the Text file connector.

## Make the connection and set up the data source

1. After you open Tableau, under **Connect**, click **Excel**.
2. Select the Excel workbook you want to connect to, and then click **Open**.

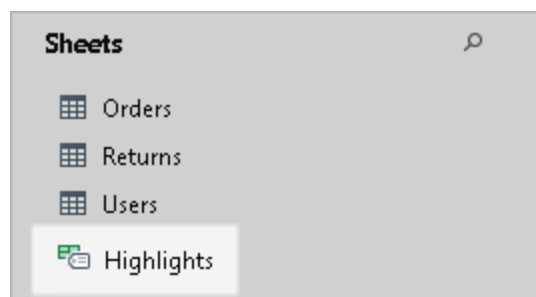

**NOTE:** Beginning with Tableau 2020.2, legacy Excel and Text connections are no longer supported. See the [Legacy Connection Alternatives](#) document in Tableau Community for alternatives to using the legacy connection.

3. On the Data Source page, do the following:
  1. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  2. If your Excel file has one table, click the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

You can also connect to a named range or an Excel table (also known as an Excel list) in the same way you connect to a worksheet. Both the named range and Excel table function as a table in Tableau.

You create named ranges in Excel by selecting a range of cells and then selecting **Define Name** on the **Formulas** tab. Similar to named ranges, you can create an Excel table in Excel by selecting a range of cells, and then selecting **Insert > Table**. When you connect to a named range or Excel table in Tableau, an icon appears next to the sheet in the Data Source page as shown below.

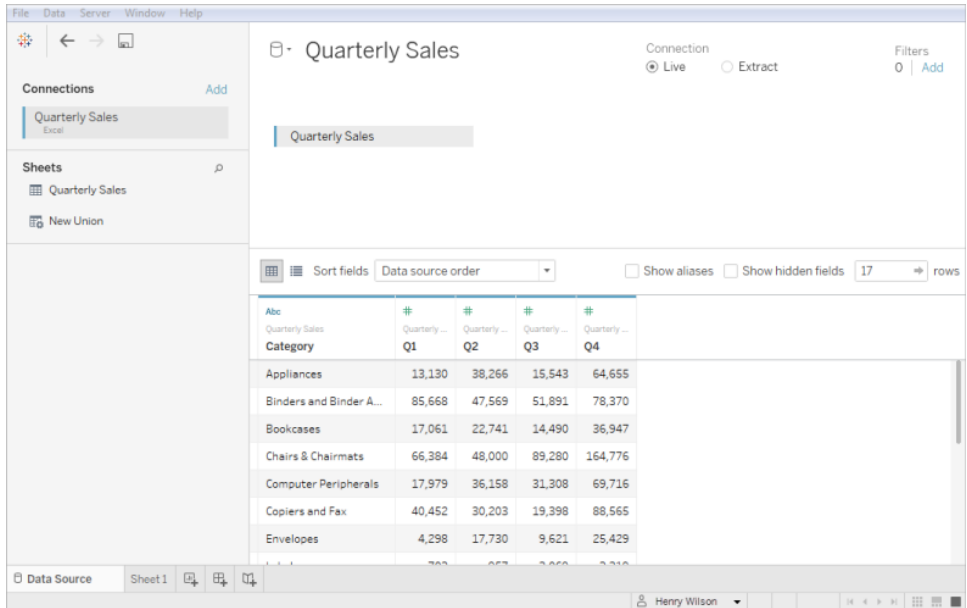

You can connect to multiple Excel workbooks at the same time as long as each connection in the data source has a unique name.

**Note:** Tableau does not support pivot tables in Excel.

### Microsoft Excel data source example

The following is an example of a Microsoft Excel data source.

**Note:** If the Excel file contains columns that are more than 254 characters wide, Tableau Desktop can't use these fields for workbooks that were created before Tableau Desktop 8.2. Also, you cannot use the legacy connection to connect to this data. Either remove the columns, modify them to fit within 254 characters prior to connecting in Tableau Desktop, or upgrade the Excel data source. For more information about upgrading data sources, see [Upgrade Data Sources on page 921](#).

### Get more data

Get more data into your data source by adding more tables or connecting to data in a different database.

- **Add more data from the current file:** From the left pane, drag additional tables to the canvas to combine data using a join or union. For more information, see [Join Your Data on page 738](#) or [Union Your Data on page 795](#).
- **Add more data from different databases:** In the left pane, click **Add** next to Connections. For more information, see [Join Your Data on page 738](#).

If a connector you want is not listed in the left pane, select **Data > New Data Source** to add a new data source. For more information, see [Blend Your Data on page 764](#).

## Set Excel table options

Excel table options are scoped to the connection. To change the table options, on the canvas, click the table drop-down arrow and then specify whether the data includes field names in the first row. If so, these names will become the field names in Tableau. If field names are not included, Tableau generates them automatically. You can rename the fields later.

## Use Data Interpreter to clean your data

If Tableau detects that it can help optimize your data source for analysis, it prompts you to use Data Interpreter. Data Interpreter can detect sub-tables that you can use and remove unique formatting that might cause problems later on in your analysis. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter on page 845](#).

## About .ttde and .hhyper files

You might notice .ttde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .ttde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

## Changes to the way values are computed

Starting from version 10.5, when you are working with extract data sources as well as data sources that use live connections to file-based data like Excel, the values in your data can be computed differently from previous versions of Tableau. This change means that you might see differences between the data and the marks in your view between version 10.4 (and earlier) and version 10.5 (and later). The purpose of this change is to improve the efficiency and scalability of your Excel data source. For more information, see [Changes to values and marks in the view on page 878](#).

In the case of an Excel data source, one example of this change is with case sensitivity. In version 10.4 (and earlier), for comparing and sorting purposes, string values are treated as case insensitive and therefore treated the same and stored as a single string value. In version 10.5 (and later), for sorting and comparing purposes, values remain case insensitive. However, values are case sensitive for storing purposes. This becomes evident when values are displayed on the data source page.

For example, suppose you have a column in your data that contains the values "House," "HOUSE," and "houSe." You see the following string values depending on the version of Tableau you are using:

- In version 10.4 and earlier, both on the data source page and view, you see: "House," "House," and "House."
- In version 10.5 and later, on the data source page you see: "House," "HOUSE," and "houSe." But in the view you see: "House," "House," and "House."

If you need to maintain case sensitivity for your data when performing a join, you can enable the **Maintain Character Case (Excel)** option from the Data menu. For more information about this option, see [Join Your Data on page 738](#).

#### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

#### Tips for Working with Your Data

Data can be organized in various ways. To take advantage of Tableau Desktop, Tableau recommends that you connect to data that is formatted for analysis. Specifically, data that is:

- as granular as possible rather than aggregated (such as daily weather data rather than monthly averages)
- organized like a database table (rather than a column-oriented table such as a crosstab)
- stripped of extraneous information (anything that's not the data and its headers)

When data is structured for analysis, it's much easier to ask and answer questions. Tableau can aggregate raw data to the desired level, rather than being restricted by the aggregations already present in the data. Groups and hierarchies can be created as needed, and calculations can be performed in the flow of analysis.

Tableau Desktop has basic cleaning options and the Data Interpreter. Tableau Prep may be necessary for more complex formatting issues.

The following Tableau Desktop-specific sections highlight and provide suggestions for resolving some common formatting or issues that can make analyzing your data difficult.

### Pivot data in crosstab format

When data is formatted as in crosstab format, the table is column oriented. In a column oriented table, the variables are stored as column headers. However, Tableau Desktop is optimized for row oriented data. In a row-oriented table, the variables are stored in the row values.

For example, suppose you have column-oriented table, which shows math, science, and history scores for grade school students.

ID	Gender	School	Math	Science	History
1	M	West	90	80	80
2	F	South	50	50	50
3	M	Central	50	80	80

Tableau Desktop is optimized to connect to row-oriented tables, where math, science, and history values are organized under a column called "Subject" and the scores for each student are organized under a column called "Score." You can pivot the columns in the rows, by manually editing your Excel data. Alternatively, connect to your Excel data from Desktop and then use the pivot option. For more information about the pivot option, see [Pivot Data from Columns to Rows](#) on page 840.

ID	Gender	School	Subject	Score
1	M	West	Math	90
1	M	West	Science	80
1	M	West	History	80
2	F	South	Math	50
2	F	South	Science	50
2	F	South	History	50
3	M	Central	Math	50
3	M	Central	Science	80
3	M	Central	History	80

### Remove pre-aggregated data

Data can often come pre-aggregated. That is, data can contain sums, averages, medians, etc. A common example of pre-aggregated data comes in the form of subtotals and grand totals. Subtotals and grand totals data are computed from the raw data, but is not part of raw data itself.

For example, suppose you have a table that contains a row of subtotals information.

ID	Gender	School	Math	Science	History
1	M	West	90	80	80
2	F	South	50	50	50
3	M	Central	50	80	80
4	M	Central	100	90	80
5	F	West	90	100	80
		<b>Subtotals</b>	<b>380</b>	<b>400</b>	<b>370</b>

In this case, pre-aggregated data needs to be removed. To use subtotals and grand totals in your analysis, manually remove this type of information from your table. Then, connect to your Excel data from Desktop and calculate subtotals and totals using the totals option. For more information, see [Show Totals in a Visualization on page 1298](#). Alternatively, connect to your Excel data from Desktop, turn on Data Interpreter, and then use the totals option. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter on page 845](#).

ID	Gender	School	Math	Science	History
1	M	West	90	80	80
2	F	South	50	50	50
3	M	Central	50	80	80
4	M	Central	100	90	80
5	F	West	90	100	80
		<del>Subtotals</del>	<del>380</del>	<del>400</del>	<del>370</del>

### Remove or exclude introductory text

Excel data that is delivered as a report can contain titles or blocks of introductory text. Because Desktop expects either column headers or row values in the first row of a table, this information can cause problems during your analysis.

For example, suppose you have a table that contains a report title and date.

<b>Excel Report</b>						
<b>January, 2017</b>						
	<b>ID</b>	<b>Gender</b>	<b>School</b>	<b>Math</b>	<b>Science</b>	<b>History</b>
	1	M	West	90	80	80
	2	F	South	50	50	50
	3	M	Central	50	80	80
	4	M	Central	100	90	80
	5	F	West	90	100	80

In this case, the title and date information needs to be removed. To use a title and date for a report, do one of the following:

- Manually remove this information from your Excel data. Then connect to your Excel data from Desktop and add a report title using the title option. For more information, see [Format Titles, Captions, Tooltips, and Legends on page 2921](#).
- Connect to your Excel data from Desktop, turn on Data Interpreter, and then use the title option. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter on page 845](#).
- If you cannot remove this information from your Excel data, create a named range and connect to the named range from Desktop. For more information, see [Excel on page 235](#).

<del><b>Excel Report</b></del>						
<del><b>January, 2017</b></del>						
	<b>ID</b>	<b>Gender</b>	<b>School</b>	<b>Math</b>	<b>Science</b>	<b>History</b>
	1	M	West	90	80	80
	2	F	South	50	50	50
	3	M	Central	50	80	80
	4	M	Central	100	90	80
	5	F	West	90	100	80

### Flatten hierarchical headers to a single row

In general, Tableau Desktop expects only the first row in your Excel data to contain column headers. Data that contains multiple layers of column headers can cause problems during your analysis.

For example, suppose you have a table that contains one major header and multiple sub-headers.

California					
ID	Gender	School	Math	Science	History
1	M	West	90	80	80
2	F	South	50	50	50
3	M	Central	50	80	80
4	M	Central	100	90	80
5	F	West	90	100	80

In this case, the hierarchy of headers must be flattened or removed. To do this, you can manually create a new column for each header in the hierarchy directly in your Excel data. Alternatively, connect to your Excel data from Tableau Desktop and then turn on Data Interpreter. Verify that your headers are flattened correctly. For more information about Data Interpreter, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter](#) on page 845.

ID	State	Gender	School	Math	Science	History
1	California	M	West	90	80	80
2	California	F	South	50	50	50
3	California	M	Central	50	80	80
4	California	M	Central	100	90	80
5	California	F	West	90	100	80

## Make sure there are no blank cells

If you create new columns for your hierarchical headers, make sure that each cell in the new columns contains values.

ID	State	Gender	School	Math	Science	History
1	California	M	West	90	80	80
2		F	South	50	50	50
3		M	Central	50	80	80
4		M	Central	100	90	80
5		F	West	90	100	80
6	Oregon	M	North	70	80	100
7		F	East	80	80	100
8		F	West	50	80	80
9		F	West	100	80	100
10		M	West	80	80	90

While you might repeat the same value for each row, it's important that each row contains the data that associates it with the data that was stored in the hierarchical header. You must manually remove blank cells from your Excel data.

<b>ID</b>	<b>State</b>	<b>Gender</b>	<b>School</b>	<b>Math</b>	<b>Science</b>	<b>History</b>
1	California	M	West	90	80	80
2	California	F	South	50	50	50
3	California	M	Central	50	80	80
4	California	M	Central	100	90	80
5	California	F	West	90	100	80
6	Oregon	M	North	70	80	100
7	Oregon	F	East	80	80	100
8	Oregon	F	West	50	80	80
9	Oregon	F	West	100	80	100
10	Oregon	M	West	80	80	90

### Remove blank rows

Make sure that there are no blank rows in your data. To fix blank rows, you must remove the blank rows from your Excel data.

<b>ID</b>	<b>Gender</b>	<b>School</b>	<b>Math</b>	<b>Science</b>	<b>History</b>
1	M	West	90	80	80
2	F	South	50	50	50
3	M	Central	50	80	80
4	M	Central	100	90	80
5	F	West	90	100	80
22	M	North	70	80	100
23	F	East	80	80	100
24	F	West	50	80	80
25	F	West	100	80	100
26	M	West	80	80	90

### Add missing headers

Make sure that there are no missing column headers. To fix missing headers, you must manually add the missing headers directly to your Excel data.

		<b>Gender</b>	<b>School</b>	<b>Math</b>	<b>Science</b>	<b>History</b>
6	Oregon	M	North	70	80	100
7	Oregon	F	East	80	80	100
8	Oregon	F	West	50	80	80
9	Oregon	F	West	100	80	100
10	Oregon	M	West	80	80	90

## Text File

This article describes how to connect Tableau to text file data and set up the data source. Tableau connects to delimited text files (\*.txt, \*.csv, \*.tab, \*.tsv).

### Make the connection and set up the data source

1. After you open Tableau, under **Connect**, click **Text File**.
2. Select the file you want to connect to, and then click **Open**.

**NOTE:** Beginning with Tableau 2020.2, legacy Excel and Text connections are no longer supported. See the [Legacy Connection Alternatives](#) document in Tableau Community for alternatives to using the legacy connection.

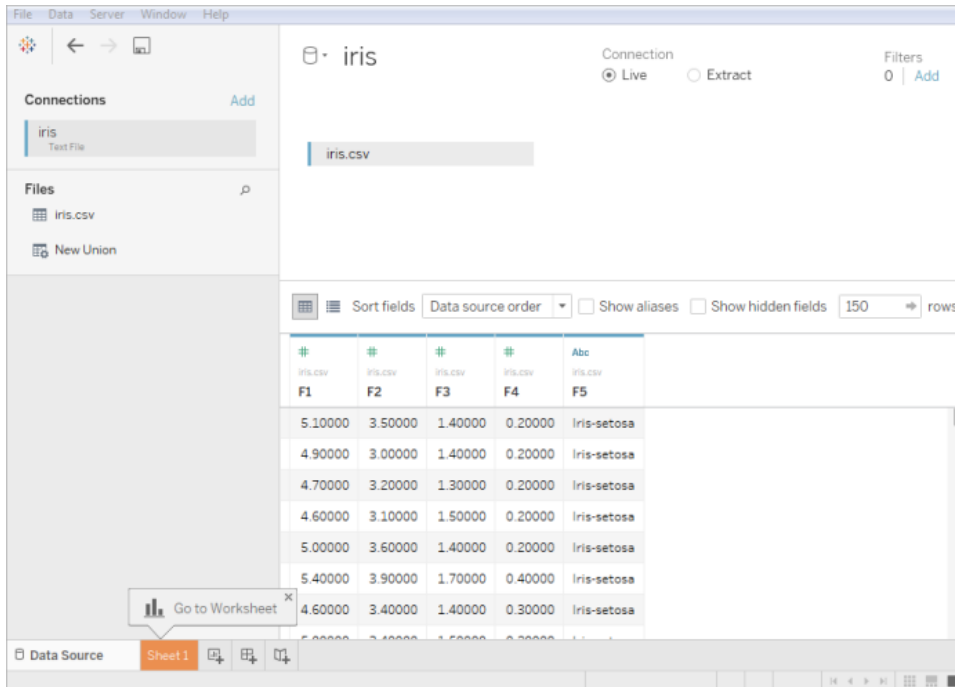

3. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to. The default name is automatically generated based on the file name.
  - b. Click the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** For text files, custom SQL is available only when using the legacy connection or in workbooks that were created before Tableau Desktop 8.2.

### Text file data source example

Here is an example of a text file data source:

## Optional settings

You can set the following options before building the view.

### Get more data

Get more data into your data source by adding more tables or connecting to data in a different database.

- **Add more data from the current file:** From the left pane, drag additional tables to the canvas to combine data using a join or union. For more information, see [Join Your Data on page 738](#) or [Union Your Data on page 795](#).
- **Add more data from different databases:** In the left pane, click **Add** next to Connections. For more information, see [Join Your Data on page 738](#).

If a connector you want is not listed in the left pane, select **Data > New Data Source** to add a new data source. For more information, see [Blend Your Data on page 764](#).

## Clean your data with Data Interpreter

If Tableau detects that it can help optimize your data source for analysis, it prompts you to use Data Interpreter. Data Interpreter can detect sub-tables that you can use and remove unique formatting that might cause problems later on in your analysis. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter on page 845](#).

## Set text file options

On the canvas, click the table drop-down arrow and then select whether the first row contains column names. This option is selected by default. Alternatively, you can have Tableau generate names when you connect. These names can be changed later. You can also select **Text file properties** to specify the following:

- Select the character that is used to separate the columns. Select from the list of characters or select **Other** to type in a custom character.
- Select the text qualifier that encloses values in the text file.
- Select a character set that describes the text file encoding. The available encodings are based on the operating system you are using. For example, on Windows, ANSI is listed as windows-1252 and OEM is listed as 437.

**Note:** In workbooks created prior to Tableau Desktop 8.2 or that use the legacy connection, you can select ANSI, OEM, UTF-8, UTF-16, or Other. When you select Other, you must specify the character set in the provided text field. This value is verified when the connection is attempted.

- Select the locale by which the file should be parsed. This option tells Tableau which decimal and thousands separator to use.

## Review the data, pivot, split, and create calculations

The first 1,000 rows of the data in the data source are automatically displayed below the canvas in the data grid. If you add tables, remove tables, or make changes to the join conditions, the data grid updates with your changes. You can also do the following in the data grid:

- Change the data type or geographical role of a column by clicking the data type icon.
- Hide a field by clicking the column drop-down arrow and selecting **Hide**.
- Rename a field by double-clicking the field name.
- Reset a field name by clicking the column drop-down arrow and selecting **Reset Name**.
- Sort fields in both the data grid and metadata grid by selecting a sort option from the **Sort fields** drop-down list.
- Sort rows in the data grid by clicking the sort button next to the column name.

- Pivot fields to transform data in a crosstab format into a columnar format. This is only available for non-legacy connection types. For more information, see [Pivot Data from Columns to Rows](#) on page 840.
- Split a string field into multiple fields. This is only available for non-legacy connection types. For more information, see [Split a Field into Multiple Fields](#) on page 853.
- Create new calculations based on existing field in the Tableau data source. Click the column drop-down arrow and select **Create Calculated Field**.
- Copy values in the grid by selecting the values and then pressing Ctrl+C (Command-C on a Mac). Alternatively, to copy values in the metadata grid, select the values, right-click (Control-click on a Mac), and then select **Copy**.

## Examine the data source structure and perform management tasks

Use the metadata area to quickly examine the general structure of the Tableau data source and its fields. If you are working with a particularly large data source, use the metadata area to perform routine data management tasks such as hide multiple fields at once or quickly rename or reset fields.

## Connect live or use an extract

At the top of the Data Source page, select **Live** or **Extract** mode. If you choose to create an extract, the **Edit** link displays. Click **Edit** to set up filters that define a subset of the data that you want to include in the extract. For more information, see [Extract Your Data](#) on page 867.

## Add data source filters

At the top of the data source page, click **Add** to add data source filters to control what data is used in included in the data source and therefore restrict the visibility and use of the fields in the data source.

## Best practices

### Collect files in a single directory

Collect all relevant text files for a multi-table connection in a single directory, with nothing else in that directory, so that users cannot inadvertently select a file that is not appropriate for the connection.

### Text file column width and size considerations

If the text file contains columns that are more than 254 characters wide, Tableau cannot use these fields for workbooks that were created before Tableau Desktop 8.2 or that use the legacy

connection. Either remove the columns, modify them to fit within 254 characters prior to connecting in Tableau, or upgrade the text file data source.

Large text files often perform poorly as a data source, because the queries can take a long time.

### About .ttde and .hhyper files

You might notice .ttde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .ttde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

### Access

This article describes how to connect Tableau to a Microsoft Access file (\*.mdb, \*.accdb) and set up the data source. Tableau supports all Access data types except OLE Object and Hyperlink.

### Before you begin

Before you begin, gather this connection information:

- Access file name.
- If the file is password protected, you need the database password.
- If the file has workgroup security, you need workgroup security credentials:
  - Workgroup file name
  - User
  - Password

Use this connector with Tableau Desktop on a Windows computer.

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Access**, select the Access file that you want to connect to, and then select **Sign In**.
  - Password protected - If the Access file is password protected, select **Database Password**, and then enter the password.
  - Workgroup security - If the Access file is protected by workgroup security, select **Workgroup Security**, and then enter the **Workgroup File** name, **User**, and **Password** into the corresponding text fields.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to. The default name is automatically generated based on the file name.
  - b. Drag a table to the canvas. You can drag a table or query.
  - c. Select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** If the Access file contains columns that are more than 254 characters wide, Tableau can't use these fields. Either remove the columns from the table or modify them to fit within 254 characters prior to connecting with Tableau.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## JSON File

This article describes how to connect Tableau to a local JSON file and set up the data source.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **JSON File**. Then do the following:
  - a. Select the file you want to connect to, and then select **Open**.
  - b. In the Select Schema Levels dialog box, select the schema levels you want to view and analyze in Tableau, and then select **OK**. For more information, see [Select schema levels on the next page](#).
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select the sheet tab to start your analysis.

### JSON file data source example

Here is an example of a JSON file as a data source using Tableau Desktop on a Windows computer:

## Select schema levels

When you connect Tableau to a JSON file, Tableau scans the data in the first 10,000 rows of the JSON file and infers the schema from that process. Tableau flattens the data using this inferred schema. The JSON file schema levels are listed in the Select Schema Levels dialog box. In Tableau Desktop, if your JSON file has more than 10,000 rows, you can use the "Scan Entire Document" option to create a schema.

**Note:** The "Scan Entire Document" option displays only for JSON files with more than 10,000 rows. It is not available on the web.

The schema levels that you select in the dialog box determine which dimensions and measures are available for you to view and analyze in Tableau. They also determine which data is published.

**Note:** When you publish a workbook to the web, any schema updates will not be available to the web version of the viz and may cause errors if the viz is subsequently refreshed

If you select a child schema level, the parent level is also selected.

For example, here's a snippet of a JSON file: The JSON file generates these schema levels:

```
{
  "quiz": {
    "sport": {
      "q1": {
        "question": "Which one is correct?",
        "options": [
          "New York Bulls",
          "Los Angeles Kings",
          "Golden State Warriros",
          "Huston Rocket"
        ],
        "answer": "Huston Rocket"
      }
    }
  },
  "maths": {
    "q1": {
      "question": "5 + 7 = ?",
      "options": [
        "10",
        "11",
        "12",
        "13"
      ],
      "answer": "12"
    },
    "q2": {
      "question": "12 - 8 = ?",
      "options": [
        "1",
        "2",
        "3",
        "4"
      ],
      "answer": "4"
    }
  }
}
```

Select Schema Levels

The schema levels you select determine which dimensions and measures are available for analysis in the worksheet.

Schema	Example Value
example_2.json	
quiz	
maths	
q1	
answer	12
question	5 + 7 = ?
options	["10"...]
q2	
answer	4
question	12 - 8 = ?
options	["1"...]
sport	
q1	
answer	Huston Rocket

10 schema levels

### Detect new fields

Sometimes, more fields exist in rows that were not scanned to create the inferred schema. If you notice that a field you need is missing under **Schema**, you can choose to do one of the following:

- Scan the entire JSON document. It may take a long time for the scan to complete.
- Select schema levels from the schema listed and then select **OK**. Tableau reads your entire document and if more fields are found, they are listed in the Select Schema Levels dialog box.

Whenever Tableau detects that new fields are available, for example, during an extract refresh or when Tableau creates an extract after you've selected the schema levels, either an information icon near the file name or a notification on the Select Schema Levels dialog box will indicate that additional fields have been found.

## Change schema levels

You can change the schema levels you selected by going to the data source page and selecting **Data > [JSON file name] > Select Schema Level**. Or, hover over the file name on the canvas and select the drop-down menu > **Select Schema Level**.

## Union JSON files

You can union JSON data. To union a JSON file, it must have a .json, .txt, or .log extension. For more information about union, see [Union Your Data on page 795](#).

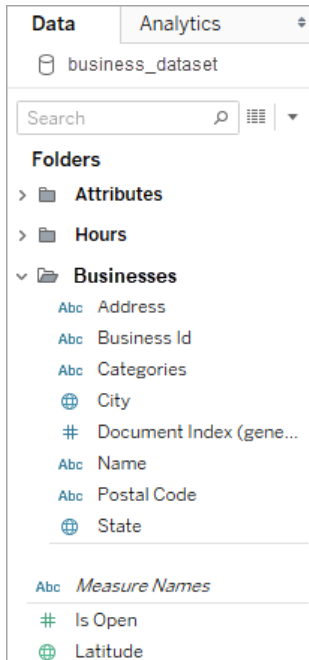

When you union JSON files, the schema is inferred from the first 10,000 rows of every file in the union.

You can change the schema levels after you union files. For more information, see [Change schema levels](#) above.

## How dimension folders are organized for hierarchical JSON files

After you select the sheet tab, the selected schema levels of your JSON file show under **Dimensions** on the **Data** pane. Each folder corresponds with the schema level you selected, and the attributes associated with that schema level are listed as children of the folder.

For example, in the following image, **Address** is a dimension under the schema level **Businesses** folder. **Categories** is also a schema level, but because it is a list of values and not a hierarchy of data, it doesn't require its own folder, but is instead grouped under a parent folder. Note that schema levels in the Select Schema Levels dialog box do not map directly to the folder structure in the **Data** pane. Folders in the **Data** pane are grouped by object so that you can easily navigate to fields and still have context for where the fields come from.

For each document, a unique index is generated and stored in the flattened representation of data. An index is also generated for each level in the schema.

For example, in the image above, in addition to the **Document Index (generated)** entry, the **Attribute** and **Hours** schema levels all have generated indexes.

### Why measures are calculated in hierarchical JSON files

When a hierarchical JSON file is flattened, data might be duplicated. To keep measures consistent with their schema levels, Tableau creates level of detail (LOD) calculations to accurately represent the data at the schema level. The original measures are located in the **Source Measures** folder and you can use them, but we recommend that you use the calculated measures.

On the **Data** pane, calculated measures are labeled as **Number of <measure name> per <parent name>**.

To view the LOD calculation for a measure, follow these steps:

1. Select the measure.
2. Select the drop-down arrow, and then select **Edit**.

The following example shows the LOD calculation for **Revenue per Document**. The formula selects the maximum revenue for each document index value.

The use of LOD calculations means that you can select multiple schema levels and be confident that the measures are not over-counted.

### Tips for working with JSON data

These tips can help you work with your JSON data in Tableau.

- Do not exceed the 10x10 limit for nested arrays.  
A high number of nested arrays creates a lot of rows. For example, 10x10 nested arrays result in 10 billion rows. When the number of rows Tableau can load into memory is exceeded, an error displays. In this case, use the Select Schema Levels dialog box to reduce the number of selected schema levels.
- A data source that contains more than 100 levels of JSON objects can take a long time to load.

A high number of levels creates a lot of columns, which can take a long time to process. As an example, 100 levels can take more than two minutes to load the data. As a best practice, reduce the number of schema levels to just the levels that you need for your analysis.

- A single JSON object cannot exceed 128 MB.

When a single object top-level array exceeds 128 MB, you must convert it to a file where the JSON objects are defined one per line.

- The pivot option is not supported.

### About TTDE and HHYPER files

You might notice .ttde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .ttde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

### PDF File

This article describes how to connect Tableau to .pdf file data and set up the data source.

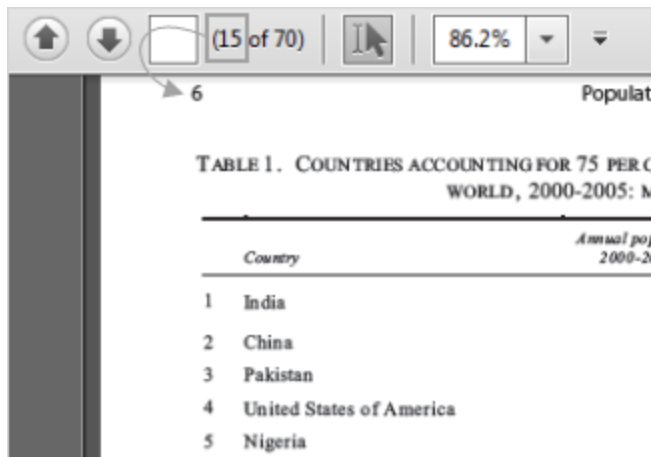

**Note:** Tableau doesn't support right-to-left (RTL) languages. If your PDF includes RTL text, characters might display in reverse order in Tableau.

### Make the connection and scan your document for tables

1. After you open Tableau, under **Connect**, click **PDF File**.
2. Select the file you want to connect to, and then click **Open**.
3. In the Scan PDF File dialog box, specify the pages in the file that you want Tableau to scan for tables. You can choose to scan for tables in all pages, just a single page, or a range of pages.

**Note:** The scan counts the first page of the file as page 1, similar to most PDF readers. When you scan for tables, specify the page number that the PDF reader displays and not the page number that might be used in the document itself, which may or may not start from page 1.

For example, suppose you want to use "Table 1" from the image below. The PDF reader displays a number, and the .pdf file displays a different number. To correctly scan for this table, specify the page number that the PDF reader displays. In this example, you specify page 15.

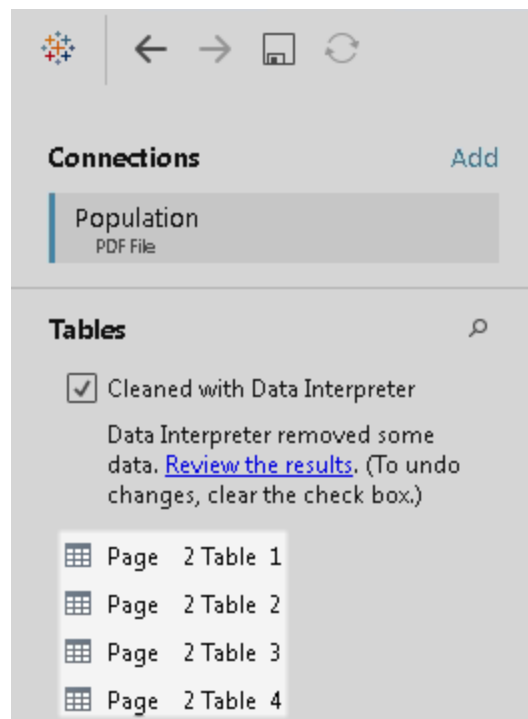

4. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to. The default name is automatically generated based on the file name.
  - b. If your file contains one table, click the sheet tab to start your analysis. Otherwise, from the left pane drag a table onto the canvas and then click the sheet tab to start your analysis.

#### **About the tables in the left pane**

Tables that are identified in the .pdf file are given unique names and are displayed in the left pane after a scan. For example, you might see a table name like "Page 1, Table 1." The first part of the table name indicates the page in the .pdf file the table came from. The second part of the table name indicates the order the table was

identified. If Tableau has identified more than one table on a page, the second part of the table name can indicate one of two things:

- Tableau has identified another unique table or sub-table on the page.
- Tableau has interpreted the table on the page in another way. Tableau might provide multiple interpretations of a table depending on how the table is presented in your .pdf file.

### PDF file data source example

Here is an example of a PDF file data source:

The screenshot shows the Tableau Desktop interface for a worksheet named 'Population'. The top navigation bar includes 'Connection' (Live/Extract) and 'Filters' (0 | Add). The left pane shows 'Connections' with a 'Population PDF File' and 'Sheets' with a list of tables from Page 2 to Page 15. The main canvas displays a table with the following data:

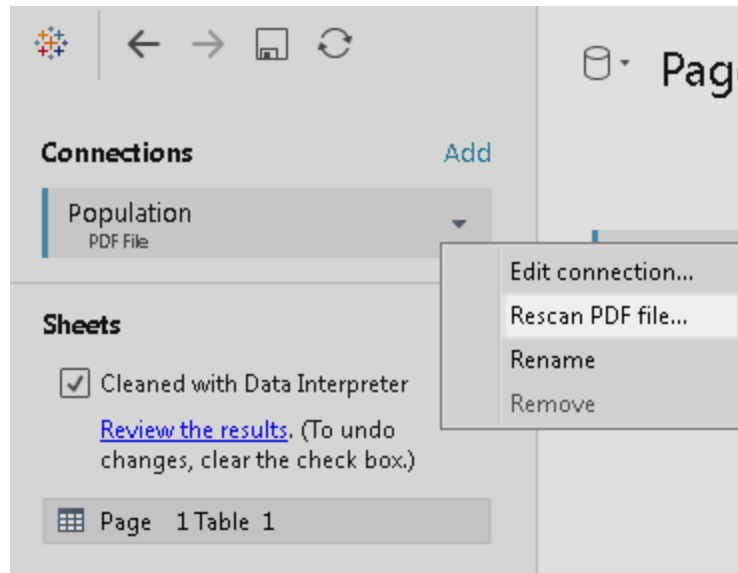

Page: 2 Table 4	Page: 2 Table 4	Page: 2 Table 4	Page: 2 Table 4
Most Populous Co ...	untries, billions)	2012 and 2050 2050 Cou...	ulation (millions)
China	1,350.00	India	1,691.00
India	1,260.00	China	1,311.00
United States	314.00	United States	423.00
Indonesia	241.00	Nigeria	402.00
Brazil	194.00	Pakistan	314.00
Pakistan	180.00	Indonesia	309.00
Nigeria	170.00	Bangladesh	226.00
Bangladesh	153.00	Brazil	213.00

## Get more data

Get more data into your data source by adding more tables or connecting to data in a different database.

- **Add more data from the current file:**
  - From the left pane, drag additional tables to the canvas to combine data using a join or union. For more information, see [Join Your Data on page 738](#) or [Union Your Data on page 795](#).
  - If the pages that were scanned in step 3 of the procedure listed above do not produce the tables that you need in the left pane, click the drop-down arrow next to the PDF File connection, and click **Rescan PDF file**. This option allows you to create a new scan so that you can specify different pages in the .pdf file to scan for

tables.

- **Add more data from a different database:** In the left pane, click **Add** next to Connections. For more information, see [Join Your Data on page 738](#).

If a connector you want is not listed in the left pane, select **Data > New Data Source** to add a new data source. For more information, see [Blend Your Data on page 764](#).

### Set table options

You can set table options. On the canvas, click the table drop-down arrow and then specify whether the data includes field names in the first row. If so, these names will become the field names in Tableau. If field names are not included, Tableau generates them automatically. You can rename the fields later.

### Use Data Interpreter to clean your data

If Tableau detects that it can help optimize your data source for analysis, it prompts you to use Data Interpreter. Data Interpreter can detect sub-tables that you can use and remove unique formatting that might cause problems later on in your analysis. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter on page 845](#).

### Union tables in your .pdf files

You can union tables in your file. For more information about union, see [Union Your Data on page 795](#).

When you use wildcard search to union tables, the result is scoped to the pages that were scanned in the initial file you connected to. For example, suppose you have three files: A.pdf, B.pdf, and C.pdf. The first file you connect to is A and you limit the scan for tables to page 1. When you use wildcard search to union tables from files B and C, the additional tables included in the union can only come from page 1 of B and page 1 of C.

## Tips for working with .pdf files

The following tips can help you work with your .pdf files in Tableau.

- **Use PDF File connector to identify just the tables in your .pdf file.**

The primary goal of the PDF File connector is to find and identify *tables* in your .pdf file. Therefore, it ignores any other information in the file that does not appear to be part of a table, including titles, captions, and footnotes. If related data is stored in one of these areas, such as in the table title, you can use Tableau to first export the .pdf file data into a .csv file, manually add the data that was stored in the table title, and then connect to the .csv file instead. For more information, see [Export your data to .csv file](#) on page 3032.

- **Use standard tables.**

In general, Tableau works best with standard tables that use a tabular format.

Ideally, the tables in your .pdf file have column headers on a single line and have rows values on a single line as demonstrated in the example below.

CITY	RANK	TOTAL COMMUTE BY BIKE	TOTAL POPULATION
DAVIS, CA	1	23.2%	66,733
BERKELEY, CA	2	9.7%	118,851
BOULDER, CO	3	8.9%	105,101
SOMERVILLE, MA	4	7.4%	78,903
CAMBRIDGE, MA	4	7.4%	109,699
PALO ALTO, CA	5	7.3%	66,968
PORTLAND, OR	6	7.2%	619,445
EUGENE, OR	7	6.8%	160,552

Colors and shading used in or around the tables can affect how the tables are identified.

Tables that have unique formatting might require some cleanup or manual editing outside of Tableau. Unique formatting can include hierarchical headers, header names that span multiple lines, row values that span multiple lines, angle headers, and stacked tables as demonstrated in the examples shown below.

NYC Administrative Code or TLC Rule Violation	LICENSE TYPE	Manhattan	Staten
80-13(A)(2), 54-13(A)(2), 55-13(A)(2) Moving Violations	UNIV	8,176	
80-14(G)(1), 55-14(G)(1), 54-14(E)(1) Use of Electronic Devices While Driving	UNIV	6,429

Pink Vanilla Cake Doughnut	119	460
Raspberry Grazed Cake Doughnut	105	299
Maple Frosted Cake Doughnut	119	430

Drivers	
TLC Driver License	153,4
Paratransit Driver License	1,86
Commuter Van Driver License	269
<b>Total Driver Licenses</b>	<b>155,6</b>
Bases	
Black Car Bases	278
Community Car Services	468
Luxury Limousine Bases	170
Commuter Van Authorizations	53
Paratransit Bases	122
<b>Total Base Licenses</b>	<b>1,09</b>

Note: Tableau does not support connections to .pdf files generated by scanning (optical character recognition) software.

- **Validate the data.**

Make sure that you validate the data in the tables that Tableau identifies in your .pdf file. You can validate the data by using either the data grid or if you used the Data Interpreter, the results workbook.

- **Avoid tables that span across pages.**

If your .pdf file contains a table that spans across pages, Tableau interprets that table as multiple tables. To resolve this issue, use a union to combine the tables. For more information, see [Union Your Data](#) on page 795.

- **Rename .pdf files whose file names contain unicode characters.**

After connecting to a .pdf file that contains unicode characters in its file name, you might see the following error.

To resolve this issue, rename the file using non-unicode characters, and connect to your .pdf file again.

- **Do not use password protected .pdf files.**

After connecting to and scanning a .pdf file for tables, you might see the following error.

Tableau shows this error when your .pdf file is password protected and unable to access its contents. Tableau is unable to support connections to password protected .pdf files.

- **Alias values that are interpreted differently or incorrectly.**

In the data grid you might notice that some values are interpreted differently from the .pdf file. You can correct this interpretation by using aliases to rename specific values within a field.

For example, suppose you see the following table after connecting to your .pdf file. Some state abbreviations are being interpreted in lowercase form, which are highlighted in blue.

City	Rank
College Station, tx	20
Tempe, az	20
Oakland, ca	20
Detroit, MI	1
Pittsburgh, PA	2
Cincinnati, OH	3
Portland, or	4

You can resolve this issue by using aliases to change the lowercase abbreviations to uppercase abbreviations. To do this, click the drop-down arrow next to the column name and select **Aliases**.

- **Resolve column headers that are interpreted as table values.**

In the data grid you might also notice that some column headers in your .pdf file are interpreted as table values instead. This can occur if your .pdf file contains tables with unique formatting or hierarchical headers. In this scenario, try the Data Interpreter first. If Data Interpreter doesn't resolve the issue, consider manually renaming the columns to their appropriate names and filtering header names that are being treated as values by using data source filters.

For example, suppose you see the following table after connecting to your .pdf file. The table headers from the .pdf file are being interpreted as table values, which are highlighted in blue.

Abc	Abc	Abc	Abc
F1	F2	F3	F4
Table Pt 2.	Energy Production	Estimates	in Trillion BTu
<i>null</i>	<i>null</i>	<i>null</i>	<i>null</i>
Year	<i>null</i>	<i>null</i>	<i>null</i>
<i>null</i>	Coal	Gas	Oil
1960	318.8	.1	42.5
1961	316.5	.1	40.2
1962	315.6	.2	43.3

One way you can resolve a header issue like this is to follow steps similar to the following:

1. Double-click the column name, and then rename F1 to Year. Repeat this step for F2 through F4 for Coal, Gas, and Oil.
2. Click the data type icon for the Year column and change it to a number data type. This causes the non-numerical values in this column to convert to null values.
3. In the upper-right corner of the data source page, click **Add**, click the **Add** button, and then select the Year field.
4. In the Filter dialog box, select both the **Null** and **Exclude** check boxes.

The rows in the Year column that contain null values are removed from the data grid, which affect the rows from the other columns in the table.

#	Abc	Abc	Abc
Year	Coal	Gas	Oil
1960	318.8	.1	42.5
1961	316.5	.1	40.2
1962	315.6	.2	43.3

### About .tde and .hhyper files

You might notice .tde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .tde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Spatial File

This topic describes how to connect Tableau to Shapefiles, MapInfo tables, KML (Keyhole Markup Language) files, TopoJSON files, GeoJSON files, and Esri File Geodatabases.

**Note:** Connecting to spatial data is supported in Tableau Desktop version 10.2 and later.

### Before you connect

Before you can connect to spatial files, make sure to include all of the following files in the same directory:

- **For Esri shapefiles:** The folder must contain `.shp`, `.shx`, `.dbf`, and `.prj` files as well as `.zip` files of the Esri shapefile.  
**For Esri File Geodatabases:** The folder must contain the File Geodatabase's `.gdb` or the `.zip` of the File Geodatabases's `.gdb`.
- **For MapInfo tables** (Tableau Desktop only): The folder must contain `.TAB`, `.DAT`, `.MAP`, and `.ID` or `.MID` and `.MIF` files.
- **For KML files:** The folder must contain the `.kml` file. (No other files are required.)
- **For GeoJSON files:** The folder must contain the `.geojson` file. (No other files are required.)
- **For TopoJSON files:** The folder must contain the `.json` or `.topojson` file. (No other files are required.)

**Note:** Flat files will pull in the contents of the entire folder. For performance reasons, remove unneeded files and reduce the amount of data in the files.

You can connect only to point geometries, linear geometries, and polygons in current versions of Tableau. You cannot connect to mixed geometry types.

If your data does not display diacritics (accent marks on characters) properly, check to make sure the file is **UTF-8** encoded.

### Make the connection and set up the data source

In Tableau Desktop: click the New Data Source icon and select **Spatial file**.  
In Tableau Cloud or Tableau Server (Creator role): Select **Create > Workbook**. Select the **Files** tab.  
Then do the following:

1. Navigate to the folder that contains your spatial data and select the spatial file you want to connect to.
2. Select **Open**.

### Spatial file data source example

Here is an example of a spatial file data source using Tableau Desktop on a Mac computer:

STRTAL	Abc TERRESTRIAL_MAMMALS.s...	# TERRESTRIAL_MA...	# TERRESTRIAL...	TERRESTRI...	Abc TERRESTRIAL_MA...	Abc TERRESTRIAL_MAMMAL...	Abc TERRESTRIAL_MAMMAL...	Abc TERRESTRIAL_MAMMAL...
	Binomial	Presence	Origin	Year	Island	Family Nam	Friendly N	Geometry
90.00	Phyllomys unicolor	1	1	2008	null	ECHIMYIDAE	Phyllomys unicolor	POLYGON
10.00	Coendou rufescens	1	1	2016	null	ERETHIZONTIDAE	Coendou rufescens	MULTIPOLYGON
14.00	Echiothrix leucura	1	1	2008	Sulawesi	MURIDAE	Echiothrix leucura	MULTIPOLYGON
14.00	Echiothrix leucura	2	1	2008	Sulawesi	MURIDAE	Echiothrix leucura	POLYGON
15.00	Echymipera clara	1	1	2008	New Guinea	PERAMELIDAE	Echymipera clara	POLYGON
15.00	Echymipera clara	1	1	2008	Japen Island	PERAMELIDAE	Echymipera clara	POLYGON
16.00	Echymipera echinis...	1	1	2008	New Guinea	PERAMELIDAE	Echymipera echinis...	MULTIPOLYGON
17.00	Echymipera davidi	1	1	2008	Kiriwina Isla...	PERAMELIDAE	Echymipera davidi	POLYGON
18.00	Echymipera kalubu	1	1	2016	Waigao	PERAMELIDAE	Echymipera kalubu	POLYGON
18.00	Echymipera kalubu	1	1	2016	Voceo	PERAMELIDAE	Echymipera kalubu	POLYGON
18.00	Echymipera kalubu	1	1	2016	Umbol	PERAMELIDAE	Echymipera kalubu	POLYGON
18.00	Echymipera kalubu	1	1	2016	Tolokiwa	PERAMELIDAE	Echymipera kalubu	POLYGON
18.00	Echymipera kalubu	1	1	2016	Su Mios	PERAMELIDAE	Echymipera kalubu	POLYGON

### Work with the Geometry column

There are many tasks that you can optionally perform on your data before you start your analysis, such as hiding or renaming fields. Note, however, the following restrictions apply when working with the Geometry column:

- You can't hide the Geometry column.
- You can't split the Geometry column.
- On the data source page, you can't create a calculated field using the Geometry column.

## About .ttde and .hhyper files in Tableau Desktop

You might notice .ttde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .ttde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

## See also

[Create Tableau Maps from Spatial Files on page 1687](#)

## Statistical File

This article describes how to connect Tableau to a statistical file and set up the data source.

Tableau connects to SAS (\*.sas7bdat), SPSS (\*.sav), and R (\*.rdata, \*.rda) data files.

**Note:** As of version 2020.1, Tableau no longer supports statistical files compressed with SASYZCR2. Use a different compression scheme to make the file readable for Tableau.

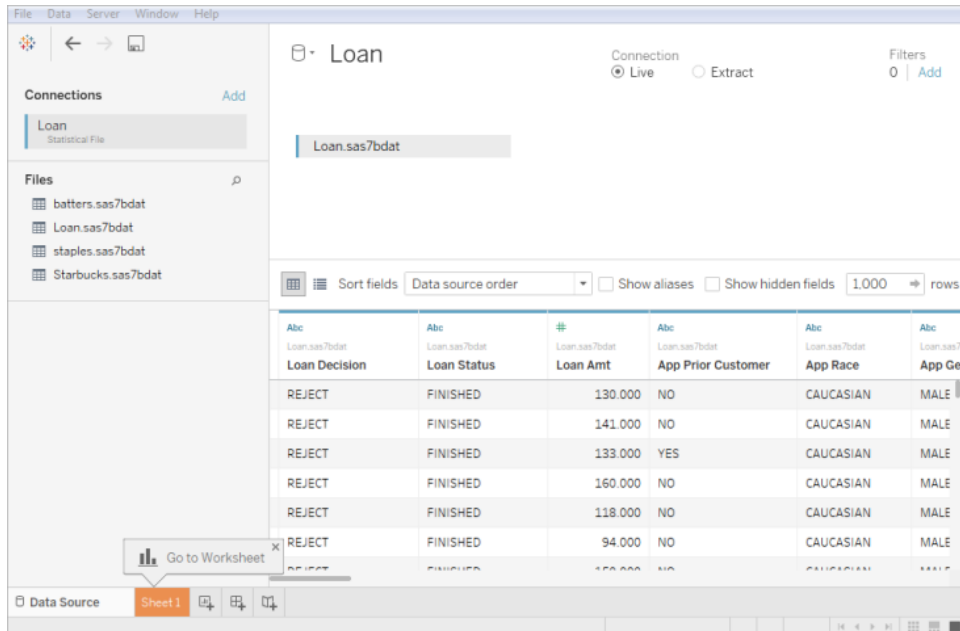

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Statistical File**, select the file that you want to connect to, and then select **Open**.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select the sheet tab to start your analysis.

For information about connecting to more than one table, see [Join Your Data on page 738](#).

### Statistical file data source example

Here is an example of a statistical file data source using Tableau Desktop on a Windows computer:

### Note the following:

- The Statistical File connector does not support value labels.
- The Statistical File connector supports only one table per statistical file.

If an error message appears, "An error occurred while communicating with the data source," make sure that your statistical file contains only one object, and that the object is a data frame or a matrix. R files may contain hidden objects in what appears to be a clean workspace. To check for hidden objects, run `ls(environment(), all.names=TRUE)` from RStudio.

- You can change the character encoding for a statistical file. For more information, see [Change the character encoding for statistical files](#).

### R data file object and format support

R data files should contain only one of the following types of objects:

- Two-dimensional matrices
- Vectors
- Factors
- Data frames

Note that if the R data file contains more than one object, Tableau will connect to the first one.

Tableau supports R data files that use binary format.

ASCII format files are not supported in Tableau Desktop. If you try to use an .rdata or .rda file with ASCII format, you'll see an error saying, "Unable to read from file the table "[TableauTemp].[filename.rdata]' does not exist". In this case, you can use RStudio to save the file to a binary format, as follows:

1. Download RStudio if you don't already have it.
2. Open your R data file in RStudio. You should see your data object in the global environment window on the upper right.
3. Save the object to a new file with the "save()" function as follows:

```
save(<objectName>, file="<filename>", ascii=FALSE)
```

where: <objectName> is your data object, <filename> is the name of your new file, and "FALSE" is case-sensitive

**Tip:** To quickly see documentation for this function, type "?save" at the command prompt.

Compressed files are not supported in Tableau Desktop. You must decompress files first with another program, such as Gzip or WinZip, before you connect with Tableau.

### Change the character encoding for a statistical file

Tableau reads the data in a statistical file (for example, an SAS or R file) based on the file's character encoding or on information in an input file. R files typically use the character encoding of the operating system, compared to SAS and SPSS files, which include the character encoding information in the file. Sometimes, you might need to specify a different encoding. For example, if a colleague sends you a statistical file with Greek character encoding, then you must specify a Greek character set to use the file with Tableau. If you need to use a different character set when reading from a statistical file, you can create a Tableau data source customization (TDC) file and specify the encoding to use.

## Create the TDC file

A .tdc file is an XML file that applies to a single data source and contains vendor and driver name information of the data source provider. For the statistical file connector, the vendor and driver name is `stat-direct`.

To create a TDC file:

1. Open a plain text editor, such as Notepad.
2. Copy the information from the sample provided below, paste it into your text file, and then specify the `source-charset` value. (For a list of encodings, see [User-defined Encodings Supported by the Statistical File Connector](#) on the next page.)
3. Save the file with a .tdc extension—for example, `r-statsfile.tdc`—to the My Tableau Repository\Datasources folder.

## Sample TDC file sets the source-charset value

The following TDC file example sets the `source-charset` value to `shift-jis` for a statistical file data source.

```
<connection-customization class='stat-direct' enabled='true' version='10.0'>
<vendor name='stat-direct' />
<driver name='stat-direct' />
  <customizations>
    <customization name='source-charset' value='shift-jis' />
  </customizations>
</connection-customization>
```

**Important:** Tableau does not test or support TDC files. These files should be used as a tool to explore or occasionally address issues with your data connection. Creating and maintaining TDC files requires careful manual editing, and there is no support for sharing these files.

## About .ttde and .hhyper files

You might notice .ttde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .ttde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other

information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

### User-defined Encodings Supported by the Statistical File Connector

This topic lists character encodings supported by Tableau Statistical File connector. The list includes single-byte, multi-byte, and Unicode user-defined encodings, as well as single-byte and multi-byte encodings that cannot currently be mapped to the corresponding SAS encodings.

## Other Files

This topic describes how to connect Tableau to supported file types, including Tableau Data Extract files and Tableau Workbooks.

1. Start Tableau and under **Connect**, select **Other Files**.
2. In the Open dialog box, navigate to and select a file.
3. Select **Open**.
4. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
5. Select the sheet tab to start your analysis.

### Tableau Data Extract data source example

Here is an example of a Tableau Data Extract file data source using Tableau Desktop on a Windows computer:

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Connect to Data by Using Tableau Server or Tableau Cloud

You can connect to data from either Tableau Desktop or a web browser by using Tableau Server or Tableau Cloud. The process differs slightly for each.

Starting in 2019.3, Tableau Catalog is available with Data Management in Tableau Server and Tableau Cloud. When Tableau Catalog is enabled in your environment, in addition to connecting to published data sources from Tableau Server or Tableau Cloud, you can connect to databases and tables from the **Search for Data** dialog on Tableau Desktop and the Connect to Data dialog in Tableau Web Authoring. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help. Starting in 2021.4, Data Management includes virtual connections, a central access point to data. For more information, see "About Virtual Connections and Data Policies" in the [Tableau Server](#) or [Tableau Cloud](#) help.

Tableau Prep Builder can connect to published data sources and you can use them as an input data source for your flow starting in version 2019.3.1. If you have Data Management with

Tableau Catalog enabled, starting in version 2020.2.2, you can also connect to databases and tables from the **Search for Data** results, just like Tableau Desktop. For more information, see [Connecting to published data sources](#) in the Tableau Prep Builder help.

## Connect from Tableau Desktop

**Note:** Starting 2019.3, on the **Connect** pane, **Tableau Server** has moved to the top of the pane under **Search for Data**. Select this option to connect to Tableau Server or Tableau Cloud from Tableau Desktop.

1. Start Tableau Desktop and on the **Connect** pane, under **Search for Data**, select **Tableau Server**.
2. To connect to Tableau Server, enter the name of the server and then select **Connect**.

To connect to Tableau Cloud, select **Tableau Cloud** under **Quick Connect**.

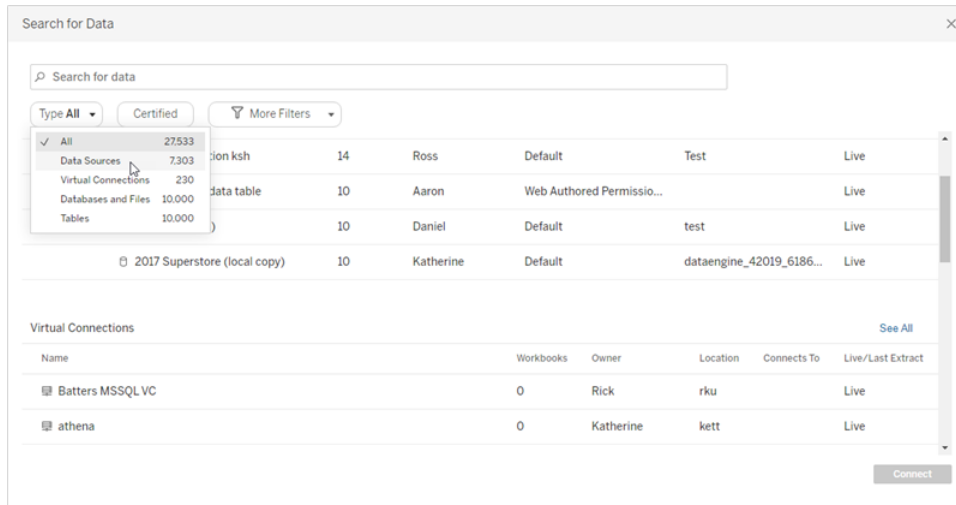

**Tip:** If you don't sign out, Tableau Desktop saves your server connection, so you can skip step 3. You can also skip it if Kerberos is enabled on Tableau Server and your computer has valid credentials. For more information, see [Automatically keep Tableau Desktop connected to Tableau Server or Online](#) on page 198.

3. To sign in:
  - For Tableau Server, enter your user name and password.
  - For Tableau Cloud, enter your email address and password.
4. Select data to connect to. The **Search for Data** dialog displays a scrollable list of mixed content that's popular. If you have a Data Management license, you can connect to data with a virtual connection, and if you have Data Management with Tableau Catalog enabled, you can also connect to external assets, like databases, files, and tables.

The responsive search field shows a list of suggestions that updates as you enter text. Filter search results by type of data, certification status, or other filters that depend on the

type of data selected. For example, some types of data may allow you to filter based on tags, connection type, data quality warnings, or other criteria. Older versions of the dialog look and function slightly differently, but the overall function is similar.

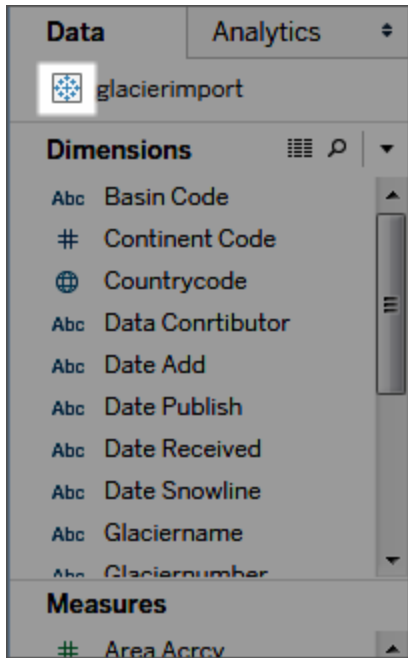

#### Note:

- Data that you don't have Connect permissions for is unavailable (gray).
  - External assets (databases, files, and tables) are unavailable (gray) until Catalog finishes ingesting them.
  - If you select a cube (multidimensional) data source, the Create Local Copy dialog box appears, and you must create a local copy of the data before you can start your analysis.
  - In Web Authoring, you can make a connection with a subset of the data connectors that Tableau Desktop supports. If a data source, database, file, or table is grayed out, you can't connect from Tableau Server or Tableau Cloud. You can, however, connect from the Tableau Desktop Connect pane, if you have the correct permissions.
5. After you select the data you want to connect to, click **Connect**.
  6. Select the sheet tab to start your analysis.

Data sources published to Tableau Server or Tableau Cloud are shown in the **Data** pane with a Tableau icon.

You might want to download a local copy of the data source so that you can, for example, work offline or make changes to a data source without modifying the original. To download a local copy, on the **Data** menu, select the data source, and then select **Create Local Copy**. A duplicate of the data source is added to the **Data** pane.

### Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

### Connect to published data sources while web authoring

Tableau Desktop users who create and customize data connections for Tableau use can publish their data sources to Tableau Server or Tableau Cloud. Publishing enables sharing data among colleagues, including those who don't use Tableau Desktop, but have permission to edit workbooks in the web editing environment.

If you have permission to edit workbooks in a browser, follow these steps to connect to published data sources when you're signed in to Tableau Server or Tableau Cloud. For more information see [Edit Tableau Views on the Web](#) and [Using Tableau on the Web](#).

**Note:** To connect to data, you need permission to create and edit views.

### Add more data to an existing view

1. On a Tableau Server or Tableau Cloud site, select a view to edit.
2. In editing mode, click the **New Data Source** icon .
3. In the **Connect to Data** page, the options you can see and select from depend on your permissions:

- **On this site.** Select a published data source from the list, and then select **Add data source**.

When Tableau Catalog is enabled in your environment, you can select **Data Sources, Databases and Files**, or **Tables and Objects** from the **Content Type** drop-down list. Then select the data you want to connect to and click **Connect**.

- **Files.** Drag and drop a file or upload one from your computer.
- **Connectors.** Connect to your data using one of the connectors listed.

### Create a workbook with a published data source

You can also connect to a published data source when creating a new workbook:

1. On a Tableau Server or Tableau Cloud site, navigate to the **Explore** page, and select **All Data Sources** from the drop-down list.
2. In the list, select the check box next to the data you want to use.
3. At the top of the page, from the **Actions** drop-down menu, select **New Workbook**.

For information about connecting to data when you're authoring on the web, see [Creators: Connect to Data on the Web](#).

## Action Vector

This article describes how to connect Tableau to an Actian Vector database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Virtual node name for the database you want to connect to
- Database name

- Authentication method: Authentication defined in the virtual node, or user name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Action Vector**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the virtual node for the database and the name of the database you want to connect to.
  - b. Specify whether to use authentication defined in the virtual node, or a specific user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.

- c. Under **Table**, select a table or use the text box to search for a table by name.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query on page 811](#).

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Alibaba AnalyticDB for MySQL

This topic describes how to connect Tableau to an Alibaba AnalyticDB for MySQL database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name or IP address of the server that hosts the database you want to connect to
- Database name
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Alibaba AnalyticDB for MySQL**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the **Server** name or IP address.
  - b. Enter the **Database** name.
  - c. Enter the **Username** and **Password**.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in

to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

- e. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Under **Table**, select a table or use the text box to search for a table by name.
- c. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Alibaba Data Lake Analytics

This topic describes how to connect Tableau to Alibaba Data Lake Analytics and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name or IP address for the server that hosts the database you want to connect to
- Port number
- Database name
- Username and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Alibaba Data Lake Analytics**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name or IP address for the **Server**.
  - b. Enter the **Port** number.
  - c. Enter the **Database** name.
  - d. Enter the **Username** and **Password**.
  - e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - f. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table or search for a table by name.
  - c. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Alibaba MaxCompute

This topic describes how to connect Tableau to Alibaba MaxCompute and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- URL of the MaxCompute service
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Alibaba MaxCompute**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the URL for the **Server**.
  - b. Enter the **Username** and **Password**.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in

to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Under **Database**, select a database from the drop-down list or enter a database name.
- c. Under **Table**, select a table or search for a table by name.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Amazon Athena

This article describes how to connect Tableau to Amazon Athena data and set up the data source.

**Note:** To connect to Amazon Athena you need ports 443 (ssl) and 444 to be open.

## Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to. The format should be as follows: `athena.[region].amazonaws.com`. For example: `athena.us-east-1.amazonaws.com`
- Name of the S3 staging directory. For example, `s3://aws-athena-query-results-123456785678-us-eastexample-2/`
- Amazon Web Services (AWS) access keys (access key ID and secret access key). For more information, see [Access keys](#) on the AWS website.
- (Optional) Initial SQL statement to run every time Tableau connects

**Tip:** To support multiple users and work groups, you can add a work group in the server field. For example: `athena.us-east-1.amazonaws.com:443;Workgroup=Name`

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Amazon Athena**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server.
  - b. Enter the name of the S3 staging directory.
  - c. Enter your AWS access key ID in the **Username** field.
  - d. Enter your AWS secret access key in the **Password** field.
  - e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

f. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Under **Connections**, select the default data source.
- b. Select the catalog and database you want to work with.
- c. Drag one or more tables to your workspace.
- d. Select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query](#) on page 811.

## Customize JDBC connections

Amazon Athena uses a JDBC connection, which you can customize using a properties file. For more information, see [Customize JDBC Connections Using a Properties File](#) in Tableau Community.

## See also

## Amazon Aurora for MySQL

This article describes how to connect Tableau to Amazon Aurora MySQL and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

**Note:** For information about requirements and considerations when connecting to data using Prep Builder, see [Connect to Data](#) in the Tableau Prep Help.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

You can connect to your data using any of the following:

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Amazon Aurora for MySQL**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter the user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.

Select the **Require SSL** check box when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source

naming convention that helps other users of the data source figure out which data source to connect to.

- b. From the **Database** drop-down list, select a database or use the text box to search for a database by name.
- c. Under **Table**, select a table or use the text box to search for a table by name.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Amazon EMR Hadoop Hive

This article describes how to connect Tableau to an Amazon EMR (Elastic MapReduce) Hadoop Hive database and set up the data source.

**Note:** Starting in version 2018.2, Tableau supports Amazon EMR Hadoop Hive only, not Impala. Amazon no longer provides Impala drivers.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to and port number
- Authentication method:

- No Authentication
- Kerberos
- Username
- Username and password
- Microsoft Azure HDInsight Service (starting in version 10.2.1)
- Transport options depend on the authentication method you choose and can include the following:
  - Binary
  - SASL
  - HTTP
- Sign-in credentials depend on the authentication method you choose and can include the following:
  - User name
  - Password
  - Realm
  - Host FQDN
  - Service Name
  - HTTP Path
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** Make sure you use the latest available drivers. To get the latest drivers, see [Amazon EMR Hadoop Hive](#) on the Tableau Driver Download page.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Amazon EMR Hadoop Hive**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the port number to use.
  - b. In the **Authentication** drop-down list, select the authentication method to use. The information you are prompted to provide depends on the authentication method you choose.
  - c. If the **Transport** drop-down list is available, select the type of transport to use.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.

Select the **Require SSL** option when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
  - c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.  
  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Work with Hadoop Hive data

### Work with date/time data

Tableau supports **TIMESTAMP** and **DATE** types natively. However, if you store date/time data as a string in Hive, be sure to store it in ISO format (YYYY-MM-DD). You can create a calculated field that uses the **DATEPARSE** or **DATE** function to convert a string to a date/time format. Use **DATEPARSE()** when working with an extract, otherwise use **DATE()**. For more information, see [Date Functions on page 2200](#).

For more information about Hive data types, see [Dates](#) on the Apache Hive website.

### NULL value returned

A **NULL** value is returned when you open a workbook in Tableau 9.0.1 and later and 8.3.5 and later 8.3.x releases that was created in an earlier version and has date/time data stored as a string in a format that Hive doesn't support. To resolve this issue, change the field type back to **String** and create a calculated field using **DATEPARSE()** or **DATE()** to convert the date. Use **DATEPARSE()** when working with an extract, otherwise use the **DATE()** function.

### High latency limitation

Hive is a batch-oriented system and is not yet capable of answering simple queries with very quick turnaround. This limitation can make it difficult to explore a new data set or experiment with calculated fields. Some of the newer SQL-on-Hadoop technologies (for example, Cloudera's Impala and Hortonworks' Stringer project) are designed to address this limitation.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Amazon Redshift

This article describes how to connect Tableau to an Amazon Redshift database and set up the data source. For instructions on setting up OAuth with Amazon Redshift, see [Set Up Amazon Redshift IAM OAuth](#) in the [Tableau Server documentation](#) or the [Tableau Cloud documentation](#).

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Authentication:
  - Username and Password
  - OAuth using [IAM](#)
    - OAuth config should be installed
    - IAM Role
  - OAuth using [IAM IDC](#)
    - OAuth config should be installed
    - Namespace (optional)
- Database name
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Amazon Redshift**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the name of the database you want to connect to.
  - b. Enter the username and password.

- c. (Optional) **Enter custom driver parameters** to modify the connection.
- d. Select the **Require SSL** check box when connecting to an SSL server.
- e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- f. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** dropdown list, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Customize the connection using driver parameters

There are times when you might want to modify the connection made with the Amazon Redshift connector. Starting in Tableau 2019.2.1, you can do this by appending driver parameters to the connection string in the **Custom driver parameters** text box:

**Note:** You can't change the driver parameters that Tableau generates; you can only append parameters.

In this example, agarcia enters parameters that enable federated authentication using IDP:

```
DbUser=agarcia;AutoCreate=1;AuthType=Plugin;plugin_name=e=Ping;IAM=1;idp_host=idp.business-example.com;idp_port=443;preferred_role=arn:aws:iam::12345:role/dev;partner_spid=urn:amazon:webservices;
```

In this example, you limit the number of rows fetched to 1000:

```
Fetch=1000;
```

For details about driver parameters, see [ODBC Driver Configuration Options](#) on the Amazon AWS website.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Amazon S3

This article describes how to connect Tableau to the driverless Amazon S3 connector and set up the data source.

### Before you begin

Before you begin, gather the following connection information:

- The AWS region of your S3 bucket.
- The S3 bucket name.
- Your AWS IAM access key for your S3 bucket (key ID and secret access key).

### Permissions

Ensure that your AWS IAM user or role has read permissions for your S3 bucket.

## Recommendations

The following recommendations can help increase performance.

- Optimal performance is achieved if the client is running in an AWS environment (for example, Tableau Desktop or Server installed in an EC2 instance or using Tableau Cloud).
- Cross region bucket support works but performance will be worse than same region access. There may be additional cost due to data egress fees.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Amazon S3** from the list of **Additional Connectors**.
2. Select **Install and Restart Tableau** to install the connector.
3. After Tableau restarts go to **Connect**, and then select **Amazon S3** from the list of installed connectors.
4. Enter your Bucket Region, Bucket Name, Access Key ID, and Secret Access Key.
5. Select **Sign In**.
6. In the contents of your bucket, select a file you want to connect to.
7. Select **Connect**.

## Set up the data source

Complete the following steps to set up the data source.

1. (Optional) Select the default data source name at the top of the page.
2. Enter a unique data source name for use in Tableau.
3. Drag one or more files you want to connect to from the left pane into the canvas.
4. To start your analysis, select the Sheet 1 tab.

## Union your data

You can union files from your S3 bucket. For more information about union, see [Union Your Data](#). To perform a wildcard union that includes files in subfolders, the root folder or bucket must have at least one file, matching the structure of the files contained in subfolders, to include in the union. This file is the first file that you connect to when creating the union.

## Known issues and limitations

The following sections have known issues and limitations that can affect how successful you're when using the Amazon S3 connector.

**Note:** This connector isn't currently supported in Tableau Prep Web Authoring or virtual connections.

### Authentication known issues and limitations

- Only Amazon IAM User secret key/access key authentication without session token is supported.

### Publishing known issues and limitations

- Workbooks and data sources must be published using the 'Embedded password' authentication option. 'Prompt user' isn't currently supported.

### Union known issues and limitations

- Only Tableau Desktop supports a Wildcard union.
- Web Authoring only supports user-defined manual union (dragging files).

### File type known issues and limitations

- CSV files must be UTF-8 encoded.
- Parquet, CSV, compressed .gz, and Excel files are supported at this time
- You can't union or join across multiple file types in a single connection (for example, Parquet & CSV together).
- Only comma-delimited CSV files are currently supported.
- The cumulative query and file size limit is 15gb.
- Excel files currently can't exceed ~100 mb due to performance issues with the Excel file parser in the connector.

### Additional Parquet file known issues and imitations

- Parquet files must be in the format described in our [Hyper API documentation](#).
- Nested columns and therefore the nested types MAP and LIST aren't supported.
- The types BSON, UUID, and ENUM aren't supported.
- The physical type FIXED\_LEN\_BYTE\_ARRAY without any logical or converted type isn't supported.
- The type DECIMAL is only supported up to 8 bytes (18 decimal digits). Consider using double if you need more than 18 decimal digits.
- The types TIME\_MILLIS and TIME\_NANOS aren't supported. Consider using TIME\_MICROS instead.

- The deprecated BIT\_PACKED encoding isn't supported. No recent Parquet files should use this encoding, as it's deprecated for over half a decade.
- The DELTA\_LENGTH\_BYTE\_ARRAY encoding and the recent BYTE\_STREAM\_SPLIT encoding aren't supported, as they aren't written by any library. If you encounter any Parquet files using these encodings, let us know.
- Supported compressions are SNAPPY, GZIP, ZSTD, and LZ4\_RAW.

## Anaplan

This article describes how to connect Tableau to Anaplan data and set up the data source.

**Warning:** The Anaplan connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. The deprecated connector will be retired 1-2 releases after the replacement connector is made available.

**Note:** Tableau is working on a replacement connector. After it's complete it will be added to this page.

**Note:** You will need to allow access to `api.anaplan.com` and `auth.anaplan.com` in your network proxy or firewall configurations in order to use the Anaplan connector.

### Before you begin

Before you begin, gather this information for connecting:

- An email address and password for your Anaplan account.
- The Anaplan workspace, model, and any exports (in CSV format) that you want to use. An Anaplan export action must be created in Anaplan before you can use the export in

Tableau. For more information about creating a module and export action in Anaplan, see [Tableau Connector for Anaplan](#) on the Anaplan Anapedia website.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Anaplan**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Do one of the following:

- Select **Credentials**, then enter your email address and password.

For single sign-on (SSO) support, ask your Anaplan Administrator to set up single sign-on. For more information, see [Single Sign-on \(SSO\)](#) on the Anaplan Anapedia website. Note that if SSO is enabled, you must be an exception user.

- Select **Certificate**, then upload files for the **Certificate** and **Private Key**.

**Note:** The uploaded certificate must be in the DER encoded binary X.509 format. The private key can be in PEM format.

An SSL certificate file typically contains text similar to this:

```
-----BEGIN CERTIFICATE-----
A long base64 string
-----END CERTIFICATE-----
```

A private key file typically contains text similar to this:

```
-----BEGIN PRIVATE KEY-----
A long base64 string
-----END PRIVATE KEY-----
```

- b. Select a workspace, model, and one or more exports.

**Note:** The export data must be in CSV format.

- c. Select **Connect**.

If Tableau can't make the connection, verify that your credentials or certificate and private key files are correct. If you still can't connect, your computer is having

trouble locating the server. Contact your network or Anaplan administrator for more assistance.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table and drag it to the top of the canvas. If you have only one table, it appears on the canvas.
  - c. Select the sheet tab to go to the worksheet.

After you select the sheet tab, Tableau imports the data by creating an extract.

Creating extracts may take some time depending on the amount of data that is included.

### Date range selections can impact performance

It's tempting to gather as much data as possible when you do an analysis, however, retrieving records from Anaplan can be time-consuming. Tableau doesn't know how much data there is in a particular date range until it retrieves the data. For this reason, you should restrict your date range at first, and then expand after you evaluate performance.

To give you a rough idea of how much time it might take to retrieve data from Anaplan, tests were conducted using a high-speed connection. This table shows how long it took in the test environment to retrieve a given number of records.

Number of records	Time to retrieve
100,000	1.7 minutes
250,000	4 minutes
500,000	8.5 minutes

### Groom your data

All data from Anaplan is returned as type **String**. To groom your data, convert the fields to the proper data type, for example, **Number** or **Date**. You can also change **Geographic Role**, and you can convert a dimension to a measure. For information about changing the data type, see [Data Types on page 158](#).

To convert a dimension to a measure, in the **Data** pane on the worksheet, select the drop-down arrow next to the field name and select **Convert to Measure**.

For information about dimensions and measures, see [Dimensions and Measures, Blue and Green](#) on page 148.

### Refresh your data

Tableau supports only extract connections for Anaplan, not live connections. You can update the data by refreshing the extract; incremental refreshes are not supported. For more information, see [Refresh Extracts](#) on page 886. For information about refresh schedules, see [Schedule Extract Refreshes as You Publish a Workbook](#) on page 3093.

**Note:** When there is a scheduled refresh of the Tableau extract on Tableau Server or Tableau Cloud, an export action is called in Anaplan. The export action creates a blocking operation that locks the model in Anaplan.

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Apache Drill

This article describes how to connect Tableau to Apache Drill data and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Type of connection:
  - Direct: server name
  - Zookeeper: quorum and cluster ID
- Authentication:
  - No authentication
  - User name and password

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Apache Drill**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Select the **Connection** method:
    - **Direct** - Enter the **Server** name.
    - **Zookeeper** - Enter the **Quorum** and **Cluster ID**.
  - b. Select the **Authentication** method:
    - **No Authentication**

- **Username and password** - Enter the user name and password.
- c. Select **Sign In**.
2. On the data source page, do the following:
    - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
    - b. Under **Schema**, select a schema from the drop-down list.
    - c. Under **Table**, select a table and drag it to the canvas.

For information about connecting to more than one table, see [Join Your Data on page 738](#).
    - d. Select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Azure Data Lake Storage Gen2

This article describes how to connect Azure Data Lake Storage Gen2 and set up the data source.

## Before you begin

Before you begin, review the items in the following list.

- Get your account credentials for Azure Active Directory via OAuth
- Get the URL for your Azure storage endpoint
- Tableau only supports OAuth for authentication. To allow authentication, you must safelist "connectors.tableau.com".

**Note:** This connector uses only the default tenant for your Azure account. To use Azure Data Lake Storage Gen2 resources with Tableau, they must be associated with the default tenant.

## Recommendation

### Setup a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau release cycles and Tableau's OAuth client rotation schedule. For information on how to configure your own OAuth client see, [Configure Custom OAuth for a site](#).

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Azure Data Lake Storage Gen2**. For a complete list of data connections, select **More** under **To a Server**.
2. In the tab Tableau opens in your default browser, do the following:
  - a. Sign in to Azure Data Lake Storage Gen2 using your Azure account. Choose one from the list, or choose **Use another account** to enter your email address or phone number.
  - b. Select **Accept** so that Tableau can access your Azure Data Lake Storage Gen2 data.
  - c. Close the browser window when notified to do so.
3. On the data source page, do the following:

- a. On the **Browse** tab, enter the Azure storage endpoint for your Azure account.

**Note:** The storage account must have "Data Lake Storage Gen2" enabled.

- b. Navigate to the file you want to use and select it.

Or

- On the **File URL** tab, enter URL for the file.

## About Azure storage accounts

When you use Tableau with Azure Data Lake Storage Gen2, the storage account you use must be set up with at least one of the following:

- Read permission explicitly granted for the files you want to access (Read / Execute for folders)
- Storage Blob Data Reader or Storage Blob Data Owner role assigned to the account

For more information about setting up a storage account, see [Create a storage account to use with Azure Data Lake Storage Gen2](#) on the Microsoft site.

An Azure storage account can have multiple endpoints associated with various services. In Tableau, you'll connect to the storage endpoint that is enabled for "Data Lake Storage Gen2".

When the storage account is configured, it must enable these CORS options for the Blob service to allow proper access from Tableau:

Allowed origins set to "\*" Allowed methods set to "GET, OPTIONS"

Allowed headers set to "\*"

An Azure storage account can have multiple endpoints associated with various services. In Tableau, you'll connect to the storage endpoint that is enabled for "Data Lake Storage Gen2".

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Azure SQL Database

This article describes how to connect Tableau to Azure SQL Database and set up the data source.

**Note:** If you're using Azure Active Directory via OAuth authentication, make sure you have already setup the server before you continue. For more information on server configuration, see [Configure Azure AD for OAuth and Modern Authentication](#).

### Before you begin

Before you begin, gather this connection information:

- Fully qualified server name that hosts the database you want to connect to; for example, myserver-20171113.database.windows.net
- (Optional) Name of the database
- Authentication method:
  - Username and password
  - Active Directory password
  - Azure Active Directory via OAuth (integrated)

**Note:** To use this option, your system administrator must enable “user consent” in your organization's Azure Active Directory tenant. For more information, see Microsoft documentation on [configuring user consent](#).

- Sign in credentials depend on the authentication method you choose and can include the following:
  - Username and password
  - Active Directory username and password
  - Azure Active Directory instance URL
- Are you connecting to an SSL server?
- Do you want to set the database isolation level to read uncommitted data?
- (Optional) Initial SQL statement to run every time Tableau connects

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Azure SQL Database**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the URL for the server that you want to connect to.
  - b. (Optional) Enter a database name if you want to connect to a contained database.
  - c. Specify how you want to sign in to the server — with a username and password, with an Active Directory username and password, or using an integrated Azure Active Directory sign in via OAuth.
  - d. Type your user name and password.  
Or, if you use Azure Active Directory via OAuth, type an Azure Active Directory instance URL. See documentation from Microsoft on [endpoints](#) for more details.

**Note:** If your organization uses more than one Azure Active Directory tenant, the Azure Active Directory instance URL must match the tenant where the database is configured. You can find the tenant ID in your Azure portal, or from your Azure administrator.

- e. Select the **Require SSL** check box when connecting to an SSL server.
- f. Specify whether to **Read uncommitted data**. This option lets Tableau run at the read-uncommitted isolation level. Long queries from Tableau, including extract refreshes, can lock the database and delay transactions. Select this option to allow queries to read rows that have been modified by other transactions even when they haven't been committed yet. When this option is cleared, Tableau uses the default isolation level specified by the database.
- g. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- h. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out

which data source to connect to.

- b. From the **Database** drop-down list, select a database.
- c. Under **Table**, select a table or use the search field to search for a table by name.

You can also specify a stored procedure in the database. For more information about stored procedures, including a list of constraints specific to SQL Server databases, see [Use a Stored Procedure on page 826](#).

- d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** Tableau Desktop doesn't support the Microsoft SQL Server TIME data type. Fields of this data type aren't imported and don't appear in Tableau Desktop. If included in stored procedures, TIME data type fields won't appear in Tableau Desktop. For more information, see [Use a Stored Procedure on page 826](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

**Note:** Azure Active Directory via OAuth (integrated) isn't supported on a Mac

## Azure SQL Synapse Analytics

This article describes how to connect Tableau to Azure Synapse Analytics (formerly Azure SQL Data Warehouse) and set up the data source.

**Note:** Make sure you have already setup the server before you continue. For more information on server configuration, see [Configure Azure AD for OAuth and Modern Authentication](#).

## Before you begin

Before you begin, gather this connection information:

- Fully qualified server name that hosts the database you want to connect to; for example, myserver-20171113.database.windows.net
- (Optional) Name of the database
- Authentication method:
  - Username and password
  - Active Directory password
  - Azure Active Directory via OAuth (integrated)

**Note:** To use this option, your system administrator must enable “user consent” in your organization's Azure Active Directory tenant. For more information, see Microsoft documentation on [configuring user consent](#).

- Sign in credentials depend on the authentication method you choose and can include the following:
  - Username and password
  - Active Directory username and password
  - Azure Active Directory instance URL
- Are you connecting to an SSL server?
- Do you want to set the database isolation level to read uncommitted data?
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer,

Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Azure Synapse Analytics**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the URL for the server that you want to connect to.
  - b. (Optional) Enter a database name if you want to connect to a contained database.
  - c. Specify how you want to sign in to the server — with a username and password, with an Active Directory username and password, or using an integrated Azure Active Directory sign-in via OAuth.
  - d. Type your user name and password.  
Or, if you use Azure Active Directory via OAuth, type an Azure Active Directory instance URL. See documentation from Microsoft on [endpoints](#) for more details.

**Note:** If your organization uses more than one Azure Active Directory tenant, the Azure Active Directory instance URL must match the tenant where the database is configured. You can find the tenant ID in your Azure portal, or from your Azure administrator.

- e. Select the **Require SSL** check box when connecting to an SSL server.
- f. Specify whether to **Read uncommitted data**. This option lets Tableau run at the read-uncommitted isolation level. Long queries from Tableau, including extract refreshes, can lock the database and delay transactions. Select this option to allow queries to read rows that have been modified by other transactions even when they have not been committed yet. When this option is cleared, Tableau uses the default isolation level specified by the database.
- g. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- h. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Database** drop-down list, select a database.
- c. Under **Table**, select a table or use the search field to search for a table by name.  
  
You can also specify a stored procedure in the database. For more information about stored procedures, including a list of constraints specific to SQL Server databases, see [Use a Stored Procedure on page 826](#).
- d. Drag a table to the canvas, and then select the sheet tab to start your analysis.  
  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** Tableau Desktop does not support the Microsoft SQL Server TIME data type. Fields of this data type are not imported and do not appear in Tableau Desktop. If included in stored procedures, TIME data type fields will not appear in Tableau Desktop. For more information, see [Use a Stored Procedure on page 826](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

**Note:** Even though the **Azure Active Directory via OAuth** option shows up on the Azure SQL Synapse Analytics connector window, it isn't supported for MAC.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Box

This article describes how to connect Tableau to Box data and set up the data source.

### Before you begin

Before you begin, get the email address and password for your Box account.

### Make the connection and set up the data source

1. On the start page, under **Connect**, click **Box**. For a complete list of connections, select **More** under **To a Server**. In the tab Tableau opens in your default browser, do the following:
  - a. Enter your email and password and then click **Authorize**.
  - b. Click **Grant access to Box**.
  - c. Close the browser window when notified to do so.
  - d. Search for or select the file to connect to, and then click **Connect**.

**Note:** This connector might not support all file types. Unsupported file types are grayed out.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Click the sheet tab to start your analysis.

### Use Data Interpreter to clean your data

If Tableau detects that it can help optimize your data source for analysis, it prompts you to use Data Interpreter. Data Interpreter can detect sub-tables that you can use and remove unique formatting that might cause problems later on in your analysis. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter](#) on page 845.

### Adding Tableau to your Box account

You can officially enable Tableau as an approved app for your Box account. For information on enabling this feature, please see [Adding Apps to Your Box Account](#) on the Box website.

## Limitations and known issues

The Box connector limits connecting to a single Excel, JSON, or text-based file.

### Known issues

- If you click **Grant Access to Box** repeatedly during the authentication phase an error results.
- Long file names cause the column to be pushed out of alignment.
- The file window does not resize.
- When using web authoring or publishing to the web, you cannot use multiple Box accounts in the same workbook. You can have multiple Box account connections in Desktop.
- In Internet Explorer 11 and Edge, you cannot access a server using an unsecured connection (http). Use a secure connection (https) or switch to another browser.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Cloudera Hadoop

This article describes how to connect Tableau to a Cloudera Hadoop database and set up the data source.

**Note:** For new connections to Impala databases, use the [Impala connector](#) rather than this one. (You can continue using this connector for existing connections.)

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to and port number
- Type of database: Hive Server 2 or Impala
- Authentication method:

- No Authentication
- Kerberos

**Note:** Due to Kerberos Domain Controller (KDC) restrictions, connection with MIT Kerberos is not supported.

- User Name
- User Name and Password
- Microsoft Azure HDInsight Service (starting in version 10.2.1)
- Transport options depend on the authentication method you choose and can include the following:
  - Binary
  - SASL
  - HTTP
- Sign-in credentials depend on the authentication method you choose and can include the following:
  - User name
  - Password
  - Realm
  - Host FQDN
  - Service name
  - HTTP path
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** Make sure you use the latest available drivers. To get the latest drivers, see [Cloudera Hadoop](#) on the Tableau Driver Download page.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Cloudera Hadoop**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the port number to use. If you are connecting using Cloudera Impala, you must use port 21050; this is the default port if you are using the 2.5.x driver (recommended).
  - b. In the **Type** drop-down list, select the type of database to connect to. Depending on the version of Hadoop and the drivers you have installed, you can connect to one of the following:
    - **Hive Server 2**
    - **Impala**
  - c. In the **Authentication** drop-down list, select the authentication method to use.
  - d. Enter the information that you are prompted to provide. The information you are prompted for depends on the authentication method you choose.
  - e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - f. Select **Sign In**.

Select the **Require SSL** option when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

- b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
- c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** This database type supports only equal (=) join operations.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Work with Hadoop Hive data

### Work with date/time data

Tableau supports TIMESTAMP and DATE types natively. However, if you store date/time data as a string in Hive, be sure to store it in ISO format (YYYY-MM-DD). You can create a calculated field that uses the DATEPARSE or DATE function to convert a string to a date/time format. Use DATEPARSE() when working with an extract, otherwise use DATE(). For more information, see [Date Functions on page 2200](#).

For more information about Hive data types, see [Dates](#) on the Apache Hive website.

### NULL value returned

A NULL value is returned when you open a workbook in Tableau 9.0.1 and later and 8.3.5 and later 8.3.x releases that was created in an earlier version and has date/time data stored as a string in a format that Hive doesn't support. To resolve this issue, change the field type back to **String** and create a calculated field using DATEPARSE() or DATE() to convert the date. Use DATEPARSE() when working with an extract, otherwise use the DATE() function.

## High latency limitation

Hive is a batch-oriented system and is not yet capable of answering simple queries with very quick turnaround. This limitation can make it difficult to explore a new data set or experiment with calculated fields. Some of the newer SQL-on-Hadoop technologies (for example, Cloudera's Impala and Hortonworks' Stringer project) are designed to address this limitation.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Databricks

This article describes how to connect Tableau to a Databricks database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- HTTP path to the data source
- Authentication method:
  - Azure Active Directory via OAuth

**Note:** To use this option, your system administrator must enable “user consent” in your organization's Azure Active Directory tenant. For more information, see Microsoft documentation on [configuring user consent](#).

- Personal Access Token
- Username / Password
- Sign in credentials that related to your chosen authentication method:
  - Azure AD endpoint
  - Personal Access Token password
  - Username and password
- In Databricks, find your cluster server hostname and HTTP path using the instructions in [Construct the JDBC URL](#) on the Databricks website.
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** If you are connecting with Azure Active Directory via OAuth, you will need version 2.6.15 or later for this driver.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Databricks**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the **Server Hostname**.
  - b. Enter the **HTTP Path** to the data source.
  - a. Select the **Authentication** method: **Azure Active Directory via OAuth**, **Personal Access Token**, or **Username / Password**.

**Note:** You can use the **Username / Password** option only if single sign-on (SSO) is disabled on the server. Otherwise, use your personal access token.

- c. Enter the sign in credentials for the authentication method you chose:
  - For Azure AD, type the URL for the **Azure AD Endpoint**.
  - For personal access token, type the corresponding **Password**. (See [Personal Access Tokens](#) on the Databricks website for information on access tokens.)
  - For username and password, type those in the fields provided.
- d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- e. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
    - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
    - b. Under **Schema**, select a schema or use the text box to search for a schema by name.
    - c. Under **Table**, select a table or use the text box to search for a table by name.
    - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.
- Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Databricks best practices and troubleshooting

For information about best practices and troubleshooting when using Tableau with Databricks clusters, see the [Tableau](#) topic on the Databricks website.

## See also

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Marketing Cloud Intelligence Connector

**Note:** The Marketing Cloud Intelligence connector replaced the Datorama connector.

This article describes how to connect Tableau to the Marketing Cloud Intelligence connector.

## Before you begin

Before you begin, gather this connection information:

- Name of the environment and workplace ID that you want to connect to
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Marketing Cloud Intelligence**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Choose the environment you want to work in.
  - b. Enter the workplace ID.
  - c. Enter the access token from [Marketing Cloud Intelligence](#).
  - d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Database** drop-down list, select a database.
  - c. Under **Table**, select a table or use the search field to search for a table by name.
  - d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.  
For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Denodo

This article describes how to connect Tableau to Denodo and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Name of the database
- Authentication method: Integrated Authentication, or Username and Password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Update 20170515 of Denodo 6.0 required

If you can't connect Tableau to your Denodo data, you might need to ask your database administrator to apply update 20170515 to the Denodo 6.0 database. For more information about update 20170515 for Denodo 6.0, see the [Denodo](#) website. (Sign in required.)

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Denodo**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter the name of the database.
  - c. Select how you want to sign in to the server. Specify whether to use **Integrated Authentication** or **Username and Password**. If the server is password protected, and you are not in a Kerberos environment, you must enter the user name and password.

**Note:** If you're using a Mac, and it is not attached to the domain correctly, the Mac won't know that Kerberos is being used in the domain, and the **Authentication** drop-down list won't be available.

Select the **Require SSL** check box when connecting to an SSL server.

- d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

- b. Under **Table**, select a table or use the text box to search for a table by name.
- c. Click the sheet tab to start your analysis.

### See also

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Dremio Connector by Dremio

**Note:** This is a partner-built connector, created and supported by Dremio. See the [Dremio web site](#) for more information.

This article describes how to connect Tableau to a Dremio data lake and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name or IP address for the server that hosts the database you want to connect to
- Port number
- Username and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Dremio** . For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name or IP address for the **Server**.
  - b. Enter the **Port** number.
  - c. Enter the **Username** and **Password**.

- d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

- e. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Under **Table**, select a table or search for a table by name.
- c. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Dropbox

This article describes how to connect Tableau to Dropbox data and set up the data source.

**Note:** "Team" folders are currently unavailable through the Dropbox connector.

## Before you begin

Before you begin, get the email address and password for your Dropbox account.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Dropbox**. For a complete list of data connections, select **More** under **To a Server**. In the tab Tableau opens in your default browser, do the following:
  - a. Enter your email and password and then select **Sign in**.
  - b. Select **Allow** to let Tableau Desktop access your Dropbox files and folders.
  - c. Close the browser window when notified to do so.
  - d. Search for or select the file to connect to, and then select **Connect**.

**Note:** This connector might not support all file types. Unsupported file types are grayed out.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select the sheet tab to start your analysis.

**Note:** Tableau doesn't support pivot tables in Dropbox.

## Use Data Interpreter to clean your data

If Tableau detects that it can help optimize your data source for analysis, it prompts you to use Data Interpreter. Data Interpreter can detect sub-tables that you can use and remove unique formatting that might cause problems later on in your analysis. For more information, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter](#) on page 845.

## Troubleshoot Dropbox issues

### Connections to multiple accounts

When using web authoring or publishing to the web, you cannot use multiple Dropbox accounts in the same workbook. You can have multiple Dropbox account connections in Desktop.

### Web authoring with Internet Explorer 11 and Edge

In Internet Explorer 11 and Edge, you cannot access a server using an unsecured connection (http). Use a secure connection (https) or switch to another browser.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Esri Connector

In Tableau, you can connect to an **Esri (ArcGIS) Server** and **ArcGIS Online**. The connector calls the Esri Services Directory REST API to find all MapServer and FeatureServer services. You can choose individual layers from those discovered services that are downloaded and stored in an extract.

**Note:** In Tableau 2022.1, the Esri connector replaced the Esri ArcGIS Server connector. The workbooks you created with the Esri ArcGIS Server (including published ones) will continue to function normally. All of those workbooks are built on extracts that are valid indefinitely. You can create new workbooks with the Esri connector.

### Download the required driver

The Esri connector requires a driver to be installed. If the driver isn't installed on the host computer, the connection dialog box displays a link to the [Driver Download](#). All Tableau Cloud sites already have the driver installed.

### Connect to Esri Services

There are two ways to connect to Esri services with the Esri connector: No authentication or OAuth.

## No authentication

Use the no authentication method if your Esri server is publicly accessible. There are thousands of such endpoints, many of which are [listed here](#). You can set up layers on your Esri server to be publicly accessible.

Follow along with this example:

1. From Tableau Desktop or Tableau Server, install the driver.
2. Start Tableau and under **Connect**, select **Esri**.

If authoring in Tableau Cloud or Tableau Server, Select **New Workbook > Connectors > Esri**.

3. Change the value under `Connect to` to `A public-facing ArcGIS server`.
4. For the ArcGIS Server URL in this example, you can use `https://services.arcgis.com/P3ePLMys2RVChkJx/ArcGIS/rest/services/AGOL_Base_2018_Final/FeatureServer`
5. Select **Sign In** (Don't worry, you aren't actually signing in.)
6. You'll see layers representing geographic levels of detail. Double-click **County**.
7. Navigate to Sheet 1. (Tableau creates an extract from the layer.)
8. Drag (or double-click) the **Shape** field onto the canvas. A map of counties in the US appears.
9. Drag the **Median Age Cy** field onto color on the **Marks** card. A choropleth of Median Age from the 2018 census renders.

## OAuth (Tableau Desktop and Tableau Cloud)

Use the OAuth method if you have an account and data saved on ArcGIS Online. You can retrieve layers from your account by entering your credentials in the Esri connector dialog.

1. From Tableau Desktop, install the driver (see above).
2. Start Tableau and under **Connect**, select **Esri**.

If authoring in Tableau Cloud or Tableau Server, select **New Workbook > Connectors > Esri**.

3. Select **Sign In**.
4. Provide your Esri credentials in the browser and select **Sign In** again.
5. A list of services available in your account appears.

## OAuth (Tableau Server)

To use the OAuth mode to connect from Tableau Server to ArcGIS Online, you must first configure both the ArcGIS Online account and Tableau Server.

## Configure ArcGIS Online

1. Obtain an ArcGIS Developer account.
2. Register a new OAuth application following the instructions found on the [arcGIS website](#).
3. Specify the Redirect URL as `https://<your Tableau Server Host>/auth/add_oauth_token`
4. Make note of the Redirect URL, Client ID, and Client Secret, as you need them to configure Tableau Server.

## Configure Tableau Server

1. From Settings, scroll to **OAuth Clients Registry**.
2. Select **Add OAuth Client**.
3. In Connection Type, select **Esri**.
4. Fill in the Redirect URL, Client ID, and Client Secret from the ArcGIS Online configuration step mentioned previously.
5. Save your Settings changes.

## Troubleshoot Esri connections

**Note:** It's important to have the current driver (version 0.73.0 or later).

ArcGIS Server layers with large geometries may not successfully download, or the download may take a long time.

## Known limitations

- When you use an OAuth connection, only items in the Owner's user account display.
- The Esri connector doesn't support definition queries. Thus, the selected layer downloads in its entirety.
- The Esri connector doesn't support live connections, and always creates an extract. A packaged workbook with an ArcGIS connection can be opened in versions of Tableau older than 2022.1, but you can't refresh the extract.
- The connector searches only for MapServer and FeatureServer service types.
- The connector ignores the esriFieldTypeBlob and esriFieldTypeRaster types.
- Esri geometry types are limited to the following:
  - esriGeometryPoint
  - esriGeometryMultipoint
  - esriGeometryLine
  - esriGeometryPath
  - esriGeometryPolyline
  - esriGeometryPolygon
  - esriGeometryEnvelope
- If the ArcGIS Server contains multiple layers or tables with identical names within a service, only one displays.

## Exasol

This article describes how to connect Tableau to data stored in the Exasol platform and set up the data source. Tableau can connect to Exasol version 4.2 and later.

### Before you begin

Before you begin, gather this connection information:

- Name of the server you want to connect to
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Exasol**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that you want to connect to.
  - b. Enter the user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.  
  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Firebird 3

This article describes how to connect Tableau to a Firebird database and set up the data source.

**Note:** In version 2020.1, the Firebird 3 connector replaced the Firebird connector. If you're using an earlier version of Tableau, go to the [Tableau Help](#) page and select the version you need from the drop-down list on the left. Then search for "Firebird" to find information on that connector.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Location of the database
- User name and password

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Firebird 3**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Enter the name of the server that hosts the database.
- b. Enter the database, or browse to the location of the database.
- c. Enter the user name and password, and then select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select a table, drag it to the canvas, and then select the sheet tab to start your analysis.

Starting in 2019.2, the Firebird connector no longer supports custom SQL connections.

### Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as `mydb.test.ourdomain.lan`, instead of a relative domain name, such as `mydb` or `mydb.test`.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

### Upgrade a Firebird extract

Beginning with version 10.5, Tableau has changed the format of extracts to the `.hyper` format. This format change requires Firebird extracts be opened and saved using an earlier version of Tableau before it can either be used with the current version of Tableau or be upgraded to the `.hyper` format. When you open and save the Firebird extract in an earlier version of Tableau, the Firebird extract is upgraded to a `.tde` format. To upgrade a Firebird extract, follow the steps listed below.

1. Get an earlier version of Tableau Desktop. To get an earlier version of Tableau Desktop, see the Tableau [Alternate Downloads Site](#) page.
2. Install the earlier version of Tableau Desktop, and then use it to open the Firebird extract.

3. Save the extract.
4. Open the upgraded Firebird extract using the current version of Tableau Desktop. The extract should work as expected.

**Note:** You can upgrade your extract from a .tde to a .hyper format by selecting **Data > Extract > Upgrade**. For more information, see [Extract Upgrade to .hyper Format on page 884](#).

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Google Analytics

**Note:** Tableau adheres to [Google's API Services User Data Policy](#) and Limited Use Requirements when using or transferring information from Google APIs to other apps.

This article describes how to connect Tableau to Google Analytics (GA) and set up the data source.

**Note:** Google Analytics 4 property isn't supported.

### Before you begin

Before you begin, gather this connection information:

- GA email address and password

### Recommendation

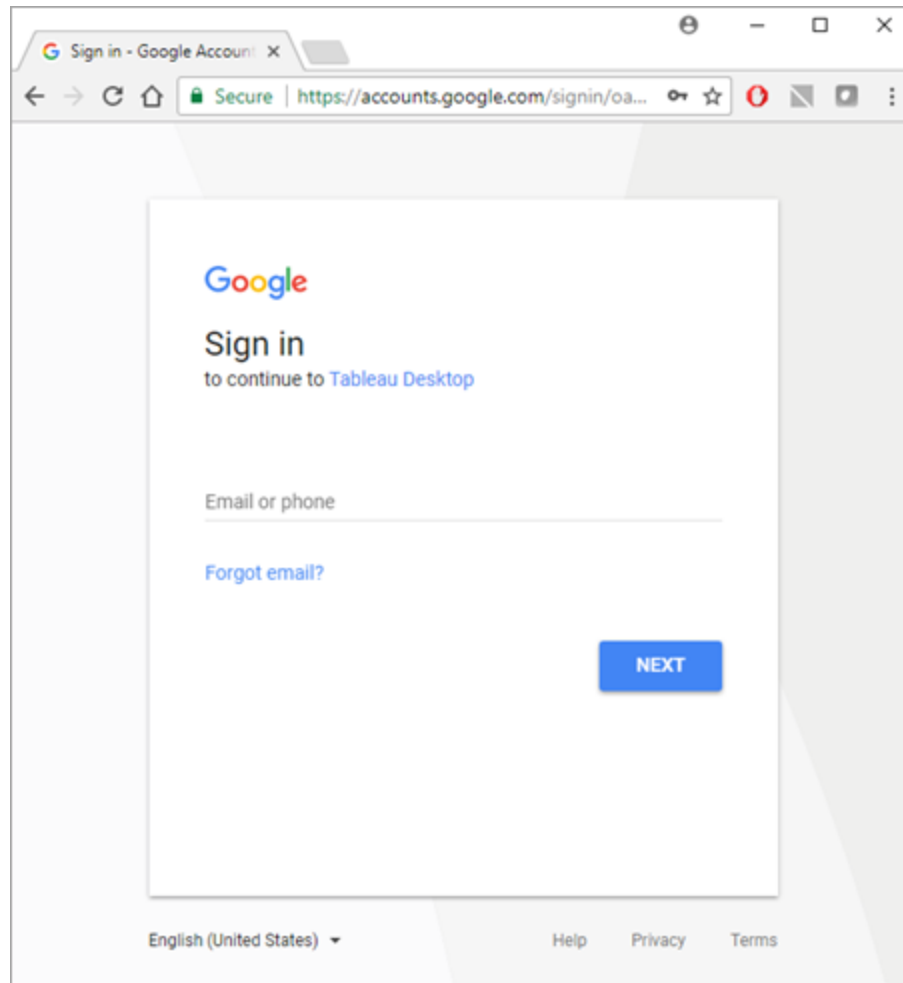

#### Setup a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau release cycles and Tableau's OAuth client rotation schedule. For information on how to configure your own OAuth client see, [Configure custom OAuth for a site](#).

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Google Analytics**. For a complete list of data connections, select **More** under **To a Server**. In the tab Tableau opens in your default browser, do the following:
  - a. Sign in to GA using your email or phone, and then select **Next** to enter your password.

- b. Select **Allow** so that Tableau Desktop can access your GA data.
  - c. Close the browser window when notified to do so.
2. On the data source page, do the following:
    - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source

naming convention that helps other users of the data source figure out which data source to connect to.

- b. Follow the steps at the top of the data source page to complete the connection.

**Step 1** – Select an Account, Property, and Profile using the dropdown menus.

**Step 2** – Select filters for a date range and a segment.

- For **Date Range**, you can select one of the predefined date ranges or select specific dates. When selecting a date range, GA can provide complete data only up to the previous full day. For example, if you choose Last 30 days, data will be retrieved for the last 30-day period ending yesterday.
- For **Segment**, select a segment to filter your data. Segments are preset filters that you can set for a GA connection. Default Segments are defined by Google, and Custom Segments are defined by the user on the GA website. Segments also help prevent sampling to occur by filtering the data as defined by the segment. For example, with a segment, you can get results for a specific platform, such as tablets, or for a particular search engine, such as Google.

**Note:** GA restricts the amount of data that it returns in a query. When you try to retrieve more data than GA allows in a single query, GA returns sampled data instead. If Tableau detects that your GA query might return sampled data, Tableau attempts to bypass the query restriction to return all data instead. For more information, see [All data vs. sampled data returned from a query](#) on the facing page below.

**Step 3** – Add dimensions and measures by using the **Add Dimension** and **Add Measure** dropdown menus, or select a predefined set of measures from the **Choose a Measure Group** dropdown menu. Some dimensions and measures can't be used together. For more information, see [Dimensions & Metrics Reference Guide](#) on the Google developer website.

- c. Select the sheet tab to start your analysis. After you select the sheet tab, Tableau imports the data by creating an extract. Tableau Desktop supports only extracts for

Google Analytics. You can update the data by refreshing the extract. For more information, see [Extract Your Data on page 867](#).

### All data vs. sampled data returned from a query

GA restricts the amount of data that it returns from a query and provides sampled data instead. Sampled data is a random subset of your data. When performing analysis on sampled data, you can miss interesting outliers, and aggregations can be inaccurate. If Tableau detects that your query might return sampled data, by default, Tableau creates multiple queries from your query, and then combines the results from the queries to return all data.

You see the following message when Tableau returns all data.

If the query stays within the boundaries of the query restrictions, GA doesn't return sampled data and you don't see the above message.

### Troubleshoot issues with returning all data

If your query continues to return sampled data, consider the following:

- **Missing required context variable** - Google Analytics 4 property isn't supported.
- **Missing date dimension** – You must use the date dimension in your query to return all data.
- **Too much data** – Your query might contain too much data. Reduce the date range. The minimum date range is one day.
- **Non-aggregatable dimensions and measures** – Some dimensions and measures can't be separated into multiple queries. If you suspect a problematic dimension or measure in your query, hover over the **All data** button to see the tooltip that shows which dimensions or measures to remove from your query.
- **Legacy workbooks** – Workbooks created in Tableau Desktop 9.1 and earlier can't return all data. Open the legacy workbook in Tableau Desktop 9.2 and later and save the workbook.

### Return sampled data

In cases when workbook performance is critical or there are specific dimensions and measures you want to use in your query that aren't supported by Tableau's default query process, use

sampled data instead. To return sampled data, select the **Sample data** button.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

[5 Tips to Get More from Google Analytics](#) - Read the Tableau whitepaper (registration or sign in required).

## Google Analytics 4

**Note:** Tableau adheres to [Google's API Services User Data Policy](#) and Limited Use Requirements when using or transferring information from Google APIs to other apps.

This article describes how to connect Tableau to Google Analytics 4 and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Google Analytics email address and password

### Recommendation

#### Set up a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau release cycles and Tableau's OAuth client rotation schedule. For information on how to configure your own OAuth client see, [Configure custom OAuth for a site](#).

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Google Analytics 4** from the list of **Additional Connectors**.
2. Select **Install and Restart Tableau** to install the connector.
3. After Tableau restarts, under **Connect**, select **Google Analytics 4** from the list of Installed Connectors.
4. Sign in with your Google email address and password.
5. Check the permission box to allow Tableau to See and download your Google Analytics data.
6. Follow the steps in the Google Analytics 4 dialog window to complete the connection.
  - a. Select an **Account** and **Property**.
  - b. In **Date Range**, select a default date range or specific dates.

The date range can be Fixed Start and End Dates, relative to a Fixed Start Date, or Relative to Refresh Date (that is, the current date on which the connection is created or refreshed).

- c. Add dimensions and metrics (measures).

**Note:** Some dimensions and measures can't be used together. For more information, see [Dimensions & Metrics Reference Guide](#) on the Google developer website.

- d. Review your connection attributes and select **Connect**.
6. (Optional) On the **Data Source** page, select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau.

For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

7. Select the Sheet tab to start your analysis. After you select the sheet tab, Tableau imports the data by creating an extract.

**Note:** Tableau only supports extracts for Google Analytics 4. You can update the data by refreshing the extract. For more information, see [Extract Your Data](#).

## Troubleshoot Google Analytics 4

### Report Types

The Google Analytics 4 connector relies on the basic Core Reporting capabilities of the Google Analytics Data API. Cohort, Pivot, Realtime, and Funnel reports aren't currently supported.

### Quotas

Usage of the Google Analytics 4 connector is subject to Google Analytics Data API quotas in the Core quota category. Additional details can be found in the [Google Analytics Data API guide](#).

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

[5 Tips to Get More from Google Analytics](#) - Read the Tableau whitepaper (registration or sign in required).

## Google BigQuery

This article describes how to connect Tableau to Google BigQuery and set up the data source.

**Note:** Some of the features and customizations listed in this article aren't supported in Tableau Prep Builder. For more information about connecting your data in Prep Builder, see [Connect to Data](#).

### Before you begin

Before you begin, gather this connection information:

- Google BigQuery email or phone, and password

### Recommendation

#### Set up a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau

release cycles and Tableau's OAuth client rotation schedule. For information on how to configure your own OAuth client, see [Configure Custom OAuth for a site](#).

### Make the connection and set up the data source

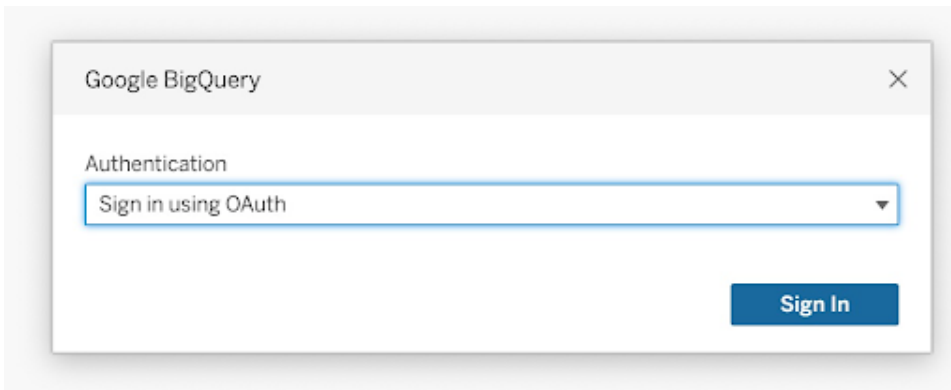

**Note:**Note: To use service account credentials for a new Google BigQuery data source, the connection must be created in Tableau Desktop.

1. Start Tableau and under **Connect**, select **Google BigQuery**.

Complete one of the following 2 options to continue.

#### Option 1:

1. In Authentication, select **Sign In using OAuth**.
2. Click **Sign In**.
3. Enter your password to continue.
4. Select **Accept** to allow Tableau to access your Google BigQuery data. You'll be prompted to close the browser.

#### Option 2:

**Tip:** If you're using Tableau Server or Tableau Cloud for publishing, you have to start with logging into the product you're using, and then add your saved Google BigQuery credentials under account settings. This prevents an "Invalid credentials error".

1. In Authentication, select **Sign In using the Service Account (JSON) file**.
2. Enter the file path or use the **Browse** button to search for it.
3. Click **Sign In**.
4. Enter your password to continue.
5. Select **Accept** to allow Tableau to access your Google BigQuery data. You'll be prompted to close the browser.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. (Optional) From the **Billing Project** dropdown list, select a billing project. If you don't select a billing project, `EmptyProject` appears in the field after you've selected the remaining fields.
  - c. From the **Project** dropdown list, select a project. Alternatively, select **publicdata** to connect to sample data in BigQuery.
  - d. From the **Dataset** dropdown list, select a data set.
  - e. Under **Table**, select a table.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

#### Notes:

- Google BigQuery has changed support from BigQuery legacy SQL (BQL) to standard SQL. Your workbooks upgrade to support standard SQL when you open them in Tableau.
- Because of the large volume of data in BigQuery, Tableau recommends that you connect live.
- The `Radians()` function isn't supported in Google BigQuery.

## Use customization attributes to improve query performance

**Note:** Customization attributes aren't currently supported in Tableau Prep Builder.

You can use customization attributes to improve the performance of large result sets returned from BigQuery to Tableau Cloud, Tableau Server, and on Tableau Desktop.

You can have the customization attributes included in your published workbook or data source, as long as you specify the attributes before you publish the workbook or data source to Tableau Cloud or Tableau Server.

### Use Google BigQuery customization attributes

Customization attributes accept integer values and affect both live queries and extract refreshes for the specified connection.

The following attributes help the most to increase the performance of large result sets:

bq-fetch-tasks	Number of parallel background tasks to use when fetching data using HTTP. The default is 10.
bq-large-fetch-rows	Number of rows to fetch in each batch for spool queries. The default is 50000.

The following attributes are also available and are used for small queries:

bq-fetch-rows	Number of rows to fetch in each batch for non-spool queries. The default is 10000.
bq-response-rows	Number of rows returned in non-spool non-batched queries. The default is 10000.

This capability setting accepts yes or no values and can be useful when testing:

CAP_BIGQUERY_FORCE_SPOOL_JOB	Force all queries to use the temp table approach. The default value is "no." Change the value to "yes" to turn on this attribute.
------------------------------	---

## How Tableau returns rows from Google BigQuery

Tableau uses two approaches to return rows from BigQuery: the default non-spool approach, or the temp table (spool) approach:

- On the first attempt, queries are executed using the default, non-spool query, which uses the `bq-fetch-rows` setting.
- If the result set is too large, the BigQuery API returns an error and the Tableau BigQuery connector retries the query by saving the results into a BigQuery temp table. The BigQuery connector then reads from that temp table, which is a spool job that uses the `bq-large-fetch-rows` setting.

## How to specify the attributes

You can specify attributes in one of two ways: in a Tableau Datasource Customization `.tdc` file, or in the workbook or data source XML.

## Specify attributes in a `.tdc` file

To specify customization attributes during a publish workbook or publish data source operation from Tableau Desktop, follow these steps:

1. Create an XML file that contains the customization attributes.
2. Save the file with a `.tdc` extension, for example, `BigQueryCustomization.tdc`.
3. Save the file to the `My Tableau Repository\Datasources` folder.

The customization attributes in the `.tdc` files are read and included by Tableau Desktop when the data source or workbook is published to Tableau Cloud or Tableau Server.

**Important:** Tableau doesn't test or support TDC files. These files should be used as a tool to explore or occasionally address issues with your data connection. Creating and maintaining TDC files requires careful manual editing, and there's no support for sharing these files.

## Example of a `.tdc` file with recommended settings for large extracts

```
<connection-customization class='bigquery' enabled='true' version='8.0' >
  <vendor name='bigquery' />
  <driver name='bigquery' />
  <customizations>
    <customization name='bq-fetch-tasks' value='10' />
  </customizations>
</connection-customization>
```

```
<customization name='bq-large-fetch-rows' value='10000' />
</customizations>
</connection-customization>
```

## Manually embed attributes in the XML of the workbook or data source file

You can manually embed customization attributes inside the 'connection' tag in the workbook.twb file or the data source .tds file. The BigQuery customization attributes are bold in the following example to make them easier for you to see.

### Example of manually embedded attributes

```
<connection CATALOG='publicdata' EXECATALOG='some-project-123'
REDIRECT_URI='some-url:2.0:oob'
SCOPE='https://www.googleapis.com/auth/bigquery
https://www.googleapis.com/auth/userinfo.profile
https://www.googleapis.com/auth/userinfo.email' authentication='yes'
bq-fetch-tasks='10' bq-large-fetch-rows='10000' bq_schema='samples'
class='bigquery' connection-dialect='google-bql' connection-
protocol='native-api' login_title='Sign in to Google BigQuery' odbc-
connect-string-extras='' project='publicdata' schema='samples'
server='googleapis.com/bigquery' server-oauth='' table='wikipedia'
username=''>
```

### Check if your workbook uses standard SQL or legacy SQL

In 2016, Google updated the BigQuery APIs to support standard SQL, in addition to still supporting BigQuery SQL (now called legacy SQL). Starting in Tableau 10.1, the Google BigQuery connector has been upgraded to support standard SQL, and also still supports legacy SQL. Standard SQL enables users of the BigQuery connector to use level of detail expressions, get faster metadata validation, and select a billing project with the connection.

Now, when you create a workbook, Tableau supports standard SQL by default. Tableau also supports legacy SQL using the **Use Legacy SQL** option on the **Data** pane. For example, when you open a workbook that was created using a previous version of Tableau Desktop, and if your workbook uses legacy SQL, the **Use Legacy SQL** option is selected.

You might want to configure the **Use Legacy SQL** option for the following reasons:

- You have an existing workbook that you want to update to use standard SQL to write level of detail expressions or to take advantage of other improvements. In this case, make sure that the **Use Legacy SQL** option isn't selected.
- You're creating a workbook that must connect to a legacy SQL view. You can't mix legacy SQL with standard SQL, so you must select the **Use Legacy SQL** option for the workbook to function.

In Google BigQuery, views are written in standard SQL or legacy SQL. You can join views written in standard SQL to views written in standard SQL, or views written in legacy SQL to views written in legacy SQL, and you can join views written in either version of SQL to a table. But you can't join views written in standard SQL and views written in legacy SQL in one workbook. When you join views, you must set the **Use Legacy SQL** check box to correspond to the SQL type used in the view you're connecting to.

**Note:** Tableau Desktop provides limited support for nested data when you use legacy SQL or standard SQL. For example, if a table contains nested data and you're using legacy SQL or standard SQL, on the data source page, **Update Now** won't work.

For more information about migrating from legacy SQL to standard SQL, see [Migrating from legacy SQL](#) on the Google Cloud Platform website.

## Use BigQuery BI Engine to Analyze Data

You can use BigQuery BI Engine to perform fast, low-latency analysis services and interactive analytics with reports and dashboards backed by BigQuery. For more information, including instructions on how to integrate BigQuery BI Engine with Tableau, see [Analyze BigQuery data by using BI Engine and Tableau](#) in Google's documentation.

## Troubleshoot Google BigQuery issues

### Connections to multiple accounts

When using web authoring or publishing to the web, you can't use multiple Google BigQuery accounts in the same workbook. You can have multiple Google BigQuery account connections in Desktop.

When publishing flows, the credentials that you use to connect to Google BigQuery in your Input step must match the credentials that are set up in the **Settings** tab in the **My Account Settings** page for Google BigQuery in Tableau Server or Tableau Cloud. If you select different credentials or no credentials in your authentication setting when publishing the flow, the flow fails with an

authentication error until you edit the connection for the flow in Tableau Server or Tableau Cloud to match those credentials.

### Web authoring with Internet Explorer 11 and Edge

In Internet Explorer 11 and Edge, you can't access a server using an unsecured connection (http). Use a secure connection (https) or switch to another browser.

## Google BigQuery JDBC

This article describes how to connect Tableau Desktop and Tableau Cloud to Google BigQuery (JDBC).

### Before you begin

Before you begin, gather this connection information.

- Google BigQuery billing project ID (Case Sensitive).

**Tip:** If you're using storage API to improve performance, the user account must have `bigquery.readsessions.getData` in their permissions.

### Driver required

This connector requires a driver to talk to the database. If the driver isn't installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) (Link opens in a new window) page where you can find driver links and installation instructions.

### Make the connection in Tableau Desktop

In Tableau Desktop, you can use 2 authentication methods with the Google BigQuery connector. You can sign in using a Service Account or using OAuth.

## Complete the following steps to sign in using a service account.

1. Start Tableau and under **Connect**, select **Google BigQuery JDBC**.
2. Enter the **Billing Project ID**. Ensure that you're using the Google Cloud billing project id, not the billing project name.
3. In **Authentication**, select **Sign In using Service Account (JSON) file**.
4. Enter the file path or use the **Browse** button to search for it.
5. (Optional) Go to the **Advanced** tab.
6. On the **Advanced** tab, select **Use Storage API**, to get faster extracts.
7. Unselect the **Enumerate All Projects** option to help increase processing times.
8. After you make changes, choose **Sign In**.
9. Enter your password to continue.
10. Select **Accept** to allow Tableau to access your Google BigQuery data. You're then prompted to close the browser. After authentication, Tableau creates a workbook using the Billing Project ID you provided.

## Complete the following steps to sign in using OAuth.

1. Start **Tableau** and under **Connect**, select **Google BigQuery JDBC**.
2. Enter the Billing Project ID. Ensure that you're using the Google Cloud billing project id, not the billing project name.
3. In **Authentication**, select **Sign In using OAuth**.
4. (Optional) Go to the **Advanced** tab.
5. On the **Advanced** tab, select **Use Storage API**, to get faster extracts.
6. Unselect the **Enumerate All Projects** option to help increase processing times.
7. Choose **Sign In**.
8. Select the account with your data in it.
9. Select **Continue** to allow Tableau to access your Google BigQuery data. After authentication, Tableau creates a workbook using the Billing Project ID you provided.

## Make the connection in Tableau Cloud

In Tableau Cloud, you can use OAuth authentication methods with the Google BigQuery connector.

1. Start Tableau and under **Connect**, select **Google BigQuery JDBC**.
2. Enter the Billing Project ID. Ensure that you're using the Google Cloud billing project id, not the billing project name.
3. In **Authentication**, select **Sign In using OAuth**.
4. (Optional) Go to the **Advanced** tab.

5. On the **Advanced** tab, select **Use Storage API**, to get faster extracts.
6. Unselect the **Enumerate All Projects** option to help increase processing times.
7. Choose **Sign In**.
8. Select the account with your data in it.
9. Select **Continue** to allow Tableau to access your Google BigQuery data. After authentication, Tableau creates a workbook using the Billing Project ID you provided.

## Migrating existing workbooks

To migrate workbooks from the Google BigQuery API connector to the JDBC connector you must manually change the data source to Google BigQuery (JDBC) and republish it.

## Google Cloud SQL

This article describes how to connect Tableau to a Google Cloud SQL database instance and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Google Cloud SQL**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter the user name and password, and then select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Database** drop-down list, select a database or use the text box to search for a database by name.
- c. Under **Table**, select a table or use the text box to search for a table by name.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Google Drive

This article describes how to connect Tableau to Google Drive and set up the data source.

**Note:** Google drive supports shared files as of 2023.1.

## Before you begin

Before you begin, gather this connection information:

- Google email address and password

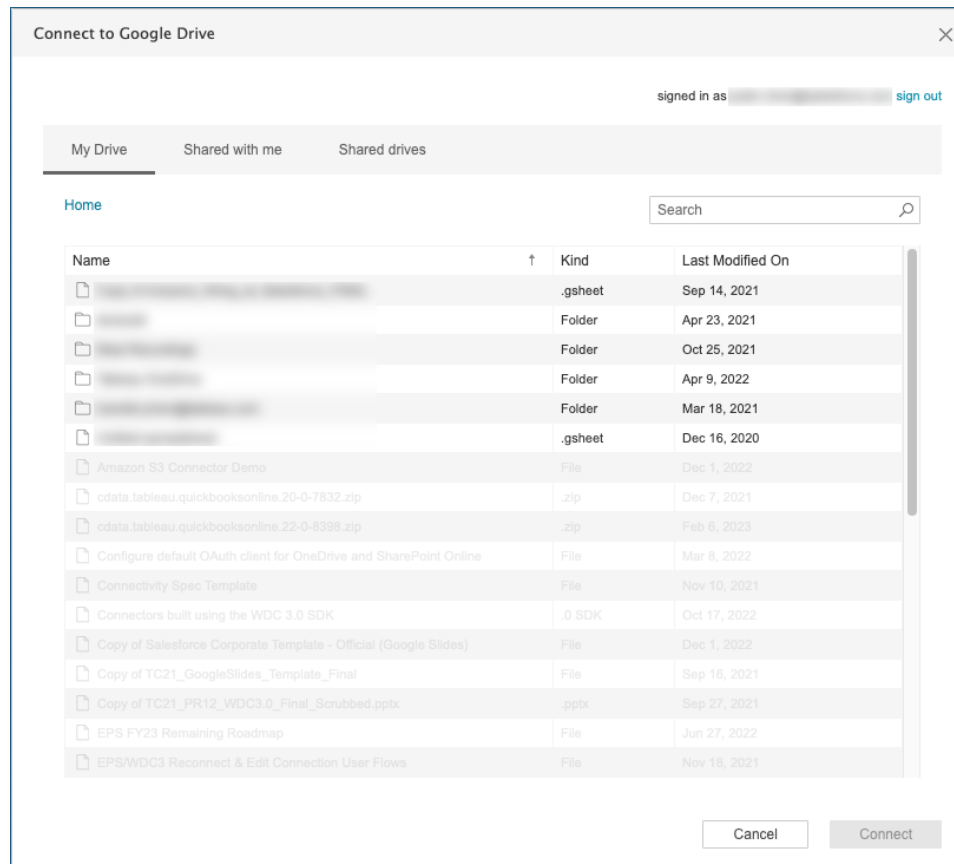

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Google Drive**. For a complete list of data connections, select **More** under **To a Server**. In the tab Tableau opens in your default browser, do the following:
  - a. Sign in to Google Drive using your email or phone, and then select **Next** to enter your password. If multiple accounts are listed, select the account that has the Google Drive data you want to access and enter the password, if you're not already signed in.

- b. Select **Allow** so that Tableau Desktop can access your Google Drive data.
- c. Close the browser window when notified to do so.
- d. Select a file from the list or use the text box to search for a file by name or URL, and then select **Connect**. You can also select a file under the Shared with me or Shared drives tab."

**Note:** This connector might not support all file types. Unsupported file types are grayed out.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data figure out which data source to connect to.
  - b. If your Google Drive file has one table, select the sheet tab to start your analysis.

### About .tde and .hhyper files

You might notice .tde or .hhyper files when navigating your computer's directory. When you create a Tableau data source that connects to your data, Tableau creates a .tde or .hhyper file. This file, also known as a shadow extract, is used to help improve the speed your data source loads in Tableau Desktop. Although a shadow extract contains underlying data and other information similar to the standard Tableau extract, a shadow extract is saved in a different format and can't be used to recover your data.

## Troubleshoot Google Drive issues

**Note:** The embedded password feature is disabled for Google Drive. You can use embedded <username> instead.

### Data limit in Google Drive

Google Drive supports a limited number of cells (in the millions) for spreadsheets that are created in or converted to Google Sheets. For more information, see [Files you can store in Google Drive](#) in the Google Drive Help.

### Connections to multiple accounts

When using web authoring or publishing to the web, you cannot use multiple Google Drive accounts, even when using different connections. You can have multiple Google Drive account connections in Desktop.

### Web authoring with Internet Explorer 11 and Edge

In Internet Explorer 11 and Edge, you cannot access a server using an unsecured connection (http). Use a secure connection (https) or switch to another browser.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Google Sheets

**Important:** Google Sheets will be fully deprecated in 12 months (appropriately April 2023). To continue un-interrupted access for workbooks follow the instructions on this page.

The Google Sheets connector has been deprecated. To continue using your workbooks, you must move your work to Google Drive. On Google Drive your workbooks keep the same functionality and you can access the same files.

This change applies to workbooks, data sources, and bookmarks on Tableau Desktop, and workbooks and data sources on Tableau Server.

## Tableau Desktop

### Move Workbooks to Google Drive

Complete the following instructions to move from Google Sheets to Google Drive.

1. Open your Google Sheets .twb or .twbx file.
2. In Google authentication, select the same account that you originally created the workbook with.
3. On the **Data Source** tab, verify that the Data Connection connects to Google Drive.
4. To finish, Save the workbook.

**Note:** If you get an “edit connection” error, you may have signed into the wrong account for a specific data source. To resolve the error, edit the connection. This may occur if you created a workbook with two or more data sources with users or relationships between files from different users.

### Move Data Sources to Google Drive

Complete the following instructions to move from Google Sheets to Google Drive.

1. Open your Google Sheets .twb or .twbx file.
2. In Google authentication, select the same account that you originally created the data source with.
3. On the **Data Source** tab, verify that the Data Connection connects to Google Drive.
4. Right-click on the data source, and then select **Add to Saved Data Sources**.
5. Save the file with the same name to ensure the update is complete.

**Note:** When you open a .tds or .tdsx file in Tableau Desktop you must go to the Data Source tab to trigger the update.

### Move Bookmarks to Google Drive

Complete the following instructions to move from Google Sheets to Google Drive.

1. Open a .tbm file with a Google Sheets connection.
2. In Google authentication, select the same account that you originally created the bookmark with.

3. On the **Data Source** tab, verify that the Data Connection connects to Google Drive.
4. Save the bookmark. See [Save Your Work](#) for more instructions.

**Note:** When you open a .tbn file there's a "worksheet unavailable" error that disappears after you authenticate and connect as normal.

## Tableau Server

Complete the following instructions to move from Google Sheets to Google Drive.

### Before You Begin

- On the **My Account Settings** page, ensure that all saved Google Sheets credentials are also in Google Drive. This makes it possible to use the same saved credentials later in the republishing process.
- Identify all workbooks that have data sources published separately.

**Note:** The embedded password feature is disabled for Google Drive. You can use embedded <username> instead.

### Move Data Sources to Google Drive

Complete the following instructions to move from Google Sheets to Google Drive.

**Note:** The embedded password feature is disabled for Google Drive. You can use embedded <username> instead.

1. Open Tableau Server and download the Google Sheets data source that you want to move.
2. In Tableau Desktop, open the downloaded file.
3. Go to the **Data Source** tab to trigger the download.
4. In Google authentication, select the same account that you originally created the saved data source with.
5. On the **Data Source** tab, verify that the Data Connection connects to Google Drive.
6. Next republish the file.

7. Under the **Server** menu, select **Publish Data Source**. There will be a warning in red saying that a file with that name exists. Continue publishing with the same name to overwrite the previous file.
8. Under publishing options, select the authentication format you want to use. If you're publishing with saved credentials, make sure to use the user name that you originally created the data source with.
9. Publish the data source.
10. Select **Yes** when it asks if you want to overwrite the data source.

**Note:** If you use "prompt" to log in, when you're redirected to the web page for the data source after publishing, verify the data source is configured correctly before attempting to migrate any workbooks that are connected.

## Workbooks with Data Sources Published Separately

For workbooks with data sources published separately, you must first migrate the separate data source, and then migrate the workbook as a whole.

Complete the following instructions to move from Google Sheets to Google Drive.

**Note:** The embedded password feature is disabled for Google Drive. You can use embedded <username> instead.

1. In Tableau Server download the separate Google Sheets data source that the workbook connects to.
2. In Tableau Desktop, open the downloaded file.
3. Go to the **Data Source** tab to trigger the download.
4. When the Google authentication pop-up occurs, select the same account that you originally created the saved data source with.
5. On the **Data Source** tab, verify that the Data Connection connects to Google Drive.
6. Go to the **Server** tab and select **Publish Data Source**
7. Under the **Server** menu, select **Publish Data Source**. There will be a warning in red saying that a file with that name exists. Continue publishing with the same name to overwrite the previous file.
8. Under publishing options, select the authentication format you want to use. If you're publishing with saved credentials, make sure to use the user name that you originally created the data source with, other wise this authentication method won't work.

9. Publish the data source.
10. Select **Yes** when it asks if you want to overwrite the data source with that name.

**Note:** If you decide to use prompt, when you're redirected to the web page for the data source after publishing, ensure that you verify the data source is configured correctly before attempting to upgrade any workbooks that are connected.

## Move Workbooks to Google Drive

After the data source is published, you'll have to upgrade the workbook.

1. In Tableau Server download the workbook that connects to the separate Google Sheets data source that you just published.
2. Go to Tableau Desktop and open the downloaded file.
3. Go to the **Data Source** tab to trigger the download
4. When the Google authentication pop-up occurs, select the same account that you originally created the saved data source with.
5. Go to the **Server** tab and select **Publish Workbook**
6. There will be a warning in red saying that a file with that name exists. Continue publishing with the same name to overwrite the previous file.
7. Under the publishing options, select **Keep existing connection** and the authentication format you want to use. If you're publishing with saved credentials, make sure to use the user name that you originally created the data source with, other wise this authentication method will not work.
8. Publish the workbook.
9. Select **Yes** when it asks if you want to overwrite the data source with that name.

## Workbooks with Embedded Data Sources

For workbooks with embedded data sources, you only need to upgrade the workbook. Complete the following instructions to move from Google Sheets to Google Drive.

**Note:** The embedded password feature is disabled for Google Drive. You can use embedded <username> instead.

1. In Tableau Server, download the workbook with the Google Sheets connection.
2. Go to Tableau Desktop, and open the downloaded file.
3. Go to the **Data source** tab to trigger the download.

4. When the Google authentication pop up occurs, select the same account that you originally created the saved data source with.
5. Go to the **Server** menu and select **Publish Workbook**.
6. There will be a warning in red saying that a file with that name already exists. Continue publishing with the same name to overwrite the previous file.
7. Under the publishing options, select **Embed Data source** and the authentication format you want to use. If you are publishing with saved credentials, make sure to use the user name that you originally created the data source with, otherwise this authentication method will not work.
8. Publish the workbook.
9. Select **Yes** when it asks if you want to overwrite the data source with that name.

## Hortonworks Hadoop Hive

This article describes how to connect Tableau to a Hortonworks Hadoop Hive database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Authentication method:
  - No Authentication
  - Kerberos
  - User Name
  - User Name and Password
  - Microsoft Azure HDInsight Service (starting in version 10.2.1)
- Transport options depend on the authentication method you choose and can include the following:

- Binary
  - SASL
  - HTTP
- Sign-in credentials depend on the authentication method you choose and can include the following:
    - User name
    - Password
    - Realm
    - Host FQDN
    - Service name
    - HTTP path
  - Are you connecting to an SSL server?
  - (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** Make sure you use the latest available drivers. To get the latest drivers, see [Hortonworks Hadoop Hive](#) on the Tableau Driver Download page.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Hortonworks Hadoop Hive**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of server that hosts the database.
  - b. In the **Authentication** drop-down list, select the authentication method to use.
  - c. Enter the information that you are prompted to provide. The information you are prompted for depends on the authentication method you choose.

- d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

- e. Select **Sign In**.

Select the **Require SSL** option when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

- 2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
- c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** This database type only support equal (=) join operations.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Work with Hadoop Hive data

### Work with date/time data

Tableau supports `TIMESTAMP` and `DATE` types natively. However, if you store date/time data as a string in Hive, be sure to store it in ISO format (`YYYY-MM-DD`). You can create a calculated field that uses the `DATEPARSE` or `DATE` function to convert a string to a date/time format. Use `DATEPARSE()` when working with an extract, otherwise use `DATE()`. For more information, see [Date Functions on page 2200](#).

For more information about Hive data types, see [Dates](#) on the Apache Hive website.

### NULL value returned

A `NULL` value is returned when you open a workbook in Tableau 9.0.1 and later and 8.3.5 and later 8.3.x releases that was created in an earlier version and has date/time data stored as a string in a format that Hive doesn't support. To resolve this issue, change the field type back to **String** and create a calculated field using `DATEPARSE()` or `DATE()` to convert the date. Use `DATEPARSE()` when working with an extract, otherwise use the `DATE()` function.

### High latency limitation

Hive is a batch-oriented system and is not yet capable of answering simple queries with very quick turnaround. This limitation can make it difficult to explore a new data set or experiment with calculated fields. Some of the newer SQL-on-Hadoop technologies (for example, Cloudera's Impala and Hortonworks' Stringer project) are designed to address this limitation.

### Truncated columns in Tableau

The default string column length for Hortonworks Hadoop Hive is 255 characters. For more information about Hortonworks Hive ODBC driver configuration options, and specifically about `DefaultStringLength`, see the [Hive ODBC Driver User Guide](#) from Hortonworks.

### See also

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## IBM DB2

This article describes how to connect Tableau to an IBM DB2 database and set up the data source. You can also use this connector to connect to an IBM DB2 for z/OS database. See the [Technical Specifications](#) to confirm which DB2 databases are supported.

**Note:** Tableau supports all versions of IBM operating system platforms except for the "i" series.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to (Host name) and port number
- Database name
- User name (User ID) and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Port settings

The port number is dependent on the type of server you are connecting to and whether you are connecting to an encrypted port. Generally, use 50000 for a non-encrypted port and 60000 for an encrypted port. It is possible that your server is configured to use a non-standard port. Contact your administrator if you don't know which port to connect to.

### SSL requirements

This connector enables you to connect to your server using SSL authentication. If you work in an SSL environment, your computer is probably already configured to support SSL. If you have trouble making an SSL connection with Tableau, make sure that the following IBM software is installed on your computer:

- IBM Data Server Runtime Client v10.5fp3 or above
- GSK8 SSL Library

**Note:** The IBM Data Server Runtime Client and GSK8 Library must have the same bitness. For example, both must be either 32-bit or 64-bit. For more information, see [Installation of the GSK8 SSL Library](#) on the IBM website.

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **IBM DB2**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database (the Host name), the port number, and the name of the database that you want to connect to.
  - b. Enter your user name (User ID) and password.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.

- d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query](#) on page 811.

**Note:** Tableau doesn't support the DECFLOAT data type.

### See also

- [Set Up Data Sources](#) on page 596 – Add more data to this data source or prepare your data before you analyze it.

[Connecting Tableau to a Db2 database](#) - Review connection instructions on the IBM website.

## IBM PDA (Netezza)

This article describes how to connect Tableau to an IBM PDA (PureData System for Analytics) database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Database name
- User name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **IBM PDA (Netezza)**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter the name of the database that you want to connect to.
  - c. Enter the user name and password.  
  
Select the **Require SSL** option when connecting to an SSL server.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table or use the text box to search for a table by name.
  - c. Drag a table to the canvas, and then select the sheet tab to start your analysis.  
  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Impala

This article describes how to connect Tableau to an Impala database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name and port of the server that hosts the database you want to connect to
- Authentication method:
  - No Authentication
  - Kerberos
  - User Name
  - User Name and Password
- Transport type (Username and Password authentication only):
  - Binary
  - SASL
- Sign-in credentials depend on the authentication method you choose and can include the following:
  - User name
  - Password
  - Realm
  - Host FQDN
  - Service name
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** Make sure you use the latest available drivers. To get the latest drivers, see [Impala](#) on the Tableau Driver Download page.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Impala**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Enter the name of the server that hosts the database and the port number to use. Port 21050 is the default .
- b. In the **Authentication** drop-down list, select the authentication method to use.
- c. Enter the information that you are prompted to provide. The information you are prompted for depends on the authentication method you choose.
- d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- e. Select **Sign In**.

Select the **Require SSL** option when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
  - c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** This database type supports only equal (=) join operations.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Intuit QuickBooks Online

This article describes how to connect Tableau to Intuit QuickBooks Online data and set up the data source.

**Note:** Tableau is working on a replacement connector. After it's complete, it will be added to this page.

**Warning:** The Intuit QuickBooks connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. The deprecated connector will be retired 1-2 releases after the replacement connector is made available.

**Note:** For the most up-to-date information on this connector, see the [Intuit QuickBooks Online](#) help topic for the current version of Tableau.

## Before you begin

Before you begin, gather this connection information:

- Your email address or user ID and password for your Quickbooks Online account.

**Note:** To connect Tableau to QuickBooks Online data, you must be a Company Administrator on the QuickBooks Online company. Only one administrator at your company can connect Tableau to QuickBooks Online.

QuickBooks Online doesn't support retrieving the Inventory Adjustment transactions. For information about when Inventory Adjustment transactions will be available in the QuickBooks Online API, see the responses to this [question](#) on the Intuit Developer website.

## Make the connection and set up a data source

1. Start Tableau and under **Connect**, select **Intuit QuickBooks Online**. For a complete list of data connections, select **More** under **To a Server**. In the tab Tableau opens in your default browser, do the following:

- a. Enter your email address or user ID and password for your QuickBooks Online account.
- b. Select **Sign In**.

QuickBooks Online periodically prompts for two-step verification. If this happens, follow the prompts to get a code to confirm your Intuit account.

- c. If more than one company is associated with your account, select the company you want to connect to.
- d. Select **Authorize** to authorize Intuit to securely share your data with Tableau Desktop.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table and drag it to the top of the canvas.
  - c. Select the Sheet 1 tab to start your analysis.

After you select the sheet tab, Tableau imports the data by creating an extract. Note that Tableau Desktop supports only extracts for QuickBooks Online. You can

update the data by refreshing the extract. For more information, see [Extract Your Data](#) on page 867.

Creating extracts may take some time depending on the amount of data that is included.

### Use the Sales and Expenses Line Items table to create accounting reports

QuickBooks Online aggregates the information needed to create a variety of reports, such as profit and loss (P&L) statements and balance sheets. Because the data is aggregated by QuickBooks Online, you can't create these kinds of reports in Tableau. To remedy this, we've added a table in Tableau, Sales and Expenses Line Items, that includes line item details with all the fields you need to create these reports.

### Sales and Expenses Line Items table structure

The Sales and Expenses Line Items table contains information for the following QuickBooks Online transactions (or documents):

Bill	Estimate	Purchase Order
Bill Payment	Invoice	Refund Receipt
Credit Memo	Journal Entry	Sales Receipt
Deposit	Payment	Vendor Credit
	Purchase	

Most of the transactions have children (or sub-items), for example, an invoice has detail items. Like this example:

Tableau Desktop and Web Authoring Help

#	SERVICE DATE	PRODUCT/SERVICE	DESCRIPTION	QTY	RATE	AMOUNT (USD)	TAX	CLASS	
1	10/29/2007	Gardening	Weekly gardening services	1	110	110.00		Landscaping	
2	11/05/2007	Gardening	Weekly gardening services plus pest control spraying	1	135	135.00		Landscaping	
3	11/12/2007	Gardening	Weekly gardening services	1	110	110.00		Landscaping	
4	11/12/2007	Plants/Trees:Misc Plants & Flow	Replaced dead flowers on side of school yard with assorted color	1	90	90.00		Landscaping	
5	11/19/2007	Gardening	Weekly gardening services	1	110	110.00		Landscaping	
6	11/26/2007	Gardening	Weekly gardening services	1	110	110.00		Landscaping	
7									
								<b>Subtotal</b>	<b>665.00</b>

Some transactions have group items, which consist of a group of other line items. Like this example:

#	SERVICE DATE	PRODUCT/SERVICE	DESCRIPTION	QTY	RATE	AMOUNT (USD)	TAX	CLASS	
<b>Line Item</b> 1		Installation	Installation of landscape design	32	35	1,120.00		Landscaping	
<b>Group Line Item</b> 2		Rock Fountain	Custom rock fountain Your customer will see all items in this bundle	1	675	675.00			
<b>Children</b>		Fountain	Rock Fountain	1	375		✓	Landscaping	
		Pump	Fountain pump	1	75		✓	Landscaping	
		Concrete	Concrete for fountain installation	1	15		✓	Landscaping	
		Installation	Installation of landscape design	6	35			Landscaping	
3									
								<b>Subtotal</b>	<b>1,795.00</b>

The **Sales and Expenses Line Items** table denormalizes the "transaction to items" relationship by including one row per item and duplicating the transaction fields on each row. In the case of a group line item with children, the table includes the group child items instead of the group.

The following image shows how these two invoices appear in Tableau with the denormalized data:

Sheet 1

Doc Number	Line ID	Line Detail Type	Line Description	Line Amount	Txn Tax Detail T..	Total Amt
118	1	SalesItemLineDetail	Weekly gardening services	110.00	0.00	665.00
	2	SalesItemLineDetail	Weekly gardening service..	135.00	0.00	665.00
	3	SalesItemLineDetail	Weekly gardening services	110.00	0.00	665.00
	4	SalesItemLineDetail	Replaced dead flowers on ..	90.00	0.00	665.00
	5	SalesItemLineDetail	Weekly gardening services	110.00	0.00	665.00
	6	SalesItemLineDetail	Weekly gardening services	110.00	0.00	665.00
	SubTotalLineDetail	SubTotalLineDetail	Null	665.00	0.00	665.00
130	1	SalesItemLineDetail	Installation of landscape ..	1,120.00	38.37	1,833.37
	3	SalesItemLineDetail	Rock Fountain	375.00	38.37	1,833.37
	4	SalesItemLineDetail	Fountain pump	75.00	38.37	1,833.37
	5	SalesItemLineDetail	Concrete for fountain inst..	15.00	38.37	1,833.37
	6	SalesItemLineDetail	Installation of landscape ..	210.00	38.37	1,833.37
	SubTotalLineDetail	SubTotalLineDetail	Null	1,795.00	38.37	1,833.37

In addition to the transactions tables, the **Sales and Expenses Line Items** table contains information for the **Account** table.

Join tables with the Sales and Expenses Line Items table

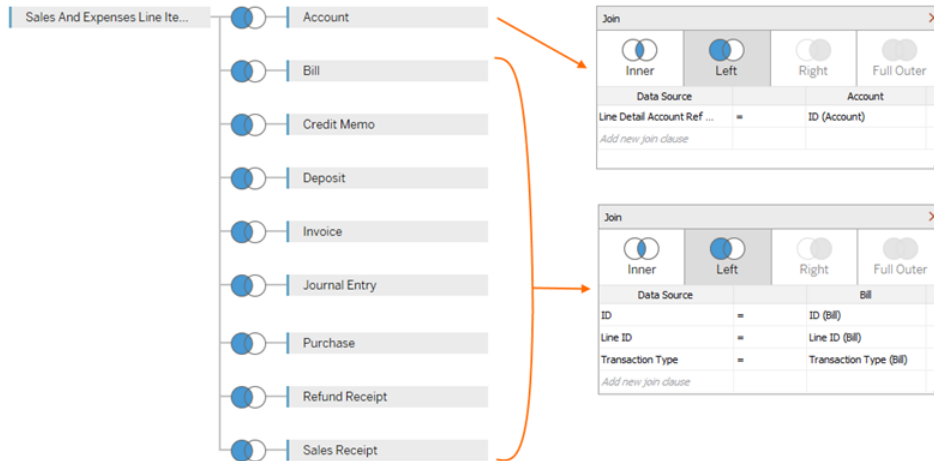

Using the **Sales and Expenses Line Items** table, you can join the **Account** and transactions tables with it to get the detailed information you need for the report you want to create.

To join the **Account** table with each line in a transaction, join [Line Detail Account Ref Value] in the **Sales and Expenses Line Items** table to [ID Account] in the **Account** table.

For the QuickBooks Online transactions tables (for example, **Bill**, **Estimate**, **Purchase Order** and so on), join [Transaction Type] + [ID] + [Line ID] in the **Sales and Expenses Line Items** table to the equivalent fields in the transactions table. For example, if you create a join with the **Bill** transactions table, the [ID] field to join on for Bill is [(ID) Bill]; the [Line ID] field to join on for Bill is [Line ID (Bill)], and so on.

The following image shows multiple joins with the **Sales and Expenses Line Items** table on the left, as well as examples of the join clauses for the **Account** table and the **Bill** table on the right.

## Tableau Desktop and Web Authoring Help

### Create the QuickBooks Online data source

These are the general steps to get you started with making a data source that you can use to create various reports, such as P&L reports:

1. Connect to QuickBooks Online.
2. On the **Data Source** page, under **Table**, select the **Sales And Expenses Line Items** table.
3. Join one or more of the tables listed in [Sales and Expenses Line Items table structure on page 380](#) to the **Sales And Expenses Line Items** table to include the data you need for the report you want to create.
4. After you create your data source, you can build your statements and analyze your data.

### Troubleshoot QuickBooks Online errors

You might see one of the following errors when you try to connect Tableau to your QuickBooks Online data.

### Workbooks saved in previous versions of Tableau

Workbooks and data sources created prior to version 2018.2 of Tableau will not be able to access tables or fields added in later versions of the connector. To resolve this, open a new workbook and create a new connection to your QuickBooks Online data source. Copy and paste the worksheets you want to keep from the previous connection, or recreate them in Tableau.

### Sorry, only administrators can buy apps...

QuickBooks Online requires that each user who connects an app to QuickBooks Online be a Company Administrator. The following Intuit error appears if you are not an administrator on the

company account:

Sorry, only administrators of <email address>'s Company can buy apps in the company.  
Please contact administrator in the company or else choose another company.

To resolve this issue, ask your company account owner to make you a Company Administrator on the account.

### Error Code: app\_already\_purchased

Only one Company Administrator is allowed to connect per application, for example to Tableau Desktop. If someone in your company has already connected Tableau to your QuickBooks Online account, the following Intuit error appears:

Oops! An error has occurred. Please close this window and try again.

Error Code: app\_already\_purchased

Message: The application has already been subscribed to by another user for this company. Please contact <email address> to make changes to this subscription.

To resolve this issue, you need to ask that Company Administrator to give up the application privileges for Tableau Desktop and provide them to you. If that's not possible, for example, because the administrator actively uses Tableau, another option is for the administrator to publish the data source to Tableau Server or Tableau Cloud, so that anyone with permission can access the data.

### Changing a Connection Opens the My Apps Page

If you need to access another QuickBooks Online company, after you sign in (and possibly go through the two-step authentication process), Intuit might show the My Apps page, rather than the "select the company to connect to" page. To resolve this issue, follow these steps:

1. Close the My Apps page.
2. On the Tableau **Connect** pane, select Intuit QuickBooks Online.
3. If more than one company is associated with your account, select the company you would like to connect to.
4. Select **Authorize** to open the Tableau data source page.

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Kognitio

This article describes how to connect Tableau to a Kognitio database and set up the data source.

**Warning:** The Kognitio connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. Typically, a deprecated connector will be retired 1–2 releases after it is deprecated.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Kognitio**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database you want to connect to.
  - b. Enter the user name and password.

- c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

- d. Select **Sign In**.

Select the **Require SSL** check box when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

- 2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
- c. Under **Table**, select a table or use the text box to search for a table by name.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

## Kyvos

This topic describes how to connect Tableau to a Kyvos database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Port number
- HTTP path to the server
- User name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Kyvos**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the **Server** name.
  - b. Enter the **Port** number.
  - c. Enter the **HTTP Path** to the data.
  - d. Enter the **Username** and **Password**
  - e. Select the **Require SSL** check box when connecting to an SSL server.
  - f. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - g. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Schema**, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## LinkedIn Sales Navigator

This topic describes how to connect Tableau to a LinkedIn Sales Navigator database and set up the data source.

**Note:** Tableau is working on a replacement connector. After it's complete, it will be added to this page.

**Warning:** The LinkedIn Sales Navigator connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the Connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as

expected. The deprecated connector will be retired 1-2 releases after the replacement connector is made available.

**Note:** For the most up-to-date information on this connector, see the [LinkedIn Sales Navigator](#) help topic for the current version of Tableau.

## Before you begin

Before you begin, get the email address or phone number, and password for the LinkedIn Sales Navigator account.

You need a Sales Navigator Enterprise plan and Sales Navigator administrator or reporting permissions. Note that a reporting user doesn't take up a Sales Navigator seat on the contract.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **LinkedIn Sales Navigator**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Select **Sign In** to authenticate to LinkedIn in your default browser.
  - b. Enter your email or phone number and your password for the LinkedIn Sales Navigator account.
  - c. Select **Sign in**.
  - d. Close the browser window when notified to do so.
  - e. In the LinkedIn Sales Navigator Connection dialog box, select the following:
    - **Contracts** : Custom or all
    - **Date Range**: Relative or fixed
  - f. Select **Connect**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble accessing LinkedIn. Contact your network or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select a standard connection or create your own custom connection.

Under **Standard Connection**, you can select from a list of predefined selections of tables and joins that represent common scenarios and use cases. Or under **Table**, you can select a table or search for a table by name.

- c. Drag the standard connection or table to the canvas, and then select the sheet tab to start your analysis.

## Use Accelerators

You can use an Accelerator to quickly build informative dashboard designs made specifically for key business metrics on Tableau Desktop and Tableau Cloud. For more information, see [Use Accelerators to Quickly Visualize Data](#) on page 2651.

## Date range selections can impact performance

It's tempting to gather as much data as possible when you run an analysis. Tableau doesn't know how much data there is in a particular date range until it retrieves the data. For this reason, you should restrict your date range at first, and then expand after you evaluate performance.

## Refresh LinkedIn Sales Navigator data

After you click the sheet tab, Tableau imports the data by creating an extract. Tableau Desktop supports only extracts for LinkedIn Sales Navigator. Note that the initial extract may take some time.

To refresh, select Data > [data source name] > Extract > Refresh.

## MariaDB

This article describes how to connect Tableau to a MariaDB database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau

displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **MariaDB**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database that you want to connect to.
  - b. Enter the user name and password, and then select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Database** drop-down list, select a database.
  - c. Under **Table**, select a table or use the search field to search for a table by name.
  - d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

### Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Marketo

This article describes how to connect Tableau to Marketo data and set up the data source.

**Note:** Tableau is working on a replacement connector. After it's complete, it will be added to this page.

**Warning:** The Marketo connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the Connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. The deprecated connector will be retired 1-2 releases after the replacement connector is made available.

### Before you begin

Before you begin, gather this connection information:

- Custom Service Endpoint
- Client ID
- Client Secret

For details about how to create the custom service information you need from Marketo to connect, see the [Custom Service](#) topic on the Marketo website.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Marketo**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter your Custom Service Endpoint, Client ID, and Client Secret.
  - b. Select **Sign In**.
  - c. Select **Filter Type: Relative date range** or **Fixed date range**, and then select or specify the range.
  - d. Select **Connect** to authorize Marketo to securely share your data with Tableau Desktop.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network or Marketo administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table and drag it to the top of the canvas.
  - c. Select the sheet tab to start your analysis.

After you select the sheet tab, Tableau imports the data by creating an extract. Note that Tableau Desktop supports only extracts for Marketo. You can update the data by refreshing the extract. For more information, see [Extract Your Data on page 867](#).

Creating extracts may take some time depending on the amount of data that is included.

### Bulk API retrieves data for some tables

Tableau uses the bulk API to retrieve data for the **All Activities**, **Leads**, and **Leads by List - <list name>** tables, thereby reducing the number of API calls. For more information, see the [Bulk Extract](#) documentation on the Marketo website.

You can use the Daily API Usage and Weekly API Usage tables to monitor your API usage.

### Use Accelerators

You can use an Accelerator to quickly build informative dashboard designs made specifically for key business metrics on Tableau Desktop and Tableau Cloud. For more information, see [Use Accelerators to Quickly Visualize Data on page 2651](#).

### Date range selections can impact performance

It's tempting to gather as much data as possible when you do an analysis, however, retrieving records from Marketo can be time-consuming. Tableau doesn't know how much data there is in a particular date range until it retrieves the data. For this reason, you should restrict your date range at first, and then expand after you evaluate performance.

To give you a rough idea of how much time it might take to retrieve data from Marketo, tests were conducted using a high-speed connection. This table shows how long it took in the test environment to retrieve a given number of records.

Number of records	Time to retrieve
1,000	4.5 seconds
10,000	45 seconds
100,000	8 minutes
1,000,000	75 minutes

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## MarkLogic

This article describes how to connect Tableau to a MarkLogic database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Port number for the ODBC server process
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **MarkLogic**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database you want to connect to.
  - b. Enter the port number for the ODBC server process of the database you want to connect to.
  - c. Enter your user name and password.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.

If the connection is unsuccessful, verify that your user name and password are correct and that the port number correctly identifies the MarkLogic database configured by your database administrator. If the connection continues to fail, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.  
  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Microsoft Analysis Services

This topic describes how to connect Tableau to a Microsoft Analysis Services database and set up a data source.

### Before you begin

Before you begin, gather this connection information:

- For a remote cube file: Server name, or URL if connecting to the server using HTTP
- For a local cube file: File name
- Authentication method: Windows Authentication or user name and password

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Microsoft Analysis Services**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Select whether to connect to a remote cube file on a server or to a local cube file.

To connect to a remote cube file, select **Server** and enter the name of the server in the text box. If you are connecting to the server using HTTP, you can enter the URL as the server name.

To connect to a local cube file, select **Local cube file** and select **Browse** to navigate to the cube file on your computer.
  - b. Select how you want to sign in to the server. Specify whether to use Windows Authentication or a specific user name and password. If the cube is password protected, and you are not in a Kerberos environment, you must enter your user name and password.

Specify whether to use Windows Authentication or a specific user name and password.

- c. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

- 2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select a database.
  - c. Select a cube from the database.
  - d. Select the sheet tab to start your analysis.

### Incompatible Measures and Dimensions

When you build views in Tableau using a Microsoft Analysis Services Cube you might see some fields highlighted in gray, or you might see a caution symbol on a field in the view with the message, "This measure is incompatible with one or more dimensions in this view." This occurs because it is possible to have measures and dimensions that don't make a lot of sense when placed in the view together. For example, you may have a measure for Sales Quota. It won't make sense to place that measure against a dimension containing products if products don't have sales quotas.

Tableau helps you figure out the dimensions and measure that can be used together in meaningful ways by highlighting unrelated dimensions and measures in gray. So in the last example, when we place Sales Quota onto a shelf, the products dimensions are highlighted in gray. Highlighted dimensions are not disabled and can still be added to the view. When you add an incompatible measure to the view, the measure is marked with a caution symbol. For more information on working with cubes, see [Cube Data Sources](#) on page 929.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Microsoft SQL Server

This article describes how to connect Tableau to a Microsoft SQL Server database and set up the data source.

**Note:** Use the Microsoft SQL Server connector to connect to Microsoft SQL Server Parallel Data Warehouse (PDW), Microsoft Azure Synapse Analytics (formerly Azure SQL Data Warehouse), or Microsoft Azure SQL Database.

## Before you begin

Before you begin, gather this connection information:

- Name of the server you want to connect to
- (Optional) Port number if you want to connect to a non-default port
- (Optional) Database name if you want to connect to a contained database
- Authentication method: Windows Authentication or user name and password
- Are you connecting to an SSL server?
- Do you want to set the database isolation level to read uncommitted data?
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Microsoft SQL Server**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server you want to connect to.

To connect to a non-default port, use the `<server name>, <port number>` format when entering the server name. For example, `ExampleServer, 8055`.
  - b. (Optional) Enter a database name if you want to connect to a contained database.
  - c. Select how you want to sign in to the server. Specify whether to use Windows Authentication or a specific user name and password. If the server is password protected, and you are not in a Kerberos environment, you must enter the user name and password.

Select the **Require SSL** check box when connecting to an SSL server.
  - d. Specify whether to **Read uncommitted data**. This option lets Tableau running at the read-uncommitted isolation level. Long queries from other transactions, including extract refreshes, can lock the database and delay Tableau's transactions. Select this option to allow queries to read rows that have been modified by other transactions even when they have not been committed yet. When this option is cleared, Tableau uses the default isolation level specified by the database.
  - e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - f. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

- b. From the **Database** drop-down list, select a database or use the text box to search for a database by name.

- c. Under **Table**, select a table or use the text box to search for a table by name.

You can also specify a stored procedure in the database. For more information about stored procedures, including a list of constraints specific to SQL Server databases, see [Use a Stored Procedure on page 826](#).

Starting with Tableau version 2018.1, you can connect to spatial columns. For more information, see [Connect to Spatial Data in a Database on page 1637](#).

- d. Drag the table or stored procedure to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

Starting with Tableau version 2018.1, you can use Custom SQL to perform advanced spatial analysis on spatial columns in Microsoft SQL Server. For more information, see [Use Custom SQL and RAWSQL to perform advanced spatial analysis on page 1638](#).

**Note:** Tableau Desktop does not support the Microsoft SQL Server TIME data type. Fields of this data type are not imported and do not appear in Tableau Desktop. If included in stored procedures, TIME data type fields will not appear in Tableau Desktop. For more information, see [Use a Stored Procedure on page 826](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Resolve "Worksheet Unavailable" error message

When you open a workbook, you may see a "Worksheet Unavailable" error message and then, when you select **Edit Connection**, you are prompted to provide your sign-in credentials. This error typically displays under one of two circumstances:

- You don't have access to a data connection used in the workbook.
- Your credentials are invalid, for example, your password has expired.

To resolve, verify that your sign-in credentials are correct. If they are, contact the Tableau administrator to ask about access to the data connection.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.

## MonetDB

This article describes how to connect Tableau to a MonetDB database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Database name
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **MonetDB**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the name of the database that you want to connect to.
  - b. Enter the user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select a schema.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## MongoDB BI Connector

This article describes how to connect Tableau to MongoDB Business Intelligence (BI) data and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password, if MongoDB authentication is enabled
- Database name associated with the user's credentials, if MongoDB authentication is enabled
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

You must install and run the MongoDB Connector for BI, version 2.1 or later, before you can connect Tableau to your MongoDB BI data.

To get the MongoDB Connector for BI, sign in to the MongoDB website and [download the connector](#). Follow the [Installation](#) instructions on the MongoDB website.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **MongoDB BI Connector**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server.
  - b. If MongoDB authentication is enabled, enter your user name with associated database name, and password. For information about the correct format to use, see [Sign in options on the next page](#). If MongoDB authentication isn't enabled, proceed to step c.

Select the **Require SSL** check box when connecting to an SSL server. For more information about connecting with SSL to MongoDB, see [Connecting Tableau to MongoDB](#) on the MongoDB website.

- c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

- d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Select the sheet tab to start your analysis.

### Sign in options

User accounts in MongoDB are associated with specific logical databases in MongoDB. So when users log into MongoDB, they need to specify the database name associated with the user's credentials. This is done by passing special options in the username string. For example, if user `henrywilson` is associated with the `example` database, he enters the following in the **Username** field.

```
henrywilson?source=example
```

You can use the `mechanism` option to define the authentication mechanism if you want to use a mechanism other than the default, SCRAM-SHA-1. For example, if user `henrywilson` wants to connect to the `example` database using challenge/response as the authentication mechanism, he enters the following in the **Username** field:

```
henrywilson?source=example,mechanism=MONGODB-CR
```

For more information about authentication options, see the [MongoDB](#) website.

## MySQL

This article describes how to connect Tableau to a MySQL database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

**Note:** For information about requirements and considerations when connecting to data using Prep Builder, see [Connect to Data](#) in the Tableau Prep Help.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **MySQL**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter the user name and password.  
Select the **Require SSL** option when connecting to an SSL server.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in

to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

- d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Database** drop-down list, select a database or use the text box to search for a database by name.
- c. Under **Table**, select a table or use the text box to search for a table by name.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## OData

This article describes how to connect Tableau to an OData data source. Tableau connects to OData V1, V2, and V4.

### Before you begin

Before you begin, gather this connection information:

- Server URL for the data you want to connect to
- Sign-in credentials (user name and password), if necessary

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **OData**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. In **Server**, type one of the following:
    - A service URL to access all feeds inside the service.
    - A feed URL to access a specific data feed.
  - b. From the **Authentication** dropdown, select the authentication mode for this connection.
    - If you select **Username and Password**, also type a username and password.
    - Otherwise, select **No Authentication**.
  - c. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

**Note:** If you publish the data source to Tableau Server or Tableau Cloud, the data source name is limited to 255 characters. Longer names cause a `RepositoryException` error.

- b. Select the sheet tab to start your analysis.

After you select the sheet tab, Tableau imports the data by creating an extract. For more information about extracts, see [Extract Your Data on page 867](#).

**Note:** Tableau Desktop only supports extracts for OData.

## OData connector support

- The OData connector supports only extracts, which means that some OData V4 functionality isn't supported. For example, interactive query arguments such as `$expand` or `$select`.
- Tableau supports these OData versions and formats:
  - OData V1 and V2 – We support OData XML/Atom format for feed responses.
  - OData V4 and V4.01 – We support OData-JSON format for feed responses.
- Tableau assumes metadata documents for all supported OData services are in XML format.
- Collection-valued properties aren't supported, Tableau interprets them as nulls.

**Note:** Tableau can't guarantee that using a third-party OData service, such as Intellex, or using a feed will result in successfully connecting and extracting data. Tableau customer support gives a basic level of troubleshooting for third-party OData connections. Tableau customer support doesn't have access to Apache Olingo library. Contact your system administrator for in-depth OData troubleshooting.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## OneDrive and SharePoint Online

This article describes how to connect Tableau to OneDrive, SharePoint Online document library data, and set up the data source.

### Before you begin

Before you begin, complete the following tasks:

1. Get the email address and password for your Microsoft account.
2. Add Delegated Permission for Microsoft Graph API to Azure AD.
3. Grant Tableau consent to use the following Application Programming Interface (API). permissions to access files in OneDrive and your Sharepoint Online document libraries:
  - Files.Read.All
  - Sites.Read.All
  - User.Read
  - Offline\_access

**Note:** The OneDrive and Sharepoint Online connector doesn't support tenant-specific connections. The application connection will need to be configured for multi-tenant on the Microsoft side.

### Recommendation

#### Set up a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau release cycles and Tableau's OAuth client rotation schedule. For information on how to configure your own OAuth client see, [Configure Custom OAuth for a site](#).

#### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **OneDrive** and **SharePoint Online**. In the tab Tableau opens in your default browser, do the following:
  - a. Enter your email address and then select **Next**.
  - b. Enter your password and then select **Sign In**.
  - c. Select **Yes** to grant Tableau access to your OneDrive files and SharePoint Online document library files.
  - d. Close the browser pane when notified to do so.
  - e. Search for or select the file to connect to, and then select **Connect**. The file can be from one of three categories:
    - OneDrive (personal files): files owned by you
    - OneDrive (shared with you): files shared with you by another owner
    - SharePoint Sites: files in SharePoint Online document libraries that you have access to

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. To start your analysis, select the sheet tab.

**Note:** Tableau doesn't support pivot tables in OneDrive or SharePoint Online document libraries.

## Use Data Interpreter to clean your data

If Tableau detects that it can help optimize your data source for analysis, it prompts you to use Data Interpreter. Data Interpreter can detect subtables you can use and remove unique formatting that can cause problems later on in your analysis. For information on data cleaning, see [Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter](#).

## Troubleshoot OneDrive and SharePoint Online

### Connections to multiple accounts

When using web authoring or publishing to the web, you can't use multiple OneDrive accounts in the same workbook. You can have multiple account connections in Desktop.

### Web authoring with Internet Explorer 11 and Edge

In Internet Explorer 11 and Edge, you can't access a server using an unsecured connection (http). Use a secure connection (https) or switch to another browser.

### Error messages

#### "OneDrive and SharePoint Online could not find the file you requested"

If you replace a file in SharePoint Online, you may encounter an error. This error occurs because each file in SharePoint Online has a unique ID, and when you replace a file, the unique ID changes, resulting in the display of an error message.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Oracle

This article describes how to connect Tableau to an Oracle database and set up the data source.

**Note:** Beginning with Tableau 2020.2, if you want to publish a data source or workbook using `net_service_names` to Tableau Server, be sure to review the changes described in the Knowledge Base article, [Setting an Oracle Connection to Use TNSNames.ora or LDAP.ora](#).

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to and the Oracle service name and port, or the TNS name
- Authentication method: Integrated Authentication or user name and password
- Are you connecting to an SSL server? You must configure the Oracle client before you can use SSL with Tableau.

If you are using version 2020.2 or later, see [Require SSL for Oracle JDBC Connections](#).

- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### JDBC driver versus OCI driver

Beginning with version 2020.2, Tableau recommends that you use the JDBC driver (available from the [Driver Download](#) page) with this connector. The newer JDBC driver resolves some limitations found with the OCI driver, such as no spatial support or Kerberos delegation on Linux.

**Note:** If you experience issues using the JDBC driver for this connector, an OCI driver is still available and can be used instead. See the [Driver Download](#) page for instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Oracle**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Enter the server name or the TNS name.
  - If you enter the server name, you must enter the Oracle service name and port number.

**Note:** To find the correct service name, open the tnsnames.ora file (in the ORACLE\_HOME/network/admin directory by default) and search for the **net\_service\_name** section. Use the value listed for **service\_name**.

- If you enter the TNS name, do **not** enter the Oracle service name and port number.
- b. Select how you want to sign in to the server. Specify whether to use Integrated Authentication or a specific user name and password.

Select the **Require SSL** check box when connecting to an SSL server.

- c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema. **Note:** Search is case-sensitive.

- c. Under **Table**, select the search icon or enter the table name and select the search icon, and then select the table.

**Note:** Search is case-sensitive.

Tableau Desktop also supports connecting to Oracle table functions, which appear under **Stored Procedures** in the left pane of the Data Source page.

Starting with Tableau version 2020.2, you can connect to spatial columns. For more information, see [Connect to Spatial Data in a Database on page 1637](#).

- d. Drag a table to the canvas, and then select the sheet tab to start your analysis.  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Use net services definitions in Tableau

To use your net services definitions in Tableau, you must set either `TNS_ADMIN` or `ORACLE_HOME` as an environment variable. To set `TNS_ADMIN` as the environment variable use the full path of the directory that contains the `tnsnames.ora` file. To set `ORACLE_HOME` as an environment variable use the path to the main Oracle directory.

## Migrate workbook from Oracle OCI connector to Oracle JDBC connector

If you create a workbook using the Oracle OCI connector with SSL and later try to open it using the JDBC-based Oracle connector, Tableau won't be able to find the corresponding SSL certificate.

## To migrate a workbook

1. Convert the certificate from PKCS12 format (used by Oracle Wallet) to JKS format. Use this command:

```
keytool -importkeystore -srckeystore PFX_P12_FILE_NAME -srcstoretype pkcs12 -  
srcstorepass PFX_P12_FILE -srcalias SOURCE_ALIAS -destkeystore KEYSTORE_  
FILE -deststoretype jks -deststorepass PASSWORD -destalias ALIAS_NAME
```

2. Modify oracle.properties to customize this connection as follows:

```
javax.net.ssl.trustStore = <new jks file path>  
javax.net.ssl.trustStoreType = JKS  
javax.net.ssl.trustStorePassword = <new jks file password>
```

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.
- [Tableau and JDBC](#) - Find tips for using and troubleshooting JDBC drivers with Tableau.
- [Require SSL for Oracle JDBC Connections](#) - Add trusted SSL certificates to your Oracle JDBC connection.
- [Troubleshooting Oracle Connection Errors](#) - Review the Tableau Knowledge Base article about how to troubleshoot errors.

## Oracle JDBC Connections with SSL

If you are connecting to an SSL (security socket layer) server, check the **Require SSL** check box.

Beginning in 2020.2, Oracle uses a JDBC connector. If your Oracle data source is configured to use SSL one-way or two-way authentication, you can include the appropriate certificates and/or key to connect.

### Require SSL

If your connection requires SSL, do the following:

1. From the connector dialog, click **Require SSL**.

2. Configure SSL as appropriate for your connection:
  - If you are using self-signed certificates or a certificate from signed by a private CA, you may need to configure trust for one-way SSL connections. [See Configure one-way SSL for Oracle.](#)
  - If you are using two way SSL, you will need to configure your client keys. See [Configure two-way SSL.](#)

### Configure one-way SSL for Oracle

To configure trust for your server certificate, see general instructions for JDBC connectors here: [Configure One-Way SSL for JDBC Connections.](#)

If you decide to use properties files to configure trust, then use the following properties for the Oracle JDBC driver.

```
javax.net.ssl.trustStore=C:\My_Folder\truststore.jks  
javax.net.ssl.trustStoreType=JKS  
javax.net.ssl.trustStorePassword=password
```

**Note:** To publish a workbook to Tableau Server, both the Tableau Desktop and Tableau Server computers must have copies of the same Oracle properties file and truststore.jks file.

## Configure two-way SSL

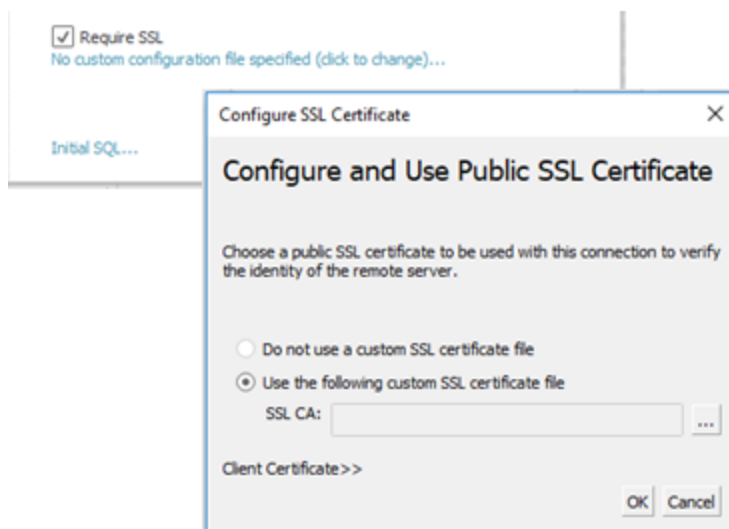

There are two options for configuring two-way SSL support with an Oracle connection:

- [Embed client certificates and private key in the data source](#)
- [Use a properties file to configure the client certificate and private key](#)

### Option 1: Embed client certificates and private key in the data source

To embed an SSL certificate, client certificate, and client key:

1. Follow the steps in [Configure one-way SSL for Oracle](#) on the previous page to configure server trust, if necessary.
2. Click **Client Certificate >>**.

3. Specify the locations for the client certificate and client key.  
The certificate and private key should be in unencrypted PEM format. See instructions

later in this document for suggestions on converting to the correct format.

## Option 2: Use a properties file to configure the client certificate and private key

To use a properties file for certificate and key configuration:

1. Modify the oracle.properties file to reflect the key store and trust store settings. Use the following as an example. Be sure to replace "My\_Folder" for the location of your files and "<password>" with your own password. Paths on OSX and Linux need only a single "/" to separate.

```
javax.net.ssl.trustStore=C:\\My_Folder\\truststore.jks
javax.net.ssl.trustStoreType=JKS
javax.net.ssl.trustStorePassword=<password>
javax.net.ssl.keyStore=C:\\My_Folder\\keystore.jks
javax.net.ssl.keyStoreType=JKS
javax.net.ssl.keyStorePassword=password
```

2. Save oracle.properties to the <Document>\MyTableau Respository\Datasources folder.
3. Copy oracle.properties, truststore.jks, and keystore.jks to the Tableau Server computer. This allows the workbook to be published to the Tableau Server.

If you use this method, you don't need to upload certificates and key via the SSL dialog. Instead, simply click **Require SSL**. This causes the Oracle JDBC connector to read the locations of the key store and trust store from oracle.properties file.

## Publish a workbook

To publish a workbook to Tableau Server, be sure the following are true:

- If you use a properties file, both the Tableau Desktop and Tableau Server computers have copies of the same Oracle properties file, truststore.jks, and keystore.jks.
- The server uses the same Oracle JDBC connector as the Tableau Desktop computer.
- If you used the **embedding** option, select “embed password” option when you publish.

### Convert key formats

There are several formats for storing SSL keys, including:

- Oracle Wallet
- JKS - Use this format if you want to configure SSL trust using properties files.
- PEM - Use this format if you want to embed the keys in the data source using Tableau interface.

The following are some suggested commands you can type at the command-line prompt to convert keys to the correct format. See the Oracle documentation for the more details.

To export server certificate from an Oracle wallet to PEM file:

```
orapki wallet export -wallet wallet_location -dn certificate_dn -cert output_certificate_
filename.pem
```

To export server certificate and client keys from Oracle wallet to JKS:

```
orapki wallet pkcs12_to_jks -wallet ./ -pwd mypasswd -jksKeyStoreLoc ./ewalletK.jks -
jksKeyStorepwd password -jksTrustStoreLoc ./ewalletT.jks -jksTrustStorepwd password
```

To export server certificate from JKS trust store to PEM file using keytool and OpenSSL:

1. Export JKS format to PKCS12 format:

```
keytool -importkeystore -srckeystore truststore.jks -destkeystore truststore.p12 -
srcstoretype JKS -deststoretype PKCS12 -srcstorepass "password" -deststorepass
"password"
```

2. Get the PEM file from PKCS12:

```
openssl pkcs12 -in truststore.p12 -out serverca.pem
```

To export server certificate and client keys from JKS trust store to PEM file using keytool and OpenSSL:

1. Export the certificate from the trust store as follows.
  - a. Export JKS format to PKCS12 format:  

```
keytool -importkeystore -srckeystore truststore.jks -destkeystore truststore.p12 -srcstoretype JKS -deststoretype PKCS12 -srcstorepass "password" -deststorepass "password"
```
  - b. Get the PEM file from PKCS12:  

```
openssl pkcs12 -in truststore.p12 -out serverca.pem
```
2. Export the client key and client certificate from the key store as follows.
  - a. Use keytool to transform JKS format to PCKS12 format:  

```
keytool.exe -importkeystore -srckeystore keystore.jks -destkeystore keystore.p12 -srcstoretype JKS -deststoretype PKCS12 -srcstorepass "password" -deststorepass "password"
```
  - b. Use OpenSSL to export the client certificate:  

```
openssl pkcs12 -in keystore.p12 -nokeys -out clientcert.pem
```
  - c. Use OpenSSL to export the client key:  

```
openssl pkcs12 -in keystore.p12 -nocerts -out clientkeyEncrypted.pem
```
  - d. Use OpenSSL to transform the encrypted version to PKCS8 format:  

```
openssl pkcs8 -topk8 -nocrypt -in clientkeyEncrypted.pem -out clientkey.pem
```

## Oracle Eloqua

This topic describes how to connect Tableau to Oracle Eloqua data and set up the data source. It also describes how date range selections can impact performance.

**Note:** Tableau is working on a replacement connector. After it's complete, it will be added to this page.

**Warning:** The Oracle Eloqua connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the Connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. The

deprecated connector will be retired 1-2 releases after the replacement connector is made available.

**Note:** For the most up-to-date information on this connector, see the [Oracle Eloqua help topic](#) for the current version of Tableau.

## Before you begin

Before you begin, gather and confirm this information for connecting:

- You must be a member of the following Eloqua security groups:
  - Advanced Users - Marketing
  - API Users
- Company Name
- Username
- Password

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Oracle Eloqua**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter **Company Name**, **Username**, and **Password**, and then select **Sign In**.
  - b. Select **Filter Type: Relative date range** or **Fixed date range**, and then select or specify the range.
  - c. Select **Connect**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network or Eloqua administrator.

After your credentials are verified, the Eloqua connector will only prompt you to authenticate when necessary. The **Sign Out** option will start the

authentication process again.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table and drag it to the top of the canvas.
  - c. Select the sheet tab to start your analysis.

After you select the sheet tab, Tableau imports the data by creating an extract. Note that Tableau Desktop supports only extracts for Eloqua. You can update the data by refreshing the extract. For more information, see [Extract Your Data on page 867](#).

Creating extracts may take some time depending on the amount of data that is included.

## Use Accelerators

You can use an Accelerator to quickly build informative dashboard designs made specifically for key business metrics on Tableau Desktop and Tableau Cloud. For more information, see [Use Accelerators to Quickly Visualize Data on page 2651](#).

## Date range selections can impact performance

It's tempting to gather as much data as possible when you do an analysis, however, retrieving records from Eloqua can be time-consuming. Tableau doesn't know how much data there is in a particular date range until it retrieves the data. For this reason, you should restrict your date range at first, and then expand after you evaluate performance. You can modify the date range on the Data Source page. Under **Connections**, select the drop-down arrow for the connection and select **Edit connection**.

To give you a rough idea of how much time it might take to retrieve data from Eloqua, tests were conducted using a high-speed connection. This table shows how long it took in the test environment to retrieve a given number of records. The connector retrieves 1000 records per request.

Number of records	Time to retrieve
50,662 records	3 minutes 17 seconds
95,214 rows	6 minutes 14 seconds
194,679 rows	12 minutes 55 seconds

## Eloqua limits

### Field limits

Some Eloqua tables can be customized to have more than 250 fields. Tableau currently retrieves the first 250 fields and ignores the rest. When you select an Events, Custom Objects, Contracts, or Accounts table, Tableau will display a warning if there are more fields than Tableau can retrieve.

### Daily table request limits

Each table requested by Tableau counts against a daily Eloqua request limit of 2000. When the limit is exceeded, Eloqua operations might choose to disable Tableau, in which case, they will contact the account owners. You can monitor your daily usage in Eloqua using the Eloqua Marketing Operations Center.

### Incremental Refresh

For all the activity labels (with the exception of "Activities- all"), you can now implement incremental refreshes. For more information, please see [Refresh Extracts on page 886](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Oracle Essbase

This article describes how to connect Tableau to an Oracle Essbase database.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

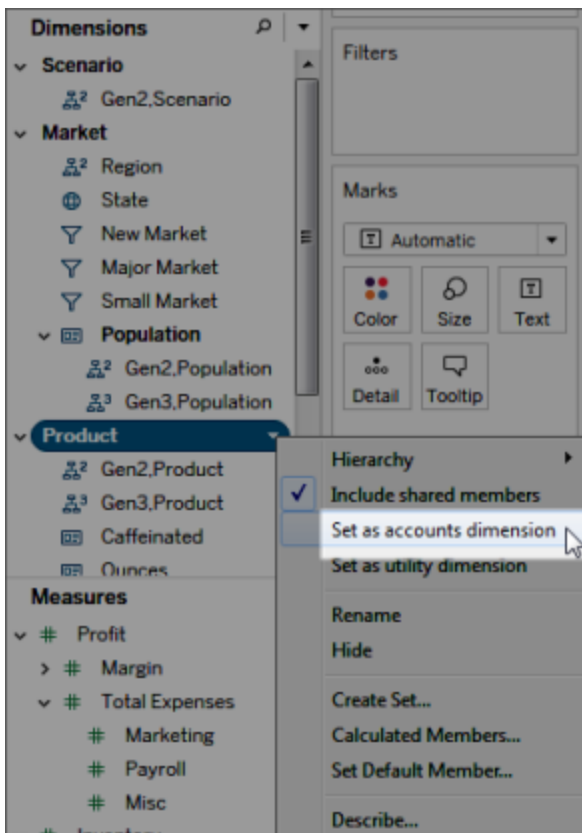

1. Start Tableau and under **Connect**, select **Oracle Essbase**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter your user name and password to sign in to the server, and then select **Sign In**.  
  
If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data

source to connect to.

- b. Search for or select an application.
- c. Search for or select a database from your application.
- d. Select the sheet tab to start your analysis.

## Set an accounts dimension

In some case, the accounts dimension for your data source can appear in the Dimensions area of the Data pane. This might occur if there is an error in the cube and another field is identified as the accounts dimension or there is no accounts dimension set at all. The accounts dimension defines the fields that are included as measures. To correct this error, right-click the field and then select **Set as Accounts Dimension** from the context menu.

## Build views with Oracle Essbase

When Tableau is connected to an Oracle Essbase data source, there are three important features that you should know about:

## Generations and Levels

In Tableau, you can work with either the generations or the levels of a dimension. The generations of a dimension are all members that are an equal distance from the root of the dimension. The levels are all members that are an equal distance from the leaves of the dimension. For balanced dimensions, you'll typically want to work with generations. However, if your dimension is ragged, then it may make more sense to navigate using levels.

By default, the generations of each dimension are listed in the Data pane. When you drag a dimension to a shelf, all generations that are ancestors of the selected generation (all generations that are above it in the hierarchy) are automatically included in the placement.

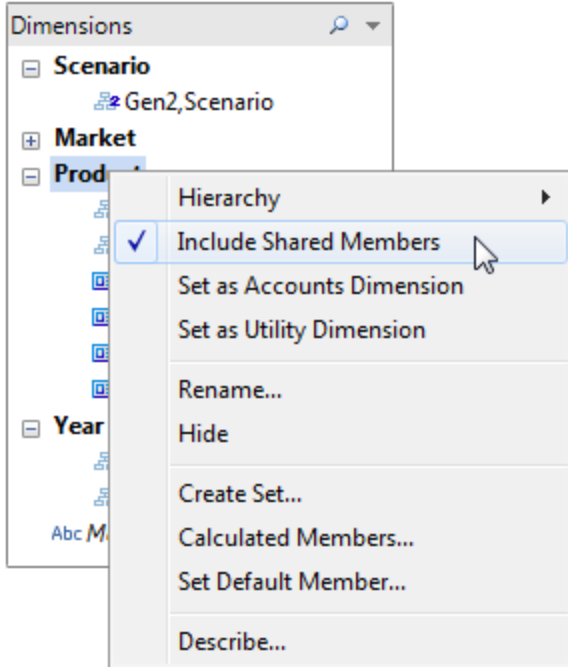

If you would rather navigate using the levels of a dimension, right-click the name of the dimension and then select **Hierarchy > Levels**.

If you are using the same dimension in multiple worksheets, you can use levels in one worksheet and generations in another worksheet simultaneously. Furthermore, you can mix generations and levels from different dimensions in the same worksheet.

## Shared Members

Shared members are dimension members that appear in more than one place in a hierarchy. For example, Diet Coke might be part of the product generation. But it might be shared by both the diet colas branch and the colas branch of the product hierarchy above it. In the database, however, the data about Diet Coke is stored just once.

By default, Tableau includes shared members in all generations (or levels) of a dimension. This means that a shared member might appear multiple times in a table. If you choose to exclude shared members, they will appear only once in a table. By default, shared members are included for all dimensions. To exclude shared members for a given dimension hierarchy, right-click the dimension name in the Data pane and select **Include Shared Members** from the menu.

The figure below shows part of a data view where shared members are included (left) and excluded (right). Notice that diet drinks are shared members.

**Includes Shared Members**

The diet drinks are listed in both the Diet Drinks hierarchy and their respective drink hierarchies.

**Does Not Include Shared Members**

The diet drinks are only listed once, in their respective drink hierarchies.

## Setting the Default Member

All multidimensional data sources have default members that are set when the data source is first built. If you find that you are creating filters all the time to look at the same specific data, you may find it useful to change the default member. For example, if you are the regional manager for the Western region in a company and you only want to look at your region's numbers, you can set the default member to the Western region.

To change the default member in Tableau, right-click a dimension hierarchy and select **Set Default Member**.

In the subsequent dialog box, select from the following options:

- Default member defined on cube – uses the default member that was defined when the cube was built. This is the default setting in Tableau.
- (All) member for the hierarchy – uses the ALL member for the selected hierarchy as the default member.
- Selected member – uses the member that you select in the bottom half of the dialog box as the default member.

The default member determines how you view the cube and so is much more powerful than applying filters. All fields will be calculated based on the default member you select. In addition, these default member settings are saved with the connection.

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Oracle NetSuite

This article describes how to connect Tableau to Oracle NetSuite and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Environment Account ID.
- Authentication information

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Oracle NetSuite**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the Application ID.
  - b. Enter the Authentication information.
  - c. Select **Sign In**.  
**Note:** If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, contact your database or network administrator.
2. On the data source page, complete the following steps:
  - a. (Optional) Select the data source name at the top of the page, and then enter a unique data source name.

- b. From the Database drop-down list, select a database.
- c. Under Table, select a table or use the search field to search for a table by name.
- d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Pivotal Greenplum Database

This article describes how to connect Tableau to a Pivotal Greenplum Database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Database name
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Pivotal Greenplum Database**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the name of the database you want to connect to.
  - b. Enter the user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in

to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Select and drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Support for spatial columns

Starting with Tableau version 2019.2, you can connect to spatial columns. For more information, see [Connect to Spatial Data in a Database on page 1637](#).

For Pivotal Greenplum Databases with spatial columns, we recommend that you use the PostgreSQL driver that is installed on Windows by default with Tableau Desktop. (Tableau already uses the PostgreSQL driver on macOS.) To use the PostgreSQL driver, you must uninstall the Pivotal Greenplum Database driver on your Windows computer, if it's installed.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as `mydb.test.ourdomain.lan`, instead of a relative domain name, such as `mydb` or `mydb.test`.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## PostgreSQL

This article describes how to connect Tableau to a PostgreSQL database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- The name of the server that hosts the database you want to connect to
- Database name
- Authentication method: Integrated Authentication or username and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **PostgreSQL**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database that you want to connect to.
  - b. Enter the name of the database.
  - c. Select how you want to sign in to the server. Specify whether to use **Integrated Authentication** or **User Name and Password**. If the server is password protected, and you aren't in a Kerberos environment, you must enter the username and password.

**Note:** If you're using a Mac that isn't attached to the domain correctly, the Mac won't know that Kerberos is being used in the domain, and the **Authentication** dropdown list isn't available.

Select the **Required SSL** check box when connecting to an SSL server.

- d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- e. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Under **Table**, select a table or use the text box to search for a table by name.  
Starting with Tableau version 2019.2, you can connect to spatial columns. For more information, see [Connect to Spatial Data in a Database on page 1637](#).
- c. Drag the table to the canvas, and then select the sheet tab to start your analysis.  
Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

**Note:** We don't recommend using [pgBouncer](#) since Tableau relies on stateful connections. If you must use pgBouncer with Tableau, then you must configure it in the following way.

server\_reset\_query=DISCARD ALL (the default)

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Presto

This article describes how to connect Tableau to a Presto database and set up the data source.

Tableau connects to Presto 141t from Teradata and to Presto on-premises and Amazon EMR Presto instances for Presto version 0.148.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Catalog
- Authentication method:
  - Username
  - LDAP

**Note:** LDAP authentication is available from Tableau Desktop version 10.3.2 forward.

- Sign-in credentials. Your choices depend on the authentication method you choose, and can include the following:
  - User name
  - Password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** If you are connecting to PrestoDB, download the appropriate driver from the PrestoDB page. If you are connecting to Trino, (previously PrestoSQL), download the appropriate driver from the Trino page. The Trino driver only works in Tableau versions 2021.3, 2021.2.2, 2021.1.5, 2020.4.8, 2020.3.12, and above.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Presto**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server you want to connect to.
  - b. Enter the catalog name.
  - c. Select the **Authentication** method: **Username** or **LDAP**, and enter the credentials you're prompted for.  
  
Select the **Require SSL** check box when connecting to an SSL server.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.  
  
If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out

which data source to connect to.

- b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
- c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.
- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

- [One-Way SSL for JDBC Connections](#) - Configure trust for a self-signed or CA certificate when you use one-way SSL with a JDBC connector.

## Progress OpenEdge

This article describes how to connect Tableau to a Progress OpenEdge database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Database name

- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Progress OpenEdge**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database you want to connect to.
  - b. Enter the name of the database.
  - c. Enter the user name and password.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table or use the text box to search for a table by name.
  - c. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.  
For more information, see [Connect to a Custom SQL Query](#) on page 811.

- [Build Charts and Analyze Data](#) on page 953 – Begin your data analysis.

## Qubole Presto

This article describes how to connect Tableau to Qubole Presto and set up the data source.

**Note:** As of 2020.3, the Qubole Presto connector is JDBC-based.

### Before you begin

Before you begin, gather this connection information:

- End Point- end point URL based on the region where you have the Qubole account
- Catalog name ('hive' is the default)
- Cluster label
- Password (API token)
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Qubole Presto**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Enter the **End Point**.

**Note:** Advanced user can use additional properties in the **Endpoint** field; for example: `https://api.qubole.com;`

`LogLevel=6;LogPath=C:\\Users\\User\\Desktop`

For more information, see the "Additional Properties (Optional)" section of the [Setting the JDBC Connection String](#) topic on the Qubole website.

- b. Enter the **Catalog** name.
- c. Enter the **Cluster Label**.
- d. Enter the **Password**, which is an API token.
- e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
- f. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Schema**, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Salesforce CRM

This article describes how to connect Tableau to Salesforce.com data and set up a data source.

### Notes:

- Beginning with Tableau Desktop version 2020.4, OAuth is used for all sign-ins. Signing in with username and password is not an available option.
- Tableau Prep Builder version 2020.2.1 supports connecting to Salesforce.com data. However, not all connector options described in this article are supported. For information about what is supported by Tableau Prep Builder, see [Connect to Salesforce data](#) in the Tableau Prep Builder help.

## Before you connect

Before you begin, gather this connection information:

- Credentials for signing in to Salesforce.com using OAuth

## Recommendation

### Setup a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau release cycles and Tableau's OAuth client rotation schedule. For information on how to configure your own OAuth client see, [Configure Custom OAuth for a site](#).

## Make the connection and set up the data source

1. Start Tableau and under Connect, select **Salesforce**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter your sign-in credentials for Salesforce.com.
  - b. Select **Log In**.
  - c. In the Allow Access dialog box, select **Allow**.
 

If the connection is unsuccessful, verify that the authentication information is correct. If the connection continues to fail, your computer is having trouble locating the server or you may not have permission to access the data. Contact your network administrator or Salesforce administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Select a standard connection or create your own custom connection.
 

Under **Standard Connection**, you can select from a list of predefined queries, which represent commonly used objects, and drag it to the canvas. Or, under **Table**, you can select a single table, which includes any custom objects your company has created, and drag it to the canvas.
  - c. Select the sheet tab to start your analysis.

## Work with a subset of columns

Beginning with Tableau Desktop versions 2020.1, you can work with a subset of columns.

If you want to select a subset of columns to work with, double-click **New Custom SQL** and use this syntax:

```
SELECT <column1, column2, [...]columnN> FROM <table>
```

For example, to work with three columns from the Org table — Account Rep, Department, and Cost Code — you could type:

```
SELECT AccountRep, Department, CostCode from Org
```

For more information, see [Connect to a Custom SQL Query on page 811](#).

## Refresh Salesforce data

After you click the sheet tab, Tableau imports the data by creating an extract. Tableau Desktop supports only extracts for Salesforce.

**Note:** The initial extract may take some time depending on the amount of data that is included.

After the initial extract, you can do a full or incremental refresh of the extract. Incremental refreshes for Salesforce data include any Salesforce object that has been added or changed since the last incremental refresh. Results returned are limited to the previous 30 days.

To refresh, select **Data** > [data source name] > **Extract** > **Refresh (Incremental)** | **Refresh (Full)**.

**Note:** The incremental refresh option doesn't support Custom SQL.

## Use Accelerators

You can use an Accelerator to quickly build informative dashboard designs made specifically for key business metrics on Tableau Desktop and Tableau Cloud. For more information, see [Use Accelerators to Quickly Visualize Data on page 2651](#).

## Use joins in Salesforce

When you set up the data source on the data source page, when you drag a table to the canvas, the list of tables you can select from to join is filtered. You can create joins on any string fields and on fields that are constrained references between tables. (Only left and inner joins are supported.) You can also add joins later. For more information, see [Join Your Data on page 738](#).

Note that Salesforce connections do not support non-equi joins and must use the equality operator (=).

## Cross-database join limitations with Salesforce

Salesforce also supports combining tables from different databases using a cross-database join. For more information, see the "Combine tables from different databases" section in [Join Your Data on page 738](#).

When a Salesforce connection is included in a multi-connection data source, the data source won't support the following features:

- Live connections
- Extract filters
- Incremental updates to the extract
- Viewing your data in the data grid

## Troubleshoot Salesforce connections

Tableau leverages the various force.com APIs to connect to Salesforce.com, Force.com, and Database.com data. These services have some restrictions on the type of data and the amount of data that you can access at a given time. If you are having trouble connecting, the following list of common restrictions may help you find a solution.

### Company account and user profile configuration

In order for Tableau to connect to Salesforce data, all of the following must be enabled on both your company's account and your user profile:

- SOAP API for signing in
- REST API for getting meta data
- BULK API for downloading objects
- REST API for downloading objects that the BULK API does not support
- Replication SOAP APIs for retrieving changes in the data

To optimize for performance and ensure the APIs are available for all of their customers, Salesforce.com balances the load by limiting the number of concurrent API requests as well as limiting the total number of API requests overall. An error occurs if these limits are reached while connected using Tableau. See the Salesforce.com developer documentation to learn more about these limits.

**Note:** Some editions of Salesforce may not allow API access at all. Contact your Salesforce administrator to verify that your account has access to the above list of APIs.

### Errors during extract

When you connect to Salesforce using Tableau, the data is automatically extracted into a Tableau Data Extract file. In some cases, certain fields cannot be extracted because of character limits. Specifically, text fields that are greater than 4096 characters and calculated

fields will not be included in the extract. If you have calculated fields in your data, you will need to recreate them in Tableau after creating the extract.

In addition, the Force.com API restricts queries to 10,000 total characters.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.
- [5 Ways to Maximize Your Salesforce Data](#) - Read the Tableau whitepaper (registration or sign in required).

## Salesforce Data Cloud

**Note:** Data Cloud was previously called Customer Data Platform (Salesforce\_cdp).

### Tableau Desktop (version 2023.2 and later)

The Salesforce Data Cloud connector was released with Tableau Desktop 2023.2. This connector seamlessly connects Tableau to Data Cloud, and is available for Tableau Desktop, Tableau Cloud, Tableau Server, and Tableau Prep.

If you're using Tableau Desktop 2023.1 or earlier, see [Tableau Desktop \(version 2023.1 and earlier\) on the next page](#).

**Note:** The Customer Data Platform connector was deprecated in October 2023 and can't be used for new connections starting in Tableau Desktop 2024.1. Existing workbooks, data sources, and other assets that use the Customer Data Platform connector will continue to work until the connector is completely removed, typically 1-2 releases after deprecation. To ensure that existing assets continue to function, Tableau strongly recommends customers modify existing assets to use the Salesforce Data Cloud connector.

### Benefits of the Data Cloud Connector

- The connector is automatically included in a Tableau Desktop installation and eliminates the additional step to install the connector with a Taco file and a JDBC driver.

- The connector is data spaces aware with improved usability that shows the object label in Tableau connect UI instead of the object API name.
- The connector is powered by accelerated queries.

## Connect to Data Cloud

Complete the following steps to connect to the Salesforce Data Cloud.

1. Select the **Data** menu, then **New Data Source**. (If you just launched Tableau Desktop, ignore this step.)
2. In the **Connect** pane, under the **To a Server** section, select **Salesforce Data Cloud**.
3. Log in and allow access when prompted.
4. Select the **Data space**. Data spaces represent a logical segregation of the data in Data Cloud. Data spaces didn't exist before the Salesforce June' 23 release.
5. If using Tableau Desktop 2024.1 or later, use **Object** to filter by the type of Data Cloud object, or select **All Objects**.

### Tableau Desktop (version 2023.1 and earlier)

**Warning:** The Customer Data Platform was deprecated in October 2023 and is unavailable in Tableau Desktop 2024.1 and later. To ensure that assets continue to function, Tableau recommends customers upgrade to Tableau Desktop 2024.1 or later and modify existing assets to use the Salesforce Data Cloud connector.

### Step 1: Install the Salesforce Data Cloud.taco file

**Note:** This step applies to versions 2021.1–2021.3. Starting in version 2021.4, the Salesforce\_CDP.taco file is automatically installed.

1. Remove or rename any Salesforce\_CDP.taco files that have been previously installed to avoid conflicts. The Tableau Desktop.taco files are installed in the following locations:
  - MacOS: /Applications/Tableau Desktop <VERSION>.app/Contents/Resources/connectors/Salesforce\_CDP.taco
  - Windows: C:\Program Files\Tableau\Tableau 2022.3\bin\connectors
2. Download the latest Salesforce Data Cloud connector (Salesforce\_CDP.taco file) from the Tableau Exchange Connectors site: [Customer Data Platform Connector](#).
3. Move the.taco file to the Tableau connector directory:
  - Windows: C:\Users[Windows User]\Documents\My Tableau Repository\Connectors

- **macOS:** `/Users/[user]/Documents/My Tableau Repository/Connectors`

### Step 2: Install the Salesforce Data Cloud JDBC driver

**Note:** Tableau version 2023.1 for Desktop is only compatible with JDBC driver version 18 and above.

1. Download the latest JDBC driver (Salesforce-CDP-jdbc-[*version*].jar file) from the Salesforce CDP GitHub site: [Salesforce-CDP-jdbc](#).
2. Move the downloaded Salesforce-CDP-jdbc-[*version*].jar file to the following location:
  - **Windows:** `C:\Program Files\Tableau\Drivers`
  - **macOS:** `/Users/[user]/Library/Tableau/Drivers`

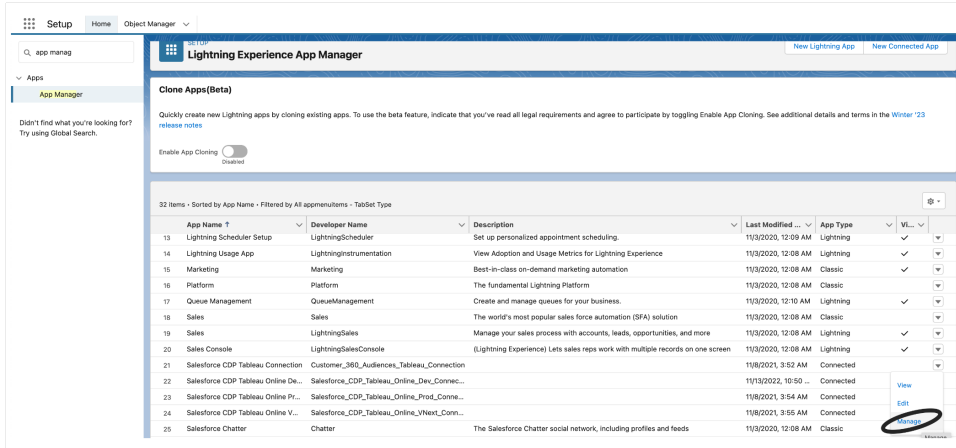

**Note:** Unhide the folders to view them.

### Step 3: Enable a High Assurance Session

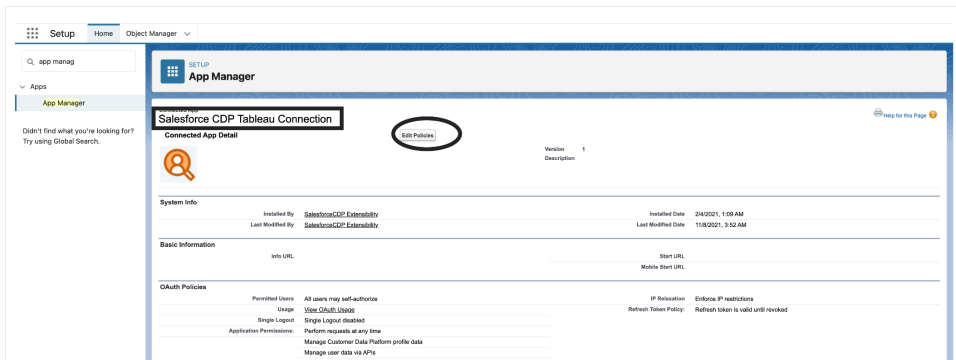

You can enable a High Assurance session in to ensure that your connected app is secure. This session policy requires users to verify their identity with multi-factor authentication when they log into the connected app.

1. Log in to Salesforce as a CDP Admin.
2. In the Salesforce Data Cloud, search for App Manager.
3. In the Setup's Quick Find, search for **Salesforce CDP Tableau Connection** in the list.
4. Select **Manage**.

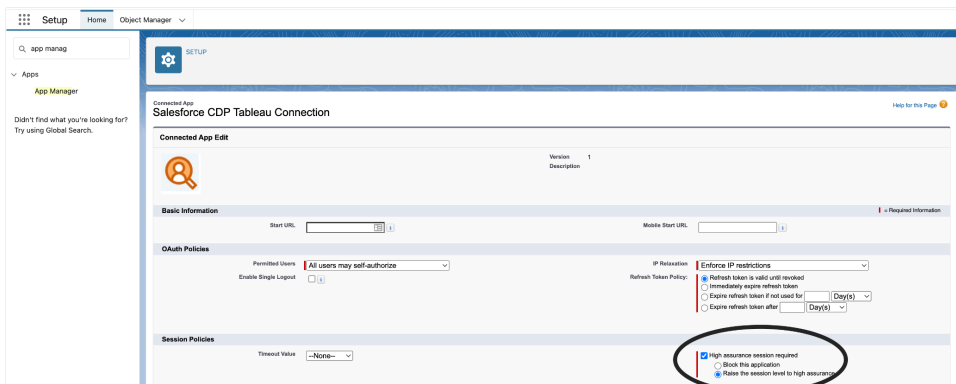

**IMPORTANT:** Make sure you're clicking the dropdown for **Salesforce CDP Tableau Connection** only!

5. Select **Edit Policies**.

6. Under **Session Policies**, select the **High assurance session-required** check box.

7. Select **Save**. High assurance config is now enabled.

## Step 4: Connect to the Salesforce Data Cloud in Tableau Desktop

1. Launch Tableau Desktop (2021.1 and later).
2. Go to **Connect, To a Server**, and select **Salesforce CDP**.
3. In the Salesforce CDP dialog, confirm that *OAuth* is selected in the **Authentication** section and *https://login.salesforce.com* is selected in the **OAuth instance URL** section.
4. Select **Sign In** to open a pane in a web browser.
5. Sign in to Salesforce with your username and password.
6. Select **Allow**.
7. Close the browser pane.

Tableau Desktop is now connected to the Salesforce Data Cloud and you can perform Tableau operations.

## Tableau Cloud and Tableau Server

Connecting using Tableau Cloud Web Authoring is similar to Tableau Desktop.

- **Tableau Cloud:** [Connect Tableau Cloud Web Authoring to Data Cloud](#)

Tableau Server requires additional configuration. Use the following links to find out more.

- **Tableau Server (Windows):** [Connect Tableau Server to Data Cloud](#)
- **Tableau Server (Linux):** [Connect Tableau Server to Data Cloud](#)

## Next Steps

### Use Accelerators for Quick Data Insights

You can quickly visualize your data using accelerators. Tableau Accelerators are pre-built dashboards designed to help you get a jump start on data analysis. Tailored to specific industries and enterprise applications. Accelerators are built with sample data that you can swap out for your own data, allowing you to discover insights with minimal setup. Accelerators are available on the [Tableau Exchange](#). For more information about accelerators, see [Use Accelerators to Quickly Visualize Data](#). You may want to try some of the following Salesforce Data Cloud accelerators.

### Salesforce Data Cloud Identity Resolution Accelerator

You can use the Identity Resolution Accelerator to explore how identity resolution in Salesforce Data Cloud is working for your business. You can view your ingested sources, how they

contribute to unified individuals, and their composition. For more information, see [Salesforce Data Cloud Identity Resolution](#).

## Salesforce Data Cloud Email Marketing Campaign Accelerator

With the CDP Email Marketing Campaign Accelerator you can monitor the efficiency of your email campaigns end to end. You can explore campaigns that have the highest conversion, email trends over time, and more. For more information, see [Salesforce Data Cloud Email Marketing Campaigns](#).

## Salesforce Data Cloud Customer Engagement Accelerator

This accelerator is an exploratory dashboard that gives marketing and sales teams a comprehensive view of the engagement levels of customers across the following channels.

- Sales
- Email
- Messages (SMS)
- Website
- Push Notifications

The accelerator helps these teams to select the best channels to interact with the customer, develop relevant messaging, and create positive customer experiences to increase loyalty and retention. For more information, see [Salesforce Data Cloud Customer Engagement](#).

## Salesforce Data Cloud

**Note:** Data Cloud was previously called Customer Data Platform (Salesforce\_cdp).

### Tableau Desktop (version 2023.2 and later)

The Salesforce Data Cloud connector was released with Tableau Desktop 2023.2. This connector seamlessly connects Tableau to Data Cloud, and is available for Tableau Desktop, Tableau Cloud, Tableau Server, and Tableau Prep.

If you're using Tableau Desktop 2023.1 or earlier, see [Tableau Desktop \(version 2023.1 and earlier\)](#) below.

**Note:** The Customer Data Platform connector was deprecated in October 2023 and can't be used for new connections starting in Tableau Desktop 2024.1. Existing workbooks, data sources, and other assets that use the Customer Data Platform connector will continue to work until the connector is completely removed, typically 1-2 releases after deprecation. To ensure that existing assets continue to function, Tableau strongly recommends customers modify existing assets to use the Salesforce Data Cloud connector.

### Benefits of the Data Cloud Connector

- The connector is automatically included in a Tableau Desktop installation and eliminates the additional step to install the connector with a Taco file and a JDBC driver.
- The connector is data spaces aware with improved usability that shows the object label in Tableau connect UI instead of the object API name.
- The connector is powered by accelerated queries.

### Connect to Data Cloud

Complete the following steps to connect to the Salesforce Data Cloud.

1. Select the **Data** menu, then **New Data Source**. (If you just launched Tableau Desktop, ignore this step.)
2. In the **Connect** pane, under the **To a Server** section, select **Salesforce Data Cloud**.
3. Log in and allow access when prompted.
4. Select the **Data space**. Data spaces represent a logical segregation of the data in Data Cloud. Data spaces didn't exist before the Salesforce June' 23 release.
5. If using Tableau Desktop 2024.1 or later, use **Object** to filter by the type of Data Cloud object, or select **All Objects**.

### Tableau Desktop (version 2023.1 and earlier)

**Warning:** The Customer Data Platform was deprecated in October 2023 and is unavailable in Tableau Desktop 2024.1 and later. To ensure that assets continue to function, Tableau recommends customers upgrade to Tableau Desktop 2024.1 or later and modify existing assets to use the Salesforce Data Cloud connector.

## Step 1: Install the Salesforce Data Cloud.taco file

**Note:** This step applies to versions 2021.1–2021.3. Starting in version 2021.4, the Salesforce\_CDP.taco file is automatically installed.

1. Remove or rename any Salesforce\_CDP.taco files that have been previously installed to avoid conflicts. The Tableau Desktop.taco files are installed in the following locations:
  - MacOS: /Applications/Tableau Desktop <VERSION>.app/Contents/Resources/connectors/Salesforce\_CDP.taco
  - Windows: C:\Program Files\Tableau\Tableau 2022.3\bin\connectors
2. Download the latest Salesforce Data Cloud connector (Salesforce\_CDP.taco file) from the Tableau Exchange Connectors site: [Customer Data Platform Connector](#).
3. Move the.taco file to the Tableau connector directory:
  - Windows: C:\Users[Windows User]\Documents\My Tableau Repository\Connectors
  - macOS: /Users/[user]/Documents/My Tableau Repository/Connectors

## Step 2: Install the Salesforce Data Cloud JDBC driver

**Note:** Tableau version 2023.1 for Desktop is only compatible with JDBC driver version 18 and above.

1. Download the latest JDBC driver (Salesforce-CDP-jdbc-[version].jar file) from the Salesforce CDP GitHub site: [Salesforce-CDP-jdbc](#).
2. Move the downloaded Salesforce-CDP-jdbc-[version].jar file to the following location:
  - Windows: C:\Program Files\Tableau\Drivers
  - macOS: /Users/[user]/Library/Tableau/Drivers

**Note:** Unhide the folders to view them.

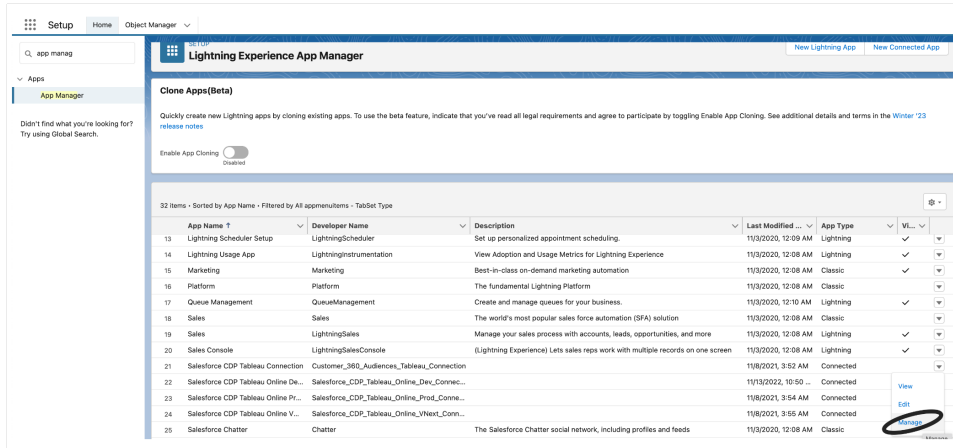

## Step 3: Enable a High Assurance Session

You can enable a High Assurance session in to ensure that your connected app is secure. This session policy requires users to verify their identity with multi-factor authentication when they log into the connected app.

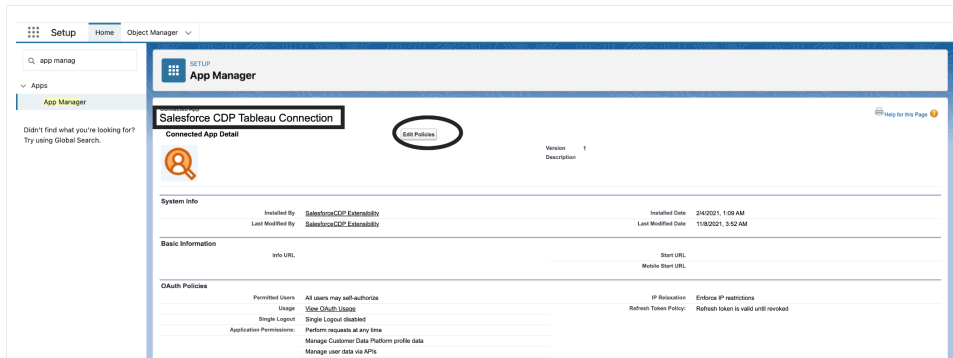

## Tableau Desktop and Web Authoring Help

1. Log in to Salesforce as a CDP Admin.
2. In the Salesforce Data Cloud, search for App Manager.
3. In the Setup's Quick Find, search for **Salesforce CDP Tableau Connection** in the list.
4. Select **Manage**.

**IMPORTANT:** Make sure you're clicking the dropdown for **Salesforce CDP Tableau Connection** only!

5. Select **Edit Policies**.

6. Under **Session Policies**, select the **High assurance session-required** check box.

7. Select **Save**. High assurance config is now enabled.

#### Step 4: Connect to the Salesforce Data Cloud in Tableau Desktop

1. Launch Tableau Desktop (2021.1 and later).
2. Go to **Connect, To a Server**, and select **Salesforce CDP**.
3. In the Salesforce CDP dialog, confirm that *OAuth* is selected in the **Authentication** section and *https://login.salesforce.com* is selected in the **OAuth instance URL** section.
4. Select **Sign In** to open a pane in a web browser.
5. Sign in to Salesforce with your username and password.
6. Select **Allow**.
7. Close the browser pane.

Tableau Desktop is now connected to the Salesforce Data Cloud and you can perform Tableau operations.

#### Tableau Cloud and Tableau Server

Connecting using Tableau Cloud Web Authoring is similar to Tableau Desktop.

- **Tableau Cloud:** [Connect Tableau Cloud Web Authoring to Data Cloud](#)

Tableau Server requires additional configuration. Use the following links to find out more.

- **Tableau Server (Windows):** [Connect Tableau Server to Data Cloud](#)
- **Tableau Server (Linux):** [Connect Tableau Server to Data Cloud](#)

## Next Steps

### Use Accelerators for Quick Data Insights

You can quickly visualize your data using accelerators. Tableau Accelerators are pre-built dashboards designed to help you get a jump start on data analysis. Tailored to specific industries and enterprise applications. Accelerators are built with sample data that you can swap out for your own data, allowing you to discover insights with minimal setup. Accelerators are available on the [Tableau Exchange](#). For more information about accelerators, see [Use Accelerators to Quickly Visualize Data](#). You may want to try some of the following Salesforce Data Cloud accelerators.

### Salesforce Data Cloud Identity Resolution Accelerator

You can use the Identity Resolution Accelerator to explore how identity resolution in Salesforce Data Cloud is working for your business. You can view your ingested sources, how they contribute to unified individuals, and their composition. For more information, see [Salesforce Data Cloud Identity Resolution](#).

### Salesforce Data Cloud Email Marketing Campaign Accelerator

With the CDP Email Marketing Campaign Accelerator you can monitor the efficiency of your email campaigns end to end. You can explore campaigns that have the highest conversion, email trends over time, and more. For more information, see [Salesforce Data Cloud Email Marketing Campaigns](#).

### Salesforce Data Cloud Customer Engagement Accelerator

This accelerator is an exploratory dashboard that gives marketing and sales teams a comprehensive view of the engagement levels of customers across the following channels.

- Sales
- Email
- Messages (SMS)
- Website
- Push Notifications

The accelerator helps these teams to select the best channels to interact with the customer, develop relevant messaging, and create positive customer experiences to increase loyalty and retention. For more information, see [Salesforce Data Cloud Customer Engagement](#).

- Salesforce Help: [Using Customer Data Platform Data in Tableau](#)

## Salesforce Marketing Cloud

This article describes how to connect Tableau to the Salesforce Marketing Cloud connector. To begin, you must install the connector and configure the instance to accept Application Programming Interface (API) connections. The Marketing Cloud connector needs a plugin (.taco file) and a driver.

**Note:** Multi-factor authentication (MFA) isn't supported.

### Driver required

Check that the driver is installed on your computer. If the driver isn't installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download page](#), where you can find driver links and installation instructions.

### MFA Work Around

If you are having problems using MFA with Salesforce Marketing Cloud. You first need to enable MFA on the web UI login, then follow the steps on the Tableau Exchange. To get the instructions, see:

[Salesforce Marketing Cloud](#)

### Install the Connector

Complete the following steps to install the connector in Tableau.

1. In Tableau, choose **Connect**.
2. Select **To a Server**.
3. In the connections list, select **Salesforce Marketing Cloud**.
4. To finish, follow the prompts to sign-in or install the connector.

### Configure the Marketing Cloud Instance

The Marketing Cloud Connector needs an API integration to be configured and given appropriate privileges. After it's configured, your instance has a Subdomain value that can be entered into Tableau's connector dialog.

**Note:** Only Marketing Cloud Administrators can configure a subdomain.

## Configure your Subdomain

1. Sign into the Marketing Cloud connector with your Marketing Cloud administrator ID.
2. Go to **Setup, Installed Packages**.
3. Select Create a new package.
4. In the **Name** field, enter a package name.
5. Choose **Create with enhanced functionality**.
6. Select **Save**.
7. In **Add Component**, under **Choose Your Component Type**, select the **API Integration** Component Type.
8. Select **Next**.
9. In **Add Component**, under **Choose Your Integration Type**, select **Server-to-Server**.
10. Select **Next**.
11. Choose your scopes. The SOAP Base URI populates.

## Refresh your data

Tableau only supports data extract connections for the Marketing Cloud connector. You can update the data by refreshing the data extract. For more information, see [Refresh Extracts](#). For information about refresh schedules, see [Schedule Extract Refreshes as You Publish a Workbook](#).

- Salesforce Help: [Using Customer Data Platform Data in Tableau](#)

## Splunk

This article describes how to connect Tableau to Splunk data and set up a data source.

**Note:** The Splunk ODBC connector is compatible with Splunk Enterprise 6.

## Before you begin

Before you begin, gather this connection information:

- Server URL, including the name of the database, if there are multiple databases
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Splunk**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the server URL. You should use HTTPS to connect to Splunk data.  
If your server contains multiple databases, enter the name of a specific database on the server.  

**Note:** Database names are case sensitive.
  - b. Enter your user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.  
If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Under **Saved Search**, enter a saved search name in the text box or select a saved search from the list, and drag it to the box at the top of the data source page.
- c. Select the sheet tab to start your analysis.

## Join limitations with Splunk

While you cannot create a join between Splunk tables, you can combine Splunk data from multiple tables by doing one of the following:

- **Set up and connect to a saved search:** Set up a saved search in Splunk that returns all the tables you need in a single search result. Then connect to this saved search from Tableau Desktop.
- **Use data blending:** Set up a data source for each Splunk table you need, then use data blending to combine the data. For more information, see [Blend Your Data on page 764](#).
- **Create an extract:** Create an extract of each Splunk table and then join the extracts together using a cross-database join. For more information, see [Extract Your Data on page 867](#) and [Join Your Data on page 738](#).

However, you can create a cross-database join between Splunk data and data from different databases (or files) with one exception. After adding a new connection to the Tableau data source, you must double-click the table in the left pane to add it to the canvas. You cannot drag the table from the left pane to the canvas as you normally would when creating a cross-database join. For more information about cross-database joins, see [Join Your Data on page 738](#).

Note: Creating a cross-database join between Splunk tables is not supported. A cross-database join between Splunk tables causes all the connections in the Tableau data source to disappear except for the last Splunk connection.

## Splunk JDBC

This article describes how to connect Tableau to Splunk data and set up a data source using the Splunk JDBC connector.

### Before you begin

Before you begin, gather this connection information:

- Server URL, including the name of the database, if there are multiple databases
- User name and password
- Access Token
- HTTPEventCollectorToken

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Splunk JDBC**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the server URL. You should use HTTPS to connect to Splunk data.
  - b. Enter your user name and password.
  - c. Select **Sign In**

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

- b. Under **Saved Search**, enter a saved search name in the text box or select a saved search from the list, and drag it to the box at the top of the data source page.
- c. Select the sheet tab to start your analysis.

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## SAP HANA

This article describes how to connect Tableau to an SAP HANA database and set up the data source.

**Note:** This connector uses JDBC drivers for Mac, Linux, and Windows. The JDBC driver for Windows is new in Tableau version 2021.1. JDBC drivers for Mac and Linux were introduced with Tableau version 2020.2. JDBC driver version 2.3.4 is the recommended version.

### Before you begin

Before you begin, gather this connection information:

- Are you making a single-node or multi-node connection?
  - SingleNode: Database server name and port number.
  - MultiNode: Database server name, host name, and port numbers.
- Authentication:
  - Windows: Windows Authentication or username and password
  - Mac: Kerberos or username and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

**Note:** If you want to connect to SAP HANA using live connections, you must disable parameters and variables. Live connections to SAP HANA calculation views don't work with Tableau Bridge if you use parameters and variables.

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

### 1. Start Tableau and under **Connect**, select **SAP HANA**.

#### a. Select the type of connection:

- **SingleNode:** Enter the name of the server that hosts the database you want to connect to, and if you're using a non-default port, the port number.
- **MultiNode:** Enter the host name and port number of each server, separated by a comma. For example:

```
host1:30015,host2:30015,host3:30015
```

#### b. Select how to sign into the server:

##### **Windows:**

- Select **Use Windows Authentication**, if your environment supports single sign-on (SSO).
- Or select **Use a specific username and password**. If the server is password protected and you aren't in a kerberos environment, you must enter the username and password.

**Mac:** Select **Kerberos** or select **Use a specific username and password**.

Select the **require SSL** option when connecting to an SSL server.

#### c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

#### d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

### 2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
- c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.

Tableau Desktop also supports connecting to SAP HANA table functions, which appear under **Stored Procedures** in the left pane of the Data Source page.

- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

The default display is column labels.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** When you create a self-join with an analytic view, and one of the tables has variables, make sure that the table with variables is on the left. Otherwise, the join may not return the expected results.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

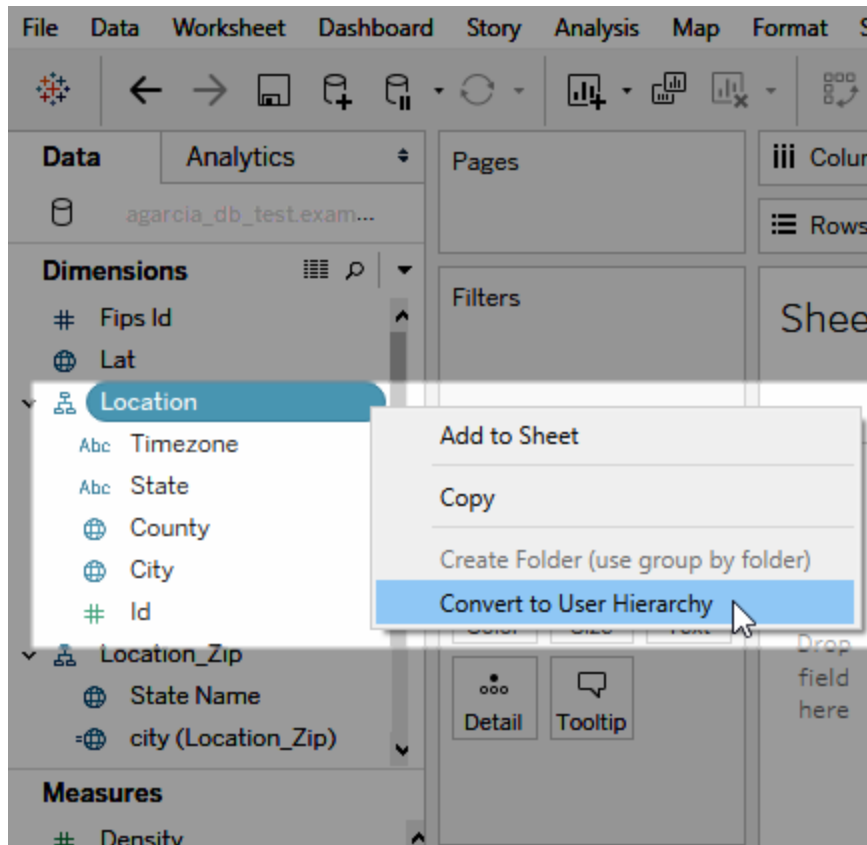

## Convert an SAP HANA level hierarchy to a user hierarchy

When you create an SAP HANA data source or workbook, you can create your own hierarchy for use in Tableau. Tableau supports level hierarchies created in SAP HANA starting in version 2019.4. When you connect Tableau to an SAP HANA calculation view with a level hierarchy, the structure of the SAP HANA level hierarchy appears in the Data pane. If you want to modify the SAP HANA level hierarchy in Tableau, you must convert the SAP HANA level hierarchy to a user hierarchy.

**Warning:** After you convert an SAP HANA level hierarchy to a user hierarchy, you can't reverse it. If you decide you want to use the SAP HANA level hierarchy instead of the user hierarchy, you must start over.

To convert to a user hierarchy, complete the following steps:

1. In the **Data** pane, select the hierarchy.
2. In the drop-down menu, select **Convert to User Hierarchy**.

## Customize JDBC connections

On Mac and Linux, SAP HANA uses a JDBC connection. You can customize the JDBC connection using a properties file. For more information, see [Customize JDBC Connections Using a Properties File](#) in Tableau Community.

## Install trusted SSL certificates on a Mac

If you want to use SSL/TLS to encrypt communications between Tableau Desktop and your database, you must add certificates to the Java certificate trust store. This is required if your

database uses self-signed certificates. To connect Tableau Desktop to your database using SSL/TLS, complete the following steps:

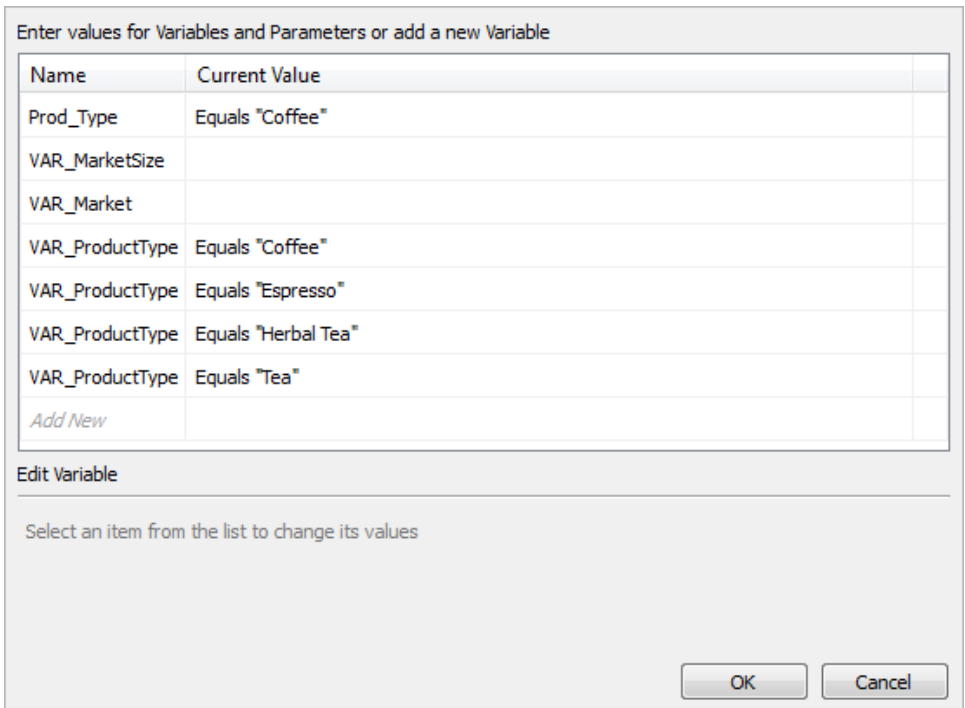

1. Start the Terminal application, and navigate to your Java Home directory. This is located at /Library/Internet Plug-Ins/JavaAppletPlugin.plugin/Contents/Home, unless you've installed the JDK or set the JAVA\_HOME environment variable.
2. Run the following command:

```
bin/keytool -importcert -keystore cacerts -alias <certificate name> -file <path to certificate file>
```

**Note:** Beginning with Tableau version 2020.2, you can import a custom certificate into the "System" keychain. For details, see [One-Way SSL for JDBC Connections](#).

### Select variables and input parameters

If the table you use includes required or optional variables or parameters, the Variables and Input Parameters dialog box opens.

- Required variables and parameters display their current value or **\*Required**.
- Optional variables and parameters display their current value or are blank.

- Prompt for the variable when the workbook is opened by selecting the check box under **Prompt**.

Select a variable or parameter and type or select a value for it. Repeat for all required values and any optional values that you want to include, and then select **OK**.

**Note:** You can use SQL query-based SAP HANA prompts.

## Support for SAP HANA single sign-on (SSO)

You can access data, publish data sources, and publish workbooks to Tableau Server, without having to reenter your username and password by configuring SAP HANA to support single sign-on (SSO). To use SSO, you must publish data sources and workbooks to Tableau Server with **Viewer credentials** authentication. To enable **Viewer credentials** authentication, you must connect to SAP HANA using Windows Authentication on a Windows computer or Kerberos on a Mac. For more information, see [Publish to the Server below](#).

- Tableau Desktop requires SAP HANA driver version 1.00.85 or later.
- You must setup Tableau Server to support SSO for SAP HANA. For information, see [Configure SAP HANA for Single Sign-On](#) in the Tableau Server Help.

## Sign in to the server

You can sign in to the SAP HANA server by entering the server name. Or you can select **Use Windows Authentication** on a Windows computer or **Kerberos** on a Mac. To finish, select **Sign In**.

## Publish to the Server

You don't have to enter credentials to access a data source or a workbook if you publish it to Tableau Server with SSO enabled. To enable SSO when you publish a data source or workbook to Tableau Server, complete the following steps:

1. Select **Server, Publish Data Source** or **Server, Publish Workbook**.
2. Under **Data Sources**, choose **Edit**.
3. In the Manage Data Sources dialog box, do the following:
  - Select the **Publish Type: Embedded in workbook** or **Published separately**.
  - Select **Viewer credentials** for **Authentication**.
4. Choose **Publish**.

## How to refresh HANA extracts when you use SSO

You can use the Tableau Data Extract Utility to automate the extract refresh task. For example, the following command refreshes a published SAP HANA extract named "mydatasource." This command specifies the following:

- The name of your Tableau Server
- The name of the data source to refresh

```
C:\Program Files\Tableau\Tableau 10.2\bin>tableau refreshextract --  
server https://mytableauserver --datasource mydatasource
```

For more information about the utility, see [Tableau Data Extract Command-Line Utility on page 894](#).

## Performance tips

You can improve performance by enabling query parameter binding.

### Use bind variables

To improve performance, Tableau can use bind variables for your SAP HANA queries.

- Queries: HANA can compile a query one time and execute it many times.
- Multi-node HANA deployments: Parametrized queries are optimally routed to the proper node.

To enable this feature, your Tableau Server Administrator can add the CAP\_ODBC\_QUERY\_USE\_PREPARE\_PARAMETER\_MARKER capability in a TDC file.

**Note:** This feature requires Tableau 2018.3 or later.

You can use CAP\_ODBC\_QUERY\_USE\_PREPARE\_PARAMETER\_MARKER with JDBC and ODBC.

## Use column metadata collection

Tableau supports column metadata collection, which may improve the load time for some views.

When Tableau reads the column metadata for a table or view, it uses a prepared query on the table by default.

**Note:** Column metadata collection is usually the most accurate option, but it can take longer to process.

You can disable prepared query metadata using a TDC file. When you use column metadata collection, Tableau uses the ODBC API, SQLColumns. While this method is faster, it may not be as accurate. Use this option cautiously and only when it seems like a good approach for your data. Use the following capabilities to enable column metadata via SQLColumns:

- CAP\_ODBC\_METADATA\_SUPPRESS\_EXECUTED\_QUERY
- CAP\_ODBC\_METADATA\_SUPPRESS\_PREPARED\_QUERY

**Note:** To apply these capabilities to temporary tables, you must install Tableau Server 2019.3.6 or later.

## TDC example for SAP HANA

Your TDC file should look like the following example.

```
<?xml version='1.0' encoding='utf-8' ?>
<connection-customization class='saphana' enabled='true' version='9.3'>
<vendor name='saphana' />
<driver name='saphana' />
<customizations>
<customization name='CAP_ODBC_QUERY_USE_PREPARE_PARAMETER_MARKER'
value='yes' />
</customizations>
</connection-customization>
```

For more information about using TDC files, see "Create a TDC file" in the [Customize and Tune ODBC Connections](#) topic. Also see the Knowledge Base article called [Using a TDC File with Tableau Server](#).

**Important:** Be sure you include enabled='true' in your connection-customization line.

## SAP NetWeaver Business Warehouse

This article describes how to connect Tableau to SAP NetWeaver Business Warehouse (BW) data and set up the data source.

Use this connector with Tableau Desktop on a Windows computer.

### Install SAP software

Before you can connect Tableau to SAP BW data, you must install SAP software on your computer. For instructions on how to install SAP software, see [Connecting to SAP BW](#) on Tableau Community.

### Before you connect

Before you connect, gather this connection information:

- Connection name
- Authentication: User name and password, or integrated authentication
- (Optional) Client for BW system
- (Optional) Language

If you want to use single sign-on, be sure that your SAP personal security environment (PSE) is configured for single sign-on.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SAP NetWeaver Business Warehouse**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Select a connection from the drop-down list.

A connection appears in the drop-down list if a system entry exists for it. You can create a new system entry using the SAP Logon utility, or contact your database administrator.

- b. Select **Authentication** method:

**Username and Password** - Enter the user name and password to sign in to the server.

**Integrated Authentication** - Select this option if your environment is configured for single sign-on (SSO). This option is configured by the Tableau Server administrator. For more information, see [Enable Single Sign-On for SAP BW](#) in the Tableau Server Help.

- c. Optionally, enter the **Client ID** for the BW system and the **Language**.

- d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. Search for or select a catalog or InfoProvider.
- c. Search for or select a cube or query.
- d. Select the sheet tab to start your analysis.

**Note:** Tableau doesn't support link nodes.

## Support for SAPUILandscape.xml

Prior to version 7.40 of the SAP GUI tools, SAP BW connections are defined on client computers in the `saplogon.ini` file. When you add a connection definition using SAP Logon, that definition is added to the `saplogon.ini` file. Tableau reads from that file to get the list of SAP BW systems to show in the **Select connection** drop-down list in the Tableau connection dialog box.

Starting in version 7.40 of the SAP GUI tools, the format of the connection definition file has changed to XML, and this connection information is now stored in `SAPUILandscape.xml` and `SAPUILandscapeGlobal.xml`. Note that Tableau doesn't support using the `SAPLOGON_LSXML_FILE` environment variable to specify the location of these files.

Tableau supports using landscape XML files located on a remote HTTP server.

## Connections in drop-down list might not work

If you update to version 7.40 of the SAP GUI tools and then have issues with the **Select connection** drop-down list where connections don't work in Tableau, it might be because Tableau doesn't support `MessageServer` elements in the `SAPUILandscape.xml` and `SAPUILandscapeGlobal.xml` file. If a connection definition references a message server, the connection will display in the **Select connection** drop-down list, but it won't connect.

## Select variables and input parameters

If the table you use includes required or optional variables or parameters, the Variables and Input Parameters dialog box opens.

Enter values for Variables and Parameters or add a new Variable

Name	Current Value
Prod_Type	Equals "Coffee"
VAR_MarketSize	
VAR_Market	
VAR_ProductType	Equals "Coffee"
VAR_ProductType	Equals "Espresso"
VAR_ProductType	Equals "Herbal Tea"
VAR_ProductType	Equals "Tea"
<i>Add New</i>	

Edit Variable

Select an item from the list to change its values

OK Cancel

- Required variables and parameters display their current value or **\*Required**.
- Optional variables and parameters display their current value or are blank.
- Prompt for the variable when the workbook is opened by selecting the check box under **Prompt**.

Select a variable or parameter and type or select a value for it. Repeat for all required values and any optional values that you want to include, and then select **OK**.

### Select the alias for a dimension

When you connect to SAP NetWeaver Business Warehouse (SAP BW) databases, you have the option to select which alias to use for dimensions. SAP BW offers a number of different options including long name, short name, medium name, and key. Sometimes the alias used by default is not very useful. You can right-click the dimension and change it to another option such as **Short name**, which changes the labels to something more meaningful.

### Support for SAP BW extracts

Starting in 10.4, you can create an extract of SAP BW data without the need for a special product key from Tableau. Prior to 10.4, SAP BW extracts were an unsupported beta feature. If you're using this beta feature, product keys will be extended through 2017, however, once the keys expire or to get support for this feature, you must upgrade to version 10.4.

When you create an extract from an SAP BW data source, Tableau converts data from the cube into a relational extract. This conversion can sometimes take a while based on the size of the cube. In addition, much of the cube metadata cannot be represented in the relational data model, so there are some limitations when working with extracts created from an SAP BW data source in Tableau Desktop. (Note that beta extract functionality was not supported in Tableau Desktop 9.0.)

### SAP BW extract features

The following features are included in SAP BW extract functionality:

- The behavior of empty user filters has changed to be consistent with the behavior on other data sources. Using an empty user filter no longer hides the dimension.
- You can use **Hide** to hide dimensions before you extract data or refresh an extract. This reduces the size of the extract and the amount of time to perform an extract.
- Hiding a dimension takes priority over creating a user filter on the dimension.
- You can rename dimensions and measures in the data grid before extracting data.
- Tableau modifies the extract query slightly to fix some of the `[cube contains no data to transform]` errors.

### SAP BW extract limitations

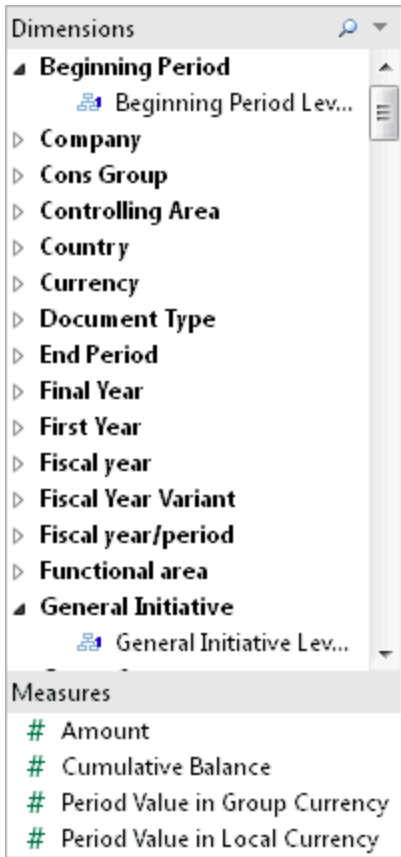

- Tableau supports only infocubes, or InfoProviders that contain only infocubes. A composite source that contains other BW object types is not supported.
- For large extracts, Tableau automatically partitions the query if the query fails or times out.
- BEx queries that contain more than 49 dimensions are not supported by SAP BW.
- You can't switch between a live connection and the extract. When you connect to an SAP BW data source, you'll have the option to Connect Live or Import the data. If you choose to Connect Live, the Extract options that are typically available for a connection are not an option. Further, if you choose to Import that data and create an extract, you cannot switch back to the live connection using the **Use Extract** command.
- You can't replace an extract with a live connection to SAP BW.
- Incremental extracts are not supported.
- When creating the extract, you can add filters to limit the data included in the extract, but these filters can be based only on hierarchies.
- Tableau doesn't support extracting the following SAP BW Objects:
  - Calculated sets.
  - Custom formatting and cell properties, except aliases.
  - User hierarchies. Hierarchies will collapse.
  - Pre-aggregated data.
  - Exception aggregation.
  - Compounding attribute.

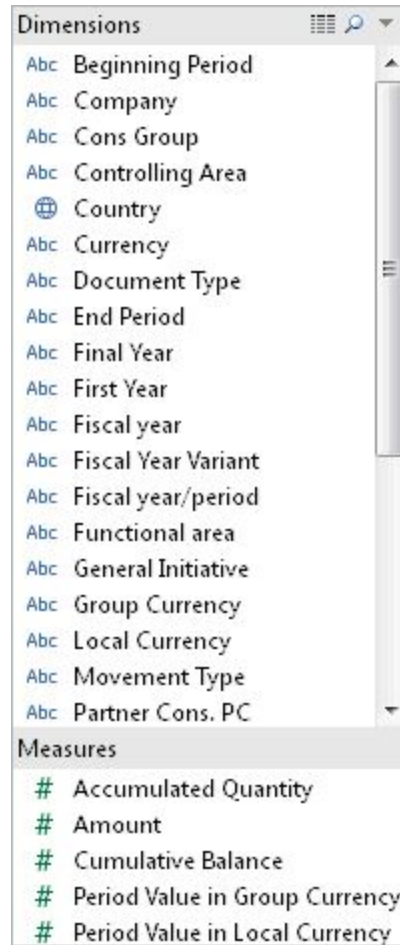

### Data displays differently for extract and live connections

In addition to the above limitations, you may notice some differences between an extract connection and live connection to SAP BW data. Specifically, when you connect to SAP BW directly, the dimensions, hierarchies, and levels are represented in the Data pane. After you create an extract, all of the fields are shown in a flat list.

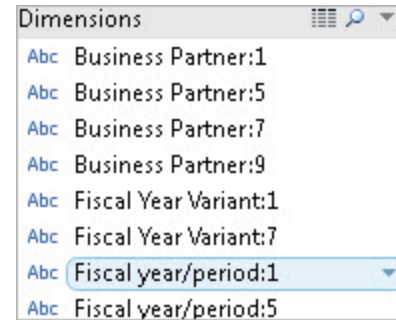

#### Live connection

#### Extract connection

When you connect to an SAP BW data source and create an extract or connect to a Tableau Data Source file (.tds) that connects to an SAP BW extract, the fields display in the Data pane as expected. However, if you connect directly to the extract file, you will see extra fields that represent the alias options. All aliases are included in the extract and are typically hidden. You can hide the alias variants that you are not using by right-clicking the field and selecting **Hide**.

**Aliases hidden****Aliases showing**

## Frequently asked questions

## Requirements

## What versions do I need?

- For the client machine where Tableau Desktop or Tableau Server is installed: SAP GUI 7.30 or later for Windows.
- For the server machine: SAP BW 7.40 or later.
- Tableau Desktop or Tableau Server, any supported version. For information about which versions are supported, see [Supported Versions](#) on the Tableau website.

## Do I need any special licenses like OpenHub to use Tableau with SAP BW?

Tableau uses the SAP OLE DB for OLAP provider (part of the Open Analysis Interfaces) to interact with SAP BW. This provider is a mechanism to do 'reporting' and retrieving 'reasonable' amounts of data. Unlike OpenHub, the interface is not designed for moving large amounts of data. You should verify with SAP that you have licensed SAP BW correctly for your environment and that your licensing terms permit the use of the OLE DB for OLAP provider for tools like Tableau.

## Does the SAP BW connector require HANA?

No. The Tableau SAP BW connector does not require HANA. The connector will work with any of the supported SAP BW backend databases such as Oracle and SQL Server. However, you may use HANA if you prefer.

## Can I connect to SAP BW using Logon Groups?

No. Tableau doesn't support connecting to SAP BW using Logon Groups.

### Connection

## Is the connection between Tableau and SAP BW a live connection or is it a Tableau extract?

Tableau supports live and extract connections to SAP BW data.

With a live connection you will always see the latest data in your workbooks and dashboards.

## Does Tableau support connecting directly to the underlying database tables that support the BW instance?

No. Tableau does not support this method for connecting to the SAP BW system.

### Performance

## How does performance compare to existing tools we use?

System performance should be comparable to existing tools. If performance is an issue in your environment, you might want to consider adopting SAP HANA in your environment. For more information, see [SAP HANA](#) on the SAP website.

### Security

## How does Tableau handle user security?

Tableau leverages all the security policies already implemented in the SAP BW server. There is no need for you to duplicate this in Tableau. All user authentication and authorization is performed by SAP BW. Tableau passes your credentials to the SAP BW system to be authenticated. Once authenticated, you will see only the objects and data that your profile or role on the SAP BW system has been enabled to access.

## How does user security work with Tableau Server when I publish a dashboard?

By default, worksheets and dashboards connected to SAP BW data require you to log into SAP BW with your SAP user name and password. However, Tableau Server can be configured to embed credentials so that you are taken directly to the published views and dashboards. In

In addition, Tableau Server offers an additional layer of security if desired. Tableau Server administrators can configure user authentication and authorization, independent and in addition to the SAP BW authentication and authorization. For more information about Tableau Server security, refer to the [Security](#) section of the Tableau Server Online Help.

## SAP SuccessFactors

This article describes how to connect Tableau to the SAP SuccessFactors application and set up the data source.

### Before you begin

Before you begin, gather the following connection information:

- Environment Account ID
- Authentication information

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SuccessFactors**. For a complete list of data connections, select **More**, under **To a Server**. Then do the following:
  - a. Enter the application ID.
  - b. Enter the authentication information.
  - c. Select **Sign In**.

**Note:** If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users figure out which data source to connect to.
  - b. From the **Database** drop-down list, select a database.
  - c. Under **Table**, select a table or use the search field to search for a table by name.

See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## SAP Sybase ASE

This article describes how to connect Tableau to an SAP Sybase ASE database and set up the data source.

Tableau connects to Sybase ASE version 15.2 and later.

### Before you begin

Before you begin, gather this connection information:

- Name of the server you want to connect to, port number, and if you use single sign-on, service name
- Authentication method: integrated authentication (single sign-on), or user name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SAP Sybase ASE**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server you want to connect to, and specify the port to use. Optionally, enter the service name. If you use single sign-on, you must enter the service name.
  - b. Select the **Authentication** method:
    - Integrated Authentication** - Select this option if your environment is configured for single sign-on (SSO).
    - Username and Password** - Enter the user name and password to sign in to the server.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Database** drop-down list, select a database or use the text box to search for a database by name.
  - c. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
  - d. Under **Table**, select a table or use the text box to search for a table by name.

You can also specify a stored procedure in the database. To access stored procedures, the database must be appropriately configured with a linked server,

which could be a remote server or a pointer to the database itself (known as *loopback*). For more information, see [Use a Stored Procedure on page 826](#).

- e. Drag a table or stored procedure to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** Kerberos authentication for SAP Sybase ASE doesn't support delegation. This means that if you selected **Integrated Authentication**, you can't use **Viewer credentials** as the **Authentication** method when you publish a workbook or data source to Tableau Server; you can only use **Server Run As account**, and the Tableau Server Run As User account must have an account in the SAP Sybase ASE database.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## SAP Sybase IQ

This article describes how to connect Tableau to an SAP Sybase IQ database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the host that hosts the database you want to connect to
- (Optional) Server name. Tableau supports Sybase IQ multiplexes, so a server name is not required.
- Authentication method: Windows Authentication or user name and password
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SAP Sybase IQ**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the host name that hosts the database that you want to connect to.
  - b. (Optional) Enter the server name.
  - c. Select how you want to sign in to the server. Specify whether to use Windows Authentication or a specific user name and password. If the server is password protected, you must enter the user name and password.
  - d. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - e. Select **Sign In**.  
  
If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Database** drop-down list, select a database or use the text box to search for a database by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.
  - d. Drag a table to the top area of the data source page, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.  
For more information, see [Connect to a Custom SQL Query](#) on page 811.

- [Build Charts and Analyze Data](#) on page 953 – Begin your data analysis.

## ServiceNow ITSM

This article describes how to connect Tableau to ServiceNow IT Service Management (ITSM) data and set up the data source.

**Warning:** The ServiceNow ITSM connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. Typically, a deprecated connector will be retired 1–2 releases after it is deprecated. You can use the ServiceNow connector from the [Tableau Exchange](#) instead.

**Note:** For the most up-to-date information on this connector, see the [ServiceNow ITSM](#) help topic for the current version of Tableau.

### Before you begin

Before you begin, gather this connection information:

- ServiceNow instance you want to connect to: cloud-based or on premises
- User name and password for a local ServiceNow account

### Connection requirements

To connect Tableau to ServiceNow, make sure that the following requirements are met:

- **Use a local ServiceNow account.** The ServiceNow API doesn't support single sign-on (SSO), so the Tableau connector can only authenticate using a local ServiceNow account. For more information, see [Use a local ServiceNow account](#) on page 484.
- **Have the correct permissions.** Access control lists (ACLs) must provide the user the permission required to access the data. For more information see [Troubleshoot data access](#) on page 484.

- **For on-premises, CORS is configured.** Before you connect to an on-premises instance of ServiceNow, you must configure CORS for Tableau in ServiceNow. For more information, see [Configure CORS for Tableau on ServiceNow](#) in Tableau Community.
- **For cloud instances, proxy connection is required.** The native ServiceNow connector routes through "servicenow-auth-proxy.connectors.tableau.com" instead of directly from the local user's IP. The proxy is necessary due to the way OAuth 2.0 is designed. It stores the unique client ID and secret required by OAuth to permit Tableau Desktop access to ServiceNow.

**Note:** Don't apply IP address access controls in ServiceNow when using a proxy connection. If you do need to apply IP address access controls, use [Find denied IP addresses](#) to find the denied IPs, and then add Allow rules for them. Be aware of that an IP associated with "servicenow-auth-proxy.connectors.tableau.com" may change. This is a cloud service and does not have static IP. Tableau does not provide or update information about the IP.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **ServiceNow ITSM**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Select **Instance Location: Cloud-based or On Premise**.
  - b. Enter your ServiceNow instance, user name, and password for a local ServiceNow account.

**Note:** When you select **On Premise**, you must enter a full URL for the ServiceNow instance.
  - c. Select **Sign In**.
  - d. Select **Filter Type: Relative date range or Fixed date range**, and then select or specify the range.
  - e. Select **Connect**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network or ServiceNow administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

- b. Under **Table**, select a table and drag it to the top of the canvas.
- c. Select the sheet tab to start your analysis.

After you select the sheet tab, Tableau imports the data by creating an extract. Note that Tableau Desktop supports only extracts for ServiceNow. You can update the data by refreshing the extract. For more information, see [Extract Your Data on page 867](#).

Creating extracts might take some time depending on the amount of data that is included.

## Use Accelerators

You can use an Accelerator to quickly build informative dashboard designs made specifically for key business metrics on Tableau Desktop and Tableau Cloud. For more information, see [Use Accelerators to Quickly Visualize Data on page 2651](#).

## Key considerations

### ServiceNow enforces an account's access permissions

ServiceNow accounts that have the Admin role can retrieve encrypted password values from the User table. This file will be null for accounts with less permissions. Because ServiceNow enforces the access permissions assigned to the account, be aware that there might be other sensitive fields in your data that an Admin can access.

### Custom tables not supported

The Tableau connector for ServiceNow ITSM supports the ITSM service, which doesn't include custom tables.

### ServiceNow provides table names

When you view tables in the Tableau connector, the tables are labeled according to their ServiceNow label, not the table name. For example, the table "sys\_user\_role" is shown by its label, "User Role". This label is determined by the ServiceNow connector.

### Display value fields aren't included in the data source

When you connect to a table that contains fields with display values (fields with a dv\_ prefix), those fields aren't included when you create a data source. You can add the display values by joining to the appropriate related tables that contain those values.

## Use a local ServiceNow account

You must use a local account to connect Tableau to your data. If you don't have a local ServiceNow account, we recommend that you ask your administrator to implement one of the following solutions:

- Create a local account and share it.
- Create a local account and temporarily share it long enough to extract the data and publish it to Tableau Cloud or Tableau Server. Then the administrator can save the new password and schedule refreshes.
- Create a local account on a non-production ("staging") instance and use it to create a data source. Give the data source to the administrator to edit the connection to point to the production instance, publish the data source to Tableau Cloud or Tableau Server, and schedule for data refreshes.
- Ask the administrator to publish the data sources you need.

## Date range selections can impact performance

When you apply a date filter, it's tempting to gather as much data as possible when you do an analysis, however, retrieving records from ServiceNow ITSM can be time-consuming. Tableau doesn't know how much data there is in a particular date range until it retrieves the data. For this reason, you should restrict your date range at first, and then expand after you evaluate performance. Date filters are applied to these tables: `metric_instance`, `change_request`, `incident`, `task`, `problem`.

To give you a rough idea of how much time it might take to retrieve data from ServiceNow ITSM, tests were conducted using a high-speed connection. This table shows how long it took in the test environment to retrieve a given number of records.

Number of records	Time to retrieve
1,000	11 seconds
10,000	2 minutes
100,000	18 minutes

## Troubleshoot data access

### For ServiceNow ITSM users

If you see an error when you try to access data, for example, "You are not authorized to access this resource...", contact your ServiceNow administrator.

## For ServiceNow administrators

ServiceNow uses access control lists (ACLs) to specify who has access to which data. Often the default permissions that are set for ServiceNow fulfillers are adequate for Tableau users to access the content they need to analyze ServiceNow ITSM data.

Tableau users need to access metadata about tables in ServiceNow, which is available in the following tables:

- `sys_dictionary` table (metadata about columns)
- `sys_db_object` table (metadata about tables)
- `sys Glide_object` table (metadata about field types)

If a Tableau user can't access ServiceNow ITSM data, make sure that the ACLs provide the user table level and field level read access to the tables above, and that there are no scripts that are locking down access.

To grant access to the metadata tables, as a best practice, you might consider creating a role with the ACLs needed to access the metadata tables, and then assign the role to a Tableau User group. Then, you can assign Tableau users to the group so that users can access the data needed for analysis in Tableau.

For information on the creation of an ACL, please see the [ServiceNow Access control list rules](#) on the ServiceNow website.

## ServiceNow

Applies to Desktop and server

This article describes how to connect Tableau to ServiceNow connector and set up the data source.

**Note:** Multi-factor authentication (MFA) isn't supported by this connector.

## Before you begin

Before you begin, gather this connection information:

- ServiceNow instance you want to connect to: cloud-based or on premises
- User name and password with appropriate data access.

## Make the connection and set up the data source

### Connection installation

You can Install the connector from the [Extension Gallery](#) or by clicking install from within Tableau Desktop.

This connector requires a plugin (taco file) and a driver to talk to the instance. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

1. Start Tableau and under **Connect**, select **ServiceNow**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter your ServiceNow instance, user name, and password.
  - b. Select **Sign In**.
  - c. Select **Connect**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network or ServiceNow administrator.
2. On the data source page, do the following:

(Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

  - a. Under **Table**, select a table and drag it to the top of the canvas.
  - b. Select the sheet tab to start your analysis.

After you select the sheet tab, Tableau imports the data by creating an extract.

### Refresh your data

Tableau only supports extract connections for ServiceNow, not live connections. You can update the data by refreshing the extract; incremental refreshes are not supported. For more information, see [Refresh Extracts](#). For information about refresh schedules see [Schedule Extract Refreshes as You Publish a Workbook](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## SharePoint Lists

The bundled connector was replaced by the SharePoint lists connector on the [Tableau Exchange](#).

**Warning:** The SharePoint Lists connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. Typically, a deprecated connector will be retired 1–2 releases after it is deprecated.

This article describes how to connect Tableau to SharePoint lists and set up the data source.

**Note:** Multi-factor authentication (MFA) isn't supported by the drivers currently available for Sharepoint Lists.

## Before you connect

Before you begin, gather this connection information:

- The URL to the SharePoint site that contains the lists you want to connect to
- The edition of your SharePoint server: on premises or SharePoint Online
- The method of authentication: third-party SSO or integrated authentication
- The user name or email address, password, and (optionally) SSO domain, if needed

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SharePoint Lists**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. In the **SharePoint Site** text box, enter the SharePoint URL. Don't include the list name in the URL.
  - b. Select the **Edition: On Premise** or **SharePoint Online**.
  - c. Select the **Authentication** method: **Username and Password**, **Third-party SSO**, or **Integrated Authentication**.
  - d. If the fields are available, enter the **Username** and **Password**, and optionally, enter **SSO Domain**.
  - e. Select **Sign In**.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. Under **Table**, select a table and drag it to the top of the canvas.
  - c. Select the sheet tab to start your analysis.

## Connection tips

- If you use SharePoint Online, select **Third-party SSO** as your **Authentication** type.
- If you use Kerberos, select **Integrated Authentication** as your **Authentication** type.
- If you use NTLM, select **Username and Password** as your **Authentication** type.
- If you select **Third-party SSO** as your **Authentication** type, enter your credentials, which might be your user name or email address, and your password. Optionally, enter the **SSO Domain**.

**Note:** Tableau currently supports only **Okta** and **OneLogin** for Third-party SSO connections.

- Any list you connect to will be the existing default SharePoint view only. This means that if any rows of data are filtered on the default view in SharePoint, you will not be able to

retrieve the filtered data. If your goal is to access everything in the SharePoint list then you will need to adjust the default view to show all rows.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

Both **Authentication** methods on a Mac require you to enter your user name and password to connect.

## Refresh your data

Tableau supports only extract connections for SharePoint lists, not live connections. You can update the data by refreshing the extract; incremental refreshes are not supported. For more information, see [Refresh Extracts on page 886](#). For information about refresh schedules, see [Schedule Extract Refreshes as You Publish a Workbook on page 3093](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## SharePoint Lists (JDBC)

This document describes how to connect Tableau to the SharePoint Lists (JDBC) driver and set up the data source.

**Note:** The SharePoint Lists JDBC connector requires Tableau 2022.3 or later and the SharePoint Lists JDBC driver.

## Before you connect

Before you begin, gather this connection information:

- The URL to the SharePoint site that contains the lists you want to connect to
- The edition of your SharePoint server: on premises or SharePoint Online
- The method of authentication: Azure AD, third-party SSO or integrated authentication
- The user name or email address, password, and (optionally) SSO domain, if needed

### Required API Permissions

Grant Tableau the following application programming interface (API) permissions.

- profile
- openid
- email
- AllSites.Manage
- offline\_access
- User.Read

### Recommendation

#### Setup a custom OAuth Client to use your company's IT policies

You can fully control your OAuth configuration according to your own IT policies with a custom OAuth client. The option to use your own OAuth client frees you from being tied to Tableau release cycles and Tableau's OAuth client rotation schedule.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SharePoint Lists (JDBC)**.
2. In the Server text box, enter the **SharePoint URL**.
3. Select the **Edition: On Premise** or **SharePoint Online**.
4. Select the **Authentication** method: **Azure AD**, **Username and Password**, **NTLM**, **ADFS** or **Basic**.
5. If Azure AD is chosen, select **Sign In**.
6. For other authentication methods, enter the required information, and then select **Sign In**.

On the Data source page, do the following:

1. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau.

For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.

2. To start your analysis, select the sheet tab.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

Both **Authentication** methods on a Mac require you to enter your user name and password to connect.

## Refresh your data

Tableau supports only extract connections for SharePoint lists, not live connections. You can update the data by refreshing the extract; incremental refreshes are not supported. For more information, see [Refresh Extracts on page 886](#). For information about refresh schedules, see [Schedule Extract Refreshes as You Publish a Workbook on page 3093](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## SingleStore

This article describes how to connect Tableau to a SingleStore database and set up the data source.

**Note:** SingleStore was **formerly named MemSQL**.

## Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- User name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **SingleStore**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database.
  - b. Enter the user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.

Select the **Require SSL** check box when connecting to an SSL server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Databases** drop-down list, select a database or use the text box to search for a database by name.
- c. Under **Table**, select a table or use the text box to search for a table by name.
- d. Drag a table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Snowflake

This article describes how to connect Tableau to a Snowflake data warehouse and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server name that you want to connect to
- Authentication method:
  - **OAuth**: Use this method if you want to enable federation from an IDP.
  - **SAML IDP**: Use this method if you want to embed the IDP credentials in the connection.
  - **Username and Password**: Use this method if you want to store user credentials in Snowflake.
- Sign in credentials depend on the authentication method you choose
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

**Note:** To support using OAuth with Snowflake, you must install an ODBC driver from Snowflake that is version 2.25.4 or more recent.

### Make the connection and set up the data source

After you select Snowflake as your connection, a POPUP menu displays with 3 tabs. Use the **General** tab for authentication. You can also use the **Initial SQL** to run a SQL command at the beginning of every connection. For more information, see [Run Initial SQL on page 591](#). You can use the **Advanced** tab to add customer connections with parameters.

### Connect Tableau to your data

1. Start Tableau and under **Connect**, select **Snowflake**.
2. Enter the name of the server that you want to connect to.
3. Select the **Authentication** method: **Username and Password**, **Okta Username and Password**, or **Sign in using OAuth**.
4. Select one of the authentication methods and complete the login steps.

#### **Okta Username and Password:**

- a. Enter the **Username** and **Password**,
- b. In the **Okta** field, enter the URL for the Okta server.

### Sign in using OAuth

- a. (Optional) Select **Initial SQL** if you want to run a SQL command at the beginning of every connection. For more information, see [Run Initial SQL on page 591](#).
  - b. Select **Sign In**.
  - c. In the web page that opens, log in to Snowflake by entering your **User Name** and **Password** and selecting **Log In**. Or select **Single Sign On** if Snowflake is configured to support SSO.
  - d. Click **OK** to confirm authorization to access your Snowflake data.
  - e. Close the browser window and Tableau.
  - f. Proceed to the next section, "Set up the data source."
5. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

### Customize the connection using driver parameters

You can modify the connection made with the Snowflake connector. You can do this by appending driver parameters to the connection string in the **Advanced** tab.

**Note:** You can't change the driver parameters that Tableau generates; you can only append parameters.

For example, this syntax specifies a proxy server to use when the `no_proxy` values are not met and which host names are allowed to bypass the proxy server:

```
Proxy=http://proxyserver.company:80;no_proxy=.trustedserver.com;
```

For another custom driver parameters example, see [Use a proxy for Snowflake on page 497](#).

**Note:** If you want customization without embedding it in the data source you can configure parameters in the registry on Windows (only parameters that are marked as "Configuration Parameters" are available). For details about driver parameters, see [ODBC Configuration and Connection Parameters](#) on the Snowflake website.

### Set up the data source

On the data source page, do the following:

1. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
2. From the **Warehouse** drop-down list, select the warehouse or use the text box to search for a warehouse by name.

**Note:** If you leave this blank and don't select a warehouse, Tableau uses your default Snowflake virtual warehouse.

For more information, see [Default virtual warehouses in Snowflake](#) below.

3. From the **Database** drop-down list, select a database or use the text box to search for a database by name.
4. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
5. Under **Table**, select a table or use the text box to search for a table by name.
6. Drag a table to the canvas, and then select the sheet tab to start your analysis.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Default virtual warehouses in Snowflake

When you create a Snowflake data source, you're creating a Snowflake warehouse (for computational resources) and Snowflake databases (for data resources). Warehouses and databases require permissions to access them. You can use different warehouses to access the same database, depending on the computation power you need, assuming you have permissions for each warehouse and database.

When you create a data source, you have the option to choose a warehouse from a drop-down list. If you leave this blank and don't select a warehouse, Tableau uses your default Snowflake virtual warehouse. If you subsequently publish that data source or workbook, when a user connects, Tableau will use that person's default Snowflake virtual warehouse.

Each user should be assigned a default warehouse so that Tableau can use that one as a default to open a workbook from a Snowflake data source.

### Configure Snowflake server support for OAuth

For information about how to configure OAuth for connections between Tableau and Snowflake, see [Configure OAuth for Snowflake Connections](#).

### Use a proxy for Snowflake

You can connect from Tableau through a proxy to Snowflake. If you are using version 2019.4 or later, you can configure it with the connector dialog by typing the required parameters in the **Advanced** tab.

For example:

```
proxy=http://proxyserver.company:80
```

For information about the parameters you should use, see the [Snowflake documentation](#).

**Note:** Tableau doesn't use a DSN to connect to Snowflake, so you can ignore the instructions in the Snowflake documentation about using a DSN.

If you're using Tableau version 2019.4, you can configure it by entering the parameters in a TDC file using `odbc-extras`.

For example:

```
<connection-customization class='snowflake' enabled='true' version='19.1'>
<vendor name='snowflake' />
<driver name='snowflake' />
  <customizations>
    <customization name='odbc-connect-string-extras'
value='proxy=http://proxyserver.company:80' />
  </customizations>
</connection-customization>
```

For more information, see the [Customize the Connection String for a Native Connector](#) article.

### Frequently asked questions

The following are some common problems and solutions.

### I have an error "This Field XXX Does Not Exist" what do I do?

This error appears when you are re-creating a calculation field, adding it to the worksheet, and replacing the data source with the Snowflake data (CustomSQL).

Use the **Replace Field References** function to resolve the error. For additional information on replacing field references, see [Replace Field References](#).

- [Best Practices for Using Tableau with Snowflake](#) on the Snowflake website (registration required).

#### See also

- [Set Up Data Sources](#) on page 596 – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data](#) on page 953 – Begin your data analysis.

### Configure OAuth for Snowflake Connections

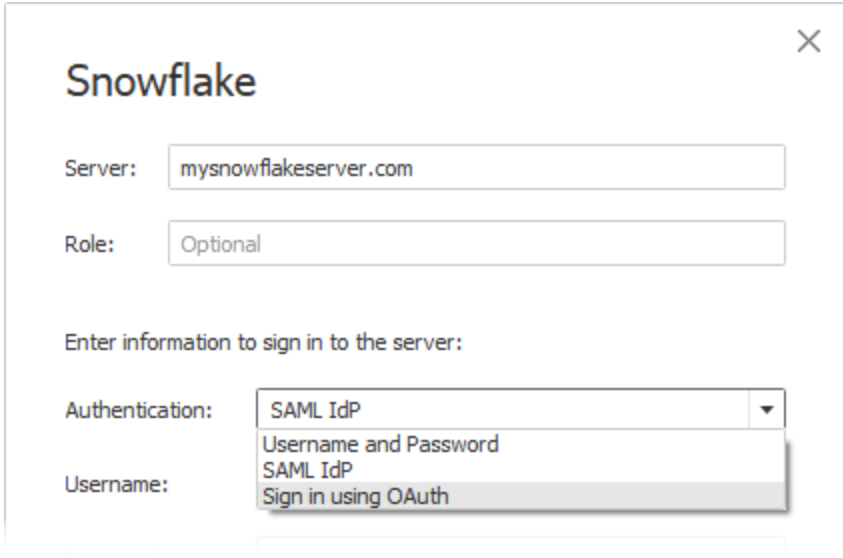

When you connect to your Snowflake data, you have three authentication options to choose from.

**OAuth:** You can use [OAuth](#) to enable federation from an IDP.

**Okta Username and Password:** You can embed the IDP credentials in the connection (only for Okta).

**Username and Password:** User credentials are stored in Snowflake.

Usually, we recommend using OAuth. This option offers the best combination of functionality and security.

With OAuth, you can:

- Use an identity provider (IdP) to facilitate access.
- Configure it to provide a single sign-on (SSO) experience.
- Enforce multi-factor authentication (MFA).

OAuth 2.0 is an industry-standard protocol for authorization.

**Note:** Be careful not to confuse this with Tableau’s **SAML IdP** authentication option in the connection dialog. You should connect using the **Sign-in using OAuth** option.

When you use OAuth, a key consideration is keeping access for content published to Tableau Server or Tableau Cloud. When Tableau content connects live to Snowflake via OAuth, owners must reauthenticate the workbook connection each time the access token expires (every 90 days by default).

See the Snowflake help topic, [Configure Snowflake OAuth for Partner Applications](#), for details on setting the access token expiration limit. If you have a business must extend this period to prevent errors on your Tableau content, contact [Snowflake Support](#) for assistance. If you don’t manually refresh your content before this time period, it can cause an error when the Tableau workbook tries to load.

### Configure OAuth between Snowflake and Tableau

In a connection between Tableau and Snowflake, each must have OAuth configured.

- **Tableau:** Tableau includes credentials for Snowflake to allow access. This happens automatically when you use the Snowflake connector in Tableau. No additional OAuth configuration is required in Tableau. For more information, see [OAuth Connections](#) in Tableau Help.
- **Snowflake:** In Snowflake, you'll enable OAuth to grant access to Tableau. Follow steps in this Snowflake help topic: [Configure Snowflake OAuth for Partner Applications](#).

**Note:** Beginning with version 2020.4, your OAuth connection can use AWS PrivateLink or Azure Private Link. For more information, see [Change Snowflake OAuth to Private Link with Saved Credentials](#).

## About using SSO with OAuth

Single Sign-On (SSO) adds another layer of security on top of OAuth authentication. A separate IdP configured for SSO manages authentication for all access activity across applications for your organization. All sign-in requests are routed to the SSO server, which displays a common sign-in dialog and checks the user's credentials against a centralized database.

**Tip:** You can use saved credentials to avoid getting reprompted for your password. For more information, see [Manage Saved Credentials for Data Connections](#).

## Configure OAuth between Okta and Snowflake

Snowflake uses Okta as the default identity provider (IdP) that provides access tokens and authenticates identities. You'll need to configure settings in Snowflake and Okta for OAuth and single sign-on (SSO) capabilities.

In Okta, you'll define Okta as an OAuth authentication server and identify Snowflake as an OAuth resource. Follow steps in this Snowflake help topic: [Configuring an Identity Provider for Snowflake](#).

The image shows a login interface for Snowflake. At the top, it says "Log in to Snowflake to continue to TABLEAUDESKTOP\_OAUTH\_INTEGRATION (Tabl". Below this is a button labeled "Single Sign On" with a blue circular icon to its left. Underneath the button is the word "or". Below "or" are two input fields: "User Name" and "Password". At the bottom of the form is a button labeled "Log In".

## About using MFA with OAuth

Multi-factor authentication (MFA) introduces yet another layer of security. It needs two or more different methods of identification before the user can access a resource. Methods might include:

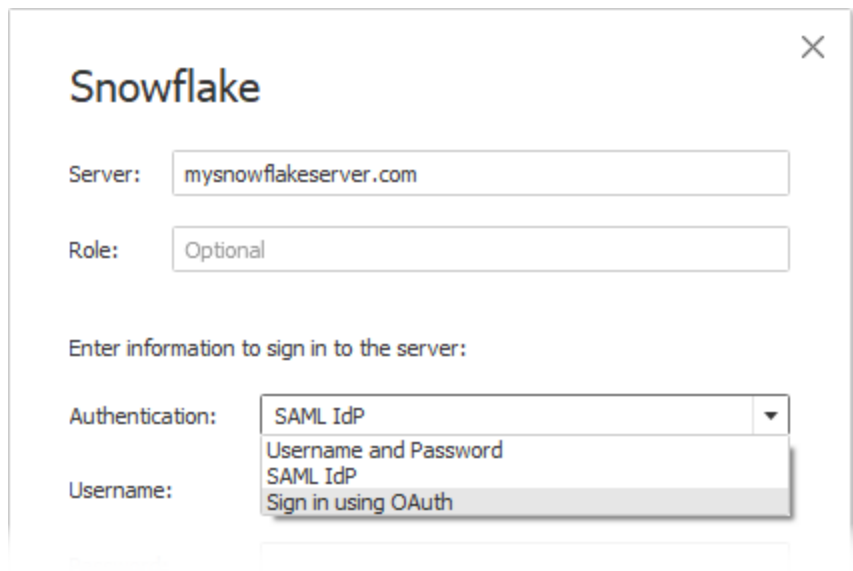

- A password
- A token from a second device
- Biometrics (fingerprint or eye scan, for example)
- Answer to a security question

You can optionally set up multi-factor authentication (MFA) with Okta or other an IdP for your connections between Tableau and Snowflake. For more on configuring MFA with Okta, see [Okta Help](#).

## Other connection options

When you connect to Snowflake from Tableau Desktop, you have two other options:

- SAML IdP
- Username and Password

The **SAML IdP** option works only if Okta is your identity provider and if MFA is disabled for users in Okta. The **SAML IdP** option supports SSO but doesn't support MFA. In this case, publishing with embedded credentials will use a specific user, but you can't employ per-user "viewer credentials" when you use Okta SAML.

**Note:** In the past, some customers have used the “[external browser](#)” option with SAML IdP as a workaround to achieve SSO between Tableau Desktop and Snowflake. It won't work for Tableau Server. We recommend that you use the OAuth connection instead.

The **Username and Password** option uses the password stored by Snowflake. This option requires users to reauthenticate with their credentials whenever they connect to Snowflake or to embed these credentials.

## Frequently asked questions

### Why do my published Snowflake data extracts fail after a period of time?

It may be that your OAuth access token has expired. You'll need to manually reauthenticate to the data source to refresh the token. If you need to extend the lifetime of these tokens in the future, you can contact [Snowflake Support](#).

### How do I choose between "Prompt User" and "Embed Credentials" options when publishing a Snowflake data source?

If you would like any user accessing the data source to use their own credentials when connecting to the data source and associated content, use the **Prompt User** option. You can choose to embed credentials so everyone who accesses that data source uses those specific credentials. This method is functionally similar to using a "service account".

### How do I use the row-level security that I've set up on Snowflake?

When users are prompted to enter their own credentials to access Snowflake from Tableau, those credentials map to the privileges they have in the Snowflake account.

## Spark SQL

This article describes how to connect Tableau to a Spark SQL database and set up the data source. Tableau can connect to Spark version 1.2.1 and later.

You can use the Spark SQL connector to connect to a Spark cluster on Azure HDInsight, Azure Data Lake, Databricks, or Apache Spark.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to and port number
- Authentication method:
  - No Authentication
  - Kerberos
  - User Name
  - User Name and Password
  - Microsoft Azure HDInsight Service
- Transport. Your choices depend on the authentication method you choose, and include the following:
  - Binary
  - SASL
  - HTTP
- Sign-in credentials. Your choices depend on the authentication method you choose, and can include the following:
  - User name
  - Password
  - Realm
  - Host FQDN
  - Service Name
  - HTTP Path
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Spark SQL**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the port number to use.
  - b. Connect to the database using SparkThriftServer. Note that the legacy SharkServer and SharkServer2 connections are provided for your use, but are not supported by Tableau.
  - c. Select the **Authentication** method. Then, based on your selection, enter the information you are prompted for.
  - d. Select **Sign In**.
    - If the server is password protected, and you are not in a Kerberos environment, you must enter the user name and password.
    - Select the **Require SSL** check box when connecting to an SSL server.
    - (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL](#).

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the schema.
  - c. In the **Table** text box, select the search icon or enter the table name and select the search icon, drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

**Note:** Starting in 2018.3, Kerberos authentication for Spark SQL supports delegation. In 2018.2 and earlier, delegation isn't supported, which means that in earlier versions you

can't use **Viewer credentials** as the **Authentication** method when you publish a workbook or data source to Tableau Server; you can only use **Server Run As account**.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Teradata

This topic describes how to connect Tableau to a Teradata database or a Teradata Unity server and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- For Teradata database: Name of the server you want to connect to
- For Teradata Unity server: URL of the server you want to connect to
- Authentication method: Teradata Database, LDAP, or Integrated Authentication
- Depending on the environment, the user name and password
- Do you need an encrypted connection?
- (Optional) Query banding and initial SQL statement to run every time Tableau connects

## Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Teradata**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database you want to connect to.
 

**Note:** You can connect to a Teradata Unity server by entering the appropriate URL in the **Server** text box.
  - b. Select how you want to sign in to the server. Specify whether to use the built-in **Teradata Database** authentication, **LDAP**, or **Integrated Authentication**.
 

If the server is password protected, and you are not in a Kerberos environment, you must select **Teradata Database** or **LDAP** and enter the user name and password.
  - c. Select the **Require Encryption** check box if you need an encrypted connection.
  - d. (Optional) Select **Query Banding and Initial SQL**.
  - e. Select **Sign In**.
 

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Database** drop-down list, select the search icon or enter the schema name in the text box and select the search icon, and then select the database.
  - c. In the **Table** text box, select the search icon or enter the table name and select the search icon, and then select the table.

You can also specify a stored procedure in the database. For more information and for a list of constraints specific to Teradata databases, see [Use a Stored Procedure on page 826](#).

- d. Drag the table or stored procedure to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## Use query bands to increase performance

When you connect to a Teradata database, you can optionally define query band statements that run during connection. These statements can increase performance, and they take advantage of the built-in security rules of the database.

Using query bands, you can pass parameters into the Teradata environment. Use these to set up a workbook to filter the data based on security rules that exist in the database. For example, you can pass in the Tableau Server user name for the current user so that when the view is loaded it only shows the data specific to that user. Query bands can also be used to improve performance. When connecting to Teradata, you can define a map between the name of the attributes passed into the query band and the corresponding values from Tableau.

**Note:** This functionality is not currently supported for web authoring.

### To set up query banding:

1. On the data source page, select **Data > Query Banding and Initial SQL**.
2. In the subsequent dialog box, specify name/value pairs in the top text box labeled Query Banding. You can use the **Insert** drop-down menu to add Tableau values. The Tableau values are described in the table below.

Value	Description	Example
<TableauMode>	The mode Tableau is operating in when generating queries. This value will either be “Connect” when retrieving metadata or “Analytical” when retrieving actual data.	Connect or Analytical
<LoginUser>	The user name of the person signed in to the database.	jsmith
<ServerUser>	<p>The signed-in Server user. Does not include domain name.</p> <p><b>Note:</b> ProxyUser returns the same value as ServerUser. However, ProxyUser sets up impersonation and stores the Tableau Server user in the query band parameter. If you are using query banding for security purposes, you should use ProxyUser instead. This will ensure that query results are not shared between different users. ServerUser should only be used for auditing purposes.</p>	jsmith
<ServerUserFull>	<p>The signed-in server user including the domain name (if the server is using Active Directory).</p> <p><b>Note:</b> ProxyUserFull returns the same value as ServerUserFull. However,</p>	domain.lan\jsmith

Value	Description	Example
	<p><code>ProxyUserFull</code> sets up impersonation and stores the Tableau Server user in the query band parameter. If you are using query banding for security purposes, you should use <code>ProxyUserFull</code> instead. This will ensure that query results are not shared between different users.</p> <p><code>ServerUserFull</code> should only be used for auditing purposes.</p>	
<ProxyUser>	Used when setting up impersonation on the server. Provides the username of the current server user.	jsmith
<ProxyUserFull>	Used when setting up impersonation on the server. Provides the username and domain name of the current server user.	domain.lan\jsmith
<TableauApp>	The name of the Tableau application.	Tableau Desktop Professional or Tableau Server
<TableauVersion>	The version of the Tableau application	6100.11.0428.0300
<WorkbookName>	The name of the workbook. Note that this only works for data sources embedded in the workbook.	Financial-Analysis

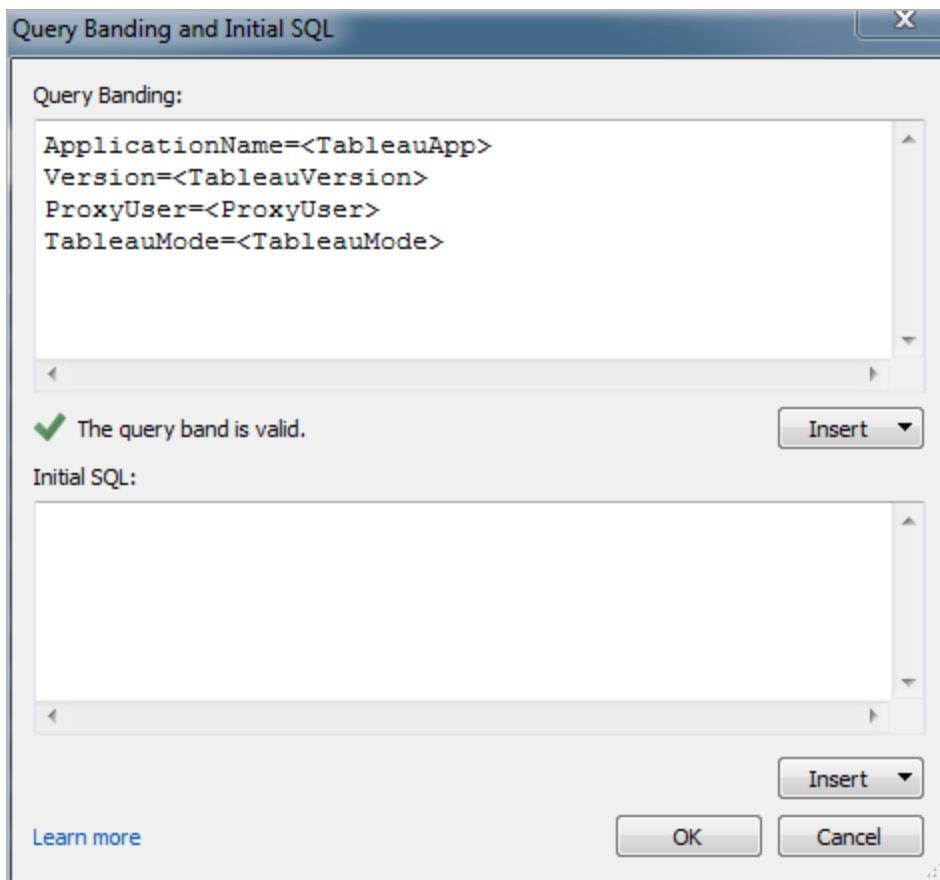

An example query band statement is shown below. This example passes the user name for the current server user.

```

ApplicationName=<TableauApp>
Version=<TableauVersion>ProxyUser=<ProxyUser>TableauMode=<TableauMode>

```

Tableau checks the statement for errors as you type. When it is valid a green check mark displays at the bottom of the text box.

### Use initial SQL commands

When you connect to a Teradata database, you can optionally specify a SQL command that will be run once upon connection. See [Run Initial SQL on page 591](#) to learn more about adding these commands to your connection.

**Note:** If Tableau detects that the Initial SQL payload cannot be delivered in one query, it attempts to split the query into separate statements, where each statement must end with a semicolon followed by a newline character, with no additional characters (such as an extra space) in between. This requirement is important because if a semicolon exists within the interior of a statement, for example within a string literal, it may not be safe to split the statement at that point. If the Initial SQL code that you specify in Tableau returns an error, and the same Initial SQL is deemed valid by the Teradata databases, it may be that Tableau has split the query incorrectly. If this happens, try reformatting the SQL code in Tableau manually.

## Teradata OLAP Connector

This article describes how to establish a Teradata OLAP connection.

### Before you begin

Before you begin, gather this connection information:

- Connection name
- User name and password

Use this connector with Tableau Desktop on a Windows computer.

When you connect to Teradata OLAP data, you select from a list of connections, each representing a system data source name (DSN). A connection appears in the drop-down list if a system DSN exists for that connection. You can use the Windows ODBC Data Source Administrator utility to create a system DSN, or contact your database administrator.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays

a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

## Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Teradata OLAP Connector**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:

- a. Select a connection from the drop-down list.
- b. Enter your user name and password to log on to the server.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

- c. Select **Sign In**.
2. On the data source page, do the following:
    - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
    - b. Search for or select a catalog.
    - c. Search for or select a cube from the catalog.
    - d. Select the sheet tab to start your analysis.

## Work with Teradata OLAP data

Named sets from a Teradata OLAP data source are displayed in the **Sets** area of the **Data** pane in Tableau. You can interact with these named sets in the same way you interact with other custom sets in Tableau. For more information, see [Create Sets on page 1040](#). You can view underlying data for Teradata OLAP data sources, provided the database administrator has enabled this functionality. For more information, see [View Underlying Data on page 2610](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## TIBCO Data Virtualization

This article describes how to connect Tableau to a TIBCO Data Virtualization (formerly called Cisco Information Server) virtual database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the data you want to connect to
- (Optional) Domain name
- Datasource name
- Authentication method: Windows Authentication, Kerberos, or user name and password
- Are you connecting to an SSL server?
- (Optional) Initial SQL statement to run every time Tableau connects

Use this connector with Tableau Desktop on a Windows computer.

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **TIBCO Data Virtualization**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the data you want to connect to.
  - b. (Optional) Enter the name of the domain.
  - c. Enter the name of the **Datasource** you want to connect to.
  - d. Select how you want to sign in to the server. Specify whether to use Windows Authentication, Kerberos, or a user name and password.  
  
Select the **Require SSL** check box when connecting to an SSL server.
  - e. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in

to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).

f. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.

2. On the data source page, do the following:

- a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
- b. From the **Catalog** drop-down list, enter the catalog name in the text box, or select the catalog from the list.
- c. From the **Schema** drop-down list, enter the schema name in the text box, or select the schema from the list.
- d. Under **Table**, enter the table name in the text box, or select the table from the list.
- e. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source. For more information, see [Connect to a Custom SQL Query on page 811](#).

### See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Vertica

This article describes how to connect Tableau to a Vertica database and set up the data source.

### Before you begin

Before you begin, gather this connection information:

- Name of the server that hosts the database you want to connect to
- Database name
- User name and password
- (Optional) Initial SQL statement to run every time Tableau connects

### Driver required

This connector requires a driver to talk to the database. You might already have the required driver installed on your computer. If the driver is not installed on your computer, Tableau displays a message in the connection dialog box with a link to the [Driver Download](#) page where you can find driver links and installation instructions.

### Make the connection and set up the data source

1. Start Tableau and under **Connect**, select **Vertica**. For a complete list of data connections, select **More** under **To a Server**. Then do the following:
  - a. Enter the name of the server that hosts the database and the name of the database that you want to connect to.
  - b. Enter the user name and password.
  - c. (Optional) Select **Initial SQL** to specify a SQL command to run at the beginning of every connection, such as when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. For more information, see [Run Initial SQL on page 591](#).
  - d. Select **Sign In**.

If Tableau can't make the connection, verify that your credentials are correct. If you still can't connect, your computer is having trouble locating the server. Contact your network administrator or database administrator.
2. On the data source page, do the following:
  - a. (Optional) Select the default data source name at the top of the page, and then enter a unique data source name for use in Tableau. For example, use a data source naming convention that helps other users of the data source figure out which data source to connect to.
  - b. From the **Schema** drop-down list, select a schema or use the text box to search for a schema by name.
  - c. Under **Table**, select a table or use the text box to search for a table by name.

- d. Drag the table to the canvas, and then select the sheet tab to start your analysis.

Use custom SQL to connect to a specific query rather than the entire data source.

For more information, see [Connect to a Custom SQL Query](#) on page 811.

## Sign in on a Mac

If you use Tableau Desktop on a Mac, when you enter the server name to connect, use a fully qualified domain name, such as mydb.test.ourdomain.lan, instead of a relative domain name, such as mydb or mydb.test.

Alternatively, you can add the domain to the list of Search Domains for the Mac computer so that when you connect, you need to provide only the server name. To update the list of Search Domains, go to **System Preferences > Network > Advanced**, and then open the **DNS** tab.

## See also

- [Build Charts and Analyze Data](#) on page 953 – Begin your data analysis.

[Vertica & Tableau Solution Overview](#) - Read the Tableau whitepaper (registration or sign in required).

[Vertica Integration with Tableau: Connection Guide](#) - Read the Vertica knowledge base article on the Vertica website.

## Web Data Connector 2.0

This article describes web data connectors, what to do before you use a connector, and how to connect Tableau to a web data connector.

**Note:** As of 2022.3 the Web Data Connector 2.0 has been replaced by Web Data Connector 3.0. For more information, please see: [Web Data Connector SDK](#)

**Warning:** The Web Data 2.0 connector is deprecated as of the 2023.1 release. You can use the connector until it's been retired. Once the connector is retired, it's removed from the Tableau user interface and any data sources using the connector will no longer work as expected. Typically, a deprecated connector will be retired 1–2 releases after it is deprecated.

### Use a web data connector

You can use a web data connector to connect to data that is accessible over HTTP and that doesn't already have a connector. A web data connector is an HTML file that includes JavaScript code. You can create your own web data connector or use one that has been created by someone else. The web data connector must be hosted on a web server running locally on your computer, on a web server in your domain, or on a third-party web server.

### Test and vet the web data connector

You should use a web data connector that you trust. If you are unfamiliar with the web data connector, you or your Tableau Server administrator should test and vet the web data connector before you use it. For more information, see [Testing and Vetting Web Data Connectors](#) in the Tableau Server Help.

### How to use a web data connector on Tableau Server and Tableau Cloud

When you use a web data connector, Tableau creates an extract of the data that the connector accesses. You can refresh the extract in Tableau Desktop.

When you publish the data source or workbook to Tableau Server, you cannot refresh the extract on Tableau Server unless the web data connector is added to the safe list on Tableau Server. If the connector requires credentials to sign in to the web-based data source, you need to ensure that the credentials are embedded with the data source. For more information, see [Web Data Connectors in Tableau Server](#) in the Tableau Server Help.

After the web data connector has been tested and vetted, the server administrator can add the URL for the connector to the safe list on the server. The server administrator should give this URL to you and to anyone else who wants to use the connector in a workbook.

If you open a workbook on Tableau Server that was created using a web data connector, but the connector has not been added to the safe list on Tableau Server, and you want to be able to refresh the extract on Tableau Server, follow the process for testing, vetting, and adding the connector to the safe list. If the connector requires credentials to sign in, you need to ensure that the credentials are embedded with the data source. You can then refresh your data on Tableau Server.

When you publish to Tableau Cloud, as a security measure, Tableau Cloud can't connect to or refresh an extract created by a web data connector. To refresh some web data connector extracts, you can use Tableau Bridge. For more information, see [When to use Tableau Bridge to keep data fresh](#) in the Tableau Cloud Help.

When you publish to Tableau Public, because you can't add a web data connector to Tableau Public, you can't refresh web data connector extracts directly on Tableau Public.

## Connect to the data source

1. Start Tableau and under **Connect**, select **Web Data Connector**. For a complete list of data connections, select **More** under **To a Server**.
2. Enter the URL of the web data connector that you want to connect to, and then press Enter.

**Note:** If you enter a URL to a website, rather than to a web data connector, an error message will appear.

3. If the connector displays a web page, enter any information that you're prompted for, and then submit the page.
4. Wait while the connector retrieves your data and imports it into Tableau as an extract.
5. Select the sheet tab to start your analysis.

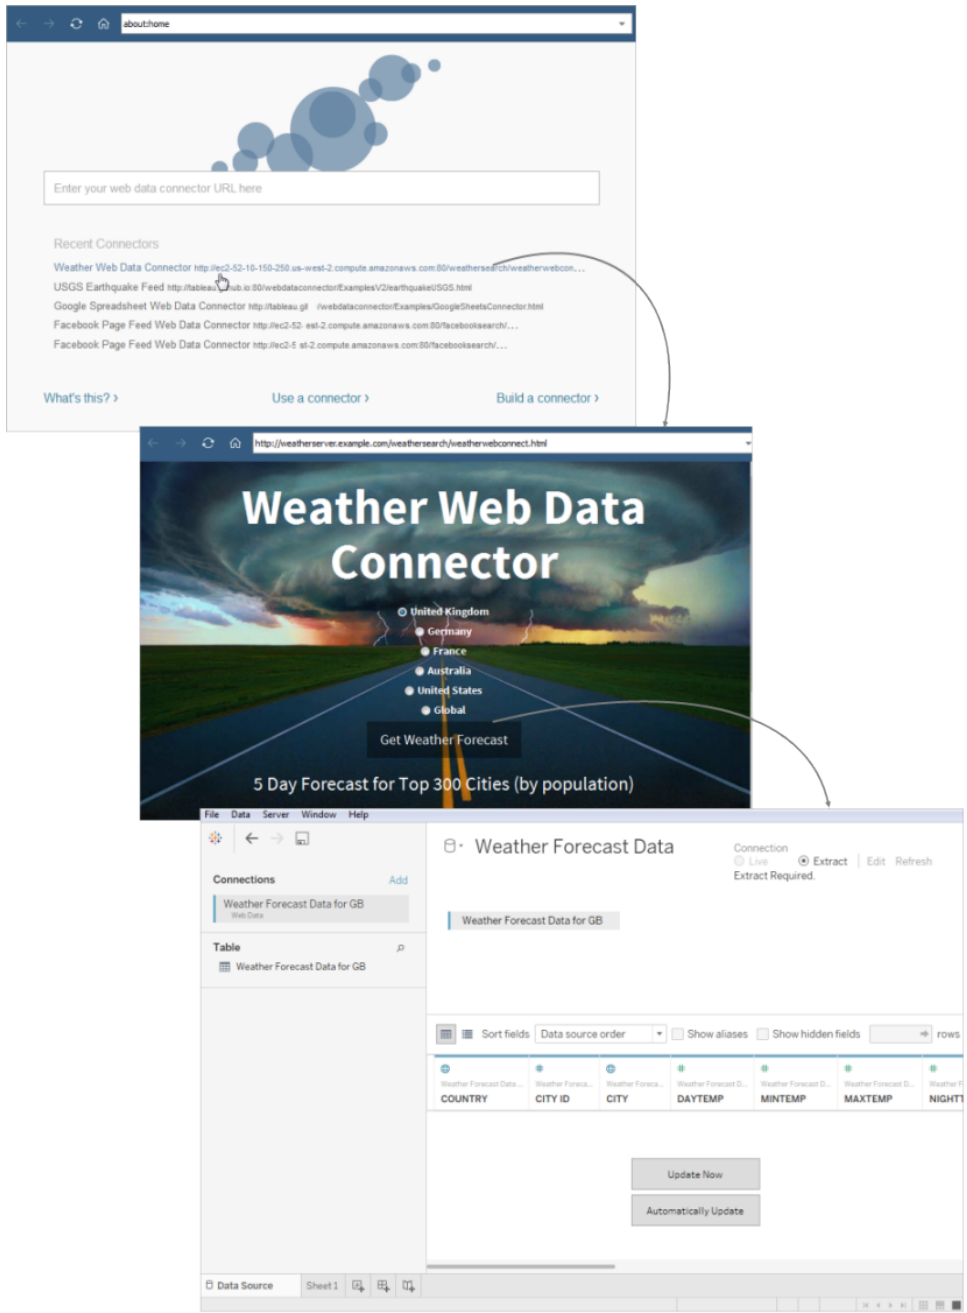

## Web data connector data source example

An example of a web data connector data source is shown below. The first time you connect to a web data connector, the connection page outlines how to connect to the web data connector.

After you connect to a web data connector, on the connection page, you can do the following:

- View a history of all the web data connectors that you've connected to, or clear the history, in the drop-down list in the address bar.
- View your five most recently used connectors under Recent Connectors.
- Select links at the bottom on the window to learn more about web data connectors:
  - **What's this?** links to an overview of this feature.
  - **Use a connector** links to this topic.
  - **Build a connector** links to the [Web Data Connector SDK](#), which provides tools and documentation for building a web data connector.

## Tableau Desktop and Web Authoring Help

### Optional settings

After you connect, you can make the following configuration changes to the data source before you start your analysis.

- **Sort fields and rows** – From the **Sort fields** drop-down list, select how you want to sort the columns in the grid or metadata grid. Sort the row values by selecting the sort button

next to the column name.

- **Rename or hide columns** – Select the column header drop-down arrow and select the option you want.
- **Split columns** – Depending on how the data is structured, you can split the columns in your data into new fields. For more information, see [Split a Field into Multiple Fields on page 853](#).
- **Create calculations** – Create a new calculation based on an existing field in the data source.
- **Copy values** – Copy values in the grid by selecting the values and then pressing Ctrl+C. Alternatively, to copy values in the metadata grid, select the values, right-click, and then select **Copy**.
- **Add new or edit other data sources** – Select the drop-down arrow next to the data source.

## Tableau support for Web Data Connector

Tableau provides limited customer support for connections using the **Web Data Connector**. Tableau does not provide support for connectors or for other programs written to interface with the WDC API. However, you can submit questions and ask for help on the [Tableau developer community forums](#).

Tableau *does* provide support for the WDC library and SDK though. If you find an issue with the WDC library, the simulator, or any of the developer samples, [submit an issue on Github](#).

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.

## Other Databases (JDBC)

When you start Tableau, under **Connect**, you can see the file and database types that are supported by Tableau Desktop. Select **More** to see the complete list. For supported files and databases, Tableau provides built-in connectors that are built for and optimized for those data sources.

**Important:** If your file or database type is listed under **Connect**, use that named connector to connect to your data.

If your file or database type is not listed on under **Connect**, you might be able to connect to it using the **Other Databases (JDBC)** connector. JDBC (Java Database Connectivity) is a standard way to connect to a database. If the database driver you want to connect with implements the JDBC standard, you can connect Tableau to your data using the JDBC driver for your database and the Tableau **Other Databases (JDBC)** connector.

When you use the **Other Databases (JDBC)** connector, you might notice significant performance differences between this "generic" connector and a named Tableau connector because the generic JDBC connection doesn't take advantage of the many connection-specific features used in a named connector to optimize performance.

## Before you begin

### Specify the right JDBC driver

JDBC drivers are self-contained .jar files. Place the .jar files in the folder for your operating system. (You need to create the folder if it doesn't already exist.)

- Windows: C:\Program Files\Tableau\Drivers
- Mac: ~/Library/Tableau/Drivers
- Linux: /opt/tableau/tableau\_driver/jdbc

**Note:** If the driver includes only a single .jar file, simply copy it to C:\Program Files\Tableau\Drivers. If the driver includes multiple files, create a subfolder "A" under C:\Program Files\Tableau\Drivers, then copy all files to folder "A".

Also note these requirements:

- You must have read permissions on the .jar file.
- Tableau requires a JDBC 4.0 or later driver.
- Tableau requires a Type 4 JDBC driver.

**Note:** To prevent secrets from logging you need to enter the secrets for JDBC connectors in either the password field on the dialog or in the driver properties.

## Dialect support

The **Other Databases (JDBC)** connector supports the following dialects, which are used to establish how Tableau translates the SQL queries that are sent to the database:

- MySQL
- PostgreSQL
- Generic SQL-92

## Gather connection information

Gather the following connection information:

- JDBC connection string to enter in the URL field when you connect. Refer to the driver's documentation to make sure you use the correct format for your JDBC driver. Here is one example:

```
jdbc:postgresql://www.exampledatabase.com:5432/databasename
```

- `jdbc` - always use the `jdbc` prefix, or else you'll disable the sign in button.
- `postgresql` - defines the class of the JDBC driver you're using. Tableau checks for a matching driver in the Tableau driver folder. The JDBC driver has a sub-protocol associated with it, such as `postgresql` for PostgreSQL or `mysql` for MySQL.
- `www.exampledatabase.com` - the network address to your database server. You can use a host name or an IP address.
- `5432` - the port that the database is responding to at the network address specified.
- `databasename` - the name of the database or schema on your database server.
- The dialect you're using: MySQL, PostgreSQL, or SQL-92.
- Credentials for signing in to the server: user name and password.
- (Optional) JDBC properties file to customize the driver behavior. For more information, see [Customize JDBC Connections Using a Properties File](#) in Tableau Community.

## Make the connection

To connect to your data using the JDBC driver, do the following:

1. Start Tableau and under **Connect**, select **Other Databases (JDBC)**. For a complete list of data connections, select **More** under **To a Server**.
2. Enter the JDBC connection string in **URL** field.
3. Select the **Dialect** from the drop-down list.
4. Enter the user name and password for signing in to the server.

5. (Optional) Browse to the JDBC properties file. When you use a properties file, it overrides class-level properties.
6. Select **Sign in**.

**Important:** When you use **Other Databases (JDBC)** to connect to a database, the outcome may vary and compatibility with Tableau Desktop features is not guaranteed.

If your connection works as you need it to, you can begin your analysis. If, however, you need to customize your JDBC connection to improve functionality and performance, refer to the articles under [See also on the next page](#).

### Configure for publishing and cross-platform portability

When you work with a generic JDBC connection, additional configuration is required to make sure that the workbooks and data sources you create can be used on different computers and platforms.

For publishing and for cross-platform portability, the driver must be installed to match the workbook or data source connection.

As an example, Ashley Garcia creates an **Other Databases (JDBC)** data source that connects using the associated JDBC driver installed on her Windows computer.

Ashley can do a couple of things with this data source to make it available for others to use.

- She can publish it to Tableau Server. When she does this, Ashley needs to ask the Tableau Server administrator to install the associated JDBC driver on the Tableau Server computer so that the data source can be accessed by Ashley and by others.
- She can email the data source to coworkers. Ashley needs to tell the coworkers to install the associated JDBC driver on their computers so that they can open the data source in Tableau Desktop.

When you try to open a workbook or data source created using the **Other Databases (JDBC)** connector and you don't have the JDBC driver installed, you'll see an error that includes the message `No suitable driver`. To resolve this error, contact the workbook or data source publisher or the Tableau Server administrator to get the JDBC driver that matches the workbook or data source. Then install the driver on your computer.

### Review your data

Tableau probably hasn't tested the database your connecting to using the **Other Databases (JDBC)** connector, so it's important that you take some time to review your data to ensure that it

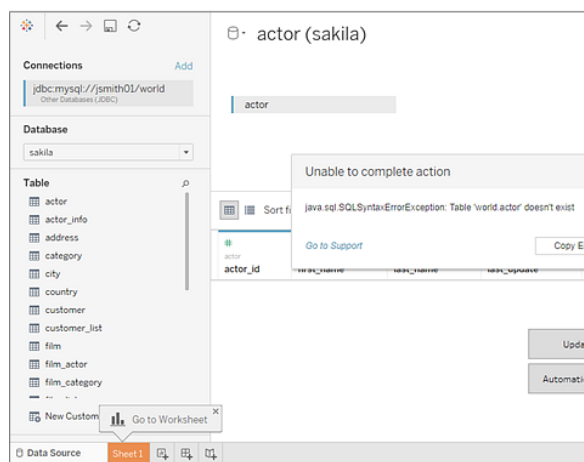

reflects what you expect.

To check the metadata, review the data tab and the data grid on the data source page to ensure that you see the right tables and columns, and that the data types are correct.

## Change your database

When you connect to data using **Other Databases (JDBC)**, you specify the database that you are connecting to in the JDBC connection string in the **URL** field. After you connect, if you want to change to another database, you need to edit the connection string or add a new connection with the new string. Otherwise you will receive an error and see results like the following examples:

### Tableau Desktop

### Tableau Prep Builder

## Tableau support for Other Databases (JDBC) connections

Tableau provides limited customer support for connections using **Other Databases (JDBC)**. For example, Support will help you if your connection works in Tableau Desktop, but doesn't work in Tableau Server. However, Tableau does not support creating or debugging JDBC properties files. For help, you can review the documentation listed under [See also below](#), and you can submit questions and ask for help on the [Tableau Developer Community forums](#).

## See also

[Tableau and JDBC](#) – Provides tips for improving performance and solving common problems.

[Customize JDBC Connections Using a Properties File](#) in Tableau Community

[Customizing JDBC Connections](#) in Tableau Knowledge Base

## Tableau and JDBC

Tableau supports JDBC (Java Database Connectivity) drivers for several connectors. This includes both official named connectors, such as Athena, and generic connector for use with other JDBC-based drivers, called **Other Databases (JDBC)**.

JDBC requires Java, which makes it platform-independent. Starting with version 2020.2, all Tableau applications are bundled with the Java Runtime, so you don't have to install it separately.

**Note:** If you're using a version of Tableau Desktop before 2020.2, see the [Driver Downloads](#) page for instructions on installing Java.

## Tune JDBC connector performance

Tableau supports the ability to customize your JDBC data connection, which can improve the connection experience. For more information, see [Customize and Tune Connections](#).

## Tableau support for JDBC connections

Tableau provides no guarantee or warranty that using the **Other Databases (JDBC)** connector with any particular JDBC driver or database will be able to successfully connect and query data. Some JDBC drivers will support the full Tableau interactive experience, while others may work only for creating extracts. Some JDBC drivers might not work with Tableau.

**Note:** Tableau will provide reasonable levels of customer support to assist in troubleshooting connections with JDBC drivers, but can't create or customize a connector to work with a specific JDBC driver.

## Frequently asked questions

Here's a list of some common problems and steps to resolution.

### I'm seeing a "Missing Java" message. What now?

This sometimes happens if you're using a version of Tableau before 2020.2 or using Kerberos on Windows. See the [Driver Downloads](#) page for instructions on installing the correct version of Java for your connector.

Starting with version 2020.2, all Tableau applications are bundled with the Java Runtime, so you won't have this error.

### **I'm seeing a "Missing Driver" message. What should I do?**

Install the driver, and any libraries it depends on, in one of the following paths:

- Windows: C:\Program Files\Tableau\Drivers
- Mac: /Library/JDBC or ~/Library/JDBC
- Linux: /opt/tableau/tableau\_driver/jdbc

Ensure that the driver is readable by the user running Tableau, or the Tableau service user.

### **I have multiple JDBC drivers installed for Tableau, but I'm having trouble connecting. What should I do?**

If you have multiple JDBC drivers installed for Tableau, they may use different version of the same third-party library. This may cause problems in unpredictable ways. If you have strange errors while connecting, and you have multiple JDBC drivers installed in the JDBC drivers folder, then you can use the following steps to isolate them.

Suppose you have these libraries installed in the JDBC folder:

- athena-driver.jar
- athena-dependency.jar
- athena-dependency.so
- postgres-driver.jar

To isolate the Athena driver from the Postgres driver, install them in separate subdirectories:

- Athena/athena-driver.jar
- Athena/athena-dependency.jar
- Athena/athena-dependency.dll
- Postgres/postgres-driver.jar

After you've moved the drivers, restart Tableau.

### **I'm seeing a "ClassNotFoundException" (or similar) message. What should I do?**

If you're running a JDBC driver that isn't Java 11 compatible, you may experience problems running Tableau.

If you think your issues might be caused by Java 11:

1. Download Java 64-bit JRE (Java Runtime Environment) or JDK (Java Development Kit) from AdoptOpenJDK:

- a. Go to <https://adoptopenjdk.net/releases.html>.
  - b. Select **OpenJDK 11**, and select **Hotspot**.
  - c. Select **Other Platforms** to view a full list of options.
  - d. Download the JRE or JDK for your operating system.
2. On the computer running Tableau, set an environment variable like one of the following:

```
TABLEAU_JAVA_HOME=C:\Program Files\AdoptOpenJDK\jre-8.0.232.09-hotspot
```

or

```
TABLEAU_JAVA_HOME=C:\Program Files\AdoptOpenJDK\jdk-8.0.252.09-hotspot
```

### How do I resolve proxy problems?

Starting with version 2019.4, when Tableau runs on Windows, it reads proxy settings by enabling the `useSystemProxies` option for **Java**.

In some cases, this can cause problems. For example, if you select “Use the same proxy server for all protocols,” the Java Virtual Machine tries to use a SOCKS proxy.

To find instructions for resolving this issue, see the Tableau Knowledge Base article called [Tableau Fails To Connect to Amazon Athena through Proxy With Error Code 37CE01A3](#). This article refers to Athena specifically, but this can apply to any JDBC connector.

### I'm having trouble connecting to a server with SSL. What can I try?

If you see an error message like “Couldn’t find SSL verification path,” you may need to configure a certificate or private keys.

See [One-Way SSL for JDBC Connections](#) for instructions on using a certificate. If you’re using an Oracle JDBC driver, see [Oracle JDBC Connections with SSL](#) for information on using the appropriate certificates and/or key to connect.

### Using Other Database (JDBC) connector with a Postgres JDBC driver, attempts to create extracts sometimes fail. What can I try?

You may run into errors if the Postgres driver fetch size isn’t set and if auto-commit is enabled. The driver will attempt to handle too much data at a time, and won’t be able to.

Try the following:

1. Set the fetch size for your data using `defaultRowFetchSize`.  
See the [JDBC Driver](#) page on the PostgreSQL site for details.
2. Disable auto-commit by creating (or editing an existing) TDC file. Include the following in the TDC file:

```
<?xml version='1.0' encoding='utf-8' ?>
<connection-customization class="genericjdbc" enabled="true"
version="10">
<vendor name="genericjdbc"/>
<driver name="postgresql"/>
<customizations>
<customization name="CAP_JDBC_QUERY_DISABLE_AUTO_COMMIT"
value="yes"/>
</customizations>
</connection-customization>
```

**Note:** While this step is required when you use the Other Database (JDBC) connector, for named Tableau connector it isn't because auto-commit is already set by default.

For more information on using a TDC file for JDBC connections, see [Customize and Tune Connections](#).

## See also

[Other Databases \(JDBC\)](#) – Describes how to connect to your data using the generic JDBC connector.

[Customize and Tune Connections](#) - Describes how to use TDC and PROPERTIES files to customize connections.

[One-Way SSL for JDBC Connections](#) – Provides instructions on using a certificate with a JDBC driver to access a server with SSL.

[Tableau JDBC Capability Customizations Reference](#) – Lists customizations you can use to define which Tableau capabilities are supported by the data source.

### One-Way SSL for JDBC Connections

If you are using regular (one-way) SSL with a JDBC based connector, and you have self-signed certificates, or certificates that are signed by a non-public certificate authority (CA), then you will need to configure trust for your certificate.

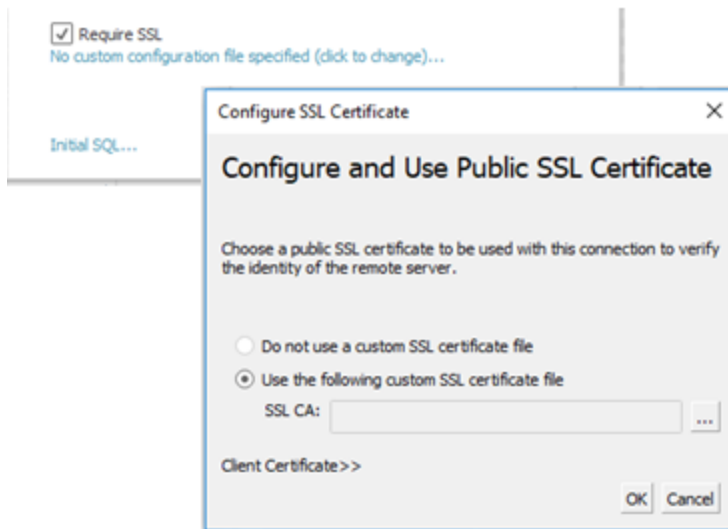

With Tableau, you can configure one-way SSL trust for JDBC connections using one of these methods:

- [Embed a certificate](#) below
- [Install a certificate in the system trust store](#) below
- [Use custom driver properties](#) on page 531

## Embed a certificate

Some connectors support embedding the certificate in the workbook or data source. If that is available, then you can use Tableau Desktop to embed the CA certificate.

## Install a certificate in the system trust store

If embedding is not available, you will need to configure the Java Runtime to trust your certificate. Also, it may be easier to do this than to embed the certificate in every workbook.

### For Windows:

You can install your CA or self-signed certificate in the Windows root CA trust store. The Java Runtime looks for trusted CAs in the system root trust store. It does not look in the intermediate certificate storage.

**Note:** If you have installed your root CA, but are still having trouble making connections, it may be caused by missing intermediate certificates. While the TLS standard requires that servers send all certificates in their chain except the root certificate, not all servers are compliant. If your server doesn't send the intermediate certificates, you can either fix the

server to properly forward intermediate certificates or install the intermediate certificates in the root trust store. Alternatively, you could choose to embed certificates in the data source or configure a trust store with driver properties.

1. In Windows, search for "certificates".
2. Select **Manage computer certificates**.
3. From the **Action** menu, select **All Tasks**, and then, depending on Windows version, do one of the following:
  - Select **Import** and then select **Local Machine**.
  - Select **Find Certificates**.
4. Browse to find your certificate file.
5. Import into "Trusted Root Certificate Authorities".

## For Mac:

To install a custom certificate on a Mac, follow these steps to import the certificate into the "System" keychain.

**Note:** Loading certificates from keychain on Mac works for most, but not all, drivers. In a small number of cases, you may need to use a PROPERTIES file to configure truststore. For more information, see [Customize and Tune Connections](#).

1. Go to <https://support.apple.com/guide/keychain-access/add-certificates-to-a-keychain-kyca2431/mac>.
2. Import the certificate into the "System" keychain (not "System Roots").
3. Enable trust as follows:
  - a. In the Keychain App, right-click the new certificate.
  - b. Select **Get Info**.
  - c. In the dialog, open the **Trust** section, and then select **When using this certificate always trust**.

**Note:** For SAP HANA connections with Tableau versions before 2020.2, you will add the certificate to the JRE instead on a Mac. For details, see the "Install trusted SSL certificates on the Mac" section in the [SAP HANA](#) connector Help topic.

## For Linux:

Many Linux distributions will generate a trust store in Java format from the system certificates. You may need to install Java from the package manager for this file to be created.

This allows the JRE to use the same certificates as the operating system.

**Note:** Tableau Server looks for this file in the standard locations:

```
/etc/ssl/certs/java/cacerts  
/etc/pki/java/cacerts
```

To install a custom CA or self-signed certificate, see the documentation for your distribution. Run the appropriate commands to generate the key store. For example:

```
update-ca-certificates
```

## Use custom driver properties

You can customize JDBC connection options, including the location of the trust store, with a properties file. This is a plain-text file containing key-value pairs for each connection parameter. For details on specific property settings, see the documentation for your driver.

For example, lines in this properties file are being used to configure trust settings:

```
javax.net.ssl.trustStore=C:\\My_Folder\\truststore.jks  
javax.net.ssl.trustStoreType=JKS  
javax.net.ssl.trustStorePassword=password
```

When you create the file and save it to the correct location, the properties in the file are applied to all JDBC connections to the same data source type.

If you use the generic "[Other Database \(JDBC\)](#)" connector, you can specify a properties file directly in the connection dialog.

For more information, see [Customize and Tune Connections](#).

## See also

- [Require SSL for Oracle JDBC Connections](#) - Installation instructions for adding trusted SSL certificates to Oracle JDBC connections.

## Other Databases (ODBC)

When you start Tableau, under **Connect**, you can see the file and database types that are supported by Tableau Desktop. Select **More** to see the complete list. For supported files and databases, Tableau provides built-in connectors that are built for and optimized for those data sources.

**Important:** If your file or database type is listed under **Connect**, use that named connector to connect to your data.

If your file or database type is not listed on under **Connect**, you might be able to connect to it using the **Other Databases (ODBC)** connector. ODBC (Open Database Connectivity) is a standard way to connect to a database. If the database driver you want to connect with implements the ODBC standard, you can connect Tableau to your data using the ODBC driver for your database and the Tableau **Other Databases (ODBC)** connector.

**Note:** Tableau Prep Builder version 2019.2.2 supports connecting to data using the Other Databases ODBC connector. However, it doesn't support the same functionality as Tableau Desktop. For Tableau Prep Builder, follow the instructions in [Connecting using ODBC](#) in the Tableau Prep Builder online help.

### Make the connection

To connect to your data using the ODBC driver, do the following:

1. Start Tableau and under **Connect**, select **Other Databases (ODBC)**. For a complete list of data connections, select **More** under **To a Server**.
2. Enter the information required to make the connection.

If table or schema names are not listed, click the search icon or enter the name in the text box and click the search icon, and then select the name.

**Note:** When you use **Other Databases (ODBC)** to connect to a database, the outcome may vary and compatibility with Tableau Desktop features is not guaranteed.

If your connection works as you need it to, you can begin your analysis. If, however, you need to customize your ODBC connection to improve functionality and performance, refer to the articles under [Other Databases \(ODBC\)](#) above.

### Configure for publishing and cross-platform portability

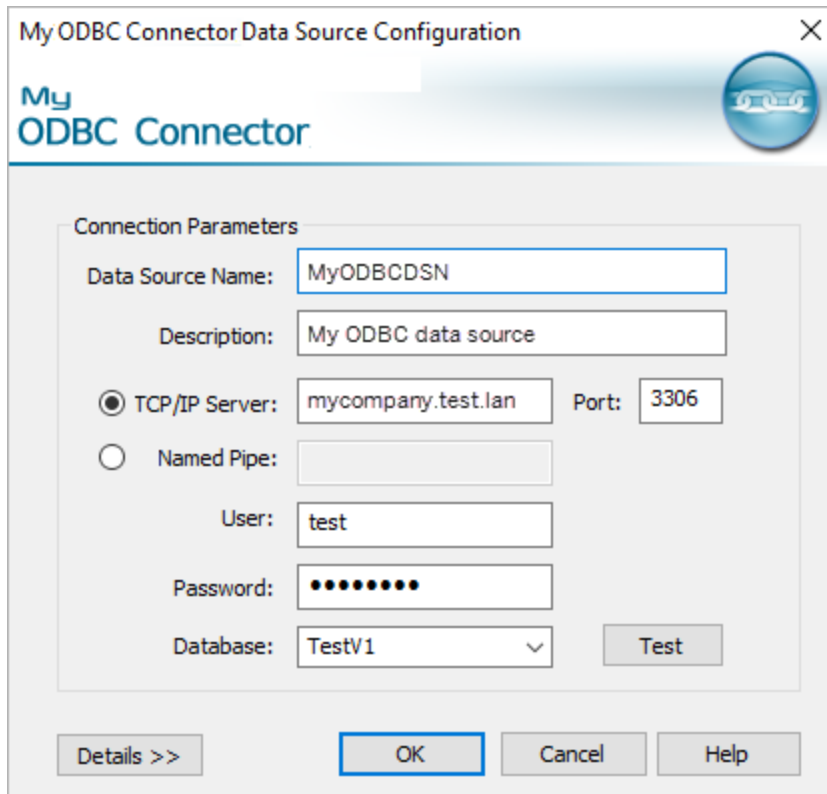

When you work with a generic ODBC connection, additional configuration is required to make sure that the workbooks and data sources you create can be used on different computers and platforms.

For publishing and for cross-platform portability:

- We recommend that you use data source names (DSNs) to accommodate different drivers and configurations between systems.
- The driver and DSN must be installed and configured to match the workbook or data source connection.

**Important:** When you set up a DSN, be aware that sensitive data (for example, user name and password) is plaintext in the logs and readable by anyone with access to the logs.

As an example, Ashley Garcia creates an **Other Databases (ODBC)** data source that connects using a DSN for which she has the associated ODBC driver installed on her Windows computer. Here is an example of the data source configuration, including the data source name, that Ashley created:

Ashley can do a couple of things with this data source to make it available for others to use.

- She can publish it to Tableau Server. When she does this, Ashley needs to ask the Tableau Server administrator to create the same DSN and install the associated ODBC driver on the Tableau Server computer so that the data source can be accessed by Ashley and by others.
- She can email the data source to coworkers. Ashley needs to tell the coworkers to install the associated ODBC driver and create the same DSN on their computers so that they can open the data source in Tableau Desktop.

When you try to open a workbook or data source created using the **Other Databases (ODBC)** connector and your workstation isn't configured correctly (you don't have the workbook or data source's DSN configured, or you don't have the ODBC driver installed), you'll see an error message that begins `Generic ODBC requires additional configuration`. To resolve this error, contact the workbook or data source publisher or the Tableau Server administrator to get the DSN and ODBC driver information that matches the workbook or data source. Then install the driver and configure the DSN on your computer.

## Create a DSN

The method you use to create a DSN depends on your operating system.

- **Windows.** Create a DSN using the ODBC Driver Manager.
- **OS X.** Create a DSN using an ODBC Manager utility. If you don't have the utility installed your Mac, you can download one from, for example, <http://www.odbcmanager.net/>. Or you can manually edit the `odbc.ini` file.
- **Linux.** Manually create a DSN by editing the `odbc.ini` file.

**Note:** Review the documentation for your operating system for specific instructions on how to create a DSN.

Review the documentation for your operating system for specific instructions on how to create a DSN.

## Tableau support for Other Databases (ODBC) connections

Tableau provides limited customer support for connections using **Other Databases (ODBC)**. For example, Support will help you with the sample code provided in Tableau documentation, or

if your connection works in Tableau Desktop, but doesn't work in Tableau Server. However, Tableau does not support creating or debugging custom TDC files. For help, you can review the other topics in this section, and you can submit questions and ask for help on the [Tableau Developer Community forums](#).

### Tableau and ODBC

Tableau includes built-in connectors for many databases. These connectors take advantage of capabilities and optimizations specific to these data sources, and they're developed and tested to ensure they are robust and provide good performance.

But you might be working with a database that Tableau doesn't have a connection for. In that case, you still might be able to connect Tableau to the database. Tableau has a connector that uses the ODBC standard. By using ODBC, you can access any data source that supports the SQL standard and implements the ODBC API.

#### ODBC basics

ODBC (Open Database Connectivity) is an industry standard that enables a wide variety of software to access data. The basis of ODBC is a standard syntax for SQL queries that is used by software applications to connect to and request data from databases. The ODBC driver, usually provided by the database vendor, accepts requests in this standard syntax and converts the request to the native format that the target database prefers. In effect, the ODBC driver is a translation layer to convert from a general-purpose request to the database-specific request.

For example, the ODBC specification details that dates should be specified in SQL statements by using the syntax: `{d 'yyyy-mm-dd'}`. This format is then translated by the driver to the proper date syntax of the actual database. If you use the ODBC connector to connect to an Oracle database, the ODBC connector sends a request to the Oracle ODBC driver in this format:

```
select name from emp where birthdate > {d '1987-12-29'}
```

The driver converts your request to the actual format the Oracle database requires, which is this:

```
select name from emp where birthdate > '29-DEC-87'
```

The ODBC specification includes syntax for making function requests, join syntax, data types, and data type conversions. The SQL language itself supports complex concepts such as nested queries, correlated subqueries, temporary tables, and a variety of functions that can be used in select, where, group by, join clauses, and more. The ODBC driver is responsible for the proper conversion of all these requests to the syntax of the target database.

## How Tableau determines the capabilities of the ODBC driver

There are differences in how each database vendor implements capabilities of the ODBC standard. Tableau uses a feature-discovery API in ODBC to question a database driver about the functionality it supports. One example of how Tableau changes behavior based on what the driver reports is the list of functions available when creating a calculated field. Fewer driver limitations means that more functions are available.

In some cases Tableau will require you to create a data extract from the data returned by the ODBC connector. And there are some ODBC drivers and databases that Tableau can't connect to.

## ODBC discovery

During the initial connection, Tableau performs requests to the driver and SQL discovery queries in order to determine the capabilities of the driver.

Some examples of the capabilities discovery that Tableau performs include:

- Available scalar and aggregate functions.
- Available date and time manipulation functions.
- Can you create temporary tables?
- Can you use IF and SELECT into statements?
- Are subqueries supported?
- Are top and limit queries supported?
- What join styles are supported (outer, inner, full)?
- Supported data types.

Based on the outcome of the capabilities discovery, Tableau will classify the current connection as being in one of four categories:

- **Fully Functional.** This is a driver that supports all the functions and capabilities that Tableau uses.
- **Minor limitations.** This is a driver that has a small number of non-critical limitations. An example would be a driver that doesn't support the full set of numeric, string, or date functions that Tableau normally makes available. Tableau will modify its behavior to account for these limitations and proceed.

- **Major limitations.** This is a driver that has a large number of limitations or critical capabilities that Tableau relies upon but that are not supported. However, even with these major restrictions, Tableau might be able to connect well enough to create a Tableau extract to retrieve the data into Tableau for further work offline from the database. In this case, Tableau will recommend that you create an extract. When you create the extract, you might not be able to create a filter on the data source to reduce the amount of data in the extract. (For more information, see [Filter Data from Data Sources on page 858.](#)) After the data has been extracted, full Tableau functionality is available when working with the extract.
- **Fatal limitations.** This is a driver that does not support even the most minimal set of capabilities that Tableau needs in order to connect and run the basic queries to create extract files. Therefore, Tableau is unable to proceed any further with this driver.

After the connection is established, if Tableau has determined that the capabilities available classify this connection as anything less than fully functional, a message is displayed to inform you of the limitations that have been detected. For example, a connection to an ODBC driver with minor limitations displays this message:

For more critical limitations, the warning dialog box will advise you to create a Tableau extract in order to proceed.

### Tune ODBC connector performance

Tableau supports the ability to customize your ODBC data connection, which can improve the connection experience. For more information, see [Customize and Tune a Connection on page 547.](#)

### Tableau support for ODBC connections

Tableau provides no guarantee or warranty that using Tableau with any particular ODBC driver or database will be able to successfully connect and query data. Some ODBC drivers will support

the full Tableau interactive experience, while others may work only for creating extracts. Some ODBC drivers might not work with Tableau.

**Note:** Tableau will provide reasonable levels of customer support to assist in troubleshooting connections with ODBC drivers, but can't create or customize a connector to work with a specific ODBC driver.

## ODBC FAQ

### What's a typical use case for the ODBC connector?

The most common use case for an ODBC connection is to access data specifically to retrieve it into a Tableau extract. Bringing this data into a Tableau extract then allows the full Tableau capabilities to work with the data. Many ODBC drivers support the needed functionality to connect and perform the simpler queries required to perform an extract. Whether you extract all of the data or just select a few columns and set some filters to retrieve a relevant subset, this use of ODBC is a good scenario to keep in mind.

### Where do I get ODBC drivers for my database?

Most database vendors distribute ODBC drivers for use with their databases. Contact your database vendor to obtain the drivers. Additionally there are a number of third party manufacturers of ODBC drivers that can provide drivers for a variety of common databases.

### What ODBC version driver do I need?

Be sure your ODBC driver is a version 3 or higher driver, meaning it implements the ODBC specification version 3. Each driver provider will have their own version numbering system for their driver versions, which will likely be different from the ODBC version number it implements. The ODBC version 3 specification was introduced in 1995, so it is likely your database provider has a driver that implements this level of compliance. We have seen a number of Tableau customers with drivers that are not version 3 compliant (which fail to connect), who then upgraded to a newer driver and were able to proceed.

### Has Tableau tested database [x]?

Tableau has tested ODBC connections with many data sources, but due to the volume of ODBC drivers available on the market we haven't tested against every possible driver, nor can Tableau

perform this breadth of testing. The best recommendation for any particular driver is to give it a try, and let us know how it works.

## What do I do if it doesn't work?

First check the driver version. If you look at the Tableau logs we will echo back the ODBC version level the driver reports. Search the logs for an entry like the following:

```
ODBCProtocol: driver ODBC version: 03.52
```

The number at the end indicates the ODBC version level. If it is less than 03.00, the driver needs to be upgraded.

If you get warnings when you connect about capabilities not supported, check with your database vendor to see if they have an updated driver that supports more capabilities. Not all drivers will work with Tableau.

## Should I use the named database connector or the ODBC connector?

If you are connecting to a database for which Tableau has a named connection option, then use the named connector. The named connectors are optimized for the particular database.

## See also

[Other Databases \(ODBC\) on page 532](#) – Describes how to connect to your data using the ODBC connector.

[Customize and Tune a Connection on page 547](#) – Describes how to customize connection information for improved functionality and performance.

[Tableau Capability Customizations Reference on page 568](#) – Lists customizations you can use to define which Tableau capabilities are supported by the data source.

[ODBC/SQL Customizations Reference on page 586](#) – Lists customizations that represent the parts of the ODBC and SQL standards that the ODBC driver reports supporting.

## Use Partner-Built Connector from the Tableau Exchange

Tableau Desktop has dozens of supported connectors you can choose from. You can also find more connectors built by partners in the Tableau Exchange.

**Note:** Connectors from the Tableau Exchange are not currently supported for use with Tableau Bridge.

For information about creating your own connector and submitting it to the Tableau Exchange, see [Connectors Built with the Tableau Connector SDK](#).

## Choose and install a partner-built connection

Partner-built or other custom connectors are available from the Connect pane. These connectors are listed under Additional Connections and are also available from the [Tableau Exchange connectors](#) page.

1. Click **Connections** in the left pane.
2. From the **Additional Connectors** section in the Connect pane, click on the connector you want to use.
3. Click **Install and Restart Tableau**.

After the connector is installed, it appears in the **To a Server** section of the Connect pane.

**Note:** If you receive a warning that the connectors can't load, install the .taco file you need from the [Tableau Exchange connectors](#) page. If you are prompted to install the drivers, go to [Tableau Exchange](#) for driver download instructions and locations.

## Make the connection

To connect to your data using the connector you installed from the Tableau Exchange, do the following:

1. Start Tableau and under **Connect**, select the name of the connector you installed. For a complete list of data connections, select **More** under **To a Server**.
2. Enter the information required to make the connection.

If table or schema names are not listed, click the search icon or enter the name in the text box and click the search icon, and then select the name.

## Work with your data

When you connect to data with a partner-built connector, it offers the same features as Tableau-supported connectors. Once you are connected, you can:

- [Define a data source](#)
- [Visualize your data](#)
- [Publish to a server](#) (when the server has the connector installed)

**Note:** Publishing to Tableau Cloud is not currently supported with partner-built connectors.

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.
- [Connectors Built with the Tableau Connector SDK](#) - Create your own connector and submit it to the Tableau Exchange.

## Connectors Built with the Tableau Connector SDK

Tableau has great connectivity that allows you to visualize data from virtually anywhere. In addition to its dozens of built-in connectors and additional partner-built connectors (available on [Tableau Exchange](#)), Tableau gives you the tools to build a customized connector with the Tableau Connector SDK.

**Note:** Connectors built using the Tableau Connector SDK are sometimes called plugins because they “plug into” Tableau so you can connect to your data.

### About Tableau Connector SDK and connector files

You can use the Tableau Connector SDK to build and custom a connector. Partner-built connectors (whether built by you or someone else) typically support most of the same features as built-in Tableau connectors. These include [defining a data source](#), [visualizing your data](#), [publishing to a server](#) (if the server has the connector), and so on.

Each connector is made up of a set of XML and JavaScript files, zipped into a single packaged .jar file, and give a ".taco" file extension. This TACO file is signed by the developer using a trusted public certificate authority. The XML and JavaScript files are configuration files that describe:

- UI elements needed to collect user input for creating a connection to a data source
- Any dialect or customizations needed for the connection
- How to connect using the ODBC or JDBC driver

A connector that is developed using the Tableau Connector SDK is appropriate for connecting to an ODBC or JDBC driver which interfaces using SQL. The underlying technology works well with relation databases.

**Note:** Partner-built connectors are not supported by Tableau. However, if you use a partner-built connector from the Tableau Exchange, click the **Support** link on that connector's page for help.

### Build your own connector

To build your own customized connector, use the tools and instructions in the [Tableau Connector SDK](#) repository on GitHub.

**Note:** If you find an issue with the SDK or any of the developer samples, [submit an issue on GitHub](#).

### Submit a connector to the Tableau Exchange

If you would like to submit your connector to the Tableau Exchange, follow [steps outlined in the Tableau Connector SDK](#).

### Use a connector built with Tableau Connector SDK

After you build a connector with the Tableau Connector SDK, follow these steps to use it with Tableau:

Tableau Desktop and Web Authoring Help

1. Download the connector file, [connector name].taco.
2. Place the .taco file in the following directory (default location):
  - For 2021.2 and newer:

<b>For Tableau Desktop</b>	<b>For Tableau Prep Builder</b>	<b>For Tableau Server, Tableau Prep Conductor, Tableau Prep Flow Authoring</b>
<ul style="list-style-type: none"> <li>• Windows - C:\Users\[Windows User-]\Documents\My Tableau Repository\Connectors</li> <li>• macOS - /Users/[user-]/Documents/My Tableau Repository/Connectors</li> </ul>	<ul style="list-style-type: none"> <li>• Windows: C:\Users\[Windows User-]\Documents\My Tableau Prep Repository\Connectors</li> <li>• MacOS: /Users//Documents/My Tableau Prep Repository/Connectors</li> </ul>	<ul style="list-style-type: none"> <li>• Windows: C:\Program Files\Tableau\Connectors</li> <li>• Linux: /opt/tableau/connectors</li> </ul>

- For 2021.1 and older:

<b>For Tableau Desktop</b>	<b>For Tableau Prep Builder</b>	<b>For Tableau Server, Tableau Prep Conductor, Tableau Prep Flow Authoring</b>
<ul style="list-style-type: none"> <li>• Windows - C:\Users\[Windows User-]\Documents\My Tableau Repository\Connectors</li> </ul>	<ul style="list-style-type: none"> <li>• Windows: C:\Users\[Windows User-]\Documents\My Tableau Prep Repository\Connectors</li> <li>• MacOS:</li> </ul>	<ul style="list-style-type: none"> <li>• Tableau Server: [Tableau_Server_Installation_Directory]/data/tabs-vc/vizqlserver/Connectors</li> </ul> <p>To enable your connector for Prep, you also need to add your taco to the following locations:</p>

<ul style="list-style-type: none"> <li>• macOS - /Users/ [user- ]/Docu- ments/My Tableau Repos- itory/Con- nectors</li> </ul>	<ul style="list-style-type: none"> <li>/User- s//Docu- ments/My Tableau Prep Repos- itory/Con- nectorsFor Tableau</li> </ul>	<ul style="list-style-type: none"> <li>• Tableau Prep Conductor: [Tableau_Server_Install- ation_Dir- ect- ory]/data/t- abs- vc/flowprocessor/Connectors</li> <li>• Tableau Prep Flow Author- ing: [Tableau_Server_Install- ation_ Dir- ect- ory]/data/t- abs- vc/- flowqueryservice/Connectors</li> </ul>
---	--	---

3. Before you connect, install the ODBC or JDBC driver. Follow the driver installation instructions provided by the source of your data.

Once you've installed the connector, it will appear in the list of connectors in Tableau.

### Connect Tableau to the data

1. Start Tableau, and under **Connect**, select the name of the connector you just installed.  
For a complete list of data connectors, select **More** under **To a Server**.
2. Enter the information that you're prompted for, and then select **Sign In**.
3. Wait while the connector retrieves your data into Tableau.
4. Select the sheet tab to start your analysis.

### About load order for connectors

If a connector has the same class as a connector that has already been registered, the new connector will be rejected. This means that connectors loaded first have precedence when two connectors share the same class name.

Tableau loads connectors by directory in the following order:

1. Built-in Tableau connectors
2. Connectors located in `C:\Program Files\Tableau\Connectors` (Windows) or `opt/tableau/connectors` (Linux)

3. Connectors located in `My Tableau Repository/Connectors`
4. (Optional) Connectors in the dev path specified by `-DConnectPluginsPath`

### See also

## Connectors Built with the Web Data Connector 3.0 SDK

The Web Data Connector 3.0 is the latest version of the web data connector, Tableau's solution for connecting to data in web applications and services that are exposed through APIs rather than ODBC or JDBC drivers.

The Web Data Connector 3.0 SDK provides the tools that you must build your own custom connector to web data. Additionally, partner-built connectors can be used from the Tableau Exchange.

**Note:** The Web Data Connector 3.0 was part of the 2022.3 Tableau release.

### About Web Data Connector 3.0

In a departure from previous iterations of web data connector, and analogous to the Tableau Connector SDK, Web Data Connector 3.0 allows you to build a custom connector to web data and package the connector as a .taco file. WDC 3.0 connectors can be used like any driver-based connector built using the Tableau Connector SDK and don't require you to host the connector on your own web server.

Like other .taco connectors, WDC 3.0 connectors are packaged and signed .jar files containing a set of XML and Javascript/TypeScript files. These files define the look and behavior of the connector including:

- A web-based connector UI
- API calls to retrieve data from your application or service endpoint
- Instructions to map the retrieved data into Tableau extracts

**Note:** Web Data Connector 3.0 remains extract-only, but otherwise allows you to visualize your data and publish your analysis just like any other data source.

## Build your own connector

To get started building your own custom connector, refer to the official [Web Data Connector 3.0 documentation](#).

## Use a connector built with the Web Data Connector 3.0 SDK

After you build a connector with the Web Data Connector 3.0 SDK, follow these steps to use it with Tableau:

1. Download the connector file, [connector name].taco.
2. Place the .taco file in the following directory (default location):

For Tableau Desktop	For Tableau Prep Builder	For Tableau Server, Tableau Prep Conductor, Tableau Prep Flow Authoring
<ul style="list-style-type: none"> <li>• Windows - C:\Users\[Windows User-]\Documents\My Tableau Repository\Connectors</li> <li>• macOS - /Users/[user-]/Documents/My Tableau Repository/Connectors</li> </ul>	<ul style="list-style-type: none"> <li>• Windows: C:\Users\[Windows User-]\Documents\My Tableau Prep Repository\Connectors</li> <li>• MacOS: /Users//[User-s//Documents/My Tableau Prep Repository/Connectors</li> </ul>	<ul style="list-style-type: none"> <li>• Windows: C:\Program Files\Tableau\Connectors</li> <li>• Linux: /opt/tableau/connectors</li> </ul>

**Note:** After you've installed the connector, it will appear in the list of connectors in Tableau.

If you find an issue with the WDC library, the simulator, or any of the developer samples, [submit an issue on Github](#).

## Connect Tableau to the data

1. Start Tableau, and under **Connect**, select the name of the connector you just installed or a complete list of data connectors, select **More** under **To a Server**.
2. Enter the information that you're prompted for, and then select **Sign In**.
3. Wait while the connector retrieves your data into Tableau.
4. Select the sheet tab to start your analysis.

## Load order for connectors

Connectors loaded first have precedence when two connectors share class names. If a connector has the same class as a connector that has already been registered, the new connector will be rejected.

Tableau loads connectors by directory in the following order:

1. Built-in Tableau connectors
2. Connectors located in `C:\Program Files\Tableau\Connectors (Windows)` or `opt/tableau/connectors (Linux)`
3. Connectors located in `My Tableau Repository/Connectors`
4. (Optional) Connectors in the dev path specified by `-DConnectPluginsPath`

## See also

- [Set Up Data Sources on page 596](#) – Add more data to this data source or prepare your data before you analyze it.
- [Build Charts and Analyze Data on page 953](#) – Begin your data analysis.
- [Tableau Connector SDK](#) - Find information and tools to build and test your own customized connector.

## Customize and Tune a Connection

You can make customizations to a connection using a TDC file.

If you're customizing a JDBC-based connection, you can also make customizations in a PROPERTY file. For details, see [Use a PROPERTIES file to customize a JDBC connection](#).

## About Special Characters

Special characters must be correctly escaped, and whether this is necessary can vary based on the character's position. For instance, if an equals sign '=' is included in the value, to the right of the initial '=', it must be properly escaped.

### Example:

```
ServiceLocation=Region=east;Name=prod;
```

Should be written as: `ServiceLocation=Region\=east;Name\=prod;`

## Use a TDC file to customize a connection

TDC (Tableau Datasource Customization) files are XML files with a ".tdc" filename extension. These files are used to customize Tableau-specific settings. For ODBC-based connection, you can also use a TDC file to define parts of the ODBC and SQL standards that the ODBC driver supports.

A TDC file contains a vendor name, driver name, and `<connection-customization>`(also includes the class)section. For a built-in connector, the vendor name and driver name must match the connector's class name. Usually, the vendor name matches the driver name. Two generic class names are used for the Other Databases connectors:

- For the Other Databases (JDBC) connector, the class name is "genericjdbc".
- For Other Databases (ODBC) connector, the class name is "genericodbc".

If an existing workbook or data source file has an enabled customization section already, Tableau uses only the customizations it defines and not any defined in the TDC file.

For more information, see [Using a TDC File with Tableau Server](#) in Tableau Knowledge Base.

### Structure of a TDC file

Each TDC file follows this basic structure:

```
<connection-customization class=DSCLASS enabled='true' version='10.0'>
  <vendor name=VENDOR />
  <driver name=DRIVER />
  <customizations>
    <customization name='CAP_FAST_METADATA' value='yes' />
    ...
  </customizations>
</connection-customization>
```

```
</customizations>  
</connection-customization>
```

A TDC file has three main sections:

- Connection customization variables
- Vendor and driver names
- The customizations themselves

The `connection-customization` section includes the following:

- **Class** The data source you want to connect to and customize.
- **Enabled** Specifies whether the TDC file connection customizations are applied. In the TDC file, always set to “true”.
- **Version** Tableau ignores the version number.

The next section is crucial because it identifies the vendor name and driver name of the database provider for this TDC file's data source. Each TDC file can bind to only one data source type. For our native data sources, these names must both match the data source class name; for example, “teradata” for our Teradata connections. For ODBC data sources, the vendor name and driver name of the TDC file must match what is reported to Tableau by the database and driver; for example, “SQLite” and “SQLite3 ODBC Driver”, respectively.

The final section lists the actual connection customizations.

For more information, see [Tableau JDBC Capability Customizations](#).

## Use a PROPERTIES file to customize a JDBC connection

PROPERTIES files are used by JDBC and passed directly through to the JDBC driver. These are plain-text files with a “.properties” filename extension. They contain key-value pairs for each connection parameter.

Using a PROPERTIES file with a JDBC connection is similar to using the `odbc-connect-string-extras` parameter in a TDC file for ODBC connections.

**Note:** A PROPERTIES file should be in Latin-1 format (see <https://en.wikipedia.org/wiki/.properties>). However, as long as it includes only ASCII characters, you can safely save the file in UTF-8 format without a BOM (byte order mark).

In the file, place each key-value pair on its own line with no delimiter. Give the file the same name as its corresponding connector, but with a “.properties” filename extension. For example, the PROPERTIES file for the SAP HANA connector would be “saphana.properties”.

- For Tableau Desktop, place PROPERTIES files in this directory:

My Tableau Repository/Datasources

- To enable a PROPERTIES file for Tableau Server, place it in this directory for each Server node:

**Windows:** ProgramData\Tableau\Tableau  
Server\data\tabsvc\vizqlserver\Datasources

**Linux:** /var/opt/tableau/tableau\_  
server/data/tabsvc/vizqlserver/Datasources/

- For Prep flows, place PROPERTIES files in these directories:

**Linux:**

/var/opt/tableau/tableau\_  
server/data/tabsvc/flowprocessor/Datasources/

/var/opt/tableau/tableau\_  
server/data/tabsvc/flowminerva/Datasources/

**Windows:**

ProgramData\Tableau\Tableau  
Server\data\tabsvc\flowprocessor\Datasources

ProgramData\Tableau\Tableau  
Server\data\tabsvc\flowminerva\Datasources

- For virtual connections, place PROPERTIES files in this directory:

**Linux:** /var/opt/tableau/tableau\_  
server/data/tabsvc/minerva/Datasources/

**Windows:** ProgramData\Tableau\Tableau  
Server\data\tabsvc\minerva\Datasources

After you save the file to the correct location, the properties are applied to all JDBC connections for that same data source type.

### Publish a workbook using a JDBC-based connection

To publish a workbook from a JDBC-based connection, you must include a copy of the PROPERTIES file on both Tableau Desktop and Tableau Server computers.

## See also

[Customize the Connection String for a Native Connector](#) – This article in Tableau Community describes how to modify the connection made with a native connector using the `odbc-connect-string-extras` customization.

## Example: Customize an ODBC Connection

When you use a connector for a database that supports SQL, Tableau generates SQL statements that are tuned for that database. Because Tableau has no representation of the SQL dialect used by an ODBC data source, it must infer the supported syntax through a variety of tests. If a driver reports incorrect or incomplete information about the SQL dialect it supports, you can use Tableau customizations to fine tune this connection information in order to improve functionality and performance.

In this article, you will make an ODBC connection, examine the resulting Tableau Data Source (TDS) file and use part of it to create a Tableau Data source Customization (TDC) file that you can then use to customize your ODBC connection. Before you begin, you should be familiar with the content in [Tableau and ODBC](#) on page 535.

**Note:** Tableau will provide reasonable levels of customer support to assist in troubleshooting connections with ODBC drivers, but can't create or customize a connector to work with a specific ODBC driver.

## Make an ODBC connection

This section shows you how to create an ODBC connection using an example. In the example, you connect to a SQLite database using the SQLite ODBC driver.

## Prerequisites

The ODBC connection in this article is based on SQLite (<http://www.sqlite.org/>), an open-source database.

You need to download the following two items:

**Disclaimer:** This information refers to a third-party product. This example is not an endorsement of this product over any other competing products.

- The SQLite 32-bit ODBC driver (required for 32-bit or 64-bit Windows). Download and install the following (select the SQLite 2 drivers):

<http://www.ch-werner.de/sqliteodbc/sqliteodbc.exe>

- A sample SQLite database created from the Microsoft example Northwind database. Download and expand the following:

<http://download.vive.net/Northwind.zip>

## Create a connection

To create an ODBC connection, you connect to the Northwind database using the SQLite3 ODBC driver, and then save the connection as a Tableau Data Source (TDS) file.

1. Open Tableau Desktop.
2. On the start page under **Connect**, click **Other Databases (ODBC)**.
 

**Note:** For a database that already has a **Tableau-supported connector**, you can click the name of that connector to create a connection.
3. Under **Connect Using**, select **Driver**, and then from the drop-down list, select **SQLite3 ODBC Driver**.
4. Click **Connect**.
5. Next to the **Database Name** text box, click **Browse**, navigate to the location of your **Northwind.sl3** file, and then click **Open**.
6. Click **OK** to close the dialog box, and then click **Sign In**.
7. On the data source page, in the **Table** text box, enter `Orders`.
8. Drag the **Orders** table to the canvas, and then click the sheet tab.
 

A "Tableau identified limitations for the ODBC data source" dialog box opens. You can review the details or dismiss the dialog box and continue. For more information, see [How Tableau determines the capabilities of the ODBC driver](#).
9. Select **Data > Orders [path to Northwind.sl3] > Add to Saved Data Sources**.
10. Click **Save**.
11. Close the workbook. When asked to save changes, click **No**.

Now you can open the TDS file to examine the SQLite connection.

## Review the XML structure of a TDS file

Open the saved Tableau Data Source (TDS) file in a text editor to view its XML structure. By default, the file you created above is named `Northwind.sl3.tds` and is in the following path:

```
Users\[your name]\Documents\My Tableau Repository\Datasources
```

or

```
Users\[your name]\Documents\My Tableau Repository (Beta)\Datasources
```

This is an XML document describing the SQLite connection to the Northwind Orders table. Within the `<connection>` section, find the `<connection-customization>` element, which contains `<customization>` elements that you can edit.

## Vendor and driver name

The connection customization section begins with the names Tableau detected for the ODBC driver and the database vendor. Tableau uses this information to associate a specific connection customization with a single type of ODBC data source. The section looks like this:

```
<connection-customization class='genericodbc' enabled='false' version='10.1'>
<vendor name='SQLite' />
<driver name='SQLite3 ODBC Driver' />
<customizations>
```

## Types of customizations

Tableau permits two types of customizations: Tableau-specific capabilities, and ODBC API calls to `SQLGetInfo`. These customizations are made of name/value pairs, with the names following a convention of `CAP_` for Tableau capabilities and `SQL_` for the `SQLGetInfo` API calls.

The saved data source file contains examples of both types of customizations. These customizations represent the values that Tableau was able to detect by querying the driver when you connected. The list of customizations might be incomplete or incorrect. You can use customization to modify and shape Tableau's behavior when connecting to an ODBC data source.

The following articles contain a complete reference for the customizations. You should have an idea of how you need to adjust your ODBC connection to perform as you expect in your environment. Review the lists to get an idea of the customizations you can use to tune your ODBC connection.

- [Tableau Capability Customizations Reference](#) on page 568
- [ODBC/SQL Customizations Reference](#) on page 586

## Format of customization values

- The customization values are all represented as strings for each name/value pair.
- Tableau capabilities are all Boolean values represented by yes or no.
- The SQLGetInfo values can be long-integer, short-integer, or string data, depending on the expected return value of SQLGetInfo for the given identifier.
- Many of the integer fields are bitmasks that represent a collection of capabilities.

## Make customizations global with a TDC file

To make your customization changes apply to all connections for a given ODBC data source, you need to create a Tableau Data source Customization (TDC) file. This file contains only the `<connection-customization>` section and is applied to any new Tableau connection that matches the database vendor name and driver name described in the TDC file (as noted in [Vendor and driver name on the previous page](#)). Any existing workbook or data source file that already has an enabled customization section will use only the customizations that it supplies, not the TDC file.

**Important:** Tableau does not test or support TDC files. These files should be used as a tool to explore or occasionally address issues with your data connection. Creating and maintaining TDC files requires careful manual editing, and there is no support for sharing these files.

## Create a TDC file

When you create a TDC file, you need to save it to the right location so that it can be used by your connection. If you create a workbook that you want to publish to Tableau Server, then you need to save the TDC file to the server as well. For more information, see [Using a TDC File with Tableau Server](#) in Tableau Knowledge Base.

## Structure of a TDC file

Each TDC file follows this basic structure:

```
<connection-customization class=DSCLASS enabled='true' version='10.0'>
```

```
<vendor name=VENDOR />
<driver name=DRIVER />
<customizations>
    <customization name='CAP_FAST_METADATA' value='yes' />
    ...
</customizations>
</connection-customization>
```

A TDC file has three main sections:

- Connection customization variables
- Vendor and driver names
- The customizations themselves

The `connection-customization` section includes the following:

- **Class** The data source you want to connect to and customize.
- **Enabled** Specifies whether the TDC file connection customizations are applied. In the TDC file, always set to “true”.
- **Version** Tableau ignores the version number.

The next section is crucial because it identifies the vendor name and driver name of the database provider for this TDC file's data source. Each TDC file can bind to only one data source type. For our native data sources, these names must both match the data source class name; for example, “teradata” for our Teradata connections. For ODBC data sources, the vendor name and driver name of the TDC file must match what is reported to Tableau by the database and driver; for example, “SQLite” and “SQLite3 ODBC Driver”, respectively.

The final section lists the actual connection customizations.

### Use the TDC file with Tableau Desktop

1. Using a text editor, copy and paste the entire `<connection-customization>` section of your saved data source file. For reference, see the [Sample SQLite TDC file](#).
2. Name the file `odbc-sqlite.tdc` and save it to `Documents\My Tableau Repository\Datasources`.

**Note:** The file must be saved with a `.tdc` extension, but the name does not matter.

3. Restart Tableau Desktop to apply the change.
4. Create a new connection to SQLite as described in [Create a connection](#).

- Go to and open the Tableau Desktop log file, and look for a record similar to the example below to verify that this customization file was applied to your new connection.

Log File Location	Example of Record
By default, C:\User- s\ <user&gt;\documents\my repos-<br="" tableau=""></user&gt;\documents\my> itory\Logs	Found matching TDC 'C:\\User- s\\<name>\\Documents\\My Tableau Repository\\Datasources\\odbc-sql- ite.tdc' for class='genericodbc', vendor='SQLite', and driver- ='SQLite3 ODBC Driver'

### Use the TDC file with Tableau Prep Builder

- Using a text editor, copy and paste the entire <connection-customization> section of your saved data source file. For reference, see the [Sample SQLite TDC file](#).
- Name the file `odbc-sqlite.tdc` and save it to the following location:

- For Windows:

```
Documents\My Tableau Prep Repository\Datasource
```

- For Mac:

```
Documents/My Tableau Prep Repository/Datasources
```

**Note:** The file must be saved with a `.tdc` extension, but the name does not matter.

- Restart Prep to apply the change.
- Go to and open the log file, and look for a record similar to the example below to verify that this customization file was applied to your new connection.

Log File Location	Example of Record
By default, C:\User- s\ <user&gt;\documents\my prep<br="" tableau=""></user&gt;\documents\my> Repository\Logs	Found matching TDC 'C:\\User- s\\<name>\\Documents\\My Tableau Prep Repos- itory\\Datasources\\odbc-sql- ite.tdc' for class='genericodbc', vendor='SQLite', and driver- ='SQLite3 ODBC Driver'

## Use the TDC file with Tableau Server

1. Using a text editor, copy and paste the entire `<connection-customization>` section of your saved data source file. For reference, see the [Sample SQLite TDC file](#).
2. Name the file `odbc-sqlite.tdc` and save it to the following location:

- For Windows:

In Tableau Server versions prior to 2018.2:

```
Program Files\Tableau\Tableau Server\<>version>\bin
```

Starting in Tableau Server version 2018.2:

```
Program Files\Tableau\Tableau Server\packages\bin.<build number>
```

Or for all Tableau Server versions:

```
ProgramData\Tableau\Tableau Server\data\tabsvc\vizqlserver\Datasources
```

To save the file, you must be a Windows Administrator on the server computer.

- For Linux:

```
/var/opt/tableau/tableau_server/data/tabsvc/vizqlserver/Datasources/
```

**Note:** The file must be saved with a `.tdc` extension, but the name does not matter. The TDC file must be saved on all server nodes for consistent behavior.

3. For Tableau Prep Conductor (running flows) or Prep Web Authoring (editing flows on the web), the TDC file must be placed in additional directories.

### Prep Conductor

- For Windows:

```
<data directory>\tabsvc\flowprocessor\Datasources
```

- For Linux:

```
<data directory>/tabsvc/flowprocessor/Datasources
```

### Prep Web Authoring

- For Windows:

```
<data directory>\tabsvc\flowminerva\Datasources
```

- For Linux:

```
<data directory>/tabsvc/flowmineva/Datasources
```

4. Restart Tableau Server to apply the change.
5. Go to and open the Tableau Server log file, and look for a record similar to the example below to verify that this customization file was applied to your new connection.

Log File Location	Example of Record
<install path>\Tableau Server\data\tabsvc\log\vizqlserver	Found matching TDC 'C:\\ProgramData\\Tableau\\Tableau Server-\\data\\tabsvc\\vizqlserver\\Datasources\\odbc-sqlite.tdc for class='genericodbc', vendor='SQLite', and driver='SQLite3 ODBC Driver'
<install path>\Tableau Server\data\tabsvc\log\background	
<install path>\Tableau Server\data\tabsvc\log\dataserver	
<install path>\Tableau Server\data\tabsvc\log\vizportal	

### Sample SQLite TDC file

```
<?xml version='1.0' encoding='utf-8' ?>
<connection-customization class='genericodbc' enabled='true' version='7.8'>
<vendor name='SQLite' />
<driver name='SQLite3 ODBC Driver' />
  <customizations>
    <customization name='CAP_CREATE_TEMP_TABLES' value='yes' />
    <customization name='CAP_QUERY_BOOLEXPRESS_TO_INTEXPRESS' value='yes' />
    <customization name='CAP_QUERY_GROUP_BY_ALIAS' value='no' />
    <customization name='CAP_QUERY_GROUP_BY_DEGREE' value='yes' />
    <customization name='CAP_QUERY_JOIN_ACROSS_SCHEMAS' value='no' />
    <customization name='CAP_QUERY_JOIN_REQUIRES_SCOPE' value='no' />
  </customizations>
</connection-customization>
```

```
<customization name='CAP_QUERY_SUBQUERIES' value='yes' />
<customization name='CAP_QUERY_SUBQUERIES_WITH_TOP' value='yes' />
<customization name='CAP_SELECT_INTO' value='no' />
<customization name='CAP_SELECT_TOP_INTO' value='yes' />
<customization name='SQL_AGGREGATE_FUNCTIONS' value='127' />
<customization name='SQL_SQL_CONFORMANCE' value='4' />
</customizations>
</connection-customization>
```

### Customize your ODBC connection

Let's assume that you've made an ODBC connection to your data source and verified that you can get the metadata and data you need. Now you need to determine if creating an extract or if using the live connection as is gives you the functionality you need. If it does, the TDC file you created is sufficient, and there is no need to customize your connection.

If the TDC file is not performing the way you want it to, you can customize the connection. You should have an idea of how you need to adjust your ODBC connection to perform as you expect in your environment. Review the lists to see the customizations you can use to tune your ODBC connection.

- [Tableau Capability Customizations Reference on page 568](#)
- [ODBC/SQL Customizations Reference on page 586](#)

### Common customizations for improving functionality

The following customizations can help improve functionality for data sources with default capabilities that are not optimal.

- `CAP_SUPPRESS_DISCOVERY_QUERIES` – Setting this value to `true` prevents Tableau from performing any SQL queries at the beginning of the connection to determine the driver's capabilities. You will need to consider which other capabilities should be explicitly enabled, since Tableau will not be able to determine those automatically.
- `SQL_SQL_CONFORMANCE` – This setting indicates which level of the SQL standard is fully supported by the data source. Tableau works best with at least entry-level conformance, so this value should be at least 1 if the data source supports it.
- `SQL_AGGREGATE_FUNCTIONS` – This setting indicates which aggregate functions are supported, such as `MIN`, `MAX`, `SUM`. A value of '127' indicates support for all standard SQL aggregate functions.

## Handle severely limited data sources

Some data sources are so severely limited that Tableau is unable to complete the steps of creating a connection. Occasionally this is due to crashes within the driver, which cause Tableau to cease working. You can use a global TDC file to prevent Tableau from issuing queries or checking for capabilities that might be associated with the instability.

To create this file, you need to know the database vendor name and ODBC driver name.

1. Create a new connection in Tableau, open your log file, and then look for a line like the following:

```
GenericODBCProtocol::Connect: Detected vendor: 'SQLite' and
driver: 'SQLite3 ODBC Driver'
```

2. Create a TDC file with the listed `vendor` name and `driver` name. See [Vendor and driver name on page 553](#) for an example.
3. Use customizations, such as `CAP_SUPPRESS_DISCOVERY_QUERIES`, to constrain Tableau's interaction with a limited data source.

## Configure ODBC driver settings

ODBC drivers provide dialog boxes for supplying connection details such as the server, user name, and password. Many offer advanced options for controlling the connection behavior. You should consider these options when exploring ways to improve the functionality or performance of your ODBC connection. In particular, look for settings that control the items listed below, as these have been the cause of past issues with ODBC connections in Tableau:

- Transaction Isolation - Prefer `READ, COMMITTED`, or `SERIALIZABLE` to ensure that queries do not include data from pending transactions in their results.
- Cursors - Prefer Holdable or Scrollable over Streaming cursors. Since Tableau closes a transaction after every read-only analytical query, streaming cursors may become truncated and lead to incomplete results displayed in Tableau.
- Row/Resultset Buffers - Prefer larger buffer sizes to improve the performance of fetching numerous rows, which can greatly improve the speed of creating extracts. This is sometimes called the cache size or response size.
- Character Set - In decreasing order of preference: UTF-16, UTF-8, ASCII.

## Advanced SQLite customizations

Tableau has special customizations for SQLite that are built in to the product. These customizations take precedence over any connection customizations for SQLite in the workbook file, data source file, or global TDS file. To make advanced changes to SQLite connection customizations, you need to trick Tableau into ignoring its own SQLite dialect. You can do so by changing the reported name of the database vendor (`<customization name='SQL_DBMS_NAME' value='SQLite' />`) to a different value such as `SQLite-Tableau`.

## ODBC documentation reference

Microsoft's MSDN has documentation for the ODBC standard. The [ODBC Appendixes](#) are the most applicable as resources for the article information, specifically:

- Appendix C: [SQL Grammar](#) - especially the [SQL Minimum Grammar](#) and [ODBC Escape Sequences](#)
- Appendix D: [Data Types](#)
- Appendix E: [Scalar Functions](#)

## Tableau JDBC Capability Customizations Reference

You can set the following capability customizations in the Tableau Datasource Customization (TDC) file to define which Tableau capabilities are supported by the JDBC connection.

Many of these customizations influence the type of SQL queries that Tableau issues. For settings that are not defined, Tableau attempts to determine the proper values for each capability by issuing various forms of SQL queries to experimentally verify which forms are supported.

CAP_CREATE_TEMP_TABLES	Set to 'yes' if Tableau can create temporary tables needed for certain complex or optimized queries. See also: CAP_SELECT_INTO.
CAP_CONNECT_STORED_PROCEDURE	Set to 'yes' to allow support for connecting to a stored procedure.
CAP_FAST_METADATA	Set to 'yes' if you have small to moderate size schemas. This capability controls whether Tableau should enumerate all of the objects immediately when you connect. Set the value to "yes" to enable this capability for better performance when creating new connections. Disable this capability to allow search for specific schemas or tables instead of retrieving all objects. You can search for all objects by using an empty string. This capability is available in 9.0 and later.
CAP_ISOLATION_LEVEL_READ_COMMITTED	Set to 'yes' to force the transaction isolation level to Read Committed if the data source supports it. Only one of the four transaction isolation levels should be set to 'yes'. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL.
CAP_ISOLATION_LEVEL_READ_UNCOMMITTED	Set to 'yes' to force the transaction isolation level to Read Uncommitted if the data source supports it. Only one of the four transaction isolation levels should be set to 'yes'. This capability can improve speed by reducing lock contention, but may result in partial or inconsistent data in query results. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL.
CAP_ISOLATION_LEVEL_REPEATABLE_READS	Set to 'yes' to force the transaction isolation level to Repeatable Reads if the data source supports

	it. Only one of the four transaction isolation levels should be set to 'yes'. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL.
CAP_ISOLATION_LEVEL_SERIALIZABLE	Set to 'yes' to force the transaction isolation level to Serializable if the data source supports it. Only one of the four transaction isolation levels should be set to 'yes'. This is a very conservative setting that may improve stability at the expense of performance. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL.
CAP_JDBC_BIND_DETECT_ALIAS_CASE_FOLDING	Set to 'yes' to allow Tableau to detect and recover from a JDBC data source that reports the field names in a result set using only uppercase or lowercase characters, instead of the expected field names.
CAP_JDBC_EXPORT_DATA_BATCH	Set to 'no' to disable the use of JDBC batch operations for data insert.
CAP_JDBC_METADATA_GET_INDEX_INFO	Set to 'no' to disable reading index information.
CAP_JDBC_METADATA_READ_FOREIGNKEYS	Set to 'no' to disable reading foreign key metadata.
CAP_JDBC_METADATA_READ_PRIMARYKEYS	Set to 'no' to disable reading primary key metadata.
CAP_JDBC_METADATA_USE_RESULTSET_FOR_TABLE	Set to 'yes' to get column metadata from the result set of a select * query. Available in Tableau 2020.4 and newer.
CAP_JDBC_QUERY_ASYNC	Set to 'yes' to run queries on another thread.
CAP_JDBC_QUERY_CANCEL	Set to 'yes' if driver can cancel queries.
CAP_JDBC_QUERY_DISABLE_AUTO_COMMIT	Set to 'yes' to disable the default auto-commit mode when running query. Available in Tableau

	2020.4 and newer.
CAP_JDBC_QUERY_FORCE_PREPARE	Set to 'yes' to always prepare the query before execution. Available in Tableau 2020.4 and newer.
CAP_JDBC_SUPPRESS_EMPTY_CATALOG_NAME	Set to 'yes' to ignore missing catalog.
CAP_JDBC_SUPPRESS_ENUMERATE_DATABASES	Set to 'yes' to disable database enumeration.
CAP_JDBC_SUPPRESS_ENUMERATE_SCHEMAS	Set to 'yes' to disable schema enumeration.
CAP_JDBC_METADATA_SUPPRESS_PREPARED_QUERY	If CAP_JDBC_METADATA_USE_RESULTSET_FOR_TABLE is enabled, set this capability to 'yes' to disable preparing the query used for reading the table metadata. We will execute the query wrapped with a where-false clause.
CAP_JDBC_USE_ADAPTIVE_FETCH_SIZE	Set to 'yes' to use ResultSet metadata to determine optimal fetch size. May require CAP_JDBC_QUERY_FORCE_PREPARE to be enabled to work properly. Available in Tableau 2020.4 and newer.
CAP_MULTIPLE_CONNECTIONS_FROM_SAME_IP	Set to 'no' to prevent Tableau from creating more than one active connection to the database. This is a conservative setting that may increase stability at the expense of performance.
CAP_QUERY_BOOLEXPRESS_TO_INTEXPRESS	Set to 'yes' if Tableau must coerce any Boolean expressions to an integer value in order include in a result set.
CAP_QUERY_FROM_REQUIRES_ALIAS	Set to 'yes' if the FROM clause must provide an alias for the given table.

CAP_QUERY_GROUP_ALLOW_DUPLICATES	Set to 'no' if SQL queries cannot contain duplicate expressions in the GROUP BY clause (this is uncommon).
CAP_QUERY_GROUP_BY_ALIAS	Set to 'yes' if SQL queries with aggregations can reference the grouping columns by their corresponding alias in the SELECT list, e.g. GROUP BY "none_ShipCountry_nk".
CAP_QUERY_GROUP_BY_DEGREE	Set to 'yes' if SQL queries with aggregations can reference the grouping columns by the ordinal position of each column, e.g. GROUP BY 2, 5. See also: CAP_QUERY_SORT_BY_DEGREE
CAP_QUERY_HAVING_REQUIRES_GROUP_BY	Set to 'yes' if Tableau must use an artificial grouping field for any query which has a HAVING clause but no grouping columns.
CAP_QUERY_HAVING_UNSUPPORTED	Set to 'yes' if the SQL syntax for HAVING is unsupported. Tableau may be able to work around this using subqueries. See also: CAP_QUERY_SUBQUERIES.
CAP_QUERY_INCLUDE_GROUP_BY_COLUMNS_IN_SELECT	Set to 'yes' to require all GROUP BY expressions to also appear in the SELECT expression list.
CAP_QUERY_JOIN_ACROSS_SCHEMAS	Set to 'yes' if SQL queries can express joins between tables located in different schemas.
CAP_QUERY_JOIN_ASSUME_CONSTRAINED	Set to 'yes' to cull inner joins even if the database tables does do not have FK-PK relationships.
CAP_QUERY_JOIN_PUSH_DOWN_CONDITION_EXPRESSIONS	Set to 'yes' to rewrite joins to simplify the ON clause conditions to simple identifier comparisons.
CAP_QUERY_JOIN_REQUIRES_SCOPE	Set to 'yes' if SQL queries must scope each join clause within parentheses to ensure a proper order of evaluation.

CAP_QUERY_JOIN_REQUIRES_SUBQUERY	Set to 'yes' to force join expressions involving more than two tables to be composed with subqueries.
CAP_QUERY_NULL_REQUIRES_CAST	Set to 'yes' if the data source requires that all NULL literals are cast to an explicit data type.
CAP_QUERY_SELECT_ALIASES_SORTED	Set to 'yes' if Tableau must impose a deterministic order on the SELECT expressions (sorted by alias) to ensure that query results can be properly matched with each field in the Tableau visualization. This is only required for data sources which do not preserve the aliases of the SELECT expressions when returning metadata with the query results.
CAP_QUERY_SORT_BY_DEGREE	Set to 'yes' if SQL queries can reference the sorting columns by the ordinal position of each column, e.g. ORDER BY 2, 5. See also: CAP_QUERY_GROUP_BY_DEGREE.
CAP_QUERY_SUBQUERIES	Set to 'yes' if the data source supports subqueries.
CAP_QUERY_SUBQUERIES_WITH_TOP	Set to 'yes' if the data source supports a TOP or LIMIT row-limiting clause within a subquery.
CAP_QUERY_SUBQUERY_DATASOURCE_CONTEXT	Set to 'yes' to use subquery filtered query context to implement data source filters. This capability is available in Tableau 8.0 through Tableau 9.3 only.
CAP_QUERY_SUBQUERY_QUERY_CONTEXT	Set to 'yes' to force Tableau to use a subquery for context filters instead of a temporary table or locally cached results.
CAP_QUERY_TOP_N	Set to 'yes' if the data source supports any form of row-limiting clause. The exact forms supported are described below.
CAP_QUERY_TOPSTYLE_LIMIT	Set to 'yes' if the data source uses LIMIT as the

	row-limiting clause.
CAP_QUERY_TOPSTYLE_ROWNUM	Set to 'yes' if the data source supports an Oracle-style filter on ROWNUM as the row-limiting clause.
CAP_QUERY_TOPSTYLE_TOP	Set to 'yes' if the data source uses TOP as the row-limiting clause.
CAP_QUERY_USE_QUERY_FUSION	Set to 'no' to prevent Tableau from combining multiple individual queries into a single combined query. Turn off this capability for performance tuning or if the database is unable to process large queries. This capability is enabled by default and is available in Tableau 9.0 and later for all data sources except Tableau data extracts. Support for this capability in Tableau data extracts is available in Tableau 9.0.6.
CAP_SELECT_INTO	Set to 'yes' if Tableau can create a table on the fly from the resultset of another query. See also: CAP_CREATE_TEMP_TABLES.
CAP_SELECT_TOP_INTO	Set to 'yes' if Tableau can use a TOP or LIMIT row-limiting clause when creating a table from a query result set.
CAP_SET_ISOLATION_LEVEL_VIA_SQL	Set to 'yes' to force Tableau to set the transaction isolation level for the data source using a SQL query. CAP_SET_ISOLATION_LEVEL_VIA_SQL must be set to 'yes' when any one of the four CAP_ISOLATION_LEVEL capabilities has been set to 'yes'.
CAP_STORED_PROCEDURE_PREFER_TEMP_TABLE	Set to 'yes' to use a temporary table to support remote queries over the stored procedure result set.
CAP_STORED_PROCEDURE_	Set to 'yes' to attempt to compute actual string

REPAIR_TEMP_TABLE_STRINGS	widths if metadata indicates no width or non-positive width.
CAP_STORED_PROCEDURE_TEMP_TABLE_FROM_BUFFER	Set to 'yes' to populate the temporary table from a result set buffered in entirety.
CAP_STORED_PROCEDURE_TEMP_TABLE_FROM_NEW_PROTOCOL	Set to 'yes' to populate the temporary table from a separate protocol created for just this operation.
CAP_SUPPRESS_DISCOVERY_QUERIES	Set to 'yes' to prevent Tableau from detecting the supported SQL syntax for a variety of clauses.
CAP_SUPPRESS_DISPLAY_LIMITATIONS	Set to 'yes' to suppress displaying any warnings about limitations for this data source.

[Other Databases \(JDBC\) on page 520](#) – Describes how to connect to your data using the Other Databases (JDBC) connector.

## Tableau Capability Customizations Reference

You can set the following capability customizations in the Tableau Datasource Customization (TDC) file to define which Tableau capabilities are supported by the ODBC connection. For more information, see [Customize and Tune a Connection on page 547](#).

Many of these customizations influence the type of SQL queries that Tableau issues. For settings that are not defined, Tableau attempts to determine the proper values for each capability by issuing various forms of SQL queries to experimentally verify which forms are supported, as described in [How Tableau determines the capabilities of the ODBC driver](#).

CAP_CREATE_TEMP_TABLES	Set to 'yes' if Tableau can create temporary tables needed for certain complex or optimized queries. See also: CAP_SELECT_INTO.
CAP_CONNECT_STORED_PROCEDURE	Set to 'yes' to allow support for connecting to a stored procedure.
CAP_FAST_METADATA	Set to 'yes' if you have small to moderate size

	<p>schemas. This capability controls whether Tableau should enumerate all of the objects immediately when you connect. Set the value to “yes” to enable this capability for better performance when creating new connections. Disable this capability to allow search for specific schemas or tables instead of retrieving all objects. You can search for all objects by using an empty string. This capability is available in 9.0 and later.</p>
<p>CAP_ISOLATION_LEVEL_READ_COMMITTED</p>	<p>Set to 'yes' to force the transaction isolation level to Read Committed if the data source supports it. Only one of the four transaction isolation levels should be set to 'yes'. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL, CAP_SET_ISOLATION_LEVEL_VIA_ODBC_API.</p>
<p>CAP_ISOLATION_LEVEL_READ_UNCOMMITTED</p>	<p>Set to 'yes' to force the transaction isolation level to Read Uncommitted if the data source supports it. Only one of the four transaction isolation levels should be set to 'yes'. This capability can improve speed by reducing lock contention, but may result in partial or inconsistent data in query results. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL, CAP_SET_ISOLATION_LEVEL_VIA_ODBC_API.</p>
<p>CAP_ISOLATION_LEVEL_REPEATABLE_READS</p>	<p>Set to 'yes' to force the transaction isolation level to Repeatable Reads if the data source supports it. Only one of the four transaction isolation levels should be set to 'yes'. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL, CAP_SET_ISOLATION_LEVEL_VIA_ODBC_API.</p>
<p>CAP_ISOLATION_LEVEL_SERIALIZABLE</p>	<p>Set to 'yes' to force the transaction isolation level to Serializable if the data source supports it. Only one of the four transaction isolation levels should</p>

	be set to 'yes'. This is a very conservative setting that may improve stability at the expense of performance. See also: CAP_SET_ISOLATION_LEVEL_VIA_SQL, CAP_SET_ISOLATION_LEVEL_VIA_ODBC_API.
CAP_SET_ISOLATION_LEVEL_VIA_ODBC_API	Set to 'yes' to force Tableau to set the transaction isolation level for the data source using the ODBC API. CAP_SET_ISOLATION_LEVEL_VIA_ODBC_API must be set to 'yes' when any one of the four CAP_ISOLATION_LEVEL capabilities has been set to 'yes'.
CAP_SET_ISOLATION_LEVEL_VIA_SQL	Set to 'yes' to force Tableau to set the transaction isolation level for the data source using a SQL query. CAP_SET_ISOLATION_LEVEL_VIA_SQL must be set to 'yes' when any one of the four CAP_ISOLATION_LEVEL capabilities has been set to 'yes'.
CAP_MULTIPLE_CONNECTIONS_FROM_SAME_IP	Set to 'no' to prevent Tableau from creating more than one active connection to the database. This is a conservative setting that may increase stability at the expense of performance.
CAP_ODBC_BIND_DETECT_ALIAS_CASE_FOLDING	Set to 'yes' to allow Tableau to detect and recover from an ODBC data source that reports the field names in a result set using only upper-case or lower-case characters, instead of the expected field names.
CAP_ODBC_BIND_BOOL_AS_WCHAR_01LITERAL	Set to 'yes' to bind a Boolean data type as a WCHAR containing values '0' or '1'.
CAP_ODBC_BIND_BOOL_AS_WCHAR_TFLITERAL	Set to 'yes' to bind a Boolean data type as WCHAR containing values 't' or 'f'.
CAP_ODBC_BIND_FORCE_DATE_	Set to 'yes' to force the Tableau native ODBC

AS_CHAR	protocol to bind date values as CHAR.
CAP_ODBC_BIND_FORCE_DATETIME_AS_CHAR	Set to 'yes' to force the Tableau native ODBC protocol to bind datetime values as CHAR.
CAP_ODBC_BIND_FORCE_MAX_STRING_BUFFERS	Set to 'yes' to force the Tableau native ODBC protocol to use maximum-sized buffers (1MB) for strings instead of the size described by metadata.
CAP_ODBC_BIND_FORCE_MEDIUM_STRING_BUFFERS	Set to 'yes' to force the Tableau native ODBC protocol to use medium-sized buffers (1K) for strings instead of the size described by metadata.
CAP_ODBC_BIND_FORCE_SMALL_STRING_BUFFERS	Set to 'yes' to force the Tableau native ODBC protocol to use small buffers for strings instead of the size described by metadata.
CAP_ODBC_BIND_FORCE_SIGNED	Set to 'yes' to force binding integers as signed.
CAP_ODBC_BIND_PRESERVE_BOM	Set to 'yes' to preserve BOM when present in strings. Hive will return BOM and treat strings containing it as distinct entities.
CAP_ODBC_BIND_SKIP_LOCAL_DATATYPE_UNKNOWN	Set to 'yes' to prevent the native ODBC Protocol from binding to columns having local data type <code>DataType::Unknown</code> in the expected metadata.
CAP_ODBC_BIND_SPATIAL_AS_WKT	Set to 'yes' to force binding Spatial data as WKT (Well Known Text)
CAP_ODBC_BIND_SUPPRESS_COERCE_TO_STRING	Set to 'yes' to prevent the Tableau native ODBC protocol from binding non-string data as strings (i.e. requesting driver conversion).
CAP_ODBC_BIND_SUPPRESS_INT64	Set to 'yes' to prevent the Tableau native ODBC protocol from using 64-bit integers for large numeric data.
CAP_ODBC_BIND_SUPPRESS_PREFERRED_CHAR	Set to 'yes' to prevent the Tableau native ODBC protocol from preferring a character type that

	differs from the driver default.
CAP_ODBC_BIND_SUPPRESS_PREFERRED_TYPES	Set to 'yes' to prevent the Tableau native ODBC protocol from binding any data according to its preferred wire types. With this capability set, Tableau will only bind according to the data types described by the ODBC driver via metadata.
CAP_ODBC_BIND_SUPPRESS_WIDE_CHAR	Set to 'yes' to prevent the Tableau native ODBC protocol from binding strings a WCHAR. Instead they will be bound as single-byte CHAR arrays, and processed locally for any UTF-8 characters contained within.
CAP_ODBC_CONNECTION_STATE_VERIFY_FAST	Set to 'yes' to check if a connection is broken with a fast ODBC API call.
CAP_ODBC_CONNECTION_STATE_VERIFY_PROBE	Set to 'yes' to check if a connection is broken with a forced probe.
CAP_ODBC_CONNECTION_STATE_VERIFY_PROBE_IF_STALE	Set to 'yes' to check if a connection is broken with a forced probe only if it is "stale" (i.e., unused for about 30 minutes).
CAP_ODBC_CONNECTION_STATE_VERIFY_PROBE_PREPARED_QUERY	Set to 'yes' to check if a connection is broken using a prepared query.
CAP_ODBC_CURSOR_DYNAMIC	Set to 'yes' to force the Tableau native ODBC protocol to set the cursor type for all statements to Dynamic (scrollable, detects added/removed/modified rows).
CAP_ODBC_CURSOR_FORWARD_ONLY	Set to 'yes' to force the Tableau native ODBC protocol to set the cursor type for all statements to Forward-only (non-scrollable).
CAP_ODBC_CURSOR_KEYSET_DRIVEN	Set to 'yes' to force the Tableau native ODBC protocol to set the cursor type for all statements to

	Keyset-driven (scrollable, detects changes to values within a row).
CAP_ODBC_CURSOR_STATIC	Set to 'yes' to force Tableau to set the cursor type for all statements to Static (scrollable, does not detect changes).
CAP_ODBC_ERROR_IGNORE_FALSE_ALARM	Set to 'yes' to allow the Tableau native ODBC protocol to ignore SQL_ERROR conditions where SQLSTATE is '00000' (meaning "no error").
CAP_ODBC_ERROR_IGNORE_SQLNODATA_FOR_COMMAND_QUERIES	Set to 'yes' to ignore when SQLExecDirect returns SQL_NO_DATA even when data is not expected back.
CAP_ODBC_EXPORT_ALLOW_CHAR_UTF8	Set to 'yes' to allow the use of single-byte char data type for binding Unicode strings as UTF-8.
CAP_ODBC_EXPORT_BIND_FORCE_TARGET_METADATA	Set to 'yes' to force binding for export based on all of the metadata from the target table instead of the ODBC metadata for the parameterized insert statement.
CAP_ODBC_EXPORT_BIND_PREFER_TARGET_METADATA	Set to 'yes' to prefer binding for export based on specific types of metadata from the target table instead of the ODBC metadata for the parameterized insert statement.
CAP_ODBC_EXPORT_BUFFERS_RESIZABLE	Set to 'yes' to allow export buffers to be reallocated after the first batch to improve performance.
CAP_ODBC_EXPORT_BUFFERS_SIZE_FIXED	Set to 'yes' to ignore the width of a single row when computing the total rows to insert at a time.
CAP_ODBC_EXPORT_BUFFERS_SIZE_LIMIT_512KB	Set to 'yes' to limit export buffers to 512 KB. This is an uncommon setting.
CAP_ODBC_EXPORT_BUFFERS_SIZE_MASSIVE	Set to 'yes' to force the use of large buffers for

	insert. If CAP_ODBC_EXPORT_BUFFERS_RESIZABLE is not set or disabled, a fixed row count is used.
CAP_ODBC_EXPORT_BUFFERS_SIZE_MEDIUM	Set to 'yes' to force the use of medium-sized buffers for insert. If CAP_ODBC_EXPORT_BUFFERS_RESIZABLE is not set or disabled, a fixed row count is used.
CAP_ODBC_EXPORT_BUFFERS_SIZE_SMALL	Set to 'yes' to force the use of small buffers for insert. If CAP_ODBC_EXPORT_BUFFERS_RESIZABLE is not set or disabled, a fixed row count is used.
CAP_ODBC_EXPORT_CONTINUE_ON_ERROR	Set to 'yes' to continue data insert despite errors. Some data sources report warnings as errors.
CAP_ODBC_EXPORT_DATA_BULK	Set to 'yes' to allow the use of ODBC bulk operations for data insert.
CAP_ODBC_EXPORT_DATA_BULK_VIA_INSERT	Set to 'yes' to allow the use of ODBC bulk operations based on 'INSERT INTO' parameterized queries.
CAP_ODBC_EXPORT_DATA_BULK_VIA_ROWSET	Set to 'yes' to allow the use of ODBC bulk operations based on a rowset cursor.
CAP_ODBC_EXPORT_FORCE_INDICATE_NTS	Set to 'yes' to force the use of indicator buffers for identifying null-terminated strings (NTS).
CAP_ODBC_EXPORT_FORCE_SINGLE_ROW_BINDING	Set to 'yes' to force the use of a single row for binding export buffers to insert data.
CAP_ODBC_EXPORT_FORCE_SINGLE_ROW_BINDING_WITH_TIMESTAMPS	Set to 'yes' to force the use of a single row for binding export buffers when dealing with timestamp data. This is required for some versions of Teradata.
CAP_ODBC_EXPORT_FORCE_STRING_WIDTH_FROM_SOURCE	Set to 'yes' to force the use of the source string

	width (from Tableau metadata), overriding the destination string width (from insert parameter metadata).
CAP_ODBC_EXPORT_FORCE_STRING_WIDTH_USING_OCTET_LENGTH	Set to 'yes' to force the use of the source string width from the octet length.
CAP_ODBC_EXPORT_SUPPRESS_STRING_WIDTH_VALIDATION	Set to 'yes' to suppress validating that the target string width can accommodate the widest source strings.
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_BATCH_MASSIVE	Set to 'yes' to commit in massive batches of INSERT statements (~100,000). This may be useful with single-row export binding.
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_BATCH_MEDIUM	Set to 'yes' to commit in medium-sized batches of INSERT statements (~50). A single statement may be bound to multiple records.
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_BATCH_SMALL	Set to 'yes' to commit in small batches of INSERT statements (~5). A single statement may be bound to multiple records.
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_BYTES_MASSIVE	Set to 'yes' to commit in massive batches of data (~100 MB).
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_BYTES_MEDIUM	Set to 'yes' to commit in medium batches of data (~10 MB).
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_BYTES_SMALL	Set to 'yes' to commit in small batches of data (~1 MB).
CAP_ODBC_EXPORT_TRANSACTIONS_COMMIT_EACH_STATEMENT	Set to 'yes' to commit after executing each INSERT statement. A single statement may be bound to multiple records.

CAP_ODBC_EXPORT_TRANSACTION_COMMIT_INTERVAL_LONG	Set to 'yes' to commit in long intervals of elapsed time (~100 seconds).
CAP_ODBC_EXPORT_TRANSACTION_COMMIT_INTERVAL_MEDIUM	Set to 'yes' to commit in medium intervals of elapsed time (~10 seconds).
CAP_ODBC_EXPORT_TRANSACTION_COMMIT_INTERVAL_SHORT	Set to 'yes' to commit in short intervals of elapsed time (~1 seconds).
CAP_ODBC_EXPORT_TRANSACTION_COMMIT_ONCE_WHEN_COMPLETE	Set to 'yes' to commit only once at the end after the export is complete.
CAP_ODBC_EXPORT_TRANSLATE_DATA_PARALLEL	Set to 'yes' to use parallel loops to translate Tableau DataValues to wire buffers on export.
CAP_ODBC_FETCH_ABORT_FORCE_CANCEL_STATEMENT	Set to 'yes' to cancel the statement handle upon interrupting SQLFetch with a cancel exception.
CAP_ODBC_FETCH_BUFFERS_RESIZABLE	Set to 'yes' to allow buffers to be reallocated after fetch to improve performance or handle data truncation.
CAP_ODBC_FETCH_BUFFERS_SIZE_FIXED	Set to 'yes' to ignore the width of a single row when computing the total rows to fetch.
CAP_ODBC_FETCH_BUFFERS_SIZE_MASSIVE	Set to 'yes' to force the use of large buffers. If CAP_ODBC_FETCH_BUFFERS_SIZE_FIXED is enabled, a fixed row count is used.
CAP_ODBC_FETCH_BUFFERS_SIZE_MEDIUM	Set to 'yes' to force the use of medium-sized buffers. If CAP_ODBC_FETCH_BUFFERS_SIZE_FIXED is enabled, a fixed row count is used.
CAP_ODBC_FETCH_BUFFERS_SIZE_SMALL	Set to 'yes' to force the use of small buffers. If CAP_ODBC_FETCH_BUFFERS_SIZE_FIXED is enabled, a fixed row count is used.

<p>CAP_ODBC_FETCH_CONTINUE_ON_ERROR</p>	<p>Set to 'yes' to allow the Tableau native ODBC protocol to continue resultset fetch despite errors (some data sources report warnings as errors).</p>
<p>CAP_ODBC_FETCH_IGNORE_FRACTIONAL_SECONDS</p>	<p>Set to 'yes' to allow the Tableau native ODBC protocol to ignore the fractional seconds component of a time value when fetching query result set data. This is useful when working with data sources that do not follow the ODBC specification for fractional seconds, which must be represented as billionths of a second.</p>
<p>CAP_ODBC_FETCH_RESIZE_BUFFERS</p>	<p>Set to 'yes' to allow the Tableau native ODBC protocol to automatically resize buffers and fetch again if data truncation occurred.</p>
<p>CAP_ODBC_FORCE_SINGLE_ROW_BINDING</p>	<p>Set to 'yes' to force the Tableau native ODBC protocol to use a single row for result set transfers instead of the more efficient bulk-fetch.</p>
<p>CAP_ODBC_IMPORT_ERASE_BUFFERS</p>	<p>Set to 'yes' to reset the contents of data buffers before fetching each block.</p>
<p>CAP_ODBC_IMPORT_TRANSLATE_DATA_PARALLEL</p>	<p>Set to 'no' to disable decoding data locally in parallel.</p>
<p>CAP_ODBC_METADATA_FORCE_LENGTH_AS_PRECISION</p>	<p>Set to 'yes' to force the Tableau native ODBC protocol to use the column "length" as the numeric precision. This is an uncommon setting.</p>
<p>CAP_ODBC_METADATA_FORCE_NUM_PREC_RADIX_10</p>	<p>Set to 'yes' to force the Tableau native ODBC protocol to assume the numeric precision is reported in base-10 digits. This is an uncommon setting.</p>
<p>CAP_ODBC_METADATA_FORCE_UNKNOWN_AS_STRING</p>	<p>Set to 'yes' to force the Native ODBC Protocol to treat unknown data types as string instead of ignoring the associated column.</p>

CAP_ODBC_METADATA_FORCE_UTF8_IDENTIFIERS	Set to 'yes' to force the protocol to treat identifiers as UTF-8 when communicating with the driver.
CAP_ODBC_METADATA_SKIP_DESC_TYPE_NAME	Set to 'yes' to remove the check for the SQL_DESC_TYPE_NAME attribute with the SQLColAttribute API.
CAP_ODBC_METADATA_STRING_LENGTH_UNKNOWN	Set to 'yes' to prevent Tableau from allocating memory based on the driver-reported string length, which may not be known or reported properly. Instead, Tableau will use a fixed-sized string length, and will reallocate as needed to handle string data that is too large for the fixed-size buffer.
CAP_ODBC_METADATA_STRING_TRUST_OCTET_LENGTH	Set to 'yes' to use the octet length reported by the driver for strings instead of computing it from the number of characters.
CAP_ODBC_METADATA_SUPPRESS_EXECUTED_QUERY	Set to 'yes' to prevent Tableau from executing a query as a means of reading metadata. While Tableau typically includes a row-limiting clause in such metadata queries (e.g., 'LIMIT', or 'WHERE 1=0'), this may not help when used with a Custom SQL connection for database systems with poor query optimizers. Note that this capability may prevent Tableau from determining the connection metadata properly.
CAP_ODBC_METADATA_SUPPRESS_PREPARED_QUERY	Set to 'yes' to prevent Tableau from using a prepared query as a means of reading metadata. A prepared query is often the fastest way to accurately read metadata. However, not all database systems are capable of reporting metadata for a prepared query without actually executing the query. Note that certain metadata -- for example from connections using Custom SQL -- cannot be retrieved if this capability and CAP_

	ODBC_METADATA_SUPPRESS_EXECUTED_QUERY are both set.
CAP_ODBC_METADATA_SUPPRESS_READ_IDENTITY_COLUMNS	Set to 'no' to prevent reading identity column metadata.
CAP_ODBC_METADATA_SUPPRESS_SELECT_STAR	Set to 'yes' to prevent reading metadata using a 'select *' query.
CAP_ODBC_METADATA_SUPPRESS_SQLCOLUMNS_API	Set to 'yes' to prevent Tableau from using older, less accurate API for reading metadata from ODBC data sources. Setting this capability allows Tableau to read metadata by issuing a full 'select *' query, which is expensive but may enable connectivity for extremely limited or unstable data sources.
CAP_ODBC_METADATA_SUPPRESS_SQLFOREIGNKEYS_API	Set to 'yes' to prevent Tableau from attempting to read metadata describing foreign key constraints. Despite the simple nature of this ODBC API, some drivers may have unstable behavior or produce inaccurate results. Setting this capability may force Tableau to generate less efficient queries involving multi-table joins.
CAP_ODBC_METADATA_SUPPRESS_SQLPRIMARYKEYS_API	Set to 'yes' to prevent Tableau from reading primary key metadata using the SQLPrimaryKeys API or an equivalent query. This capability is available in Tableau 9.1 and later.
CAP_ODBC_METADATA_SUPPRESS_SQLSTATISTICS_API	Set to 'yes' to prevent reading unique constraints and table cardinality estimates using the SQLStatistics API or an equivalent query. This capability is available in Tableau 9.0 and later.
CAP_ODBC_QUERY_USE_PREPARE_PARAMETER_MARKER	Enable to use prepared statements with parameter markers instead of literal values.

	Applies only for floating point, integer, and string values.
CAP_ODBC_REBIND_SKIP_UNBIND	Set to 'yes' to force the Tableau native ODBC protocol to rebind a column directly and skip unbinding, which reduces ODBC API calls when resizing buffers to refetch truncated data.
CAP_ODBC_SUPPORTS_LONG_DATA_BULK	Set to 'yes' if driver can fetch multiple long-data rows at a time.
CAP_ODBC_SUPPORTS_LONG_DATA_ORDERED	Set to 'yes' if driver requires long-data columns to come after non-long-data ones.
CAP_ODBC_SUPPRESS_INFO_SCHEMA_STORED_PROCS	Set to 'yes' to prevent the INFORMATION_SCHEMA schema from being queried when enumerating stored procedures.
CAP_ODBC_SUPPRESS_INFO_SCHEMA_TABLES	Set to 'yes' to prevent tables from "information_schema" schema from being returned by EnumerateTables.
CAP_ODBC_SUPPRESS_PG_TEMP_SCHEMA_TABLES	Set to 'yes' to prevent tables from "pg_temp" schema from being returned by EnumerateTables.
CAP_ODBC_SUPPRESS_PREPARED_QUERY_FOR_ALL_COMMAND_QUERIES	Set to 'yes' to execute all commands directly (i.e., no prepared statement).
CAP_ODBC_SUPPRESS_PREPARED_QUERY_FOR_DDL_COMMAND_QUERIES	Set to 'yes' to execute DDL commands (e.g. CREATE TABLE) directly (i.e., no prepared statement).
CAP_ODBC_SUPPRESS_PREPARED_QUERY_FOR_DML_COMMAND_QUERIES	Set to 'yes' to execute DML commands (e.g. INSERT INTO) directly (i.e., no prepared statement).
CAP_ODBC_SUPPRESS_PREPARED_QUERY_FOR_NON_COMMAND_QUERIES	Set to 'yes' to execute all non-command queries directly (no prepared statement).

COMMAND_QUERIES	
CAP_ODBC_SUPPRESS_SYS_SCHEMA_STORED_PROCS	Set to 'yes' to explicitly add the "SYS" schema to the schema exclusions when enumerating stored procedures.
CAP_ODBC_TRANSACTIONS_COMMIT_INVALIDATES_PREPARED_QUERY	Set to 'yes' to indicate that a transaction will invalidate all prepared statements and close any open cursors.
CAP_ODBC_TRANSACTIONS_SUPPRESS_AUTO_COMMIT	Set to 'yes' to prevent the Native ODBC Protocol from using default auto-committing transaction behavior in ODBC. This capability cannot be used with CAP_ODBC_TRANSACTIONS_SUPPRESS_EXPLICIT_COMMIT.
CAP_ODBC_TRANSACTIONS_SUPPRESS_EXPLICIT_COMMIT	Set to 'yes' to prevent the Native ODBC Protocol from explicitly managing transactions. This capability cannot be used with CAP_ODBC_TRANSACTIONS_SUPPRESS_AUTO_COMMIT.
CAP_ODBC_TRIM_CHAR_LEAVE_PADDING	Set to 'yes' to leave whitespace padding at the end of a character or text data type. Most data sources will trim this whitespace automatically, but the behavior depends on the driver.
CAP_ODBC_TRIM_VARCHAR_PADDING	Set to 'yes' to force the Tableau native ODBC protocol to trim trailing whitespace from VARCHAR columns which the driver has erroneously padded.
CAP_ODBC_UNBIND_AUTO	Set to 'yes' to force the Tableau native ODBC protocol to unbind and deallocate columns automatically, which can reduce ODBC API calls.
CAP_ODBC_UNBIND_BATCH	Set to 'yes' to force the Tableau native ODBC protocol to unbind and deallocate columns in a single batch operation, which can reduce ODBC

	API calls.
CAP_ODBC_UNBIND_EACH	Set to 'yes' to force the Tableau native ODBC protocol to unbind and deallocate columns individually, which may improve stability.
CAP_ODBC_UNBIND_PARAMETERS_BATCH	Set to 'yes' to unbind all parameters in a single batch operation.
CAP_ORACLE_SHOW_ALL_SYNONYM_OWNERS	Set to 'yes' to list all the owners in the all_synonyms view for Oracle. This capability is available in 9.0 and later.
CAP_QUERY_BOOLEXPRESS_TO_INTEXPRESS	Set to 'yes' if Tableau must coerce any Boolean expressions to an integer value in order include in a result set.
CAP_QUERY_FROM_REQUIRES_ALIAS	Set to 'yes' if the FROM clause must provide an alias for the given table.
CAP_QUERY_GROUP_ALLOW_DUPLICATES	Set to 'no' if SQL queries cannot contain duplicate expressions in the GROUP BY clause (this is uncommon).
CAP_QUERY_GROUP_BY_ALIAS	Set to 'yes' if SQL queries with aggregations can reference the grouping columns by their corresponding alias in the SELECT list, e.g. GROUP BY "none_ShipCountry_nk".
CAP_QUERY_GROUP_BY_DEGREE	Set to 'yes' if SQL queries with aggregations can reference the grouping columns by the ordinal position of each column, e.g. GROUP BY 2, 5. See also: CAP_QUERY_SORT_BY_DEGREE
CAP_QUERY_HAVING_REQUIRES_GROUP_BY	Set to 'yes' if Tableau must use an artificial grouping field for any query which has a HAVING clause but no grouping columns.
CAP_QUERY_HAVING_UNSUPPORTED	Set to 'yes' if the SQL syntax for HAVING is

	unsupported. Tableau may be able to work around this using subqueries. See also: CAP_QUERY_SUBQUERIES.
CAP_QUERY_INCLUDE_GROUP_BY_COLUMNS_IN_SELECT	Set to 'yes' to require all GROUP BY expressions to also appear in the SELECT expression list.
CAP_QUERY_JOIN_ACROSS_SCHEMAS	Set to 'yes' if SQL queries can express joins between tables located in different schemas.
CAP_QUERY_JOIN_ASSUME_CONSTRAINED	Set to 'yes' to cull inner joins even if the database tables does do not have FK-PK relationships.
CAP_QUERY_JOIN_PUSH_DOWN_CONDITION_EXPRESSIONS	Set to 'yes' to rewrite joins to simplify the ON clause conditions to simple identifier comparisons.
CAP_QUERY_JOIN_REQUIRES_SCOPE	Set to 'yes' if SQL queries must scope each join clause within parentheses to ensure a proper order of evaluation.
CAP_QUERY_JOIN_REQUIRES_SUBQUERY	Set to 'yes' to force join expressions involving more than two tables to be composed with subqueries.
CAP_QUERY_NULL_REQUIRES_CAST	Set to 'yes' if the data source requires that all NULL literals are cast to an explicit data type.
CAP_QUERY_SELECT_ALIASES_SORTED	Set to 'yes' if Tableau must impose a deterministic order on the SELECT expressions (sorted by alias) to ensure that query results can be properly matched with each field in the Tableau visualization. This is only required for data sources which do not preserve the aliases of the SELECT expressions when returning metadata with the query results.
CAP_QUERY_SORT_BY_DEGREE	Set to 'yes' if SQL queries can reference the sorting columns by the ordinal position of each column, e.g. ORDER BY 2, 5. See also: CAP_

	QUERY_GROUP_BY_DEGREE.
CAP_QUERY_SUBQUERIES	Set to 'yes' if the data source supports subqueries.
CAP_QUERY_SUBQUERIES_WITH_TOP	Set to 'yes' if the data source supports a TOP or LIMIT row-limiting clause within a subquery.
CAP_QUERY_SUBQUERY_DATASOURCE_CONTEXT	Set to 'yes' to use subquery filtered query context to implement data source filters. This capability is available in Tableau 8.0 through Tableau 9.3 only.
CAP_QUERY_SUBQUERY_QUERY_CONTEXT	Set to 'yes' to force Tableau to use a subquery for context filters instead of a temporary table or locally cached results.
CAP_QUERY_TOP_0_METADATA	Set to 'yes' if the data source can handle a "TOP 0" request for retrieving metadata.
CAP_QUERY_TOP_N	Set to 'yes' if the data source supports any form of row-limiting clause. The exact forms supported are described below.
CAP_QUERY_TOPSTYLE_LIMIT	Set to 'yes' if the data source uses LIMIT as the row-limiting clause.
CAP_QUERY_TOPSTYLE_ROWNUM	Set to 'yes' if the data source supports an Oracle-style filter on ROWNUM as the row-limiting clause.
CAP_QUERY_TOPSTYLE_TOP	Set to 'yes' if the data source uses TOP as the row-limiting clause.
CAP_QUERY_USE_QUERY_FUSION	Set to 'no' to prevent Tableau from combining multiple individual queries into a single combined query. Turn off this capability for performance tuning or if the database is unable to process large queries. This capability is enabled by default and is available in Tableau 9.0 and later for all data sources except Tableau data extracts. Support for this capability in Tableau data extracts is available in Tableau 9.0.6.

CAP_QUERY_WHERE_FALSE_METADATA	Set to 'yes' if the data source can handle a "WHERE <false>" predicate for retrieving metadata.
CAP_SELECT_INTO	Set to 'yes' if Tableau can create a table on the fly from the resultset of another query. See also: CAP_CREATE_TEMP_TABLES.
CAP_SELECT_TOP_INTO	Set to 'yes' if Tableau can use a TOP or LIMIT row-limiting clause when creating a table from a query resultset.
CAP_STORED_PROCEDURE_PREFER_TEMP_TABLE	Set to 'yes' to use a temporary table to support remote queries over the stored procedure result set.
CAP_STORED_PROCEDURE_REPAIR_TEMP_TABLE_STRINGS	Set to 'yes' to attempt to compute actual string widths if metadata indicates no width or non-positive width.
CAP_STORED_PROCEDURE_TEMP_TABLE_FROM_BUFFER	Set to 'yes' to populate the temporary table from a result set buffered in entirety.
CAP_STORED_PROCEDURE_TEMP_TABLE_FROM_NEW_PROTOCOL	Set to 'yes' to populate the temporary table from a separate protocol created for just this operation.
CAP_SUPPRESS_DISCOVERY_QUERIES	Set to 'yes' to prevent Tableau from detecting the supported SQL syntax for a variety of clauses.
CAP_SUPPRESS_DISPLAY_LIMITATIONS	Set to 'yes' to suppress displaying any warnings about limitations for this data source.

**ODBC/SQL Customizations Reference below** – Lists customizations that represent the parts of the ODBC and SQL standards that the ODBC driver reports supporting.

## ODBC/SQL Customizations Reference

You can set the following customizations in the Tableau Datasource Customization (TDC) file to define parts of the ODBC and SQL standards that the ODBC driver supports.

### Documentation resources for SQLGetInfo

The names of these customizations come from the identifiers used as parameters to SQLGetInfo.

For more information, see the MSDN documentation and the source code header file `sqlext.h` for the numeric and bit-mask values associated with each customization.

- The Microsoft documentation for the ODBC API function SQLGetInfo:  
<http://msdn.microsoft.com/en-us/library/ms711681%28VS.85%29.aspx>
- A sample header file, `sqlext.h`, for the ODBC API identifier values used with SQLGetInfo:  
<http://cpansearch.perl.org/src/MIMER/DBD-Mimer-1.00/sqlext.h>

### SQLGetInfo long-integer values

SQL_ODBC_INTERFACE_CONFORMANCE	Currently unused.
SQL_SQL_CONFORMANCE	Integer bitmask. Defines the level which the data source conforms to the SQL standard: '1' for entry-level SQL-92 conformance, '2' for FIPS 127-2 transitional, '4' for Intermediate and '8' for Full conformance.
SQL_CATALOG_USAGE	Integer bitmask. Defines the SQL statements in which a catalog identifier can be used.
SQL_SCHEMA_USAGE	Integer bitmask. Defines the SQL statements in which a schema identifier can be used.

SQL_AGGREGATE_FUNCTIONS	Integer bitmask. Defines which standard SQL aggregation forms are supported.
SQL_NUMERIC_FUNCTIONS	Integer bitmask. Defines which SQL scalar numeric functions are supported.
SQL_STRING_FUNCTIONS	Integer bitmask. Defines which SQL scalar string functions are supported.
SQL_TIMEDATE_FUNCTIONS	Integer bitmask. Defines which SQL scalar date / time functions are supported.
SQL_TIMEDATE_ADD_INTERVALS	Integer bitmask. Defines which date / time intervals are supported with the <code>TIMESTAMPADD</code> scalar function.
SQL_TIMEDATE_DIFF_INTERVALS	Integer bitmask. Defines which date / time intervals are supported with the <code>TIMESTAMPDIFF</code> scalar function.
SQL_DATETIME_LITERALS	Integer bitmask. Defines which SQL-92 literals are supported for representing DATE / TIME constants and INTERVALs.
SQL_SYSTEM_FUNCTIONS	Integer bitmask. Defines support for special SQL system scalar functions: <code>IFNULL</code> , <code>DBNAME</code> and <code>USERNAME</code> .
SQL_SQL92_VALUE_EXPRESSIONS	Integer bitmask. Defines which logical functions are supported for testing and manipulating values: <code>CASE</code> , <code>CAST</code> and <code>NULLIF</code> .
SQL_SQL92_NUMERIC_VALUE_FUNCTIONS	Integer bitmask. Defines which functions can produce a numeric value from non-numeric data, including: <code>EXTRACT</code> (for date / time part extraction), <code>CHAR_LENGTH</code> , <code>CHARACTER_LENGTH</code> and <code>POSITION(.. IN ..)</code> .
SQL_SQL92_STRING_FUNCTIONS	Integer bitmask. Defines which string manipulation functions are supported.
SQL_SQL92_DATETIME_FUNCTIONS	Integer bitmask. Defines which date / time manipulation functions are supported for determining the current date,

	time or timestamp.
SQL_OJ_CAPABILITIES	Integer bitmask. Defines which type of outer joins are supported.
SQL_SQL92_RELATIONAL_JOIN_OPERATORS	Integer bitmask. Defines which types of JOIN operators are supported, e.g. INNER, OUTER.
SQL_SQL92_PREDICATES	Integer bitmask. Defines which predicates are supported for logical tests of values, e.g. IS NULL, LIKE, IN.
SQL_CONVERT_FUNCTIONS	Integer bitmask. Defines which ODBC scalar functions are supported for CASTing or CONVERTing one data type to another.
SQL_CONVERT_TINYINT	Integer bitmask. Determines which other data types that this named type can be converted to using the ODBC scalar function CONVERT.
SQL_CONVERT_SMALLINT	Integer bitmask. Same as above.
SQL_CONVERT_INTEGER	Integer bitmask. Same as above.
SQL_CONVERT_BIGINT	Integer bitmask. Same as above.
SQL_CONVERT_REAL	Integer bitmask. Same as above.
SQL_CONVERT_FLOAT	Integer bitmask. Same as above.
SQL_CONVERT_DOUBLE	Integer bitmask. Same as above.
SQL_CONVERT_CHAR	Integer bitmask. Same as above.
SQL_CONVERT_VARCHAR	Integer bitmask. Same as above.
SQL_CONVERT_LONGVARCHAR	Integer bitmask. Same as above.
SQL_CONVERT_DECIMAL	Integer bitmask. Same as above.
SQL_CONVERT_NUMERIC	Integer bitmask. Same as above.

SQL_CONVERT_BIT	Integer bitmask. Same as above.
SQL_CONVERT_GUID	Integer bitmask. Same as above.
SQL_CONVERT_BINARY	Integer bitmask. Same as above.
SQL_CONVERT_VARBINARY	Integer bitmask. Same as above.
SQL_CONVERT_LONGVARBINARY	Integer bitmask. Same as above.
SQL_CONVERT_DATE	Integer bitmask. Same as above.
SQL_CONVERT_TIME	Integer bitmask. Same as above.
SQL_CONVERT_TIMESTAMP	Integer bitmask. Same as above.
SQL_CONVERT_INTERVAL_DAY_TIME	Integer bitmask. Same as above.

SQLGetInfo short-integer values

SQL_CURSOR_COMMIT_BEHAVIOR	Short integer value. "0" if the prepared statements are closed upon commit for the data source.
SQL_MAX_IDENTIFIER_LEN	Integer value. Defines the maximum number of characters that can be used in an identifier. Tableau leaves room for one extra character as the string terminator.
SQL_TXN_CAPABLE	Short integer value. "0" if the data source does not support the transaction.
SQL_QUOTED_IDENTIFIER_CASE	Integer bitmask.

SQLGetInfo string values

SQL_COLUMN_ALIAS	Boolean value. "Y" if the data source supports using aliases for columns listed in the SELECT clause.
------------------	---

SQL_IDENTIFIER_QUOTE_CHAR	String value. Indicates the character which can be used for quoting identifiers. Because the connection customization is an XML document, any entities must properly be encoded. For example, double-quotes will be '&quot;'. Additionally this character is assumed to work as the opening and closing character around identifiers, so some data sources which require '[' to enclose identifiers will not be supported.
SQL_CATALOG_NAME_SEPARATOR	Character value. Indicates the separator character to use between identifiers when qualifying them with a catalog, schema or table name. This is typically the period character.
SQL_SPECIAL_CHARACTERS	String value. Indicates the special characters which are allowed in identifier strings.
SQL_CATALOG_TERM	String value. This is the descriptive term for a database catalog, which appears in the Tableau connection dialog for this ODBC data source.
SQL_SCHEMA_TERM	String value. This is the descriptive term for a database schema, which appears in the Tableau connection dialog for this ODBC data source.
SQL_TABLE_TERM	String value. This is the descriptive term for a database table, which appears in the Tableau connection dialog for this ODBC data source.
SQL_DRIVER_NAME	String value. This is the name of the database ODBC driver.
SQL_DRIVER_VER	String value. This is the version number of the ODBC driver.
SQL_DRIVER_ODBC_VER	String value. This is the version of the ODBC API which the driver supports.
SQL_ODBC_VER	String value. This is the version of ODBC which the

	Windows ODBC Driver Manager supports. This should not need to be customized.
SQL_DBMS_NAME	String value. This is the name of the database vendor.
SQL_DBMS_VER	String value. This is the version of the database system.
SQL_SERVER_NAME	String value. This is the named network address of the database server.
SQL_USER_NAME	String value. This is the name of the currently authenticated user.

## Run Initial SQL

**Note:** Tableau Prep Builder version 2019.2.2 and later supports using Initial SQL, but doesn't yet support all of the same options supported by Tableau Desktop For information about using Initial SQL with Tableau Prep Builder, see [Use Initial SQL to query your connections](#) in the Tableau Prep Builder Salesforce Help.

When connecting to some databases, you can specify an initial SQL command that will run or use a cached value when a connection is made to the database, for example, when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server.

**Note:** Initial SQL is different than a custom SQL connection. A custom SQL connection defines a relation (or table) to issue queries against. For more information, see [Connect to a Custom SQL Query](#).

You can use this command to:

- Set up temporary tables to use during the session.
- Set up a custom data environment.

You have the option to add an initial SQL command in the Server Connection dialog box or on the Data Source page.

**Note:** If your data source supports running an initial SQL statement, an **Initial SQL** link appears in the lower-left corner of the Server Connection dialog box. For information about your data source, see [Supported Connectors](#).

## To use initial SQL

1. In the Server Connection dialog box, click **Initial SQL**. Or, on the Data Source page, select **Data > Initial SQL** or **Data > Query Banding and Initial SQL** depending on the database you connect to.
2. Enter the SQL command into the Initial SQL dialog box. You can use the **Insert** dropdown menu to pass parameters to your data source.

**Note:** Tableau doesn't examine the statement for errors. This SQL statement is sent to the database when you connect.

Your software license may restrict you from using initial SQL with your connection. If you publish to Tableau Server, the server must be configured to allow Initial SQL statements. By default, the server software is configured to allow these statements to run when the workbook is loaded in a web browser.

Administrators can configure the server to ignore initial SQL statements by using the `tsm configuration set` command:

```
tsm configuration set -k vizqlserver.initialsql.disabled -v true
```

If the server doesn't allow initial SQL statements, the workbook opens, but the initial SQL commands aren't sent.

For more information about the `tsm configuration set` command, see the [Tableau Server Help](#).

### Parameters in an initial SQL statement

You can pass parameters to your data source in an initial SQL statement. The following list has several benefits of using parameters in a initial SQL statement.

- You can configure impersonation using the **TableauServerUser** or **TableauServerUserFull** parameters.
- If your data source supports it, you can set up row-level security (for example, for Oracle VPD or SAP Sybase ASE) to make sure that users see only the data that they're authorized to see.
- You can provide more details in logging, for example, the Tableau version or the workbook name.

The following parameters are supported in an initial SQL statement:

Parameter	Description	Example of returned value
<b>TableauServerUser</b>	The username of the current server user. Use when setting up impersonation on the server. Returns an empty string if the user	jsmith

	isn't signed in to Tableau Server.	
<b>TableauServerUserFull</b>	The username and domain of the current server user. Use when setting up impersonation on the server. Returns an empty string if the user isn't signed in to Tableau Server.	domain.lan\jsmith
<b>TableauApp</b>	The name of the Tableau application.	Tableau Desktop Professional  Tableau Server
<b>TableauVersion</b>	The version of the Tableau application.	9.3
<b>WorkbookName</b>	The name of the Tableau workbook. Use only in workbooks with an embedded data source.	Financial-Analysis

**Warning:** Tableau Desktop doesn't include domain. You can include it if you aren't using delegation and you set tsm configuration set `-k DelegationUseFullDomainName=-v true--force-keys`

The following examples show different ways you can use parameters in an initial SQL statement.

- This example sets the security context on Microsoft SQL Server:

```
EXECUTE AS USER = [TableauServerUser] WITH NO REVERT;
```

- This example shows how, on a DataStax data source, you can use parameters to add detail to logging or to set up a session variable to track the data:

```
SET TABLEAUVERSION [TableauVersion];
```

- This example can be used to help set up row-level security for Oracle VPD:

```
begin
```

```
  DBMS_SESSION.SET_IDENTIFIER([TableauServerUser]);
```

```
end;
```

**Note:** Oracle PL/SQL blocks require a trailing semicolon to terminate the block. Consult Oracle documentation for the proper syntax.

### Defer execution to the server

You can defer an initial SQL statement so that it's executed only on the server. One reason to defer execution to the server is if you don't have permission to execute the commands that set up impersonation. Use `<ServerOnly></ServerOnly>` tags to enclose the commands to be executed only on the server.

Example:

```
CREATE TEMP TABLE TempTable(x varchar(25));
INSERT INTO TempTable VALUES (1);
<ServerOnly>INSERT INTO TempTable Values(2);</ServerOnly>
```

### Security and impersonation

When you use the **TableauServerUser** or **TableauServerUserFull** parameter in an initial SQL statement, you'll create a dedicated connection that can't be shared with other users. This can also restrict cache sharing, which can enhance security, but may also slow performance.

### Troubleshoot 'create table' for MySQL and Oracle connections

For MySQL connections, tables aren't listed after using initial SQL to create a table

After you connect to MySQL and run an initial SQL statement, the tables might not show because of the way Tableau constructs the query.

```
CREATE TABLE TestV1.testtable77(testID int);
```

To resolve this issue, add `IF NOT EXISTS` to the SQL statement:

```
CREATE TABLE IF NOT EXISTS TestV1.TestTable(testID int);
```

For Oracle connections, using initial SQL to create a table causes Tableau to stall

After you connect to Oracle and run an initial SQL statement, Tableau is stalled with a spinning wheel because of the way Tableau constructs the query.

```
CREATE TABLE TEST_TABLE (TESTid int)
```

To resolve this issue, use the following SQL statement:

```
BEGIN
EXECUTE IMMEDIATE 'create table test_table(testID int)';
EXCEPTION
WHEN OTHERS THEN NULL;
END;
```

## Set Up Data Sources

After you connect to your data, use the Data Source page to set up the data source and prepare your data for analysis. There are many optional configurations that you can make before you begin your analysis. The configurations that you make on the Data Source page creates the data source that Tableau uses to interpret and interact with your data.

The topics in this section describe how to use these configurations in order to optimize your data source for analysis.

## Plan the Data Source

At the center of Tableau is your data. How successful you are with exploring data, answering questions, and building visualizations for yourself or others to consume all depend on the underlying data.

If your goal is to do some quick exploration or ad-hoc analysis, you might be able to hop in, connect to some data, drag and drop a bit to build some vizs, and hop out with the information you need. But if your goal is to create an analysis or data source that will be used more than once, it's best to think through and plan your data source.

## Tableau data sources

A Tableau data source is the link between your source data and Tableau. It is essentially the sum of your data (either as a live connection or an extract), the connection information, the names of tables or sheets containing data, and the customizations that you make on top of data to work with it in Tableau. Those customizations include things like how the data is combined and metadata such as calculations, renamed fields, and default formatting.

A Tableau *data source* may contain multiple *data connections* to different databases or files. Connection information includes where the data is located, such as a file name and path or a

network location, and details on how to connect to your data, such as database server name and server sign-in information.

**Note:** The terms *data source* and *data connection* have been used indiscriminately in the past and may lack clear distinction in older materials.

It's also important to bear in mind the difference between the Tableau data source (Tableau's access to your data and all the customizations that may be involved) and the source data itself (such as a database or Excel spreadsheet). Planning a data source in the sense of designing a database is not the scope of this topic.

Tableau data sources can remain embedded in the workbook where they were originally created, or they can be published separately. Published Data Sources allow for centralization and scaling of curated data sources. See [Best Practices for Published Data Sources on page 3070](#) for more information.

## Considerations for a Tableau data source

Before anything else, make sure you're clear on the purpose of the data source. If you're creating a catch-all data source for a wide variety of users with broad questions, you'd go about it differently than if you were constructing a niche data source optimized for performance. It's important to know your goal from the outset.

With that goal in mind, there are several items to consider and plan before you build a data source in Tableau:

- Location and access
- Shape and cleanliness
- The data model and combining data
- Metadata and customization
- Scalability, security, and discoverability
- Performance and freshness

### Location and access

The location of your data can be as simple as a single excel file on your computer or a Google sheet you've created, or as complex as multiple databases using various technologies. Access can also involve specific drivers or connectors for a database or login information for a database server.

### Questions to consider:

- Do the correct Tableau users have access and permissions to the data and to Tableau?
- What user account should be used to log into the database?
- Will user filtering or [row level security](#) be needed?
- Is the source data on premises or in the cloud?
  - This may have [implications if the data is published to Tableau Cloud](#).
- Are there [Supported Connectors on page 235](#)?
- Are there any limitations for that database (does it support all the functionality you hope to use)?

## Shape and cleanliness

Your organization may already have well-structured data that you can connect to or ETL processes you can leverage, or you may need to use Tableau Prep Builder to perform cleaning and shaping operations to get your data into a useful format.

### Questions to consider:

- Is the data well-structured for use with Tableau?
- Should [Tableau Prep Builder](#) and Tableau Prep Conductor be used to clean and [auto-mate](#) data prep flows?
- What calculations or manipulations would be best done natively in Tableau?
- Is any of this data unnecessary? Is any data missing?

## The data model and combining data

Tableau needs to know how to query the data, which is conveyed by [The Tableau Data Model on page 664](#). If the data comes from multiple tables, the data needs to be combined. Methods for combining data include relationships, joins, unions, and blends.

### Questions to consider:

- Is the data spread across multiple systems?
- What is the best way to combine each table of data?

## Metadata and customization

Data is often stored in a way that isn't easy for a person to use comfortably. For example, default field names can be unwieldy, custom formatting may be desired, definitions of abbreviations or codes may be missing, or common calculations may not be present in the underlying data. Creating a [metadata](#) layer with those pieces of information can make the data much easier to understand and use.

### Questions to consider:

- What calculations should be added?
- Are the table and field names understandable?
- Are the default settings for the fields useful or should they be customized?
- Are there any adjustments that should be made to support [Ask Data](#) or [Tableau Catalog](#)?

*Note that Explain Data does not support multi-table data sources at this time.*

### Scalability, security, and discoverability

A data source may remain in the workbook where it was created—an [embedded data source](#)—or it may be published to Tableau Server or Tableau Cloud independently of any analysis as a content asset all its own. This centralization of published data sources has the added benefit of security and scaling, allowing multiple users to access a consistent data source. Published data sources can also take advantage of [Tableau Catalog](#) and recommendations and provide a single source of truth for an organization.

#### Questions to consider:

- Should the data source stay embedded in the workbook?

*(The following questions assume the data source is published)*

- Where will the data source be published?
- Who will own the data source?
- What [authentication](#) and [permissions](#) should it have?
- Will it be [certified](#)?

### Performance and freshness

In addition, Tableau data sources can be live connections to the source data or the data can be copied out as a refreshable extract. Extracts can boost the analysis performance or prevent resource drains against database systems.

#### Questions to consider:

- Should the data connection be live or an [extract](#)?
- If extracted, will there be a refresh schedule? ([Tableau Server](#) | [Tableau Cloud](#))
- If published to Tableau Cloud, will [Tableau Bridge](#) need to be used?

### Build quality data sources

There's a lot that goes into a well-designed and performant data source. You don't have to publish your first attempt, though. Like creating a good visualization, building a data source can be an ongoing process. Try your hand at combining the data you think you need and then see if you can build the viz you want. You can always go back and write a new calculation or bring in

another table of data. Do some user testing and ask a colleague if they can figure out your field names.

Of course, it's best to only publish data sources you're confident in and only certify ones that have passed quality assurance. By the time your data source is in front of users, they should be able to trust it.

## Combine Data

If your data comes from one table, you can [connect to your data](#) to create the data source, drag the table onto the canvas, and then start building your view. But if your data is spread across multiple tables—or across multiple databases—you'll need to combine it. Combining data happens on the Data Source Page.

### Single database

1. Connect to your data. This creates a data source.
2. Drag a table or sheet of data to the canvas and release it.
3. Drag a second table or sheet to the canvas and release it. Either a noodle will form, indicating an automatic relationship has formed, or the Edit Relationship dialog will open, prompting you to tell Tableau which field those tables relate the two tables.
4. Continue adding tables.

### Multiple databases

1. Connect to your data. This creates a data source.
2. Drag a table or sheet of data to the canvas and release it.
3. After bringing out the first table of data, click the **Add** link to the right of the Connections heading in the Left pane.
4. Switch between data connections in the Left pane, then drag out the desired table to the canvas and release it. Either a noodle will form, indicating an automatic relationship has formed, or the Edit Relationship dialog will open, prompting you to tell Tableau which field those tables relate the two tables.
5. Continue adding tables, switching between data connections as relevant.

**Note:** In order to relate tables across different databases, they must be added as **data connections** within the same data source, not a new **data source**. Data connections are added from the Add link in the Left pane. New data sources can be created from the Data

menu or the drop down menu from the icon next to the Data Source's name, as seen in the image below.

## Methods of combining data

Relationships are the default way to combine data in Tableau. Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. If necessary, tables can also be joined or unioned. Data sources can also be blended. Let's take a look the options for how data can be combined in Tableau and some of the situations when each method is useful.

Relationships	<p>Establish the potential for joins between two tables based on related fields. Does not merge data together to create a new, fixed table. During analysis, queries the relevant tables automatically using the contextually-appropriate joins to generate a custom table of data for that analysis.</p> <p>Maintains the appropriate level of detail, does not lose data, keeps appropriate aggregations, and handles nulls.</p>
Joins	<p>Merge two tables of data based on a join clause and join type to form a new, fixed table of data. Often used to add new columns of data across the same basic row structure.</p> <p>May cause data loss with some join types if fields are not present in all tables. May cause data duplication if tables are at different levels of detail.</p>
Unions	<p>Merge two or more tables of data to form a new, fixed table of data. Used to append (add new rows of) data across the same basic column structure.</p>

**Blends** Work across two or more separate Tableau data sources. Data remains separate. Tableau queries the data sources independently and visualizes the results together in the view, based on the linking fields established for that sheet. Mimics the behavior of a left join and may filter data from secondary data sources.

**Note:** It's also possible to combine data with [Custom SQL](#). Most of the time, it's best to combine data directly in the canvas or with data blending. This allows Tableau the greatest flexibility for optimization. However, in certain scenarios, there may be reasons to use Custom SQL. Keep in mind doing so can have performance implications because Tableau is forced to execute the Custom SQL statement as written.

## Relationships

Relating is a method for working with data from multiple tables based on shared fields—columns—between those tables. Establishing a relationship informs Tableau how rows can be connected across tables. Tableau holds that information but does not immediately bring the rows together. Instead, when a visualization is created, the fields involved in the analysis are traced back through the relationship and the appropriate data is returned from its original table.

Because the data is never fully brought together into a single table outside the context of a visualization, relationships are useful when the data is at different levels of detail, or granularity. For example, if you need to work with data about daily rainfall in one table but hourly temperatures in another.

Tableau supports relationships between tables in the same database and between tables in different databases.

For more information about how to combine tables using relationships, see [Relate Your Data on page 622](#) and these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

## Join

Joining is a method for combining tables related by common fields. The result of combining data using a join is a table that extends horizontally by adding columns of data.

For more information about how to join data in Tableau, see [Join Your Data](#) on page 738.

### Data blending

When you use data blending to combine your data, you combine data in what is called a primary data source with common fields from one or more secondary data sources.

Data blending is useful when you need to change how the data source is configured on a sheet-by-sheet basis, when you want to combine databases that don't allow relationships or joins such as cube data sources or Published Data Sources.

The result of combining data using data blending is a virtual table that extends horizontally by adding columns of data. The data from each data source will be aggregated to a common level before being displayed together in the visualization.

For more information about how data blending works and how to blend your data in Tableau, see [Blend Your Data](#) on page 764.

### Union

Unioning is a method for appending values (rows) to tables. You can union tables if they have the same columns. The result of combining data using a union is a virtual table that has the same columns but extends vertically by adding rows of data.

You can union tables in one of two ways: manually or using wildcard search. For more information about how to union data using one of these methods in Tableau, see [Union Your Data on page 795](#).

## Structure Data for Analysis

There are certain concepts that are fundamental to understanding data prep and how to structure data for analysis. Data can be generated, captured, and stored in a dizzying variety of formats, but when it comes to analysis, not all data formats are created equal.

Data preparation is the process of getting well formatted data into a single table or multiple related tables so it can be analyzed in Tableau. This includes both the structure, i.e. rows and columns, as well as aspects of data cleanliness, such correct data types and correct data values.

**Tip:** It may help to go through the following topic with a data set of your own. If you do not already have a data set you can use, see our tips for [finding good data sets](#).

### How structure impacts analysis

The structure of your data may not be something you can control. The rest of this topic assumes you have access to the raw data and the tools needed to shape it, such as Tableau Prep Builder. However, there may be situations when you can't pivot or aggregate your data as desired. It is often still possible to perform the analysis but you may need to change your calculations or how you approach the data. For an example of how to perform the same analysis with different data structures, see Tableau Prep Day in the Life Scenarios: [Analysis with the Second Date in Tableau Desktop](#). But if you can optimize the data structure it will likely make your analysis much easier.

### Data Structure

Tableau Desktop works best with data that is in tables formatted like a spreadsheet. That is, data stored in rows and columns, with column headers in the first row. So what should be a row

or column?

### What is a row?

A row, or record, can be anything from information around a transaction at a retail store, to weather measurements at a specific location, or stats about a social media post.

It's important to know what a record (row) in the data represents. This is the *granularity* of the data.

Here, each record is a day

Here, each record is a month

Date	Max TemperatureF	Mean TemperatureF	Date	Max TemperatureF	Mean TemperatureF	Min TemperatureF
1/1/2015	42		January	63	45	26
1/2/2015	42		February	62	49	33
1/3/2015	41		March	69	51	31
1/4/2015	51		April	77	52	37
1/5/2015	54		May	82	59	43
1/6/2015	54		June	92	68	49
1/7/2015	46		July	95	71	54
1/8/2015	46		August	92	69	54
1/9/2015	50		September	81	61	45
1/10/2015	46		October	74	58	45
			November	60	44	25

**Tip:** A best practice is to have a unique identifier (UID), a value that identifies each row as a unique piece of data. Think of it like the social security number or URL of each record. In Superstore, that would be Row ID. Note that not all data sets have a UID but it can't hurt to have one.

Try to make sure you can answer the question "What does a row in the data set represent?". This is the same as answering "What does the TableName(Count) field represent?". If you can't articulate that, the data might be structured poorly for analysis.

## Aggregation and Granularity

A concept related to what makes up a row is the idea of aggregation and granularity, which are opposite ends of a spectrum.

Aggregation

- refers to how multiple data values are brought together into a single value, such as counting all the Google searches for Pumpkin Spice or taking the average of all the temperature readings around Seattle on a given day.
- By default, measures in Tableau are always aggregated. The default aggregation is SUM. You can change the aggregation to options like Average, Median, Count Distinct, Minimum, etc.

### Granularity

- refers to how detailed the data is. What does a row or record in the data set represent? A person with malaria? A provinces' total cases of malaria for the month? That's the granularity.
- Knowing the granularity of the data is crucial to working with level of detail (LOD) expressions.

Understanding aggregation and granularity is a critical concept for many reasons; it impacts things like finding useful data sets, building the visualization you want, relating or joining data correctly, and using LOD expressions.

**Tip:** For more information, see [Data Aggregation in Tableau](#).

### What is a field or column?

A *column* of data in a table comes into Tableau Desktop as a *field* in the data pane, but they are essentially interchangeable terms. (We save the term *column* in Tableau Desktop for use in the columns and rows shelf and to describe certain visualizations.) A field of data should contain items that can be grouped into a larger relationship. The items themselves are called *values* or *members* (only discrete dimensions contain members).

What values are allowed in a given field are determined by the *domain* of the field (see the note below). For example, a column for "grocery store departments" might contain the members "deli" "bakery", "produce", etc., but it wouldn't include "bread" or "salami" because those are items, not departments. Phrased another way, the domain of the department field is limited to just the possible grocery store departments.

Additionally, a well-structured data set would have a column for "Sales" and a column for "Profit", not a single column for "Money", because profit is a separate concept from sales.

- The domain of the Sales field would be values  $\geq 0$ , since sales cannot be negative.
- The domain of the Profit field, however, would be all values, since profit can be negative.

**Note:** *Domain* can also mean the values present in the data. If the column "grocery store department" erroneously contained "salami", by this definition, that value would be in the domain of the column. The definitions are slightly contradictory. One is the values that could or should be there, the other is values that actually are there

## Categorizing fields

Each column in the data table comes into Tableau Desktop as a field, which appears in the **Data** pane. Fields in Tableau Desktop must be either a dimension or measure (separated by a line within tables in the **Data** pane) and either discrete or continuous (color coded: blue fields are discrete and green fields are continuous).

- *Dimensions* are qualitative, meaning they can't be measured but are instead described. Dimensions are often things like city or country, eye color, category, team name, etc. Dimensions are usually discrete.
- *Measures* are quantitative, meaning they can be measured and recorded with numbers. Measures can be things like sales, height, clicks, etc. In Tableau Desktop, measures are automatically aggregated; the default aggregation is SUM. Measures are usually continuous.
- *Discrete* means individually separate or distinct. Toyota is distinct from Mazda. In Tableau Desktop, discrete values come into the view as a label and they create panes.
- *Continuous* means forming an unbroken, continuous whole. 7 is followed by 8 and then it's the same distance to 9, and 7.5 would fall midway between 7 and 8. In Tableau Desktop, continuous values come into the view as an axis.
- Dimensions are usually discrete, and measures are usually continuous. However, this is not always the case. Dates can be either discrete or continuous.
  - Dates are dimensions and automatically come into the view as discrete (aka date parts, such as "August", which considers the month of August without considering other information like the year). A trend line applied to a timeline with discrete dates will be broken into multiple trend lines, one per pane.
  - We can choose to use continuous dates if preferred (aka date truncations, such as "August 2024", which is different than "August 2025"). A trend line applied to a timeline with continuous dates will have a single trend line for the entire date axis.

**Tip:** For more information, see [Dimensions and Measures, Blue and Green](#).

In Tableau Prep, no distinction is made for dimensions or measures. Understanding the concepts behind discrete or continuous are important, however, for things like understanding the detail versus summary presentation of data in the profile pane.

- Detail: the detail view shows every domain element as a discrete label and has a visual scrollbar to provide a visual overview of all the data.
- Summary: the summary view shows the values as binned on a continuous axis as a histogram.

## Binning & Histograms

A field like age or salary is considered continuous. There is a relationship between the age 34 and 35, and 34 is as far from 35 as 35 is from 36. However, once we're past age 10 or so, we usually stop saying things like we're "9 and a half" or "7 and  $\frac{3}{4}$ ". We're already binning our age to neat year-sized increments. Someone who is 12,850 days old is older than someone who is 12,790 days old, but we draw a line and say they're both 35. Similarly, age groupings are often used in place of actual ages. Child prices for movie tickets might be for kids 12 and under, or a survey may ask you to select your age group, such as 20-24, 25-30, etc.

Histograms are used to visualize the distribution of numerical data using binning. A histogram is similar to a bar chart, but rather than being discrete categories per bar, the rectangles making up the histogram span a *bin* of a continuous axis, such as range of the number of blossoms (0-4, 5-9, 10-14, etc.). The height of the rectangles is determined by frequency or count of those values. Here, the y-axis is the count of plants that fall into each bin. Seven plants have 0-4 blossoms, two plants have 5-9 blossoms, and 43 plants have 20-24 blossoms.

In Tableau Prep, the summary view is a histogram of binned values. The detail view shows the frequency for every value and has a visual scrollbar off to the side that shows the overall distribution of the data.

Summary view

Detail view

## Distributions and outliers

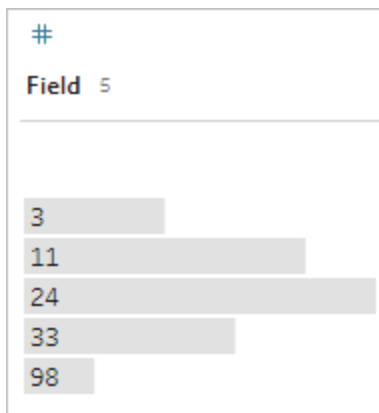

Seeing the distribution of a data set can help with outlier detection.

- *Distribution*: the shape of the data in a histogram, though this depends on the size of the bins. Being able to see all your data in a histogram view can help identify if the data seems correct and complete. The shape of the distribution will only be of use if you know the data and can interpret whether or not the distribution makes sense.
  - For example, if we were to look at a data set of the number of homes with broadband internet from 1940-2017, we'd expect to see a very skewed distribution. However, if we were to look at the number of homes with broadband internet from January 2017 to December 2017 we'd expect a fairly uniform distribution.
  - If we were to look at a data set of Google searches for "Pumpkin Spice Latte", we'd expect to see a fairly sharp peak in the fall, whereas searches for ""convert Celsius to Fahrenheit" would likely be fairly stable.
- *Outlier*: a value that is extreme compared to other values. Outliers may be correct values or they may be indicative of an error.

- Some outliers are correct and indicate actual anomalies; these should not be removed or modified.
- Some outliers indicate issues with data cleanliness, such as a salary of \$50 instead of \$50,000 because a period was typed instead of the comma.

## Visual outlier detection with distributions

If you were to see a list like this:

at first glance it doesn't look odd. But if, instead of a list of labels, this was plotted on a continuous binned axis, it would look like this:

And it's much more obvious that the last observation is farther away from the first and may be an outlier due to error.

## Data Types

Databases, unlike spreadsheets, usually enforce strict rules on data types. Data types classify the data in a given field and provide information about how the data should be formatted, interpreted, and what operations can be done to that data. For example, numerical fields can have mathematical operations applied to them and geographic fields can be mapped.

Tableau Desktop assigns whether a field is a dimension or measure, but fields have other characteristics that depend on their data type. These are indicated by the icon each field has (though some types share an icon). Tableau Prep uses the same data types. If data type is enforced on a column and an existing value doesn't match its assigned data type, it may be displayed as null (because "purple" doesn't mean anything as a number).

Some functions require specific data types. For example, you cannot use CONTAINS with a numerical field. Type functions are used to change the data type of a field. For example, DATEPARSE can take a text date in a specific format and make it a date, thus enabling things like automatic drill down in the view.

Icon	Data type
Abc	Text (string) values

Icon	Data type
	Date values
	Date & Time values
	Numerical values
	Boolean values (relational only)
	Geographic values (used with maps)

**Tip:** For more information, refer to the Help article on [Data Types](#).

## Pivot and Unpivot Data

People-friendly data is often captured and recorded in a wide format, with many columns. Machine-readable data, like Tableau prefers, is better in a tall format, with fewer columns and more rows.

**Note:** Traditionally, pivoting data means going from tall to wide (rows to columns), and unpivoting means going from wide to tall (columns to rows). However, Tableau uses the word *pivot* to mean going from wide (people-friendly) to tall (machine-readable) by turning columns into rows. In this document, *pivot* will refer to the Tableau sense of the word. For clarity, it can help to specify "pivot columns to rows" or "pivot rows to columns".

For more information, refer to the Help articles [Pivot Your Data](#) and [Tips for Working with your Data](#).

## Wide data

In the WHO malaria data set, there is a column for country, then a column per year. Each cell represents the number of cases of malaria for that country and year. In this format we have 108 rows and 16 columns.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P
1	Country	2014	2013	2012	2011	2010	2009	2008	2007	2006	2005	2004	2003	2002	2001	2000
2	Afghanistan	61362	39263	54840	77549	69397	64880	81574	92202	86129	116444	242022	360940	415356		94475
3	Algeria	0	0	55	1	1	0	3	27	1	2	3	6	8	8	35

16	Burkina Faso	5428655	3769051	3858046	428113	804539	182527	36514	44246	44265	21335	18256				
17	Burundi	4563773	4141297	3151076	1671874	1762447	1185637	876741	1101644	701721	277464	242206	262450	277128	217016	208906

It's easy for a person to read and understand this format. However, if we were to bring this data into Tableau Desktop, we get a field per column. We have a field for 2000, a field for 2001, a field for 2002, etc.

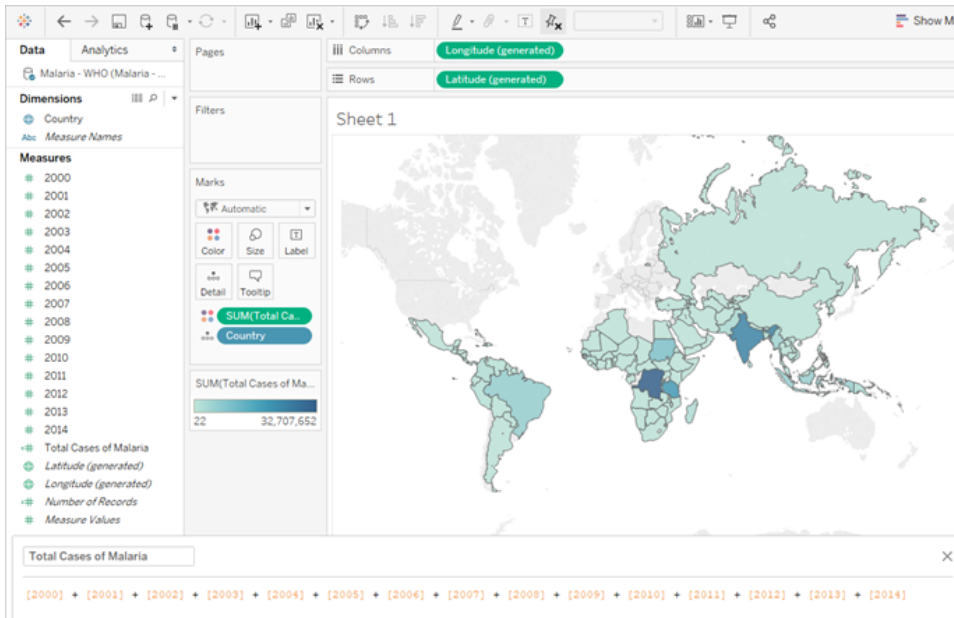

To think of it another way, there are 15 fields that all represent the same basic thing—number of reported cases of malaria—and no single field for time. This makes it very hard to do analysis across time as the data is stored in separate fields.

## Example: working with wide data

Q: How would we create a map that shows the total number of malaria cases per country from 2000 to 2014?

A: Create a calculated field to sum all the years.

Note: this image has not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

Another indication that this format isn't ideal for analysis can be seen in the fact that nowhere do we have information about what the actual values mean. For Algeria in 2012, we have the value 55. Fifty five what? It's not clear from the structure of the data.

	A	B	C	D	E
1	<b>Country</b>	<b>2014</b>	<b>2013</b>	<b>2012</b>	<b>2011</b>
2	<b>Afghanistan</b>	61362	39263	54840	77549
3	<b>Algeria</b>	0	0	55	1
4	<b>Angola</b>	2298979	1999868	1496834	1632282

If the name of the column isn't describing what the values are but rather conveys additional information, this is a sign the data needs to be pivoted.

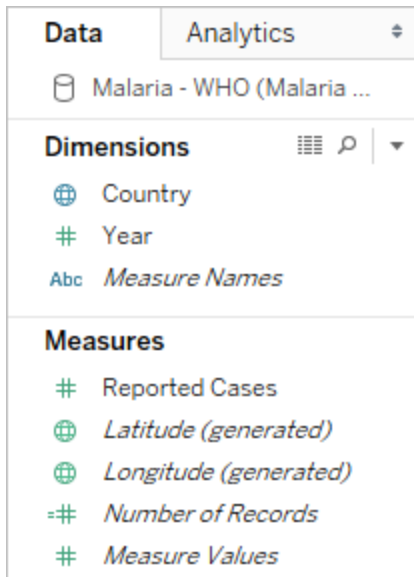

### Tall data

If we pivot the data, we reshape the data from wide to tall. Now, rather than having a column for each year, we have a single column, Year, and a new column, Reported Cases. In this format we have 1,606 rows and 3 columns. This data format is taller rather than wider.

	A	B	C
1	Country	Year	Reported Cases
2	Afghanistan	2000	94,475
3	Afghanistan	2001	
4	Afghanistan	2002	415,356
5	Afghanistan	2003	360,940
6	Afghanistan	2004	242,022
7	Afghanistan	2005	116,444
8	Afghanistan	2006	86,129
9	Afghanistan	2007	92,202
10	Afghanistan	2008	81,574
11	Afghanistan	2009	64,880
12	Afghanistan	2010	69,397
13	Afghanistan	2011	77,549
14	Afghanistan	2012	54,840
15	Afghanistan	2013	39,263
16	Afghanistan	2014	51,263

Now in Tableau Desktop, we have a field for Year and a field for Reported Cases as well as the original Country field. It's much easier to do analysis because each field represents a unique quality about the data set—location, time, and value.

Note: this image has not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

## Example: working with tall data

Q: How would we create a map that shows the total number of malaria cases per country from 2000 to 2014?

A: Use the Reported Cases field.

Note: this image has not been updated to reflect the most current UI. The Data pane no longer shows Dimensions and Measures as labels.

Now it's easy to see that for Algeria in 2012, the 55 refers to the number of reported cases (because we could label this new column).

	A	B	C
1	Country	Year	Reported Cases
28	Algeria	2011	1
29	Algeria	2012	55
30	Algeria	2013	0

**Note:** In this example, the wide data consisted of a single record per country. With the tall data format, there are now 15 rows for each country (one for each of the 15 years in the data). It's important to keep in mind that there are now multiple rows per country.

If there was a column for Land Area, that value would be repeated for each of the 15 rows for each country in a tall data structure. If you created a bar chart by bringing out **Country** to **Rows** and **Land Area** to **Columns**, by default the view would sum the land area for all 15 rows per country.

For some fields it may be necessary to compensate for double counting values by aggregating with an average or minimum rather than sum or filtering.

### Normalization

Relational databases are made up of multiple tables that can be related or linked together in some way. Each table contains a unique identifier, or key, per record. By relating or joining on the keys, records can be linked to provide more information than is contained in a single table. What information goes into each table is dependent on the data model used, but the general principle is around reducing duplication.

For example, consider event planning for an event like a wedding. We need to keep track of information at the level of groups (such as families or couples) as well as the level of individuals.

A table could be created that combines all the information together:

ID	Name	Group	Dietary	Seating	Attending	Address	Invitation	Gift	Bride
10	Cedar	Tree	Omnivore	1	yes	87 Forest Ave	sent	pebble	yes
11	Redwood	Tree	Omnivore	1	yes	87 Forest Ave	sent	pebble	yes
12	Fir	Tree	Vegan	1	yes	87 Forest Ave	sent	pebble	yes
13	Madrona	Tree	Omnivore		no	87 Forest Ave	sent	pebble	yes
14	Chanterelle	Mushroom	Omnivore	2	yes	3 Troll St	sent	leaf	no
15	Cremini	Mushroom	Kosher	2	yes	3 Troll St	sent	leaf	no
16	Portobello	Mushroom	Omnivore	2	yes	3 Troll St	sent	leaf	no
17	Hydrangea	Flower				652 Meadow Ln	undeliverable		yes
18	Dahlia	Flower				652 Meadow Ln	undeliverable		yes

However, if an address is incorrect and needs to be fixed, it must be fixed across multiple rows, potentially leading to errors or conflicts. A better structure is to create two tables, one for information that pertains to the group (such as address and if the invitation was sent) and one for information pertaining to the individuals (for things like seating assignments and dietary restrictions).

Group table

Individual table

ID	Group	Address	Invitation	Gift	Bride
34	Tree	87 Forest Ave	sent		
35	Mushroom	3 Troll St	sent		
36	Flower	652 Meadow Ln	undeliverable		

ID	Name	Group	Dietary	Seating	Attending
10	Cedar	Tree	Omnivore	1	yes
11	Redwood	Tree	Omnivore	1	yes
12	Fir	Tree	Vegan	1	yes
13	Madrona	Tree	Omnivore		no
14	Chanterelle	Mushroom	Omnivore	2	yes
15	Cremini	Mushroom	Kosher	2	yes
16	Portobello	Mushroom	Omnivore	2	yes
17	Hydrangea	Flower			
18	Dahlia	Flower			

It's much easier to track and analyze group-level information in the group table and individual-level information in the individual table. For example, the number of chairs needed can be obtained from the number of Attending = Yes records in the individual table, and the number of stamps needed for thank-yous can be obtained from the number of records in the group table where Gift isn't null.

The process of breaking up all the data into multiple tables—and figuring out which table contains which columns—is called *normalization*. Normalization helps reduce redundant data and simplifies the organization of the database.

However, there may be times when information is needed that spans multiple tables. For example, what if we wanted to balance seating arrangements (individuals) such that groups from the bride's side are intermingled with groups from the groom's side? (The bride or groom affiliation is tracked at the group level.) To achieve this, we need to relate the tables back together so the individuals are associated with information about their group. Proper normalization isn't just breaking up tables, it also requires the presence of a shared, related field or unique identifier that can be used to combine the data back together again. Here, that related field is Group. That field is present in both tables, so we can join on this field and return to our original, single table format. This is a *denormalized* structure.

So why didn't we just keep the original denormalized table? It is harder to maintain and was storing redundant information. At scale, the level of data duplication can become massive. Storing the same information over and over isn't efficient.

Normalized tables have a few key properties:

- Each row needs a unique identifier
- Each table needs a column or columns that can be used to connect it back to other tables (key).

These shared (key) columns are used for relating or joining tables back together. For our data, the relationship or join clause would be on the Group field in each table.

### Join Types

Although the default method for combining data in Tableau Desktop is relating, there are cases when you may want to join tables in Tableau Desktop or Tableau Prep Builder. For a basic overview of joins and join types, see [Join Your Data](#).

Name	# of Siblings
Taylor	2
Alex	3
Shannon	0
Tracy	1

Name	Eye Color
Taylor	Blue
Alex	Brown
Morgan	Brown

**Inner Join**

Name	# of Siblings	Eye Color
Taylor	2	Blue
Alex	3	Brown

**Left Join**

Name	# of Siblings	Eye Color
Taylor	2	Blue
Alex	3	Brown
Shannon	0	<i>null</i>
Tracy	1	<i>null</i>

**Right Join**

Name	Eye Color	# of Siblings
Taylor	Blue	2
Alex	Brown	3
Morgan	Brown	<i>null</i>

**Outer Join**

Name	# of Siblings	Eye Color
Taylor	2	Blue
Alex	3	Brown
Shannon	0	<i>null</i>
Tracy	1	<i>null</i>
Morgan	<i>null</i>	Brown

## "Tidy" Data

Hadley Wickham published an article in 2014 in the Journal of Statistical Software called "Tidy Data" (August 2014, Volume 59, Issue 10). This article does an excellent job of laying out a framework for data that is well-structured for analysis. The article can be found [here](#) (Hadley Wickham's Academic Portfolio) or [here](#) (hosted by r-project.org).

**Note:** The article is hosted on external websites. Tableau cannot take responsibility for the accuracy or freshness of pages maintained by external providers. Contact the owners if you have questions regarding their content.

## Relate Your Data

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. A relationship describes how two tables relate to each other, based on common fields, but doesn't merge the tables together. When a relationship is created between tables, the tables remain separate, maintaining their individual level of detail and domains.

Think of a relationship as a contract between two tables. When you're building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

**Learn more:** The ability to combine data using relationships is an important feature of Tableau's new data modeling capabilities. For more information, see [What's Changed with Data Sources and Analysis on page 640](#). Learn more about how relationships work in these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

**Watch a video:** For an introduction to using relationships in Tableau, see this 5-minute video.

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

[Action Analytics](#) also provides helpful video podcasts on using relationships in Tableau. For an introduction, see [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the Action Analytics website [Library](#) to see other podcasts.

## What are relationships?

Relationships are the flexible, connecting lines created between the logical tables in your data source. Some people affectionately call relationships "noodles," but we usually refer to them as "relationships" in our help documentation.

We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. **Use joins only when you absolutely need to.**

Relationships provide several advantages over using joins for multi-table data:

- You don't need to configure **joins types** between tables. You only need to select the fields to define the relationship.
- Related tables remain separate and distinct; they aren't merged into a single table.
- Relationships use joins, but they're automatic. Tableau automatically selects join types based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data.
- Tableau uses relationships to generate correct aggregations and appropriate joins during analysis, based on the current context of the fields in use in a worksheet.
- Multiple tables at different levels of detail are supported in a single data source. You can build data models that contain more tables, and reduce the number of data sources needed to build a viz.
- Unmatched measure values aren't dropped (no accidental loss of data).
- Avoids data duplication and filtering issues that can sometimes result from joins.
- Tableau generates queries only for the data that is relevant to the current view.

For related information, see:

- **Use Relationships for Multi-table Data Analysis** on page 637
- **How Relationships Differ from Joins** on page 675
- **How Analysis Works for Multi-table Data Sources that Use Relationships** on page 695
- **Don't Be Scared of Relationships** on page 715

## Requirements for relationships

- When relating tables, the fields that define the relationships must have the same data type.
- You can't define relationships based on geographic fields.
- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

Factors that limit the benefits of using related tables:

- Dirty data in tables (for example, tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters limits Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.
- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

## Data that can't be related

Most relational connection types are completely supported. Cubes, SAP HANA (with OLAP attribute), JSON, and Google Analytics are limited to a single logical table in Tableau 2020.2. Stored procedures can only be used within a single logical table.

Published data sources can't be related to each other.

### Unsupported

- Cube databases don't support the new logical layer. Connecting to a cube offers the same experience as pre-2020.2.
- Stored Procedures: Don't support federation, relationships, or joins. They're represented in a single logical table, and don't allow opening the Join/Union canvas (physical layer).
- Splunk: Doesn't support left joins (and therefore relating logical tables).
- JSON: Doesn't support federation, custom SQL, joins, or relationships (only unions).
- Datasources that don't support LOD calcs. For more information, see [Data Source Constraints for Level of Detail Expressions](#) on page 2547.

### Limited support

- Salesforce and WDC Standard Connections: These are represented as joined tables within a logical table. Adding these connections is currently only supported for single, logical table data sources. Standard connections can't join to an existing table.
- SAP HANA: Doesn't currently support relating logical tables when the connection has the OLAP attribute set.

## Create and define relationships

After you drag the first table to the top-level canvas of the data source, each new table that you drag to the canvas must be related to an existing table. When you create relationships between tables in the logical layer, you're building the data model for your data source.

**Note:** In Tableau 2020.3 and later, you can create relationships based on calculated fields, and compare fields used for relationships using operators in the relationship definition.

## Create a relationship

You create relationships in the logical layer of the data source. This is the default view of the canvas that you see in the Data Source page.

**Note:** The Salesforce connector doesn't support inequality operators. Google Big Query and MapR connectors support non-equal joins starting with version 2021.4. The MapR connector is deprecated as of version 2022.3.

1. Drag a table to the canvas.
2. Drag another table to the canvas. When you see the "noodle" between the two tables, drop that table.

The Edit Relationship dialog box opens. Tableau automatically attempts to create the relationship based on existing key constraints and matching fields to define the relationship. If it can't determine the matching fields, you'll need to select them.

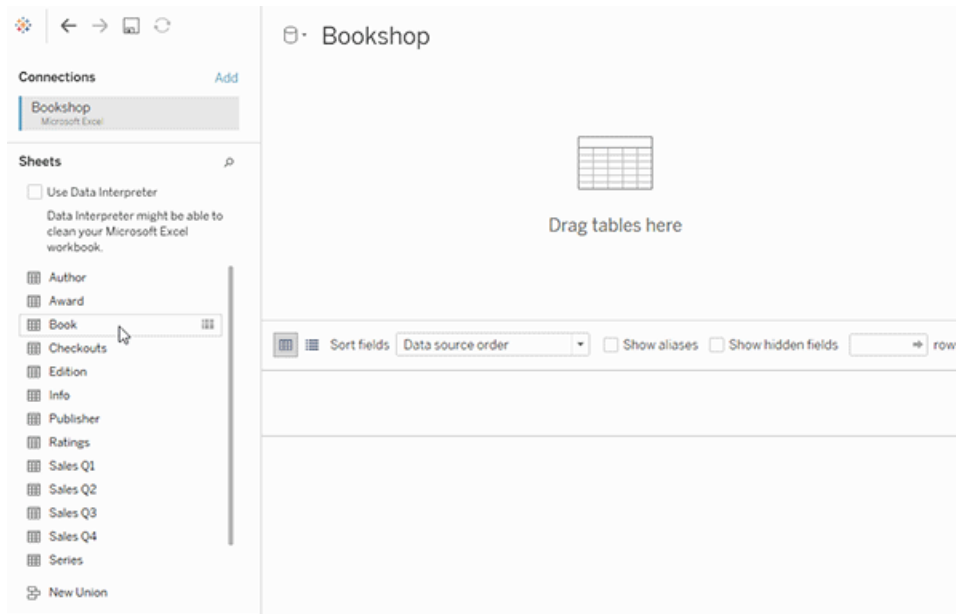

**To change the fields:** Select a field pair, and then click in the list of fields below to select a new pair of matching fields.

**To add multiple field pairs:** After you select the first pair, click **Close**, and then click **Add more fields**.

If no constraints are detected, a **Many-to-many** relationship is created and referential integrity is set to **Some records match**. These default settings are a safe choice and provide the most flexibility for your data source. The default settings support full outer joins and optimize queries by aggregating table data before forming joins during analysis. All column and row data from each table becomes available for analysis.

In many analytical scenarios, using the default settings for a relationship gives you all of the data you need for analysis. Using a many-to-many relationship will work even if your data is many-to-one or one-to-one. If you know the particular cardinality and referential integrity of your data, you can adjust the [Performance Options settings](#) to describe your data more accurately and optimize how Tableau queries the database.

3. Add more tables following the same steps, as needed.

After you have built your multi-table, related data source, you can dive into exploring that data. For more information, see [How Analysis Works for Multi-table Data Sources that Use Relationships](#) on page 695 and [Troubleshooting multi-table analysis](#) on page 710.

### Move a table to create a different relationship

To move a table, drag it next to a different table. Or, hover over a table, click the arrow, and then select **Move**.

# Tableau Desktop and Web Authoring Help

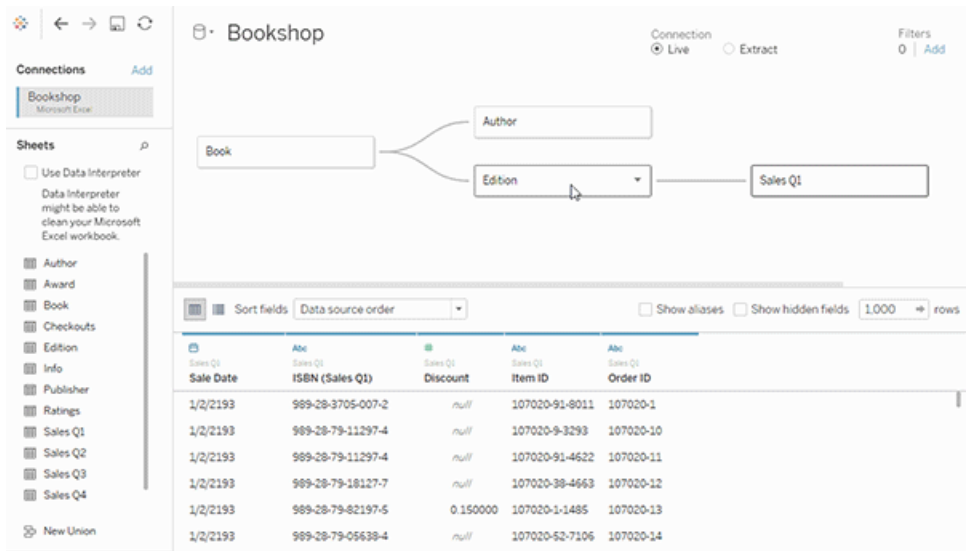

**Tip:** Drag a table over the top of another table to replace it.

## Change the root table of the data model

To swap the root table with another table: Right-click another logical table in the data model, and then select **Swap with root** to make the change.

## Remove a table from a relationship

To move a table, hover over a table, click the arrow, and then select **Remove**.

Deleting a table in the canvas automatically deletes its related descendants as well.

### View a relationship

- Hover over the relationship line (noodle) to see the matching fields that define it. You can also hover over any logical table to see what it contains.

The screenshot shows the Tableau interface for a 'Bookshop' data source. It displays a relationship between 'Book' and 'Author' tables. A tooltip is shown over the relationship line, indicating the relationship is 'Book to Author' with a 'Many to Many' cardinality and the related field 'Auth ID = AuthID (Author)'. Below the relationship view, there is a data table with the following columns and rows:

Award Title (Award)	Award	Year Won	Book Book ID	Book Title
(im)Mortality	Young Reader's Choic...	2192	MM424	(im)Mortality
Alanna Saves the Day	Caldecott Medal	2186	AD222	Alanna Saves

### Edit a relationship

- Click a relationship line to open the **Edit Relationship** dialog box. You can add, change, or remove the fields used to define the relationship. Add more field pairs to create a compound relationship.

To add multiple field pairs: After you select the first pair, click **Close**, and then click **Add more fields**.

The screenshot shows the Tableau Desktop interface for a data source named 'Orders (SuperStore)'. The 'Connections' pane on the left shows 'SuperStore (Microsoft Excel)'. The 'Sheets' pane lists 'Cities', 'Orders', and 'States'. The main canvas displays a data model where the 'Orders' table is connected to 'Cities' and 'States' tables. Below the canvas, a table displays data for 'City (Cities)', 'State (Cities)', and 'City Population'.

City (Cities)	State (Cities)	City Population
Henderson	Kentucky	183,870
Los Angeles	California	396,462
Fort Lauderdale	Florida	395,526
Concord	North Carolina	13,181
Seattle	Washington	225,068
Fort Worth	Texas	45,198

## Tips on creating relationships

- The first table that you drag to the canvas becomes the root table for the data model in your data source. After you drag out the root table, you can drag out more tables in any order. You'll need to consider which tables should be related to each other, and the matching field pairs that you define for each relationship.
- Before you start creating relationships, viewing the data from the data source before or during analysis can be useful to give you a sense of the scope of each table. For more information, see [View Underlying Data on page 2610](#). You can also use View Data to see a table's underlying data when a relationship is invalid.
- If you're creating a star schema, it can be helpful to drag the fact table out first, and then relate dimension tables to that table.
- Each relationship must be made of at least one matched pair of fields. Add multiple field pairs to create a compound relationship. Matched pairs must have the same data type. Changing the data type in the Data Source page doesn't change this requirement. Tableau will still use the data type in the underlying database for queries.
- Relationships can be based on calculated fields. You can also specify how fields should be compared by using operators when you define the relationship.
- Deleting a table in the canvas automatically deletes its related descendants as well.

- You can swap the root table with another table. Right-click another logical table in the data model, and then select **Swap with root** to make the change.

## Validate relationships in your data source

You have several options for validating your data model for analysis. As you create the model for your data source, we recommend going to the sheet, selecting that data source, and then building a viz to explore record counts, unmatched values, nulls, or repeated measure values. Try working with fields across different tables to ensure everything looks how you expect it to.

What to look for:

- Are your relationships in the data model using the correct matching fields for their tables?
- What are the results of dragging different dimensions and measures into the view?
- Are you seeing the expected number of rows?
- Would compound relationships make the relationship more accurate?
- If you changed any of the [Performance Options settings](#) from the default settings, are the values in the viz what you expect? If not, check the settings, or reset to the default.

Options for validating relationships and the data model:

- Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. To see the count for a table, drag its Count field into the view. To see the count for all tables, select the Count field for each table in the Data pane, and then click the Text Table in Show Me.
- Click **View Data** in the Data pane to see the number of rows and data per table. Also, before you start creating relationships, viewing the data from the data source before or during analysis can be useful to give you a sense of the scope of each table. For more information, see [View Underlying Data on page 2610](#).
- Drag dimensions onto rows to see the Number of Rows in the status bar. To see unmatched values, click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**. You can also drag different measures to the view, such as *<YourTable>(Count)* from one of the tables represented in your viz. This ensures that you'll see all values of the dimensions from that table.

**Tip:** If you would like to see the queries that are being generated for relationships, you can use the Performance Recorder in Tableau Desktop.

1. Click the Help menu, and then select **Settings and Performance > Start Performance Recording**.

2. Drag fields into the view to build your viz.
3. Click the Help menu, and then select **Settings and Performance > Stop Performance Recording**.
4. In the Performance Summary dashboard, under Events Sorted By Time, click an "Executing Query" bar and view the query below.

Another more advanced option is to use the [Tableau Log Viewer](#) on GitHub. You can filter on a specific keyword using `end-protocol.query`. For more information, start with the [Tableau Log Viewer wiki page](#) in GitHub.

## Dimension-only visualizations

When using a multi-table data source with related tables: If you build a dimension-only viz, Tableau uses inner joins and you won't see the full unmatched domain.

To see partial combinations of dimension values, you can:

- Use Show Empty Rows/Columns to see all of the possible rows. Click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**.
- Add a measure to the view, such as `<YourTable>(Count)` from one of the tables represented in your viz. This ensures that you'll see all values of the dimensions from that table.

For more information, see [How Analysis Works for Multi-table Data Sources that Use Relationships](#) on page 695 and [Troubleshooting multi-table analysis](#) on page 710.

## Relationships (logical tables) versus joins (physical tables)

While similar, joins and relationships behave differently in Tableau, and are [defined in different layers of the data model](#). You create relationships between logical tables at the top-level, logical layer of your data source. You create joins between physical tables in the physical layer of your data source.

Joins merge data from two tables into a single table before your analysis begins. Merging the tables together can cause data to be duplicated or filtered from one or both tables; it can also cause NULL rows to be added to your data if you use a left, right, or full outer join. When analyzing joined data, you need to make sure that you correctly handle the effects of the join on your data.

**Note:** When duplication or the filtering effects of a join might be desirable, use joins to merge tables together instead of relationships. Double-click a logical table to open the physical layer and add joined tables.

A relationship describes how two independent tables relate to each other but doesn't merge the tables together. This avoids the data duplication and filtering issues that might occur in a join and can make working with your data easier.

<b>relationships</b>	<b>joins</b>
Defined between logical tables in the Relationship canvas (logical layer)	Defined between physical tables in the Join/Union canvas (physical layer)
Don't require you to define a join type	Require join planning and join type
Act like containers for tables that are joined or unioned	Are merged into their logical table
Only data relevant to the viz is queried. Cardinality and referential integrity settings can be adjusted to optimize queries.	Run as part of every query

<b>relationships</b>	<b>joins</b>
Level of detail is at the aggregate for the viz	Level of detail is at the row level for the single table
Join types are automatically formed by Tableau based on the context of analysis. Tableau determines the necessary joins based on the measures and dimensions in the viz.	Join types are static and fixed in the data source, regardless of analytical context. Joins and unions are established prior to analysis and don't change.
Rows aren't duplicated	Merged table data can result in duplication
Unmatched records are included in aggregates, unless explicitly excluded	Unmatched records are omitted from the merged data
Create independent domains at multiple levels of detail	Support scenarios that require a single table of data, such as extract fil-

<b>relationships</b>	<b>joins</b>
	ters and aggregation

## Relationships versus blends

While both relationships and blends support analysis at different levels of detail, they have distinct differences. One reason you might use blends over relationships is to combine published data sources for your analysis.

<b>relationships</b>	<b>blends</b>
Defined in the data source	Defined in the worksheet between a primary and a secondary data source
Can be published	Can't be published
All tables are equal semantically	Depend on selection of primary and secondary data sources, and how those data sources are structured.
Support full outer joins	Only support left joins
Computed locally	Computed as part of the

<b>relationships</b>	<b>blends</b>
	SQL query
Related fields are fixed	Related fields vary by sheet (can be customized on a sheet-by-sheet basis)

## Features of different options for combining data: Relationships, joins, and blends

There are many ways to combine data tables, each with their own preferred scenarios and nuances.

- Relate** Use when combining data from different levels of detail.
- Requires matching fields between two logical tables. Multiple matching field pairs can define the relationship.
  - Automatically uses correct aggregations and contextual joins based on how fields are related and used in the viz.
  - Supports many-to-many and outer joins.
  - Relationships are consistent for the entire workbook and can be published.
  - Can be published, but

you can't relate published data sources.

- Can't define relationships based on calculated fields or geographic fields.
- Using data source filters limits join culling benefits of relationships.

**Join** Use when you want to add more columns of data across the same row structure.

- Requires common fields between two physical tables.
- Requires establishing a join clause and a join type.
- Can join on a calculation.
- Joined physical tables are merged into a single logical table with a fixed combination of data.
- May cause data loss if fields or values aren't present in all tables (dependent on join types used).
- May cause data duplication if fields are at different levels of detail.
- Can use data source filters.

**Union** Use when you want to add

more rows of data with the same column structure.

- Based on matching columns between two tables.
- Unioned physical tables are merged into a single logical table with a fixed combination of data.

**Blend** Use when combining data from different levels of detail.

- Can be used to combine published data sources, but can't be published.
- Can be used between a relational data source and a cube data source.
- Data sources can be blended on a per-sheet basis.
- Are always effectively left joins (may lose data from secondary data sources).

## Use Relationships for Multi-table Data Analysis

Tables that you drag into this canvas use relationships. Relationships are a flexible way to combine data for multi-table analysis in Tableau.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to](#). Learn more about the basics of creating relationships in this 5-minute video.

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

Learn more about how relationships work in these Tableau blog posts:

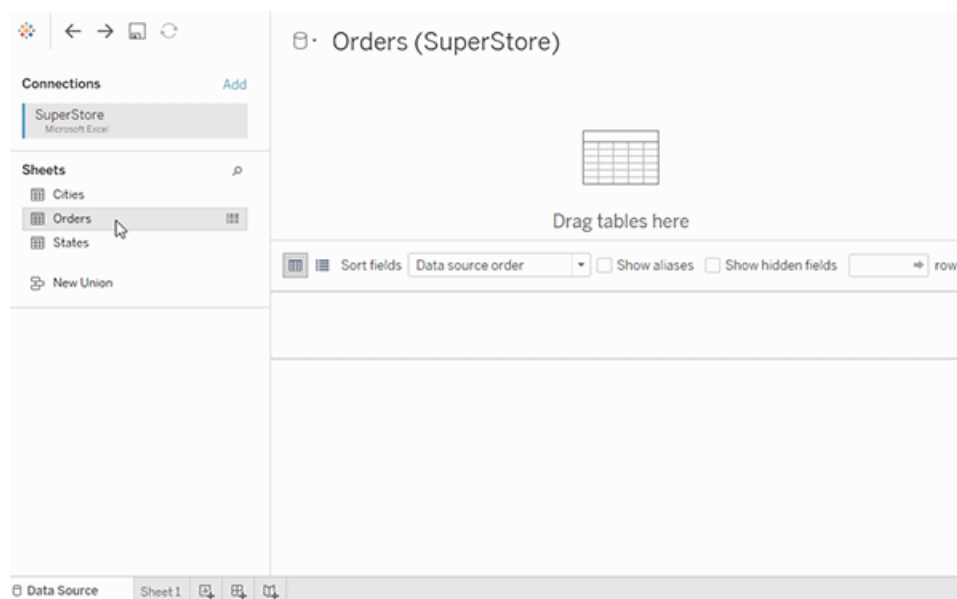

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

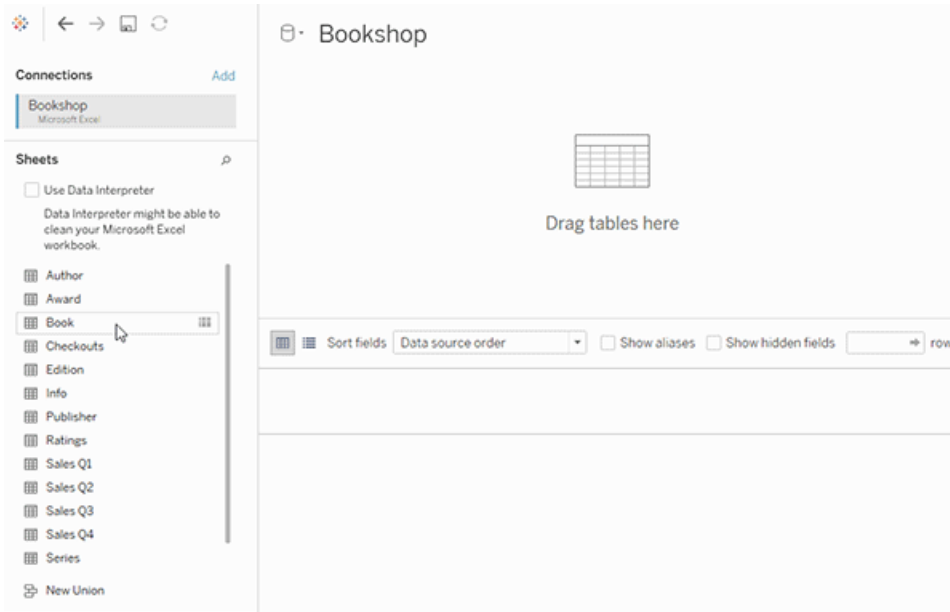

## Are you building a new data source and workbook?

Drag a table to the Data Source page canvas to start building your data source.

A data source can be made of a single table that contains all of the dimension and measure fields you need for analysis...

Or, you can create a multi-table data source by dragging out more tables and defining their relationships...

Watch this 1-minute video about getting started with using relationships.

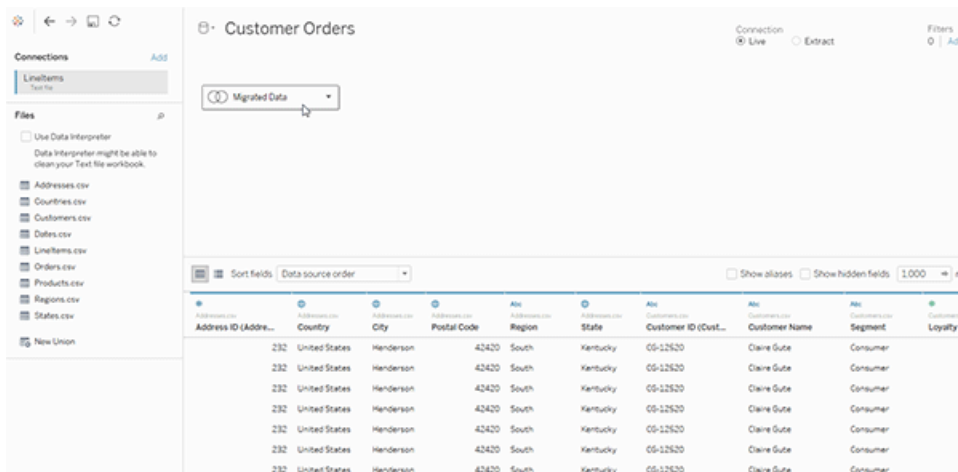

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

For more information about using relationships, see [Relate Your Data](#), [How Relationships Differ from Joins](#) on page 675, [The Tableau Data Model](#) on page 664, and [Create and define relationships](#).

For more information on changes to data sources and analysis in Tableau 2020.2, see [What's Changed with Data Sources and Analysis in 2020.2](#) and [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#).

## Are you opening an older workbook or data source?

When you open a pre-2020.2 workbook or data source in 2020.2, your data source will appear as a single logical table in the canvas, with the name "Migrated Data" or the original table name. Your data is preserved and you can continue to use the workbook as you did before.

To see the physical tables that make up the single logical table, double-click that logical table to open it in the physical layer. You will see its underlying physical tables, including joins and unions.

For more information on changes to data sources and analysis in Tableau 2020.2, see [What's Changed with Data Sources and Analysis in 2020.2](#) and [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#).

## What's Changed with Data Sources and Analysis

Starting in Tableau version 2020.2, we've made several major enhancements to make multi-table analysis easier and more intuitive. This topic describes these changes.

New data modeling capabilities in Tableau help you more easily analyze data across multiple tables. With a new logical layer and relationships in data sources, you can create multi-table data models in the form of star and snowflake schemas with multiple fact tables at different levels of detail (LOD).

- **Data sources are easier to build, maintain, and analyze.** Data sources now have a new logical layer where you can create flexible relationships between tables. Create multi-table, multi-fact data models by relating tables at different levels of detail. Bring in data from multiple tables more easily and maintain fewer data sources to meet your analytical needs.
- **Relationships make the analysis experience more intuitive.** You no longer need to engage in extensive join planning and make assumptions about what join types will be required to make your data ready for analysis. Tableau automatically selects join types

based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data. You can see aggregations at the level of detail of the fields in your viz rather than having to think about the underlying joins. Relationships can be many-to-many and support full outer joins. You don't need to use LOD expressions such as FIXED to deduplicate data in related tables.

- **The Data Source page, View Data window, and Data pane have been updated to support a multi-table analysis experience.** Your first view of the Data Source page canvas is now the logical layer, where you can define relationships between tables. In support of multi-table analysis, several parts of the Tableau interface have changed. The Data Source page (canvas, data grid), View Data window, and the Data pane in the worksheet have all been updated to support a multi-table analysis experience. For more information, see [Changes to different parts of the interface](#). The API to access View Data has also been updated to support multi-table analysis.
- **Context-aware queries bring in relevant data when it's needed.** A data source that uses relationships makes it easier to bring more tables, more rows of data, and multiple fact tables into a single data source. Rather than querying the entire data source, Tableau brings in data from the tables that are needed for the worksheet, based on the fields at play in the visualization.

**Watch a video:** For an overview of data source enhancements and an introduction to using relationships in Tableau, see this 5-minute video.

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

Learn more about how relationship queries work in these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

## Changes to data sources, the data model, and query semantics

### Support for multi-table data sources

Data sources in Tableau recognize and preserve normalized data. With multi-table data sources, Tableau can handle multiple levels of detail in a single data source. This support makes it easier

for you to prepare and explore your data without having to write specialized calculations to control aggregations like averages and totals. Combine tables in star and snowflake schemas to seamlessly relate multiple fact tables. The new logical layer uses contextual, dynamic joins and gives you better domain control (see [Supported data model schemas on page 671](#)).

Tableau recognizes and maintains the underlying relationships between tables, so fewer joins and calculations should be needed. Because these enhanced data sources can answer a wider variety of questions, you can consolidate the number of distinct data sources you need to create and maintain. Fewer data sources are needed to represent the same data.

## What didn't change?

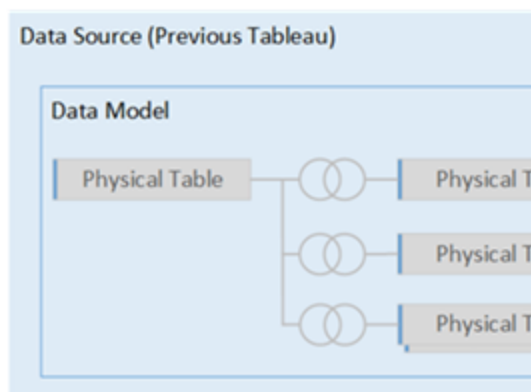

Relationships in the logical layer give you more options for combining data above in previous versions (nothing has been taken away). You can still create single-table data sources in Tableau. You can build a logical table using a combination of joins, unions, custom SQL, and so on. The behavior of single-table analysis in Tableau has not changed. Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau version 2020.1 and earlier.

Also see [Questions about Relationships, the Data Model, and Data Sources on page 653](#).

## New logical layer in the data source

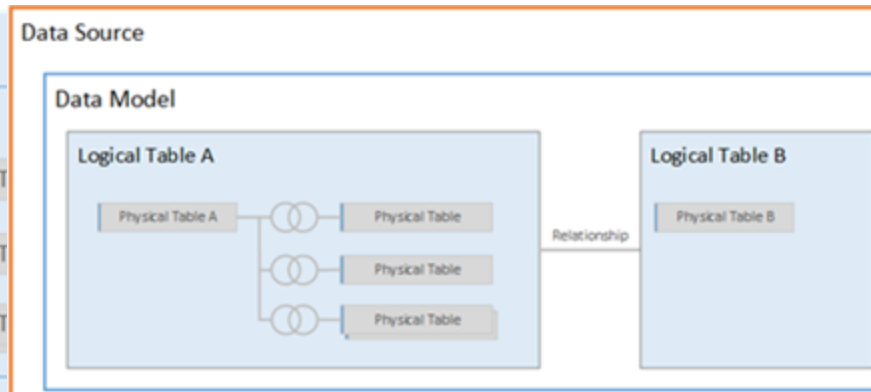

In previous versions of Tableau, the data model in your data source consisted of a single, physical layer where you could specify [joins](#) and unions. Tables added to the physical layer (joined or unioned) create a single, flattened table (denormalized) for analysis.

### Previous versions

In Tableau version 2020.1 and earlier, the data model has only the physical layer

### 2020.2 and later

In Tableau version 2020.2 and later, the data model has two layers: the logical layer and the physical layer

Starting in Tableau version 2020.2, the data model in your data source includes a new semantic layer above the physical layer—called the logical layer—where you can add multiple tables and relate them to each other based on matched field pairs. Tables at the logical layer are not merged in the data source, they remain distinct (normalized), and maintain their native level of detail.

Logical tables act like containers for physical tables. You can still use joins and unions between physical tables. Just double-click a logical table to open it and work with joins or unions.

The logical layer makes it easier for you to combine your data for a variety of analytics scenarios. You can now use and create normalized data models in the form of star and snowflake schemas, and flexible models with fact tables at different grains.

For more information, see [The Tableau Data Model on page 664](#) and [Supported data model schemas on page 671](#).

### New query semantics based on relationships

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. Relationships can be many-to-many and support full outer joins. You don't need to use LOD expressions such as FIXED to deduplicate data in related tables.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to](#).

- **No up-front join type.** You only need to select matching fields to define a relationship (no join types). Because you don't specify the join type, you won't see a Venn diagram when you are setting up relationships.
- **Automatic and context-aware.** Relationships defer joins to the time and context of analysis. Tableau automatically selects join types based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data. You can see aggregations at the level of detail of the fields in your viz rather than having to think about the underlying joins.
- **Flexible.** When you combine tables using relationships, it's like creating a custom, flexible data source for every viz, all in a single data source for the workbook. Because Tableau queries only tables that are needed based on fields and filters in a viz, you can build a data source that can be used for a variety of analytic flows.

For more information, see [Relate Your Data, Don't Be Scared of Relationships](#), and [Relationships, part 1: Introducing new data modeling in Tableau](#).

**Note:** To go to the original join canvas, double-click a logical table in the top level view (the logical layer of the data source). You still can add joins and unions between tables in the physical layer of the data source. For more information, see [The Tableau Data Model](#) on page 664.

## Migrated data sources

When you open a pre-2020.2 workbook or data source in Tableau version 2020.2 and later, your data source will appear as a single logical table in the canvas. You can continue to use the workbook as you did before.

If your data source contained multiple joined or unioned tables, the single logical table is displayed with the name "Migrated Data". You can rename the Migrated Data table.

To see the physical tables that make up the single logical table, double-click that logical table to open it in the physical layer. You will see its underlying physical tables, including joins and unions.

Address ID (Addre...	Country	City	Postal Code	Region	State	Customer ID (Cust...	Customer Name	Segment	Loyalty R
232	United States	Henderson	42420	South	Kentucky	00-12520	Claire Gute	Consumer	
232	United States	Henderson	42420	South	Kentucky	00-12520	Claire Gute	Consumer	
232	United States	Henderson	42420	South	Kentucky	00-12520	Claire Gute	Consumer	
232	United States	Henderson	42420	South	Kentucky	00-12520	Claire Gute	Consumer	
232	United States	Henderson	42420	South	Kentucky	00-12520	Claire Gute	Consumer	
232	United States	Henderson	42420	South	Kentucky	00-12520	Claire Gute	Consumer	

## Web Authoring

Your workbook must use an embedded data source for you to be able to edit relationships and performance options in the Data Source page in web authoring in Tableau Server or Tableau Cloud.

## Extracts

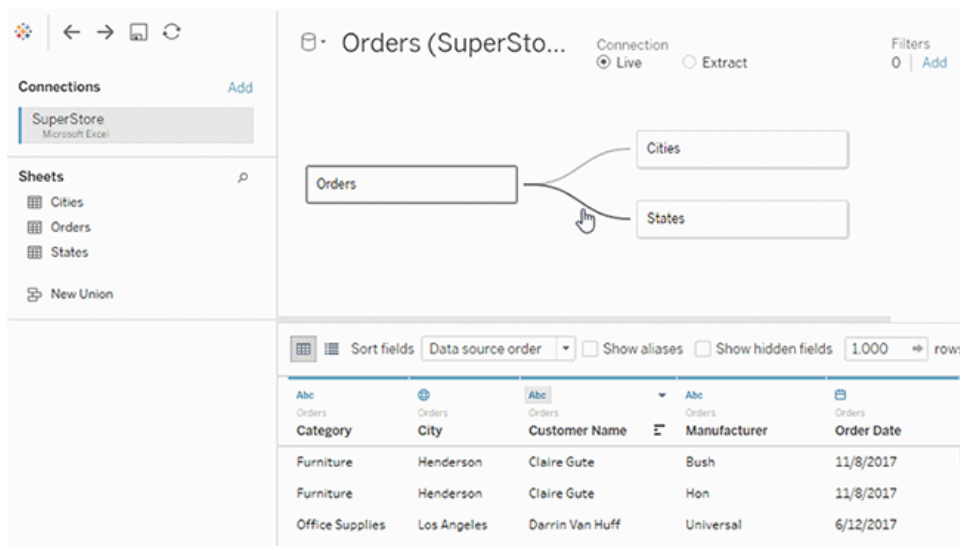

Extract data is now stored based on logical tables (replaces the Single Table option) or physical tables (replaces the Multiple Tables option). For more information, see [Extract Your Data on page 867](#).

## Changes to different parts of the interface

### Data Source page changes

The Data Source page canvas now has two layers: a logical layer and a physical layer. The default view that you see in the Data Source page is new; it now shows the logical layer, which uses relationships ("noodles") between tables.

You still can add joins and unions between tables in the physical layer, just double-click a logical table in the logical, top-level view to switch to the physical layer. For more information, see [The Tableau Data Model on page 664](#).

## Data Grid

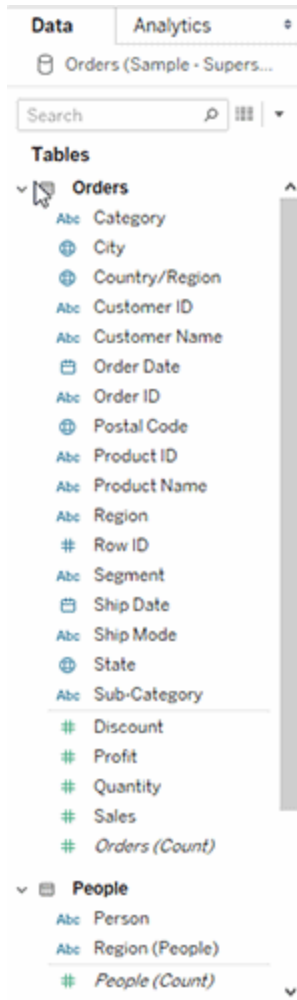

When the data source is made of multiple, related tables, selecting a logical table displays that table's data in the data grid below. With relationships, the data has not been merged, so you are seeing the values for the currently selected logical table. If you need to pivot columns, you must open a logical table and pivot the data in the physical table view of the data source.

## Data pane in worksheets

To support relationships and multi-table analysis, the Data pane has been updated.

You will no longer see the Dimensions and Measures labels in the Data pane. Dimension and measure fields can be organized by table (**Group by Data Source Table**) or folder (**Group by Folder**). Dimensions are displayed above the gray line, and measures below the gray line for each table or folder. In some cases, a table might show only dimensions, or only measures to start with.

You will no longer see the Number of Records field in data sources that contain logical tables. Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. In the previous example you can see *Addresses(Count)*, *Customers(Count)*, and *LineItems(Count)*.

COUNT of table = SUM of Number of Records per table. You can't build calculations on top of a table's *Count* field. *Count* is aggregate-only.

**Note:** You might see the *Number of Records* field in the Data pane if you open a pre-2020.2 workbook that used *Number of Records* in a view.

Calculated fields are listed with their originating field, if all of their input fields come from the same table.

Sets and groups are displayed under the table with their originating field.

Fields that don't belong to a specific table or aren't grouped under a folder are displayed in the general area below the tables. These include: aggregated calculations, calculations that use fields from multiple tables, Number of Records when applicable, Measure Names, and Measure Values.

## View Data

In the View Data window, when the data source contains multiple logical tables, the number of rows and data are listed at the native level of detail for each table in separate tabs.

For more information, see [View Underlying Data on page 2610](#).

Calculated fields are listed with their originating field.

LOD calculations won't necessarily appear in View Data for a logical table because an LOD calculation might be at a different granularity than the table itself. If the dimensionality of an LOD calc includes fields from a single table, that LOD calculation will appear in its owning table in the Data pane.

## View Data column order changes in Tableau version 2020.2 and later

When you open a data source from a Tableau version 2020.1 and earlier in Tableau version 2020.2 and later, the column order may be different. Columns may be displayed differently in the View Data window, and the column order may be different when you export it to CSV format.

This change in how column order is handled in the View Data window is required to support relationships and logical tables.

If you use scripts that depend on a customized column order, we recommend using the Tableau Extensions API for View Data to download underlying data to CSV format.

## Changes to analysis with multi-table data sources

Using a data source that has multiple, related tables affects how analysis works in Tableau. Because multiple, related tables have independent domains and retain their native level of detail, when you drag fields into the view:

- Data is queried at its natural level of detail.
- Only data that is relevant to a viz is queried.
- The relationships between the tables affect the results of the query. The flow of building a viz can vary depending on how tables of fields are related to each other in the data model, or if they aren't related directly.

Benefits of using multi-table data sources with relationships:

- Relationships use joins, but they are automatic. Tableau automatically selects join types based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data.
- Tableau uses relationships to generate correct aggregations and appropriate joins during analysis, based on the current context of the fields in use in a worksheet.
- Multiple tables at different levels of detail are supported in a single data source, so fewer data sources are needed to represent the same data.
- Unmatched measure values are not dropped (no accidental loss of data).
- Avoids data duplication and filtering issues that can sometimes result from joins.

For more information, see [Relate Your Data](#) on page 622, [How Analysis Works for Multi-table Data Sources that Use Relationships](#) on page 695 and [Troubleshooting multi-table analysis](#) on page 710.

For related information about how relationship queries work, see these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)

## What didn't change?

The behavior of single-table analysis in Tableau has not changed. Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau pre-2020.2.

### Dimension-only visualizations

When using a multi-table data source with related tables: If you build a dimension-only viz, Tableau uses inner joins and you won't see the full unmatched domain.

To see partial combinations of dimension values, you can:

- Use Show Empty Rows/Columns to see all of the possible rows. Click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**. Be aware that this setting will also trigger densification for Date and Numeric Bin fields, which may be unwanted.
- Add a measure to the view, such as *<YourTable>(Count)* from one of the tables represented in your viz. This ensures that you will see all values of the dimensions from that table.

## Unmatched values behavior for dimensions that might surprise you

When you build a visualization that uses dimensions from multiple logical tables, the behavior can be initially surprising. By default, if the dimensions in a visualization or the inputs to a row-

level calculations use fields from multiple logical tables, Tableau will only display results where all the dimensions have matching values.

For example, consider a data set that contains two logical tables, Customers and Purchases, where some Customers have made no Purchases and have no matching rows in the Purchases table. If you bring the dimension [Customers].[Customer Name] into play, you will see a list of all customers regardless of whether or not they made a Purchase. If you then add the dimension [Purchases].[Product] to the visualization, Tableau will change to just show the Customers who made purchases along with the Products they bought.

This is the default behavior. Here are several ways you can work with this behavior:

- Use Show Empty Rows/Columns to see all of the possible rows and bring back the unmatched dimension values. Click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**. Be aware that this setting will also trigger densification for Date and Numeric Bin fields, which may be unwanted.
- Convert one of the dimensions to a measure. For example, switching to use COUNT ([Purchases].[Product]) will keep Customers with no purchases and display a "0" for them. This may not be a viable approach if you want to see all the Products.
- Bring a measure into the view from the table with unmatched values. For example, adding COUNT([Customers]) on the detail shelf will bring back the unmatched customers, while still showing all the Products.
- Instead of relating the two tables at the logical level, you can join them using an outer join at the physical level, as in previous versions of Tableau. This approach will show the unmatched values, with a few side effects. Queries will always be issued querying both tables, NULL values will appear in visualizations and quick filters even when no fields from the unmatched table are used, and you will have to write LOD calculations to remove any unwanted duplication introduced by the join.

### Using a table's Count field instead of Number of Records

You will no longer see the Number of Records field in data sources that contain logical tables. Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. In the previous example you can see *Addresses(Count)*, *Customers(Count)*, and *LineItems(Count)*.

COUNT of table = SUM of Number of Records per table. You can't build calculations on top of a table's *Count* field. *Count* is aggregate-only.

**Note:** You might see the *Number of Records* field in the Data pane if you open a pre-2020.2 workbook that used *Number of Records* in a view.

## Cross-table calculations

You can write calculations that span multiple tables. Be aware that cross-table calculations use inner join query semantics by default. The calculation lives on top of the join between the logical tables that it references. Also, it is now possible to write row-level calculations across tables that result in outer joins.

Calculations are evaluated after Null dimensions are added, so you can change a Null to something else using a calculation like: `IFNULL([Dimension], "Missing")`.

## Grand totals using SUM

Grand totals using SUM reflect the actual total at the native level of detail of a field's logical table, rather than the SUM of subtotals.

## Nulls and automatic joins that result from relationships

In Tableau version 2020.2 and later, when performing joins that result from relationships, Tableau does not join nulls against nulls.

## Unmatched null behavior

When you add a measure to the view, a Null dimension value is added when the measure has values that are not associated with a dimension.

This behavior occurs because Tableau treats unmatched values (or non-associated dimension values) the same as true NULL values in the underlying data source. Values for both will be aggregated together or filtered together.

For example, with `SUM(Sales), [State]` every matched State represents a state. Its SUM(Sales) is the sum for a single state. For unmatched nulls, SUM(Sales) may reflect many states.

If you don't want this behavior, you can clean your data to make sure that every row in the measure table matches a row in the dimension table. You can use Tableau Prep for this. Or, within a sheet, you can filter out the Null by clicking on the Null and selecting **Exclude**. After you do this, you can edit the relationship between the measure table and the dimensions table by selecting **All Records Match** in the Performance Options settings.

## Dealing with unmatched nulls in the Edit Filter dialog box

When you apply a filter to a dimension, the rules for when the Null appears are:

- On the General tab, you can explicitly include or exclude the Null row using the check box.
- On the Wildcard tab, the setting won't impact whether or not Null appears (since it only filters out text values and Null is not treated as a text value).
- On the Condition or Top tabs, using a setting other than **None** will cause the "Null" state to be filtered out.

## Validating relationships

You have several options for validating your data model for analysis. As you create the model for your data source, we recommend going to a sheet, selecting that data source, and then building a viz to explore record counts, expected data, unmatched values, nulls, or repeated measure values. Try working with fields across different tables to ensure everything looks how you expect it to.

What to look for:

- Are your relationships in the data model using the correct matching fields for their tables?
- Would adding multiple matching field pairs make the relationship more accurate?
- What are the results of dragging different dimensions and measures into the view from different tables?
- Are you seeing the expected number of rows?
- If you changed any of the [Performance Options settings](#) from the default settings, are the values that you are seeing in the viz what you would expect? If they aren't, you might want to check the settings, or reset to the default.

Options for validating relationships and the data model:

- Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. To see the count for a table, drag its Count field into the view. To see the count for all tables, select the Count field for each table in the Data pane, and then click the Text Table in Show Me.
- Click **View Data** in the Data pane to see the number of rows and data per table. Also, before you start creating relationships, viewing the data from the data source before or during analysis can be useful to give you a sense of the scope of each table. For more information, see [View Underlying Data on page 2610](#).
- Drag dimensions onto rows to see the Number of Rows in the status bar. To see unmatched values, click the **Analysis** menu, and then select **Table Layout > Show**

**Empty Rows** or **Show Empty Columns**. You can also drag different measures to the view, such as `<YourTable>(Count)` from one of the tables represented in your viz. This ensures that you will see all values of the dimensions from that table.

**Tip:** If you would like to see the queries that are being generated for relationships, you can use the Performance Recorder in Tableau Desktop.

1. Click the Help menu, and then select **Settings and Performance > Start Performance Recording**.
2. Drag fields into the view to build your viz.
3. Click the Help menu, and then select **Settings and Performance > Stop Performance Recording**. The Performance Recording workbook will automatically open.
4. In the Performance Summary dashboard, under Events Sorted By Time, click an "Executing Query" bar and view the query below.

Another more advanced option is to use the [Tableau Log Viewer](#) on GitHub. You can filter on a specific keyword using `end-protocol.query`. For more information, start with the [Tableau Log Viewer wiki page](#) in GitHub.

## Questions about Relationships, the Data Model, and Data Sources

These are some of the questions we've heard related to data modeling and relationships in Tableau. If you have a question that isn't in this list, please share it with us by clicking the blue **Send feedback** icon in the bottom right corner of this Help page, (click Yes or No, add your question in the Comment field, and then click Send).

### Relationships

Is a relationship just a different name for a join?

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. A relationship describes how two independent, logical tables relate to each other, but does not merge the tables together ([What is a logical table?](#)). When a relationship is created between tables, the tables remain separate (normalized), maintaining their native level of detail and domains. You can use relationships to create multi-fact data models.

You can't set a join type for relationships. Relationships defer joins to the time and context of analysis. Tableau automatically selects what join types should be used based on the current fields in use in the viz. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data. You can see aggregations at the level of detail of the fields in your viz rather than having to think about the underlying joins.

Relationships can be many-to-many and support full outer joins. You don't need to use LOD expressions such as FIXED to deduplicate data in related tables.

**Learn more:** For related information on combining data using relationships, also see these topics and blog posts:

- [Relate Your Data](#)
- [The Tableau Data Model](#) on page 664
- [How Relationships Differ from Joins](#) on page 675
- [Use Relationships for Multi-table Data Analysis](#) on page 637
- [Don't Be Scared of Relationships](#) on page 715
- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

## Can I use joins between logical tables?

You must use relationships between logical tables. You can only use joins between physical tables contained in a logical table. Double-click a logical table to open it.

We recommend using relationships as your first approach to combining your data because it makes your data preparation and analysis easier and more intuitive. Use joins only when you absolutely need to. Situations where you might still use joins include when you want to:

- Continue to use a data source from a pre-2020.2 version to Tableau that you have upgraded to 2020.2
- Explicitly use a specific join type
- Use a data model that supports shared dimensions

## Where did joins go? Can I still combine table data using joins?

Joins are still an option for combining your data. You just need to open a logical table to work with joins (double-click a logical table to open it). Tables that you join get merged into a single logical table.

[Where did joins go?](#) on page 678

## Are relationships like blends? When should I use a blend?

While both relationships and blends support analysis at different levels of detail, they have distinct differences. If you want to combine data from published data sources, blends are

currently your only option.

You might also choose to use blends when the fields used to join two tables are dependent on the worksheet.

Blends only support left joins, while relationships support full outer joins. Blends can be customized on a per-sheet basis.

[Relationships versus blends on page 634](#)

## Data sources, data model, and connections

### How have data sources changed?

In Tableau version 2020.1 and earlier, tables that you combined in the Data Source page using joins and unions made up the data model in a data source. The data was merged into a single, flat table.

Starting in Tableau 2020.2, a new logical layer has been added to Tableau's data model. The logical layer and relationships expand your options for bringing the data you need into Tableau. You can now create normalized data sources with multiple tables at different levels of detail. Related tables aren't merged; they remain distinct. Using relationships makes creating and analyzing data across multiple tables more flexible and more intuitive.

You can still create single-table data sources in Tableau. You can build a logical table using a combination of joins, unions, custom SQL, and so on. The behavior of single-table analysis in Tableau has not changed. Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau pre-2020.2. When you upgrade a workbook or data source to Tableau version 2020.2 and later, will contain a single logical table that represents your pre-2020.2 data source, and it will work the same as it did before.

### What are logical tables and physical tables?

Starting in Tableau version 2020.2, data sources use a data model that has two layers: a logical layer where you can relate tables, and a physical layer where tables can be joined or unioned. Tables that you drag to the logical layer use relationships and are called logical tables. Every logical table can contain one more physical tables in the physical layer.

For more information, see [The Tableau Data Model on page 664](#).

### Can relationships exist between tables from different connections?

Yes. You can create a data source with relationships between tables from different connections. For more information, see [Combine Data on page 600](#) in [Plan the Data Source on page 596](#).

## Can I use inequality operators or calculated fields to define relationships?

In Tableau 2020.3 and later, you can create relationships based on calculated fields, and compare fields used for relationships using operators in the relationship definition.

Note that the following connectors do not support inequality operators:

- Google BigQuery
- MapR
- Salesforce

## Do all connection types support logical tables and relationships?

Most relational connection types are completely supported. Cubes, SAP HANA (with OLAP attribute), JSON, and Google Analytics are limited to a single logical table in 20.2. Stored procedures can only be used within a single logical table.

Published data sources can't be related to each other.

### Unsupported

- Cube databases do not support the new logical layer. Connecting to a cube offers the same experience as pre-2020.2.
- Stored Procedures: Don't support federation, relationships, or joins. They are represented in a single logical table, and don't allow opening the Join/Union canvas (physical layer).
- Splunk: Doesn't support left joins (and therefore relating logical tables).
- JSON: Doesn't support federation, custom SQL, joins, or relationships (only unions).
- Datasources that do not support LOD calcs. For more information, see [Data Source Constraints for Level of Detail Expressions on page 2547](#).

### Limited support

- Salesforce and WDC Standard Connections: These are represented as joined tables within a logical table. Adding them is currently only supported for single logical table data sources. Standard connections cannot join to an existing table.
- SAP HANA: Doesn't support relating logical tables when the connection has the OLAP attribute set.

## What types of data models are supported?

See [The Tableau Data Model on page 664](#) and [Supported data model schemas on page 671](#)

### Is there a classic view of the Data Source page that I can use?

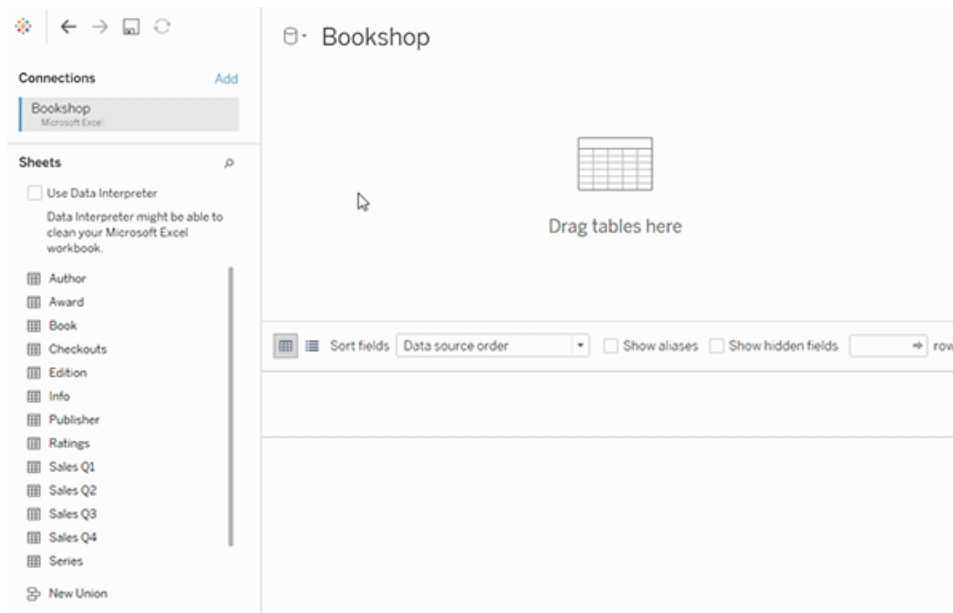

The physical layer of the Data Source page canvas is basically the "classic view" of the Data Source page in previous versions of Tableau.

The default view of Data Source canvas is the logical layer in Tableau version 2020.2 and later. You must double-click a logical table in the Data Source page canvas to go to the physical layer of the canvas.

### How do I create a single-table data source?

Drag a single table into the canvas (logical layer) of the Data Source page. In the worksheet, use the fields from that table in the Data pane for analysis.

You can add more data inside the single, logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged into their single, logical table.

This example shows the Book table in the Relationships canvas (logical layer) of the data source. Double-clicking the Book logical table opens the Join/Union canvas (physical layer). The joins merge the Award and Info tables with the Book table.

## Has row-level security changed?

Row-level security works the same. For information on row-level security, see [Best Practices for Row Level Security](#) in Tableau Server help.

## How do I use custom SQL in the new data model?

Double-click the New Custom SQL option in the left pane of the Data Source page (as before). The custom SQL will be contained by a single logical table.

## What happens to my older data sources when I open them in Tableau version 2020.2 and later?

The data is migrated without changes and you can continue to use the workbook as you did before.

When you open a pre-2020.2 workbook or data source in Tableau version 2020.2 and later, your data source will appear as a single logical table in the canvas with the name "Migrated Data". You can rename the Migrated Data table.

Your original, denormalized data may have been originally built from one or more tables using joins and unions. When you open the data source in Tableau version 2020.2 and later, Tableau migrates the denormalized data model to a single logical table in the new data model to ensure that your data and workbooks are migrated without changes.

To see the physical tables that make up the single logical table, double-click that logical table to open it in the physical layer. You will see its underlying physical tables, including joins and unions.

## Do I need to change my migrated data source to use relationships instead of joins?

If you have existing multi-table data sources defined using physical layer joins, they will still work as they did before. You don't have to change your data source. You can relate logical tables to your migrated table, but you can't downgrade logical tables.

You might consider changing you data source to use relationships instead of joins if you want to add more tables to your data model. This will require you to remove tables from the physical layer, and then add them to the logical layer.

## How do I view or edit the data model on the web?

You can view and edit the data model of a published data source on the web. For more information, see [Edit a Published Data Source on page 3081](#).

## Can I use a data source on Tableau Server or Tableau Cloud (version 2020.2 and later) in a previous version of Tableau Desktop (version 2020.1 and earlier)?

If you attempt to open a published data source or published workbook from Tableau Server or Tableau Cloud version 2020.2 and later in a previous version of Tableau Desktop (version 2020.1 and earlier), any logical tables that were related to the root table in the data source will be removed. Only the root table (the first table added to that data source model) will remain.

If you attempt to use a local data source in a previous version of Tableau:

- Tableau displays a warning that the data source is from a newer version of Tableau that isn't compatible with the previous version.
- On the Data Source page, only the root table will remain in the data source.
- In the Data pane in a Tableau Desktop worksheet, Tableau displays errors (red exclamation points) next to affected fields that are not part of the root table.

If you attempt to use a published data source in a previous version of Tableau:

- Tableau displays a warning that the data source is from a newer version of Tableau that isn't compatible with the previous version.
- In the Data pane in a Tableau Desktop worksheet, Tableau displays an error (red exclamation point) next to the selected data source and a message that the connection needs to be updated. Click **Show Details** for more information about the error.

## Can published data sources be related to each other?

You can't relate published data sources to each other. But you can edit and view the data model for a published data source.

If you want to combine data from published data sources, blends are currently your only option.

[Relationships versus blends on page 634](#)

## How do extracts work with related logical tables?

Extract data is now stored based on logical tables (replaces the Single Table option) or physical tables (replaces the Multiple Tables option). For more information, see [Extract Your Data on page 867](#).

## If I need to downgrade to Tableau version 2020.1 and earlier, what happens to relationships between logical tables?

If you downgrade a workbook to Tableau version 2020.1 and earlier, any logical tables that were related to the root table in the model will be removed from the data source. Only the root table

(the first table added to that model) will remain.

All sheets in the workbook used fields from logical tables (non-root) become invalid, because their tables and fields have been removed from the data model.

Downgrading works best for workbooks that contain single-table data sources.

### How does the new data model work with cubes?

Cubes work the same as in previous versions of Tableau. A cube data source will appear as a single-table data source, just like it is today. You can't create relationships using cube data.

### Interaction with other Tableau features and products

#### Does Explain Data work with multi-table data sources that use relationships?

In Tableau version 2020.3 or later, you can use Explain Data with data sources that contain multiple, related tables. Cardinality and Referential Integrity settings for relationships must be set up correctly for Explain Data to analyze multi-table, related data.

In Tableau version 2020.2 and earlier, you can use Explain Data with a single-table data sources only. Your data source can have a single, logical table that is defined by one or more physical tables.

#### Does Ask Data work with multi-table data sources?

Ask Data fully supports multi-table, normalized data sources.

#### How do new data modeling capabilities affect using Tableau Bridge?

Using the latest version of Tableau Bridge should provide full compatibility with Tableau version 2020.2 and later data modeling functionality.

#### When should I use Tableau Prep vs. authoring in Tableau Desktop, Tableau Cloud, or Tableau Server to create a data source?

Tableau Prep cleans data, and creates flows, extracts, and published data sources that contain physical tables.

In Tableau Desktop, and in Tableau Cloud and Tableau Server web authoring, you can create data sources that use normalized data models. These data models can be made of logical tables and physical tables, and your data sources can be saved as live data sources or as extracts.

Only logical tables can be related. Physical tables can be joined and unioned.

## Analysis with multi-table data sources

### Does analysis work differently with multi-table data sources that use relationships?

Using a data source that has multiple, related tables affects how analysis works in Tableau. Because multiple, related tables have independent domains and retain their native level of detail, when you drag fields into the view:

- Data is queried at its natural level of detail.
- Only data that is relevant to a viz is queried.
- The relationships between the tables affect the results of the query. The flow of building a viz can vary depending on how tables of fields are related to each other in the data model, or if they aren't related directly.

For more information, see [Don't Be Scared of Relationships](#), [How Analysis Works for Multi-table Data Sources that Use Relationships](#) on page 695, [Unmatched values behavior for dimensions that might surprise you](#) on page 649, and [Troubleshooting multi-table analysis](#) on page 710.

### Do LODs work the same with the new data model? When should I use an LOD?

LOD expressions and calculations work the same. Since Tableau now understands the level of detail (LOD) of your input tables, you shouldn't need to use LOD calculations to remove unwanted duplication due to joins.

You may still want to use LOD calcs to:

- Handle unwanted duplication in your source tables.
- Compute multi-level aggregations (e.g. an average over a sum)
- To do cohort analysis (e.g. to compute the first order date for each customer)

If the dimensionality of an LOD calculation includes fields from a single table, that LOD calculation will appear in its owning table in the Data pane.

### How can I tell if I combined my data correctly with relationships?

You have several options for validating your data model for analysis. As you create the model for your data source, we recommend going to a sheet, selecting that data source, and then building a viz to explore record counts, expected data, unmatched values, nulls, or repeated measure values. Try working with fields across different tables to ensure everything looks how you expect it to.

What to look for:

- Are your relationships in the data model using the correct matching fields for their tables?
- Would adding multiple matching field pairs make the relationship more accurate?
- What are the results of dragging different dimensions and measures into the view?
- Are you seeing the expected number of rows?
- If you changed any of the [Performance Options settings](#) from the default settings, are the values that you are seeing in the viz what you would expect? If they aren't, you might want to check the settings, or reset to the default.

Options for validating relationships and the data model:

- Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. To see the count for a table, drag its Count field into the view. To see the count for all tables, select the Count field for each table in the Data pane, and then click the Text Table in Show Me.
- Click **View Data** in the Data pane to see the number of rows and data per table. Also, before you start creating relationships, viewing the data from the data source before or during analysis can be useful to give you a sense of the scope of each table. For more information, see [View Underlying Data on page 2610](#).
- Drag dimensions onto rows to see the Number of Rows in the status bar. To see unmatched values, click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**. You can also drag different measures to the view, such as *<YourTable>(Count)* from one of the tables represented in your viz. This ensures that you will see all values of the dimensions from that table.

Can I see the queries that Tableau is generating for relationships?

If you would like to see the queries that are being generated for relationships, you can use the Performance Recorder in Tableau Desktop.

1. Click the Help menu, and then select **Settings and Performance > Start Performance Recording**.
2. Drag fields into the view to build your viz.
3. Click the Help menu, and then select **Settings and Performance > Stop Performance Recording**. The Performance Recording workbook will automatically open.
4. In the Performance Summary dashboard, under Events Sorted By Time, click an "Executing Query" bar and view the query below.

Another more advanced option is to use the [Tableau Log Viewer](#) on GitHub. You can filter on a specific keyword using `end-protocol.query`. For more information, start with the [Tableau Log Viewer wiki page](#) in GitHub.

## Changes to different parts of the interface

### How has the Data Source page changed? The data grid? View Data? The Data pane?

The Data Source page (canvas, data grid), View Data, and Data pane have been updated to support a multi-table analysis experience.

Your first view of the data source canvas is now the logical layer, which is where you define relationships. The data grid shows row data for each table's level of detail.

In the Data pane, fields and calculated fields are automatically organized by their native level of detail.

The View Data window displays row level data at the correct level of detail, without replication, to make validation easier. Get row counts for each table in the Data pane using *Table(Count)* fields.

[Data Source page changes on page 645](#)

[Data Grid on page 645](#)

[View Data on page 648](#)

[Data pane in worksheets on page 646](#)

### View Data column order changes in Tableau 2020.2 and later

When you open a data source from a previous version of Tableau in Tableau 2020.2 and later, the column order may be different. Columns may be displayed differently in the View Data window, and the column order may be different when you export it to CSV format.

This change in how column order is handled in the View Data window is required to support relationships and logical tables.

If you use scripts that depend on a customized column order, we recommend using the Tableau Extensions API for View Data to download underlying data to CSV format.

### How does Count of Table work versus Number of Records?

You will no longer see the Number of Records field in data sources that contain logical tables. Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. In the previous example you can see *Addresses(Count)*, *Customers(Count)*, and *LineItems(Count)*.

COUNT of table = SUM of Number of Records per table. You can't build calculations on top of a table's *Count* field. *Count* is aggregate-only.

**Note:** You might see the *Number of Records* field in the Data pane if you open a pre-2020.2 workbook that used *Number of Records* in a view.

## Where are sets, groups, and calculated fields shown?

If the field belongs to a table, it is listed under the table. If it doesn't, it is listed in the general area at the bottom of the Data pane.

Calculated fields are listed with their originating field, if all of their input fields come from the same table.

Sets and groups are displayed under the table with their originating field.

Fields that don't belong to a specific table are displayed in the general area below the tables. These include: aggregated calculations, calculations that use fields from multiple tables, Measure Names, and Measure Values.

## The Tableau Data Model

Every data source that you create in Tableau has a data model. You can think of a data model as a diagram that tells Tableau how it should query data in the connected database tables.

The tables that you add to the canvas in the **Data Source** page create the structure of the data model. A data model can be simple, such as a single table. Or it can be more complex, with multiple tables that use different combinations of relationships, joins, and unions.

The data model has two layers:

- The default view that you first see in the Data Source page canvas is the *logical layer* of the data source. You combine data in the logical layer using relationships (or noodles). Think of this layer as the Relationships canvas in the Data Source page. For more information, see [Use Relationships for Multi-table Data Analysis on page 637](#).
- The next layer is the *physical layer*. You combine data between tables at the physical layer using **joins** and unions. Each logical table contains at least one physical table in this layer. Think of the physical layer as the Join/Union canvas in the Data Source page. Double-click a logical table to view or add joins and unions.

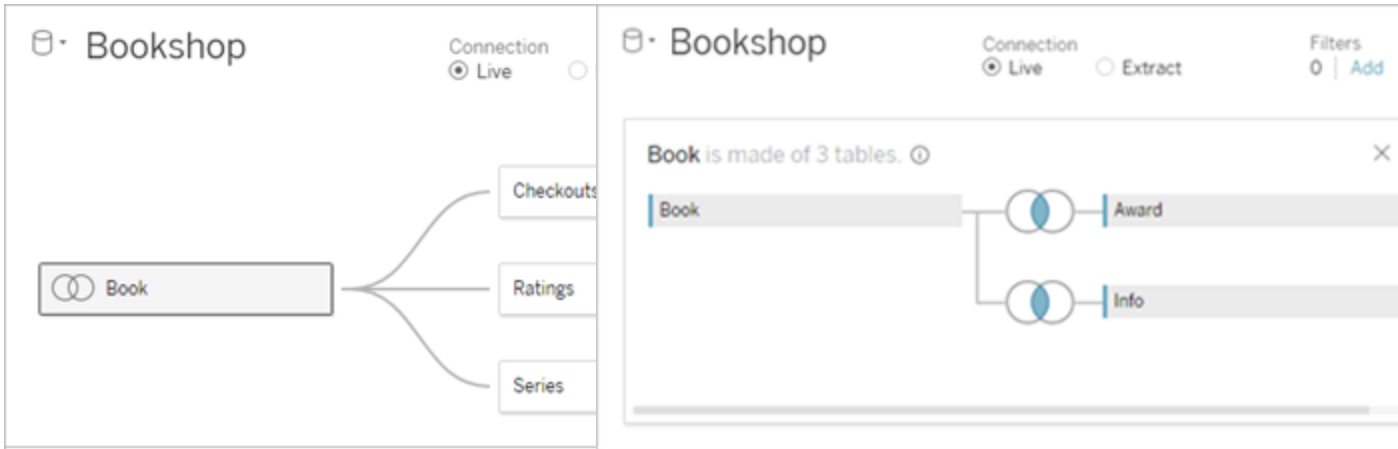

**Logical Layer**

Noodles = Relationships

**Physical Layer**

Venn diagram = Joins

The top-level view of a data source with multiple, related tables. This is the logical layer. Logical tables can be combined using relationships (noodles). They don't use join types. They act like containers for physical tables.

Double-click a logical table to open it and see its physical tables. Physical tables can be combined using joins or unions. In this example, the Book logical table is made of three, joined physical tables (Book, Award, Info).

**Logical Layer**

Relationships canvas in the Data Source page

Tables that you drag here are called logical tables

Logical tables can be related to other logical tables

Logical tables are like containers for physical tables

Level of detail is at the row level of the logical table

Logical tables remain distinct (normalized), not merged in the data source

**Physical Layer**

Join/Union canvas in the Data Source page

Tables that you drag here are called physical tables

Physical tables can be joined or unioned to other physical tables

Double-click a logical table to see its physical tables

Level of detail is at the row level of merged physical tables

Physical tables are merged into a single, flat table that defines the logical table

## Layers of the data model

The top-level view that you see of a data source is the **logical layer** of the data model. You can also think of it as the Relationships canvas, because you combine tables here using relationships instead of joins.

When you combine data from multiple tables, each table that you drag to the canvas in the logical layer must have a relationship to another table. You do not need to specify join types for relationships; during analysis Tableau automatically selects the appropriate join types based on the fields and context of analysis in the worksheet.

The **physical layer** of the data model is where you can combine data using joins and unions. You can only use pivots in this canvas. You can think of it as the Join/Union canvas. In previous versions of Tableau, the physical layer was the only layer in the data model. Each logical table can contain one or more physical tables.

**Important:** You can still create single-table data sources in Tableau that use joins and unions. The behavior of single-table analysis in Tableau has not changed. Your upgraded workbooks will work the same as they did before 2020.2.

**Learn more:** For related information on combining data using relationships, also see these topics and blog posts:

- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

## Understanding the data model

In previous versions of Tableau, the data model had only the physical layer. In Tableau 2020.2 and later, the data model has the logical (semantic) layer and a physical layer. This gives you more options for combining data using schemas to fit your analysis.

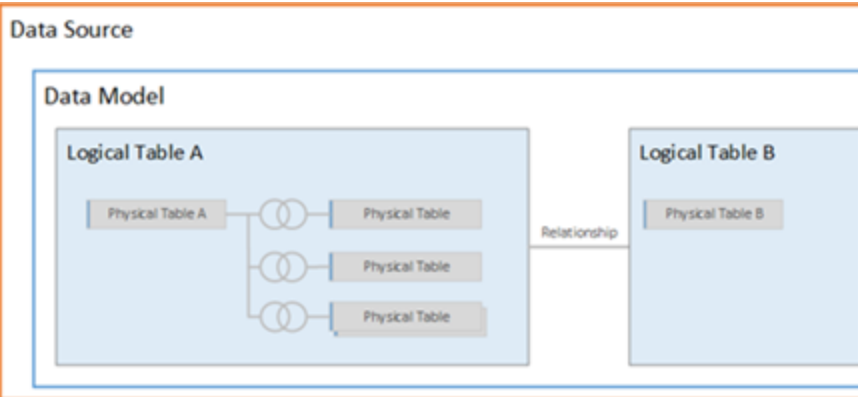

In Tableau 2020.2 and later, a logical layer has been added in the data source. Each logical table contains physical tables in a physical layer.

In previous versions of Tableau, the data model in your data source consisted of a single, physical layer where you could specify joins and unions. Tables added to the physical layer (joined or unioned) create a single, flattened table (denormalized) for analysis.

**Previous versions**

**2020.2 and later**

In versions of Tableau before 2020.2, the data model has only the physical layer

In 2020.2 and later, the data model has two layers: the logical layer and the physical layer

As of Tableau 2020.2, the data model in your data source includes a new semantic layer above the physical layer—called the logical layer—where you can add multiple tables and relate them to each other. Tables at the logical layer are not merged in the data source, they remain distinct (normalized), and maintain their native level of detail.

Logical tables act like containers for merged physical tables. A logical table can contain a single, physical table. Or it can contain multiple physical tables merged together through joins or unions.

## Build a new model

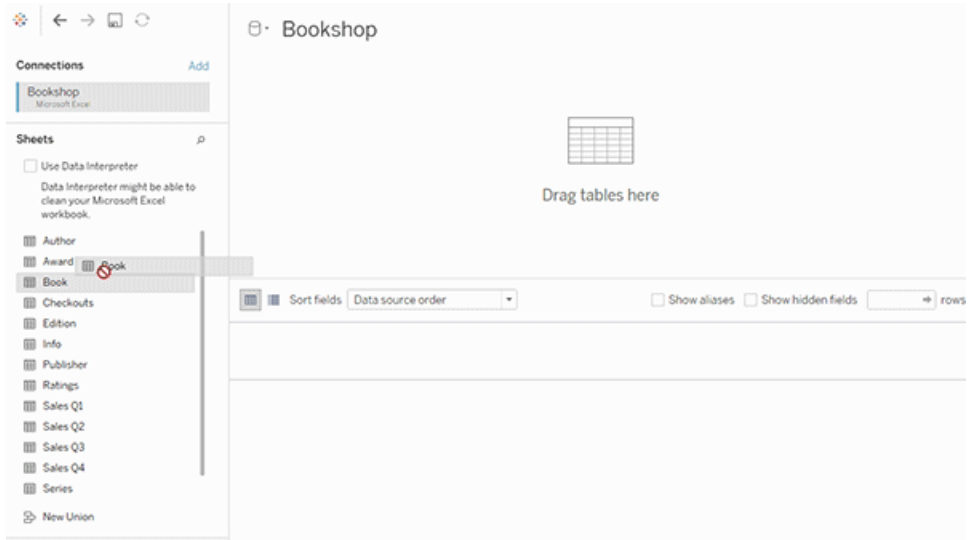

When you add one or more tables to the logical layer, you are essentially building the data model for your data source. A data source can be made of a single, logical table, or you can drag multiple tables to the canvas to create a more complex model.

- The first table that you drag to the canvas becomes the root table for the data model in your data source.
- After you drag out the root table, you can drag out additional tables in any order. You will need to consider which tables should be related to each other, and the matching field pairs that you define for each relationship.
- If you are creating a star schema, it can be helpful to drag the fact table out first, and then relate dimension tables to that table.
- Deleting a table in the canvas automatically deletes its related descendants as well. If you delete the root table, all other tables in the model are also removed.
- Each relationship must be made of at least one matched pair of fields. Add multiple field pairs to create a compound relationship. Matched pairs must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- Relationships can be based on calculated fields.
- You can specify how fields used in the relationships should be compared by using operators when you define the relationship.

For more information about relationships, see [Create and define relationships](#) in [Relate Your Data](#).

## Multi-table model

- To create a multi-table model, drag tables to the logical layer of the Data Source page canvas.

Tables that you drag to the logical layer of the Data Source page canvas must be related to each other. When you drag additional tables to the logical layer canvas, Tableau automatically attempts to create the relationship based on existing key constraints and matching fields to define the relationship. If it can't determine the matching fields, you will need to select them.

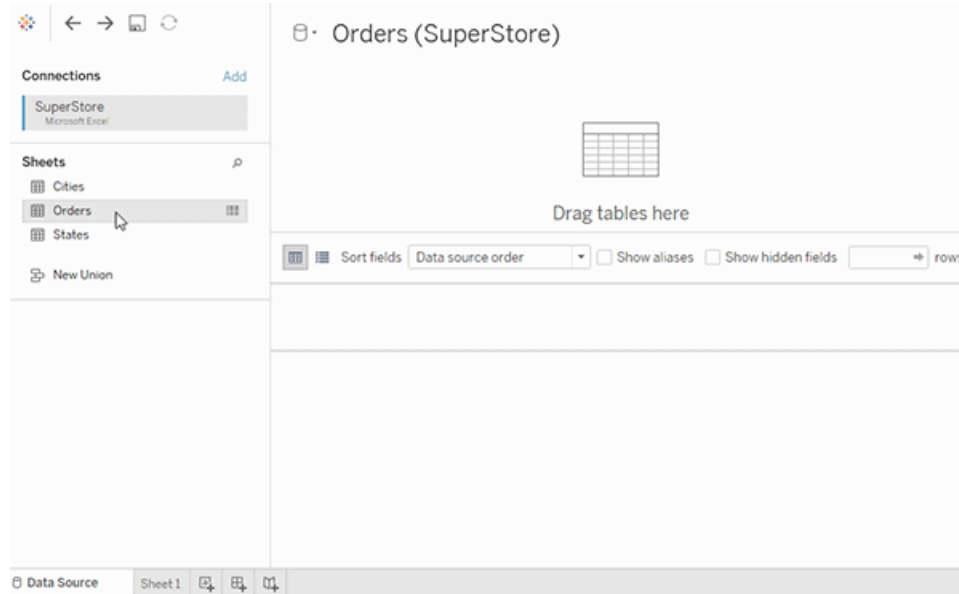

If no constraints are detected, a **Many-to-many** relationship is created and referential integrity is set to **Some records match**. These default settings are a safe choice and provide the most a lot of flexibility for your data source. The default settings support full outer joins and optimize queries by aggregating table data before forming joins during analysis. All column and row data from each table becomes available for analysis.

You can add more data inside any logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged in their logical table.

Follow the steps in [Create and define relationships](#) to combine multiple tables.

### Single-table model

- To create a single-table model, drag a table into the logical layer canvas of the Data Source page. You can then use the fields from that table in the Data pane for analysis.

## Single-table model that contains other tables

You can add more data inside the single, logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged in their logical table.

This example shows the Book table in the Relationships canvas (logical layer) of the data source. Double-clicking the Book logical table opens the Join/Union canvas (physical layer).

In this example, the joins merge the Award and Info tables with the Book table. In this case, the join between Book and Award will be one-to-many, at the level of detail of awards. This would duplicate measure values for Book and Info. To avoid duplication, you could relate Award and Info to Book instead of joining them inside of the Book logical table.

### Supported data model schemas

The data modeling capabilities introduced to Tableau in 2020.2 are designed to make analysis over common multi-table data scenarios—including star and snowflake data models—easy. The following types of models are supported in Tableau data sources.

#### Single-table

Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau pre-2020.2. You can build a logical table using a combination of joins, unions, custom SQL, and so on.

#### Star and snowflake

In enterprise data warehouses, it is common to have data structured in star or snowflake schemas where measures are contained in a central fact table and dimensions are stored separately in independent dimension tables. This organization of data supports many common analysis flows including rollup and drill down.

These models can be directly represented with relationships in the data modeling capabilities available starting with Tableau 2020.2.

Drag the fact table into the model first and then relate the dimension tables to the fact table (in a star schema) or to other dimension tables (in a snowflake).

Typically, in a well-modeled star or snowflake schema, the relationships between the fact table and the dimension tables will be many-to-one. If this information is encoded in your data warehouse, Tableau will automatically use this to set the relationship's Performance Options. If not, you can set this information yourself. For more information, see [Optimize Relationship Queries Using Performance Options](#).

In a well-modeled star or snowflake schema, every row in the fact table will have a matching entry in each of the dimension tables. If this is true and captured in your data warehouse integrity constraints, Tableau will automatically use this information to set the referential integrity setting in Performance Options. If some fact table rows do not have a matching row in a dimension table (sometimes called "late-arriving dimensions" or "early-arriving facts"), Tableau will default to retaining all rows when computing measures, but may drop values when showing dimension headers. For more information, see [Optimize Relationship Queries Using Performance Options](#).

### Star and snowflake with measures in more than one table

In some star or snowflake schemas, all the measures for your analysis are contained in the fact table. However, it is often true that additional measures of interest may be related to the dimension tables in your analysis. Even if the dimension tables do not contain measures, it is common in analysis to want to count or otherwise aggregate dimension values. In these cases, the distinction between fact tables and dimension tables is less clear. To create clarity when

viewing your data model, we recommended adding the finest grain table to the data source canvas first, and then relating all other tables to that first table.

If you were to join these tables together into a single logical table, the measures in the dimension tables would be replicated, resulting in distorted aggregates unless you took precautions to deduplicate the values using LOD calculations or COUNT DISTINCT. However, if you instead create relationships between these tables, Tableau will aggregate measures before performing joins, avoiding the problem of unnecessary duplication. This relieves you of the need to carefully track the level of detail of your measures.

### Multi-fact analysis

Tableau’s data modeling capabilities support some forms of multi-fact analysis. Additional fact tables (containing measures) can be added to any of the previously mentioned models as long as they only relate to a single dimension table. For example, you can bring two or more fact tables together to analyze a shared dimension, such as in Customer 360-like analyses. These fact tables can be at a different level of detail than the dimension table, or from each other. They can also have a many-to-many relationship with the dimension table. In these scenarios, Tableau will ensure that values are not replicated before aggregation.

If you don't have a shared dimension table that relates your fact tables, you can sometimes dynamically build one using custom SQL or by using joins or unions of other dimension tables.

Two fact tables can be related directly to each other on a common dimension. This type of analysis works best when one of the fact tables contains a superset of the common dimension.

### Unsupported models

- Multiple fact tables related to multiple shared dimension tables.** In some use cases it is common to have multiple fact tables related to multiple shared dimension tables. For example, you might have two fact tables, Store Sales and Internet Sales, related to two common dimension tables, Date and Customer. Typically, such scenarios would require creating a circular relationship in your data model. Circular relationships are not currently supported.

You can approximate this type of model by merging some of the tables in the physical layer. For example, you might be able to union Store Sales and Internet Sales into a single table, which can then be related to Date and Customer. Alternatively, you might be able to cross-join Date and Customer to create a single dimension table which can then be related to Store Sales and Internet Sales.

- **Directly relating 3 or more fact tables on shared dimensions.** While it is possible to build this model in the logical layer, you might see unwanted results, unless you only use dimensions from a single table.

### Requirements for relationships in a data model

- When relating tables, the fields that define the relationships must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- You can't define relationships based on geographic fields.
- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

### Factors that limit the benefits of using related tables

- Dirty data in tables (i.e. tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters will limit Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.
- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

### How Relationships Differ from Joins

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. You don't define join types for relationships, so you won't see a Venn diagram when you create them.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

- **No up-front join type.** You only need to select matching fields to define a relationship (**no join types**). Tableau first attempts to create the relationship based on existing key constraints and matching field names. You can then check to ensure they are the fields you want to use, or add more field pairs to better define how the tables should be related.
- **Automatic and context-aware.** Relationships defer joins to the time and context of analysis. Tableau automatically selects join types based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data. You can see aggregations at the level of detail of the fields in

your viz rather than having to think about the underlying joins. You don't need to use LOD expressions such as FIXED to deduplicate data in related tables.

- **Flexible.** Relationships can be many-to-many and support full outer joins. When you combine tables using relationships, it's like creating a custom, flexible data source for every viz, all in a single data source for the workbook. Because Tableau queries only tables that are needed based on fields and filters in a viz, you can build a data source that can be used for a variety of analytic flows.

For more information, see [Relate Your Data](#) and [Don't Be Scared of Relationships](#).

**Joins are still available as an option for combining your data.** Double-click a logical table to go to the join canvas. For more information, see [Where did joins go? on page 678](#)

**Watch a video:** For an introduction to using relationships in Tableau, see this 5-minute video.

**Note:** The interface for editing relationships shown in this video might differ slightly from the current release but has the same functionality.

For related information about how relationship queries work, see these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

## Characteristics of relationships and joins

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to.](#)

Here are some advantages to using relationships to combine tables:

- Make your data source easier to define, change, and reuse.
- Make it easier to analyze data across multiple tables at the correct level of detail (LOD).
- Do not require the use of LOD expressions or LOD calculations for analysis at different levels of detail.
- Only query data from tables with fields used in the current viz.

## Relationships

- Are displayed as flexible noodles between logical tables
- Require you to select matching fields between two logical tables
- Do not require you to select join types
- Make all row and column data from related tables potentially available in the data source
- Maintain each table's level of detail in the data source and during analysis
- Create independent domains at multiple levels of detail. Tables aren't merged together in the data source.
- During analysis, create the appropriate joins automatically, based on the fields in use.
- Do not duplicate aggregate values (when Performance Options are set to Many-to-Many)
- Keep unmatched measure values (when Performance Options are set to Some Records Match)

## Joins

Joins are a more static way to combine data. Joins must be defined between physical tables up front, before analysis, and can't be changed without impacting all sheets using that data source. Joined tables are always merged into a single table. As a result, sometimes joined data is missing unmatched values, or duplicates aggregated values.

- Are displayed with Venn diagram icons between physical tables
- Require you to select join types and join clauses
- Joined physical tables are merged into a single logical table with a fixed combination of data
- May drop unmatched measure values
- May duplicate aggregate values when fields are at different levels of detail
- Support scenarios that require a single table of data, such as extract filters and aggregation

## Requirements for using relationships

- When relating tables, the fields that define the relationships must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- You can't define relationships based on geographic fields.
- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

## Factors that limit the benefits of using related tables

- Dirty data in tables (i.e. tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters will limit Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.
- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

## Where did joins go?

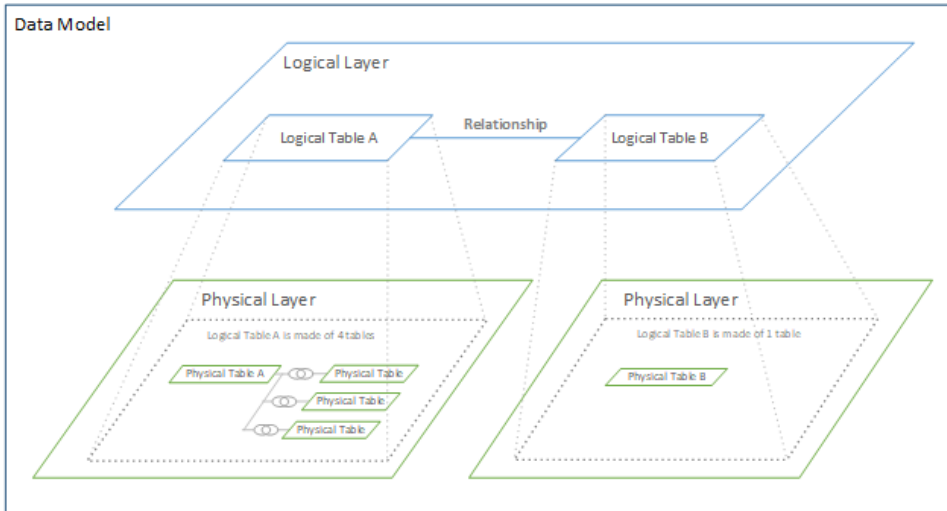

You can still specify joins between tables in the physical layer of a data source. Double-click a logical table to go to the Join/Union canvas in the physical layer and add joins or unions.

Every top-level, logical table contains at least one physical table. Open a logical table to view, edit, or create joins between its physical tables. Right-click a logical table, and then click **Open**. Or, just double-click the table to open it.

When you create a data source, it has two layers. The top-level layer is the logical layer of the data source. You combine data between tables in the logical layer using relationships.

The next layer is the physical layer of the data source. You combine data between tables at the physical layer using joins. For more information, see [Logical and physical tables in the data model](#).

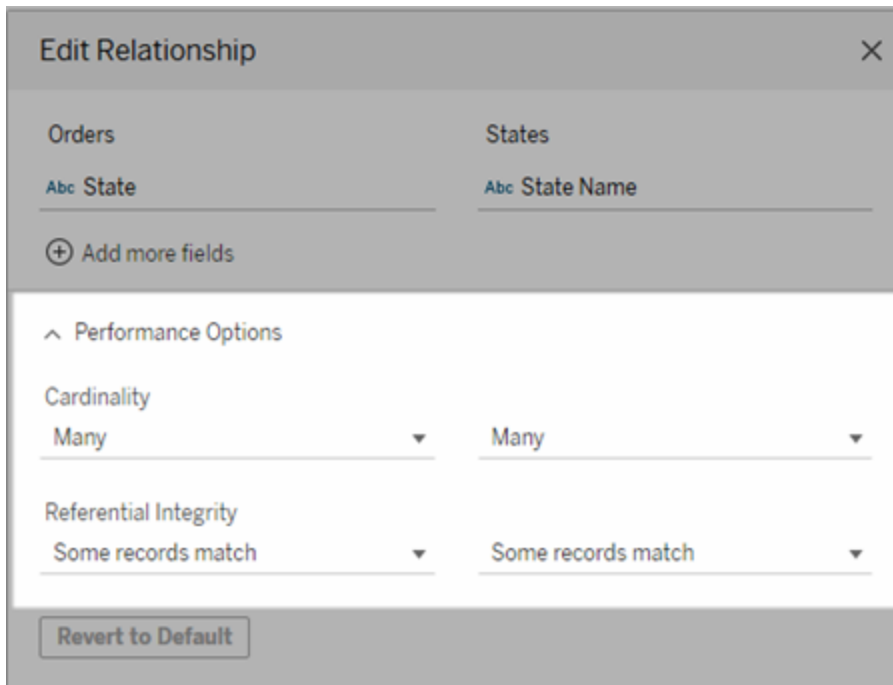

## Optimize Relationship Queries Using Performance Options

Performance Options are optional settings that define the cardinality (uniqueness) and referential integrity (matching records) between the two tables in a relationship. These settings help Tableau optimize queries during analysis.

- **If you aren't sure what to choose**, use the recommended default settings indicated by Tableau. Using the defaults is safe and will automatically generate correct aggregations and joins during analysis. If you don't know the cardinality or referential integrity, you don't need to change these settings.
- **If you know the shape of your data**, you can optionally change these settings to represent uniqueness and matching between the records in the two tables.

In many analytical scenarios, using the default settings for a relationship will give you all of the data you need for analysis. In some scenarios, you might want to adjust the Performance Options settings to describe your data more accurately. For more details about using relationships to combine and analyze data, see [Relate Your Data](#) and this Tableau blog post: [Relationships, part 1: Introducing new data modeling in Tableau](#).

## What the Cardinality and Referential Integrity settings mean

### Cardinality options

Cardinality settings determine if Tableau aggregates table data before or after automatically joining the data during analysis.

- Select **Many** if the field values aren't unique, or you don't know. Tableau will aggregate the relevant data before forming joins during analysis.
- Select **One** if field values are unique. During analysis, the relevant data will be joined before aggregation. Setting this option correctly optimizes queries in the workbook when the field values in the relationship are unique. However, selecting **One** when field values aren't unique can result in duplicate aggregate values being shown in the view.

**Note:** Selecting **One** treats records as if each key value is unique and there is at most only one row with a null value.

### Referential Integrity options

Referential Integrity settings determine the type of join used to get the dimension values for a measure during analysis.

- Select **Some Records Match** if some values in the field don't have a match in the other table, or you don't know. During analysis, Tableau uses outer joins to get dimensions values for a measure. All measure values will be shown in the view, even unmatched measures.
- Select **All Records Match** if values in the field are guaranteed to have a match in the other table. This setting generates fewer and simpler joins during analysis, and optimizes queries. You might see inconsistent results during analysis (unmatched values removed or missing in view) if there are unmatched values in this table.

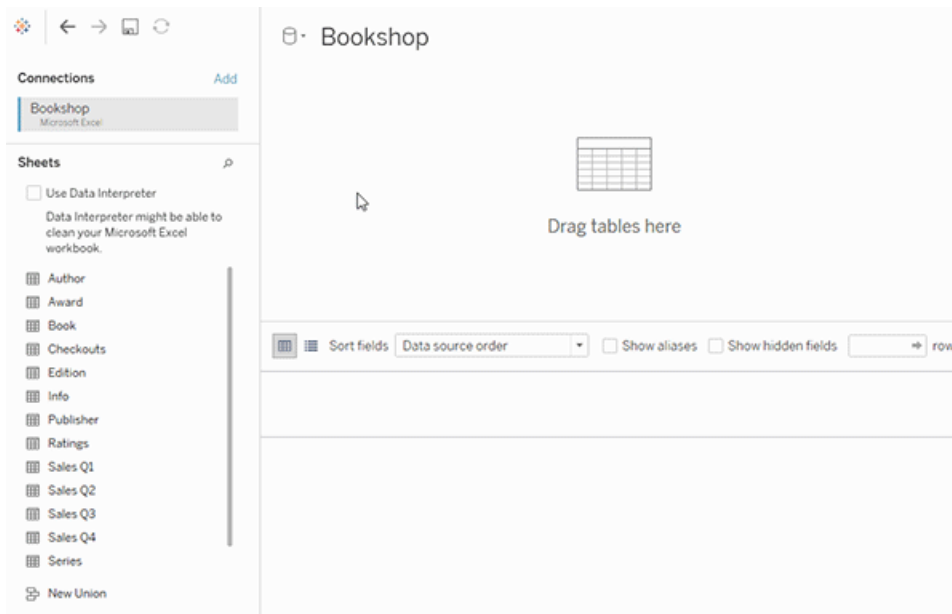

**Notes:** Selecting **All Records Match** treats records as if no null values exist in the fields used for the relationship. During analysis, Tableau will use inner joins to get dimension values for a measure. By default, Tableau will never join null keys.

For more information about Cardinality and Referential integrity as concepts, see [Cardinality and Referential Integrity](#).

### Where did joins go?

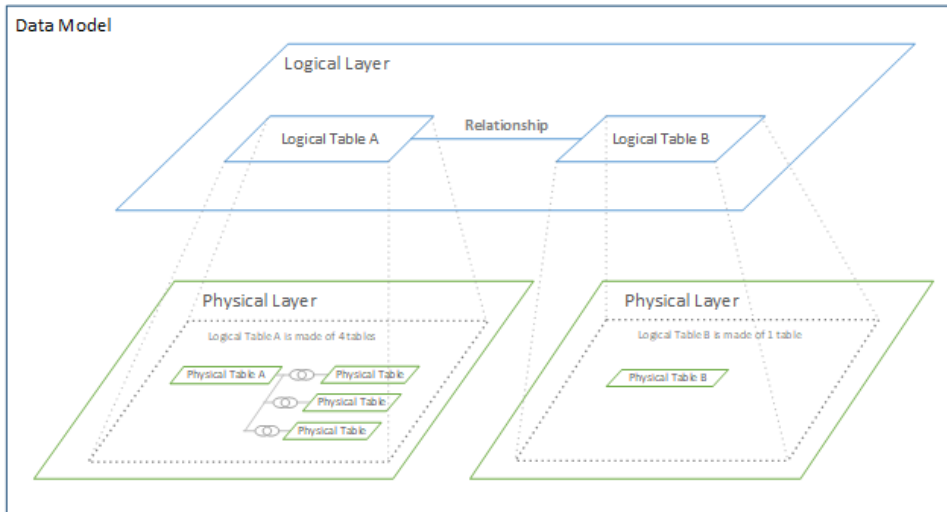

You can still specify joins between tables in the physical layer of a data source. Double-click a logical table to go to the join canvas.

Every top-level, logical table contains at least one physical table. Open a logical table to view, edit, or create joins between its physical tables. Right-click a logical table, and then click **Open**. Or, just double-click the table to open it.

When you create a data source, it has two layers. The top-level layer is the logical layer of the data source. You combine data between tables in the logical layer using relationships.

The next layer is the physical layer of the data source. You combine data between tables at the physical layer using joins. For more information, see [Logical and physical tables in the data model](#).

## Tips on using Performance Options

If you know the shape of your data, you can use the optional settings in Performance Options to establish the cardinality of the tables to each other (one-to-one, one-to-many, many-to-many) and indicate referential integrity (values from one table will always have match in the other table).

Instead of thinking of the settings in Performance Options as “yes” and “no”, think of them as “yes” and “I don’t know”. If you are sure that a table's values are unique, select **One**. If you are sure that each record in one table matches one or more records in the other table, select **All Records Match**. Otherwise, leave the default settings as they are.

If you aren't sure about the shape of your data, use the default settings. When Tableau can't detect these settings in your data, the default settings are:

- Cardinality: Many-to-Many
- Referential integrity: Some Records Match

If Tableau detects key relationships or referential integrity in your data, those settings will be used and indicated as "detected".

To reapply the default settings, click **Revert to Default**.

## Terms defined

*Cardinality* refers to the uniqueness of data contained in a field (column) or combination of fields. When the tables you want to analyze contain many rows of data, queries can be slow (and performance of the overall data source is affected) so we recommend choosing a method for combining data based on the cardinality of the related columns between tables.

- **Low cardinality:** When related columns have a lot of repeated data. For example, a table called Products might contain a Category column that contains three values: Furniture, Office Supplies, and Technology.
- **High cardinality:** When related columns have highly unique data. For example, a table called Orders might contain an Order ID column that contains a unique value for every order of product.

*Referential integrity* means that one table will always have a matching row in the other table. For example, a Sales table will always have a matching row in the Product Catalog table.

## Cardinality and Referential Integrity

Setting up a data source, no matter how you combine the data, requires understanding the data structure of each table and how they can be combined. There are several key elements that should be considered:

- **Level of detail:** how detailed the data is—its granularity. This can be thought of as answering the question “what defines a row?”. For more information on granularity, see [Structure Data for Analysis on page 604](#)
- **Shared field:** there must be at least one field that can be used to form the link between tables. For a join, these fields define the *join clause*. In related tables, they establish the *relationship*.
- **Cardinality:** how many or how few unique values there are for the shared field (uniqueness). For more information, see the next section.
- **Referential Integrity:** a value in one table is guaranteed to have a match in the other table. In other words, there can't be a record in one table that does not have a corresponding record in the other table. For more information, see below.

## Cardinality

*Cardinality* in a single column or field refers to how unique its values are. Low cardinality means there are only a few unique values (such as in a field for eye color). High cardinality means there are a lot of unique values (such as in a field for phone numbers).

Cardinality between tables is similar, but refers to whether a row from one table *could be* linked with more than one row in another table. (It's important to remember that cardinality does not address whether there is missing data in either table. The presence or absence of missing data is referential integrity. Although these concepts work together, they are two different attributes of the relationship.)

The options are one-to-one, one-to-many, many-to-one, or many-to-many.

### One-to-one

- *Definition:* Each value of the shared field in one table is related to **at most** one value in the shared field in the other table.
- *Abbreviation:* 1:1

*Example:* Every car has its own license plate and a license plate is specific to an individual car. Car-to-license is one-to-one.

Note that even if a car is unregistered or a license plate number hasn't yet been assigned to a car, that discrepancy is described by the referential integrity. A car can only have one license plate and a license plate can only be assigned to one car,

so the cardinality remains one-to-one.

**One-to-many or Many-to-one**

- *Definition:* Each value of the shared field in one table can be related to multiple rows the other table (that value is repeated in the other table).
- *Abbreviation:* m:1 or 1:m
- The order of the tables determines whether it is many-to-one or one-to-many (similar to left and right joins).

*Examples:* Many employees have the same manager. Employees-to-manager is many-to-one. Manager-to-employee is one-to-many.

**Many-to-many**

- Multiple values of the shared field in one table can be related to multiple

rows in the other table (values of the shared field can be repeated in multiple rows in either table).

- Abbreviated as m:m.
- This is the default setting if no other settings are detected in the data source.

*Examples:* An actor is in many movies and a movie has many actors. Actor-to-movie is many-to-many. Multiple books can be purchased in the same transaction and a book can be purchased multiple times. ISBN-to-OrderID is many-to-many.

Cardinality can be specified in the Performance Options settings. For more information, see [Optimize Relationship Queries Using Performance Options](#) on page 679.

## Referential Integrity

There's a related concept called referential integrity, which means a row in one table will always have a matching row in the other table, as determined by the value of their shared fields. If the database contains no records for cars without license plates or license plates without cars, that relationship has referential integrity.

In Tableau, referential integrity is configured on each side of the relationship. In the Performance Options settings, **Some records match** means there isn't (or you don't know if there

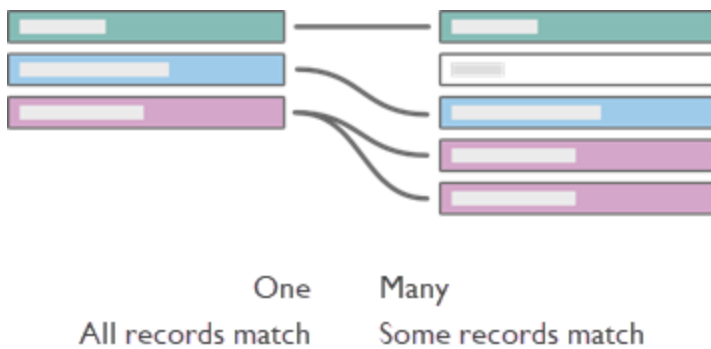

is) referential integrity. **All records match** means there is referential integrity. The default setting is to not assume referential integrity (Some records match).

For more information, see [Optimize Relationship Queries Using Performance Options](#) on page 679.

### Test yourself

Can you define the cardinality and referential integrity of each diagram? What does this mean in words?

Example:

If we set the left table as books and the right table as authors linked on AuthorID, translate the diagram into words:

- **One book can have multiple authors** (the purple records show one row in the book table on the left corresponding to multiple records in the author table on the right).
- **No authors have more than one book** (each author record on the right leads only one book record on the left).
- **There are no books without authors** (no records on the left fail to correspond to a record on the right).
- **Some authors may not have books** (the gray author record on the right has no corresponding book record on the left.)

*Click each section below to expand it.*

### Check your knowledge

Solution

An author can write multiple books; there may be authors without books. A book may have multiple authors; there may be books without authors.

Each book has exactly one author. Each author has written at most one book; there may be authors without books.

Every author has at least one book; there may be authors with multiple books. Each book has at most one author; there may be books without authors.

Every author has at least one book; there may be authors with multiple books. Each book has exactly one author.

Every author has exactly one book. Every book has at most one author; there may be books without authors.

### Why does it matter?

Correctly configuring the cardinality or referential integrity settings can boost performance through query optimization. Incorrect configurations, however, can lead to issues of aggregation due to loss or duplication of data. The default Performance Option settings are **Many** for cardinality and **Some records match** for referential integrity. These should only be adjusted if you are sure of the correct characteristics of your data.

For more information about how Tableau handles each setting, see [What the Cardinality and Referential Integrity settings mean](#) on page 680.

### An example in Tableau

Let's explore what happens when cardinality is configured improperly.

**Note:** The following example uses a subset of tables from [The Bookshop data set on page 189](#). You can [download the workbook](#) to follow along, or download the raw data to create the data sources yourself. The tables used are **Books**, **Info** and **Edition** from *Bookshop.xlsx* (keeping only some fields) and **LibraryProfile** and **Catalog** from *BookshopLibraries.xlsx*.

The Book and Info tables have a one-to-one relationship—Info is essentially additional columns for the Book table. Because of this, while they could be related, it makes sense to join them to create a new logical table that has all the columns. Edition has a many-to-one relationship with this combined table as there can be multiple editions for a single book, usually with different formats. (Note that the diagram below shows the relationship from the Book+Info table to Edition, so it is one-to-many.)

Edition is related to Catalog as a one-to-many relationship on ISBN. The Catalog and LibraryProfile tables are related many-to-many on Library ID. The key point is that the LibraryProfiles table has multiple rows per library, one for each staff type (Librarian, Library Assistant, Library Technician). For more information about the structure of these tables, see [The Bookshop data set on page 189](#).

## The right settings

When the Catalog-LibraryProfile relationship is set up correctly, we can make a simple viz that shows the number of staff for each library for several books. This is a silly viz to make, but it's useful to illustrate the point. Idle Hour Library has 130 staff regardless of which book we're talking about. There are three values for staff type, so each total is made up of three records—the number in parentheses.

Title	Bide Awhile	Idle Hour Library	IndieUnBound	Old Friend Libr..
Alanna Saves the Day	35 (3)	130 (3)	56 (3)	25 (3)
Banana Slug and the Glass Half Full	35 (3)	130 (3)	56 (3)	25 (3)
Banana Slug and the Lost Cow	35 (3)	130 (3)	56 (3)	25 (3)
Banana Slug and the Mossy Rock	35 (3)	130 (3)	56 (3)	25 (3)
Banana Slug and Xyr Friends	35 (3)	130 (3)	56 (3)	25 (3)
Heliotrope Pajamas	35 (3)	130 (3)	56 (3)	25 (3)

Staff count by library and title. (Numbers in parentheses indicate the number of records in each mark.)

### The wrong settings: one-to-one

When the relationship is erroneously set as one-to-one, in the viz each title from Catalog is effectively paired with only one record from the LibraryProfile table (as indicated by the record count in parentheses).

Title	Bide Awhile	Idle Hour Library	IndieUnBound	Old Friend Libr..
Alanna Saves the Day	6 (1)	16 (1)	2 (1)	3 (1)
Banana Slug and the Glass Half Full	6 (1)	16 (1)	2 (1)	3 (1)
Banana Slug and the Lost Cow	6 (1)	16 (1)	2 (1)	3 (1)
Banana Slug and the Mossy Rock	6 (1)	16 (1)	2 (1)	3 (1)
Banana Slug and Xyr Friends	6 (1)	16 (1)	2 (1)	3 (1)
Heliotrope Pajamas	6 (1)	16 (1)	2 (1)	3 (1)

Staff count by library and title. (Numbers in parentheses indicate the number of records in each mark.)

Above, we can see that each library only displays their minimum number of staff. (Refer to the bolded numbers in the viz below. The lowest number of staff is the number reflected in the Staff Count viz.)

Staff Type	Bide Awhile	Idle Hour Library	IndieUn..	Old Friend L..
Librarians	9	53	7	<b>3</b>
Library Assistants	<b>6</b>	<b>16</b>	47	17
Library Technicians	20	61	<b>2</b>	5
Grand Total	35	130	56	25

Staff breakdown by type and library.

For more information about how relationships become contextual joins for a viz, see [Introducing the new data modeling in Tableau](#) on the Tableau blog.

## The wrong setting: joining

While there are ways to work around this sort of issue—Level of Detail expressions being a common one—joining tables that have different granularity or “many” in their cardinality can cause duplication. Here, the staff counts are accurate for titles that only have one format, but for the books that have two formats in the Editions table, that doubling is passed along to the staff counts as well (note the record counts in parentheses that are 6 instead of the correct 3).

Title	Bide Awhile	Idle Hour Library	IndieUnBound	Old Friend Libr..
Alanna Saves the Day	35 (3)	130 (3)	56 (3)	25 (3)
Banana Slug and the Glass Half Full	35 (3)	260 (6)	56 (3)	25 (3)
Banana Slug and the Lost Cow	35 (3)	260 (6)	56 (3)	25 (3)
Banana Slug and the Mossy Rock	35 (3)	260 (6)	56 (3)	25 (3)
Banana Slug and Xyr Friends	35 (3)	260 (6)	56 (3)	25 (3)
Heliotrope Pajamas	35 (3)	260 (6)	112 (6)	25 (3)

Staff count by library and title. (Numbers in parentheses indicate the number of records in each mark.)

## The wrong setting: incorrectly assuming referential integrity

Telling Tableau there is referential integrity (all records match) when this isn't the case can cause dropped values. Here, these two vizzes are similar but the one on the right is from a data source configured to assume referential integrity. That viz has lost the nulls. While this can be fine in some circumstances, it's important to understand what those nulls represent. Here, where the viz shows the number of editions in each library, the nulls indicate two editions that are present in the edition table but aren't held by any library. This could be an important oversight, and it's one that incorrectly assuming referential integrity would overlook.

[Explore the workbook](#) and its data sources to see what other issues may arise from improperly combined tables.

## Performance impacts

If mis-configuring these settings can cause missing or duplicated data, why does Tableau allow them to be changed at all? In many cases, you can and should leave the default settings: relate tables instead of joining, leave the cardinality as many-to-many, and don't assume referential integrity. Especially if you're not sure what the settings should be.

However, cardinality and referential integrity are Performance Options because there can be performance implications to the defaults. If you're sure about the structure of your data, configuring the correct settings can reduce the query execution to improve the speed.

## Under the hood

**Note:** This section uses analogies to other data combination techniques to provide a conceptual framework only. It is not a technical description of how Tableau uses the performance settings for relationships.

### Cardinality

The cardinality of the relationship impacts when aggregation happens. This can be thought of in terms of blending. Data blending queries two data sources independently. Each data source is aggregated as necessary to the desired level of detail for the view regardless of the other data source. For relationships, the cardinality setting impacts whether the aggregation happens before or after the join.

In the example above, the Many setting means the number of staff for each library is aggregated before combining that data with the book information, thus ensuring every book has the correct numbers. When the cardinality was incorrectly set to One, the number of staff was not aggregated before it was combined with the book data, leading to incorrect values.

Note that not only are the incorrect values shown, all the values are assigned to the staff type Librarians, despite the fact they are taken from all three staff types. Misconfiguration of this setting can cause unpredictable and incorrect values. This filtering of results only happens when a field from another table on the other side of the incorrectly set relationship is used in the view.

Staff Counts m:m				
Staff Type	Bide Awhile	Idle Hour		Old Friend Library
		Library	IndieUnBound	
Librarians	9	53	7	3
Library Assistants	6	16	47	17
Library Technicians	20	61	2	5

Staff Counts 1:1 (multi table)				
Staff Type	Bide Awhile	Idle Hour		Old Friend Library
		Library	IndieUnBound	
Librarians	6	16	2	3
Library Assistants				
Library Technicians				

Staff Counts 1:1 (single table)				
Staff Type	Bide Awhile	Idle Hour		Old Friend Library
		Library	IndieUnBound	
Librarians	9	53	7	3
Library Assistants	6	16	47	17
Library Technicians	20	61	2	5

If the values are unique, however, Tableau is free to remove the pre-join aggregation if it optimizes the query.

### Referential Integrity

Although referential integrity refers to a setting for relationships, it can be thought of in terms of join types. A full outer join will retain all records, regardless of whether or not there is a match in the other table, but at a performance cost. If you're not sure if records would be lost, an outer join is safer. This is how tables are treated when there may not be referential integrity (Some records match).

An inner join will retain only those records where there is a match from both tables, dropping records that do not appear in each table. If you know an inner join won't eliminate necessary data, it is more efficient. If the Performance Options are set to All records match, referential integrity is assumed and joins are performed without considering unmatched values.

An incorrect referential integrity setting can have a filter-like effect on the combined data, removing unmatched values. For more information on the power of retaining unmatched

records, see [Asking questions across multiple related tables](#) on the Tableau blog. For more information on join types, see [Join Your Data](#) on page 738.

## Keep the defaults

If your analysis has acceptable performance, we strongly encourage leaving the default Performance Option settings of many-to-many and not assuming referential integrity. The power of relationships comes from their ability to provide accurate, contextually appropriate results based on the tables that are used in the analysis. Changing these settings removes the [semantic flexibility of relationships](#).

## How Analysis Works for Multi-table Data Sources that Use Relationships

Using a data source that has multiple, related tables affects how analysis works in Tableau. Because multiple, related tables have independent domains and retain their native level of detail, when you drag fields into the view:

- Data is queried at its natural level of detail.
- Only data that is relevant to a viz is queried.
- The relationships between the tables affect the results of the query. The flow of building a viz can vary depending on how tables of fields are related to each other in the data model, or if they aren't related directly.

For an overview of data source enhancements and an introduction to using relationships, see this 5-minute video.

**Note:** The interface for editing relationships shown in this video and in this topic differs slightly from the current release but has the same functionality.

Learn more about how relationships work in [Don't Be Scared of Relationships](#) on page 715 and these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

**Note:** You can still create single-table data sources in Tableau. You can build a logical table using a combination of joins, unions, custom SQL, and so on. The behavior of single-table analysis in Tableau has not changed. Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau pre-2020.2.

## Considerations for analysis

### Validating relationships

You have several options for validating your data model for analysis. As you create the model for your data source, we recommend going to a sheet, selecting that data source, and then building a viz to explore record counts, expected data, unmatched values, nulls, or repeated measure values. Try working with fields across different tables to ensure everything looks how you expect it to.

What to look for:

- Are your relationships in the data model using the correct matching fields for their tables?
- Would adding multiple matching field pairs make the relationship more accurate?
- What are the results of dragging different dimensions and measures into the view?
- Are you seeing the expected number of rows?
- If you changed any of the [Performance Options settings](#) from the default settings, are the values that you are seeing in the viz what you would expect? If they aren't, you might want to check the settings, or reset to the default.

Options for validating relationships and the data model:

- Every table includes a count of its records, as a field named *TableName(Count)*, at the level of detail for that table. To see the count for a table, drag its Count field into the view. To see the count for all tables, select the Count field for each table in the Data pane, and then click the Text Table in Show Me.
- Click **View Data** in the Data pane to see the number of rows and data per table. Also, before you start creating relationships, viewing the data from the data source before or during analysis can be useful to give you a sense of the scope of each table. For more information, see [View Underlying Data on page 2610](#).
- Drag dimensions onto rows to see the Number of Rows in the status bar. To see unmatched values, click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**. You can also drag different measures to the

view, such as *<YourTable>(Count)* from one of the tables represented in your viz. This ensures that you will see all values of the dimensions from that table.

**Tip:** If you would like to see the queries that are being generated for relationships, you can use the Performance Recorder in Tableau Desktop.

1. Click the Help menu, and then select **Settings and Performance > Start Performance Recording**.
2. Drag fields into the view to build your viz.
3. Click the Help menu, and then select **Settings and Performance > Stop Performance Recording**. The Performance Recording workbook will automatically open.
4. In the Performance Summary dashboard, under Events Sorted By Time, click an "Executing Query" bar and view the query below.

Another more advanced option is to use the [Tableau Log Viewer](#) on GitHub. You can filter on a specific keyword using `end-protocol.query`. For more information, start with the [Tableau Log Viewer wiki page](#) in GitHub.

## Dimension-only visualizations

When using a multi-table data source with related tables: If you build a dimension-only viz, Tableau uses inner joins and you won't see the full unmatched domain.

To see partial combinations of dimension values, you can:

- Use Show Empty Rows/Columns to see all of the possible rows. Click the **Analysis** menu, and then select **Table Layout > Show Empty Rows** or **Show Empty Columns**. Be aware that this setting will also trigger densification for Date and Numeric Bin fields, which may be unwanted.
- Add a measure to the view, such as *<YourTable>(Count)* from one of the tables represented in your viz. This ensures that you will see all values of the dimensions from that table.

For more information, also see [Unmatched values behavior for dimensions that might surprise you on page 649](#) and [Troubleshooting multi-table analysis on page 710](#).

## When to use LOD calculations and expressions

Because Tableau understands the level of detail (LOD) of your input tables, you shouldn't need to use LOD calcs to remove unwanted duplication due to joins.

You may still want to use LOD calcs to:

- Handle unwanted duplication in your source tables.
- Compute multi-level aggregations (e.g. an average over a sum)
- To do cohort analysis (e.g. to compute the first order date for each customer)

If the dimensionality of an LOD calc includes fields from a single table, that LOD calculation will appear in its owning table in the Data pane.

## Examples of multi-table analysis

The following set of examples show how data might be queried across multiple, related tables. This multi-table data source contains a short list of actors' appearances in different movie roles.

A row in the Appearances table means that an Actor played a particular Character in a specific Movie. In this data set, an Actor can have zero or more Appearances.

Learn more about how relationships work in these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)

### Example 1: Analysis of a single question in joined data versus related data

When you connected to data in Tableau before 2020.2, your data source could consist of a single table, or multiple tables that were joined or unioned together into a single, denormalized table. Starting with Tableau 2020.2, Tableau recognizes and preserves normalized data for multi-table data sources, where the table data remains separate, and each table maintains its native level of detail. The following examples show how analysis differs between single table and multi-table data sources.

This example shows three tables of movie data: Appearances, Actors, and Movies.

Movie	Character	Actor
The Fellowship of the Ring	Gimli	John Rhys-Davies
The Return of the King	Gimli	John Rhys-Davies
The Return of the King	Treebeard	John Rhys-Davies
The Two Towers	Gimli	John Rhys-Davies
The Two Towers	Treebeard	John Rhys-Davies
Casino Royale	James Bond	Peter Sellers
Dr. Strangelove	Dr. Strangelove	Peter Sellers
Dr. Strangelove	Group Captain Mandr...	Peter Sellers
Dr. Strangelove	President Muffiey	Peter Sellers
From Russia With Love	James Bond	Sean Connery
The Hunt for the Red October	Marko Ramius	Sean Connery

Actor	Height (cm)
John Rhys-Davies	185
Peter Sellers	173
Sean Connery	189
Jodie Foster	161

Movie	World Premiere	Gross (USD millions)
The Fellowship of the Ring	12/19/2001	869
The Return of the King	12/18/2002	1,119
The Two Towers	12/17/2003	923
Casino Royale	4/13/1967	22
Dr. Strangelove	1/29/1964	94
From Russia With Love	5/27/1964	24
The Hunt for the Red October	3/2/1990	200
Casablanca	11/26/1942	4

These tables can be joined together, joining the Appearances table with the Actors table on Actor = Actor and the Appearances table with the Movies table on Movie = Movie. If the joins are

full outer joins so no rows are lost, the final output looks like this. Note that fields that are used in the join clauses appear twice.

Actor (Actors)	Height (cm)	Movie	Character	Actor	Movie (Movies)	World Premiere	Gross (USD millio...
John Rhys-Davies	185	The Fellowship of the Ring	Gimli	John Rhys-Davies	The Fellowship of the Ring	12/19/2001	869
John Rhys-Davies	185	The Return of the King	Gimli	John Rhys-Davies	The Return of the King	12/18/2002	1,119
John Rhys-Davies	185	The Return of the King	Treebeard	John Rhys-Davies	The Return of the King	12/18/2002	1,119
John Rhys-Davies	185	The Two Towers	Gimli	John Rhys-Davies	The Two Towers	12/17/2003	923
John Rhys-Davies	185	The Two Towers	Treebeard	John Rhys-Davies	The Two Towers	12/17/2003	923
Peter Sellers	173	Casino Royale	James Bond	Peter Sellers	Casino Royale	4/13/1967	22
Peter Sellers	173	Dr. Strangelove	Dr. Strangelove	Peter Sellers	Dr. Strangelove	1/29/1964	94
Peter Sellers	173	Dr. Strangelove	Group Captain Mandr...	Peter Sellers	Dr. Strangelove	1/29/1964	94
Peter Sellers	173	Dr. Strangelove	President Muffley	Peter Sellers	Dr. Strangelove	1/29/1964	94
Sean Connery	189	From Russia With Love	James Bond	Sean Connery	From Russia With Love	5/27/1964	24
Sean Connery	189	The Hunt for the Red October	Mario Ramius	Sean Connery	The Hunt for the Red October	3/2/1990	200
Jodie Foster	161	null	null	null	null	null	null
null	null	null	null	null	Casablanca	11/26/1942	4

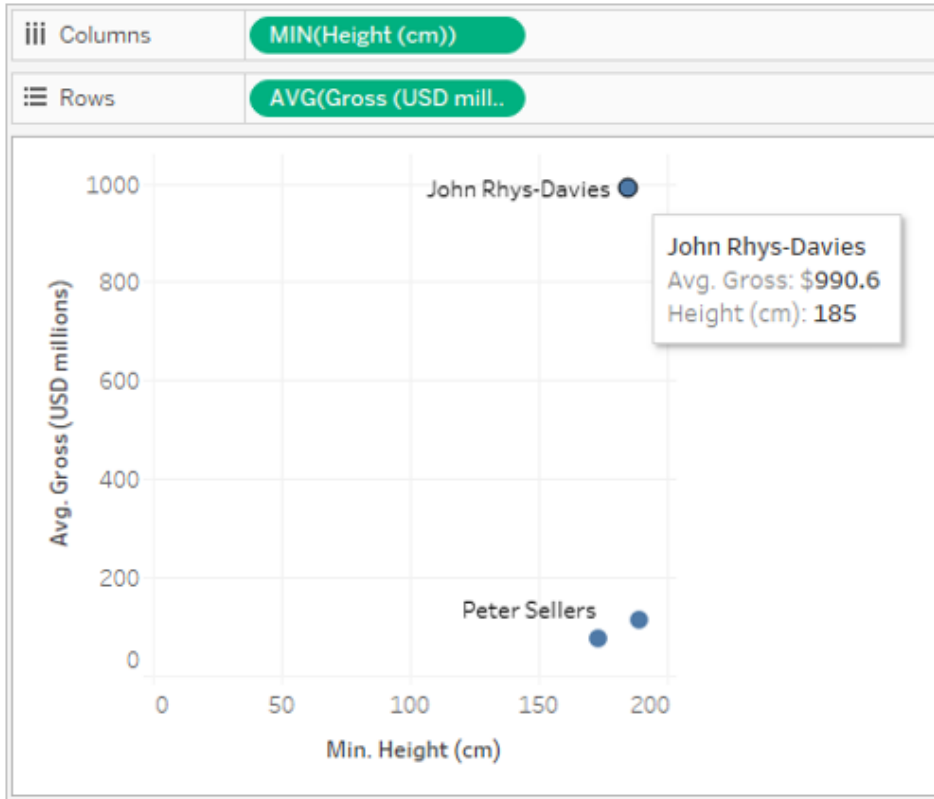

Data that is brought together into a single table in this way is called denormalized or flattened.

This joined data is flattened data. Each row consists of an actor’s appearance as a character in a movie (so John Rhys-Davies has two rows for The Return of the King because he played two characters); therefore the granularity of the data is at the level of a character in a movie. Information that is relevant in multiple rows is duplicated. The Return of the King’s premiere date is present twice because there are two characters from that movie in the data set. John Rhys-Davies’ height is listed five times because there are 5 unique combinations of character/movie for him as an actor.

This flattened data therefore has some characteristics to be aware of. For example, if you wanted to plot actor height by the average gross of their movies, you might assume we could bring out Height to columns and Gross to Rows, then take the average of the Gross. But if you do that the default view doesn’t seem right. Here John Rhys-Davies is supposed to be 925cm tall, which is over 30 feet!

This is because the default aggregation is SUM. There are 5 rows in the data for him, so we get his true height of 185cm five times. You could fix this by changing the aggregation on Height, say to average or minimum. This effectively returns the value for only one row (since they are all the same).

When you change the aggregation the heights are much more realistic. But now you need to pay attention to average gross. Remember that Tableau considers all five rows for John Rhys-Davies' height. When you think about the average gross for the movies he was in, it shouldn't be the average of five rows, but rather the average of three movies. You don't want to count the gross for Return of the King twice just because he played two characters in it. But is that what is happening?

Doing some quick math, the Lord of the Rings movies should have an average of  $(869 + 923 + 1119)/3$ , or \$970.3. However, the value in the scatterplot is \$990.6. The current average is from the five rows  $(869 + 923 + 923 + 1119 + 1119)/5$ .

This isn't as easy to fix as the height issue with changing the aggregation. You need to use a **Level of Detail (LOD) expression** to alter which level of detail Tableau looks at, going from the default—Appearance—up to the level of Movie. You could create a calculation for LOD Gross as `{FIXED [Movie] : MIN([Gross (USD millions)])}` and then take the average of that new LOD Gross field for our view.

The LOD expression can be read as “for each movie, return its minimum Gross”. This removes the duplication problem because the gross is always returned per movie, even though the view is constructed with movie and actor.

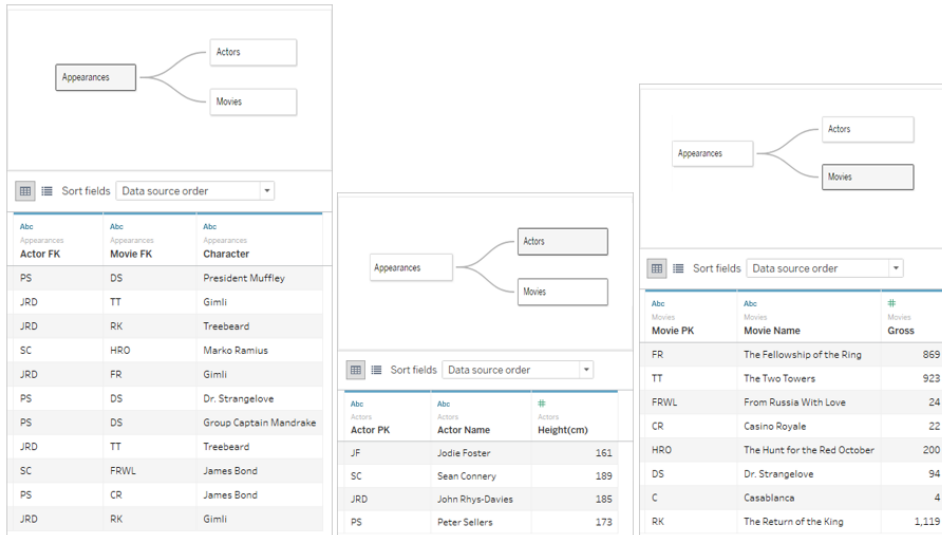

Now the numbers are correct. John Rhys-Davies is 185cm tall, and the average gross for his movies in this data set is 970.3. You would need to understand how data was being replicated and how Tableau aggregated the data to display it before you could ensure the correct values were returned.

## Normalized data in multiple tables

Creating relationships between logical tables may seem similar to creating joins, but instead of flattening the data into a single table, with all the replications that can entail, Tableau stays aware of the relationships between the tables. Information is brought out of each table at the appropriate level of detail and related to other data.

On the **Data Source** page, you won't see the "full" grid view of the flattened table. It doesn't exist. Tableau keeps all three tables as they are and merely establishes the relationships, pulling together the required data as needed by the view.

## Tableau Desktop and Web Authoring Help

To create the same scatterplot, drag Height and Gross into the view, and set Gross to average. That's it! Tableau looks at the way each table's data is related to data from other related tables and infers how the height should be displayed (by actor) and how the average gross should be computed (by movie).

### Example 2: Dimension from a single table

If the dimensions in your visualization come from a single table, Tableau queries just the one table and shows results for the entire domain. You can add measures and still see the entire domain.

For example, using the Movie Appearances data source introduced above, adding the Actor field to a visualization results in the following visualization:

Columns	
Rows	
Actor (Actor)	
Bennidict Cumberbatch	Abc
Chris Hemsworth	Abc
Ian McKellen	Abc
John Rhys-Davies	Abc
Robert Downey Jr	Abc
Scarlett Johansson	Abc
Sigourney Weaver	Abc

Because the only dimension in the viz came from the Actors table, Tableau will run a query against just the Actors table. All actors that appear in the Actors table are displayed in the viz, regardless of whether they have any Appearances.

Bringing the Appearance Actor field into the view as a measure, and then applying a COUNT aggregation creates a view that shows the number of appearances by actors. Notice that Sigourney Weaver does not have any appearances, but her name is still in the view.

### Example 3: Dimensions from multiple tables

If the dimensions in the view are from multiple tables, Tableau finds the table that relates all the dimensions and shows the domain from that table. As a result, some dimension values that you saw in Example 1 change.

For example, dragging a field from the Movies table into the viz changes the query. Because the Movies and Actors tables are related by the Appearances table, the query returns only the Actor/Movie pairs that exist in the Appearances table.

Because Sigourney Weaver does not have any Appearances in this data set (and, thus, is not related to any of the Movies in the data set), the viz of Actor/Movie pairs does not show her:

Columns		
Rows		
Actor (Actor)	Movie (Movie)	
<b>Bennidict Cumberbatch</b>	Avengers Infinity War	Abc
	Dr Strange	Abc
	Sherlock	Abc
	Thor Ragnarok	Abc
<b>Chris Hemsworth</b>	Avengers Age of Ultron	Abc
	Avengers Infinity War	Abc
	Dr Strange	Abc
	The Avengers	Abc
<b>Ian McKellen</b>	Thor Ragnarok	Abc
	Fellowship of the Ring	Abc
	Return of the King	Abc
<b>John Rhys-Davies</b>	The Two Towers	Abc
	Fantastic Four Animated ..	Abc
	Fellowship of the Ring	Abc
	Return of the King	Abc
<b>Robert Downey Jr</b>	The Incredible Hulk Anima..	Abc
	The Two Towers	Abc
	Avengers Age of Ultron	Abc
	Avengers Infinity War	Abc
<b>Scarlett Johansson</b>	Sherlock Holmes	Abc
	The Avengers	Abc
	Avengers Age of Ultron	Abc
<b>Scarlett Johansson</b>	Avengers Infinity War	Abc
	The Avengers	Abc
	Avengers Age of Ultron	Abc

#### Example 4: Measures that can't be split by a dimension

If a measure can't be split by a dimension, Tableau replicates the measure across that dimension.

The next visualization shows the total amount grossed by Movie. Since both fields come from the Movies table, Tableau will query only the Movies table.

The Movies table includes the already aggregated Gross receipts for each movie, as shown in the following visualization (the gross for Infinity War was not available at the time this data set was created and is shown as zero).

If you add Actor to this visualization, Tableau knows that it cannot break down the Movie Gross receipts by Actor, since this more granular information is not available in the data model. Instead, Tableau shows the Movie Gross receipts for each movie, replicated across actors.

**Example 5: Dimension that isn't hierarchically related to a measure**

Removing the Movie dimension from the previous visualization queries the sum of the Movie Gross measure for each Actor. The result is the aggregated Movie Gross for every movie the actor appeared in.

In this case there isn't a hierarchical relationship between the dimension, Actor, and the measure, Movie Gross—multiple actors may have appeared in the same movie. For example, Benedict Cumberbatch and Chris Hemsworth both appeared in Dr. Strange. In this case, Tableau includes the Movie Gross for Dr. Strange in both actors' totals.

Because the same Movie Gross value is included in multiple actors' totals, Tableau won't directly sum over these values.

However, when totals are shown for this visualization, note that Tableau correctly computes the total Movie Gross without including duplicate movies.

### Troubleshooting multi-table analysis

The following situations are possible with multi-table, related tables. This table describes known scenarios and high-level descriptions for how to troubleshoot your analysis.

<b>Analysis Situation</b>	<b>Description</b>
Inner join for dimension-only vizs	<p>You may not immediately see all of the values you were expecting when you add multiple dimensions to the same view. Or, you might notice that adding a new dimension to the viz from a different table causes some values to disappear from the viz.</p> <p>Tableau will use queries that preserve the combination of values that actually exist in the data. This means that you will see rows that would be produced by an inner join of the tables providing dimensions to the viz.</p> <p>If you want to see partial combinations of the dimension values, you can either turn on Show Empty Rows/Columns to see all of the possible rows, or you can add a measure, such as <code>&lt;MyTable&gt;(Count)</code>, from one of the tables represented in the view to ensure you see all values of the dimensions from that table.</p>
Constants in calculations	<p>In a multi-table datasource, constant values behave as though they come from their own table with a single row. If you aggregate a constant value, it will behave as though the aggregate was on a single row. <code>Sum(10)</code> will always equal 10. <code>Avg(10)</code> will also always equal 10. <code>Count(10)</code> will always equal 1.</p> <p>To ensure backwards compatibility, constant values on a single-logical table data source will behave as though the constant value is replicated for each value in the table.</p> <p>Constants in row level calculations do not change the row level of detail of the calculation. The calculation <code>[Sales] + 10</code> will behave as though it came from the same table as the <code>[Sales]</code> field.</p>
Forcing outer join	<p>Tableau ensures that all measure values are represented in the viz (along with all combinations of dimen-</p>

Analysis Situation	Description
I'm not seeing the measure values I would expect from a cross-table calculation	<p>sion values that actually occur in the data) so if you want to ensure you are seeing all of the possible values in your data including "unmatched nulls" you can do so by bringing measures into the view from each table in the worksheet.</p> <p>The domain of a calculation is the inner join of its inputs. If there are not matching values from all of the inputs of the measure calculation they will not be included in the measure calculation.</p> <p>Consider using an LOD calculation to move the measure values to the same object before creating the row-level calculation.</p>
Calculation to switch between fields from different logical tables gives unexpected results	<p>If you have a calculation that switches between row level fields, either using a case statement, if statement, or a function like "IFNULL", you may see unexpected results, because this calculation is being computed for every row, where row is the inner join between the inputs of the calculation.</p> <p>A better approach is to switch between Aggregated values, rather than trying to switch within the row level calculation. This will also produce better performance in single table scenarios.</p> <p>Alternately, this is only an issue for calculations that span between tables, so using LOD calculations to bring all of the fields to the same table will work as well.</p> <p>Don't do this:</p> <pre data-bbox="691 1625 1365 1696">SUM( IF [Parameter] == "Foo" THEN [Field 1] ELSE [Field 2] END )</pre> <p>Do this:</p>

Analysis Situation	Description
Unexpected unmatched nulls	<pre>IF [Parameter] == "Foo" THEN SUM([Field 1]) ELSE SUM([Field 2]) END</pre> <p>You may see measure values associated with a null dimension value that you didn't expect. This can possibly be a sign that the relationships in the data source were incorrectly configured. It may also indicate that there are actually unmatched values from the table that contains the measure, that have no corresponding row in the dimension table.</p> <p>In the past, this data might have been lost if the wrong join type was selected. When you use relationships, these unmatched values are preserved. If you don't want to see the unmatched values, you can exclude them using a filter.</p>
Incorrect aggregate values	<p>Are you using relationships or joins? With relationships, aggregates are computed correctly by default. When using joins, you may need to write LOD calcs to deduplicate values.</p> <p>Have you incorrectly set Performance Options on relationships? Try resetting the Performance Options to the default and see if that produces the correct aggregations.</p>
Dimensions replicate measure values rather than partitioning them.	Check that the fields used to define relationships are correct.
Dimension filters don't subset measures.	
Tableau is generating too many queries or queries with many left joins	Check the logs or performance recording to see how many queries are generated and how many left joins are used. With the new data modeling capabilities, Tableau

Analysis Situation	Description
Queries have many sub-queries	<p>generates queries with left joins and/or additional queries to make sure that unmatched measure values are always included in the visualization. If you don't need to see the unmatched values, use filters to remove the unmatched (NULL) values from your visualization. This should result in fewer queries.</p> <p>If you know that your data doesn't have any unmatched values, you can set the Referential Integrity setting for each relationship to "All Values Match" in Performance Options. This will also result in fewer queries.</p> <p>You can also reduce the complexity of your visualization to reduce the number of queries generated. Removing measures and hiding Filter controls are key ways to simplify queries multi-table, related data.</p> <p>Check the logs or performance recording to see the complexity of the queries Tableau generates.</p>
I was using joins to filter data	<p>Tableau automatically generates subqueries to deduplicate data, when necessary, to generate correct aggregates. This is similar to queries generated by LOD calculations.</p> <p>If you know the relationships between the logical tables in your data have many-to-one or one-to-one cardinality, then you can set this cardinality information in the relationship Performance Options. This will allow Tableau to eliminate unnecessary subqueries since it will know that no duplication can happen.</p> <p>In 2020.2, Tableau will work hard to recover unmatched values. Sometimes that means it will use a left join where you might have specified an inner join to intentionally filter out data.</p>

**Analysis Situation**

**Description**

If you filter out the unmatched values that are brought in by this join, Tableau will be able to optimize the query back to an inner join.

Depending on your specific scenario, it might make sense to model this inner join as a physical join within a logical table. This is especially powerful if a table containing measures is being used to filter a dimension table, as it will not introduce additional measure replication.

## Don't Be Scared of Relationships

The new data modeling capabilities create flexible data sources built around relationships.

Relationships combine data from different tables by looking at what columns (fields) those tables have in common and using that information to bring information from each table together in the analysis.

Unlike joins or unions, relationships form a data source without flattening multiple tables into a single table. Because of this, related data sources know which table each field is from. That means each field keeps its context, or level of detail. Related data sources can therefore handle tables with different granularity without issues of duplication or data loss.

In a related data source, the joins aren't fixed up front. Instead of merging all the data (and having to work with all the data regardless of what each viz requires), only the relevant data is combined—per sheet and as necessary. As you drag and drop, Tableau evaluates the relationships of the relevant fields and tables. Those relationships are used to write queries with the correct join types, aggregations, and null handling.

You can think about how the data fits together and what questions you want to answer, rather than how to combine the data or compensate for artifacts from the data source.

Relationships don't replace the previous ways of combining data: joins, unions, and blends. Rather, relationships are the new, flexible way to bring data together from multiple sources. The existing methods aren't going away, and are still useful in specific scenarios.

**Note:** For related information on how relationship queries work, see these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

## Use Relationships

This topic walks through building a related data source and using one for analysis. If you would like to follow along, you can [download the Bookshop data set](#). Choose Bookshop.xlsx for the raw data to start from scratch, or MinimalBookshop.tdsx to start with the related data source basics configured for you.

**Note:** Relationships are available in Tableau 2020.2 and later.

## Video: Migrated Data

If you open an existing workbook from a previous version of Tableau (version 2020.1 or earlier) in Tableau 2020.2 or later, your data source tab might show a **Migrated Data** table.

There are multiple videos embedded in this topic. For your convenience, a transcript is provided in the expandable section underneath each video.

## Migrated Data video transcript

If you open a workbook created before relationships were available (before version 2020.2), your data source may look different. If there were joined or unioned tables, they appear as a single logical table named Migrated Data. Double click to see the underlying tables—they're still there, and your analysis will still behave as expected.

Note that when you're only using the Migrated Data table, the Data pane behaves more like previous versions of Tableau Desktop.

You can even relate new tables to the directly to the Migrated Data table to extend the data model.

Once you've added relationships to the data model, the Data pane updates to the new layout, with dimensions and measures maintained within each table, and the Migrated Data table is displayed as a single, merged table.

## Video: Relate tables

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

## Relate tables video transcript

To build a data source of related tables, connect to your data and drag a table to the canvas. Drag out a second table. A relationship will automatically form if it can. If Tableau cannot detect the related fields, you will be prompted to select them yourself.

The canvas you're seeing is a new layer of the data model where you can relate tables together. Dragging out additional tables adds them to the data model. The noodle shows which tables are related.

Relationships can be based on calculated fields. You can also specify how fields should be compared by using operators when you define the relationship.

## Add joins

You can create a join by double clicking on a table to open the join canvas (also referred to as the physical layer), and then dragging out a table to create a join. Creating joins is the same experience as previous versions of Tableau—you can set a join clause, including a calculation if necessary, and configure the join type.

Once you close the join canvas, the table on the relationship canvas (also referred to as the logical layer) has a join icon to indicate the underlying join. This is because a join merges its tables together to form a single, new table. Related tables remain distinct.

## Add unions

Add unions by dragging out New Union. Unions, like joins, actually merge the data, and show an icon on the logical layer. We recommend always renaming unions—or any tables with unclear names—to something more useful.

## Video: Performance Options

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

## Performance Options video transcript

For any relationship, there are performance options as well as related fields. Tableau automatically chooses safe defaults for these options. However, if you are sure of the characteristics of your data, changing these options can give Tableau more information about how to best configure automatic joins during analysis. Setting the cardinality and referential integrity options gives Tableau more information about how to optimize queries.

### Cardinality

Cardinality indicates whether or not the linking field records are unique. If multiple books can have the same author, but each author is listed only once in the author table, the cardinality for AuthID would be Many for Books and One for Author between those two tables. This setting impacts how Tableau handles aggregation before or after the join.

### Referential integrity

Referential integrity indicates whether or not a record in one table is guaranteed to have a relationship in another table. If every book has an author, Book has referential integrity to Author. If not every author has a book, Author does not have referential integrity to Book. This setting impacts how Tableau chooses a join type and handles unmatched records.

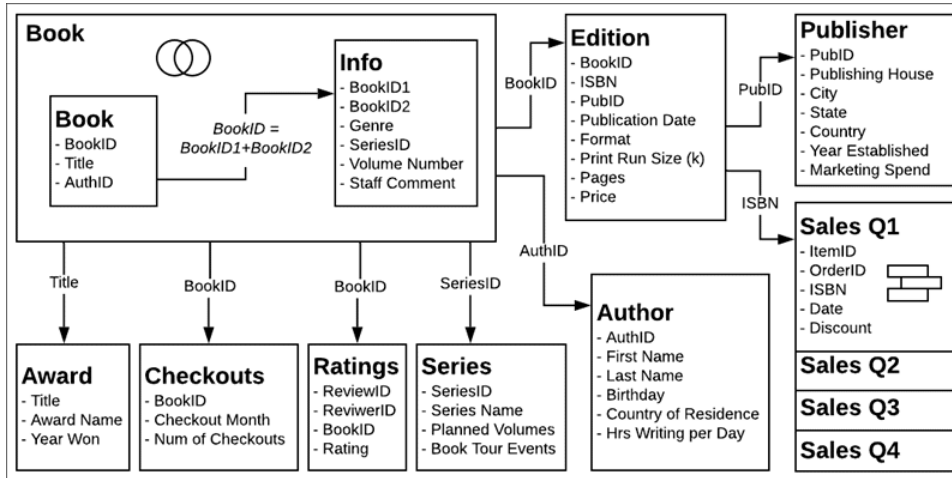

For more information, see [Cardinality and Referential Integrity](#) on page 683.

### Example: Bookshop Data

We'll do some analysis with this data source in a moment, so let's talk about the data.

The data set is around (fictitious) books, and it's important to consider the distinction between a book and an edition. A book is the conceptual work itself, with attributes such as the title, author, and genre. There are also editions of a book, with attributes such as a price and format (hardcover or paperback), that are identified with an ISBN. An edition of a book has a publisher and a page count, whereas a book may have won an award or be in a series.

You can follow along by downloading [MinimalBookshop.tdsx](#), or be adventurous and build the model yourself from [Bookshop.xlsx](#). Note that you can hide many of the ID fields once the tables are combined.

Video: Work with multiple tables

**Note:** The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

## Work with multiple tables video transcript

### The Data Source page

Before we go to a sheet tab, notice that the data grid view, below, shows only the fields from one table at a time. If we click to another table, we'll see the data it contains. There is no overall view because related data is not brought together until it's used in an analysis. For now, the data remains in each table and is therefore displayed by table.

If we click on a table with an underlying join or union, we do see that merged data, with any nulls that may involve.

## The Data pane

When we click onto a sheet, you may notice that the Data pane looks different than in previous versions of Tableau. Instead of the primary organization of dimensions and measures, it's now focused on tables. Each table has its own breakdown for dimensions and measures, indicated by this line. It's possible to still group by folders instead, if you choose.

## Number of Records and Count

There is also no **Number of Records** field. This is because the concept of Number of Records has changed. There isn't a single Number of Records for the data source. Each table has a **Count** field, which can be thought of as a local Number of Records for that table.

To get a sense of the number of records for multiple tables at the same time, you can use Measure Names and Measure Values or multi-select the count fields and use Show Me to create a viz.

Video: Basic calculations

## Basic calculations video transcript

There are a few calculations we can do to make this data set a bit friendlier. First, we can create a calculation for the full author name that brings together first name and last name. We'll create a calculation called **Author Name** that is simply first name, a space, and last name. Note that this calculation stays in the Author table because it uses fields only from that table.

```
[First Name] + " " + [Last Name]
```

When we make a sale, the sales amount is a combination of the price—fixed by the publisher and specific to the edition, or the ISBN—and any discount at the time of the sale. So the calculation **Sales Amount** will be price times one minus the discount. Note that we're using the ZN—or Zero Null—function to handle sales without discounts so we don't get nulls. This calculation goes to the shared area at the bottom of the Data pane as it uses fields from multiple tables. Aggregated calculations will also go to the bottom of the Data pane.

```
[Price] * (1-ZN([Discount]))
```

Video: Sets and groups

## Sets and groups video transcript

We'll create a set for books to identify if they're in a series. In the Book table, right click on **Title** and select Create > Set. We'll name it **In a series**. On the **Condition** tab, choose **By field** with **Series Name, Count**, as  $\geq 1$ .

In the Edition table, the Format field is quite detailed, including specifying mass market and trade paperback. Sometimes that detail is useful, but sometimes we want to generalize between hardcover and paperback. Right click on **Format** field in the Data pane and select Create > Group. We'll name it **Cover**. Control-click to select everything except Hardcover and then click **Group**. The name of the group is automatically highlighted, and we can call it **Paperback**.

Like with the Author Name calculation, these items we just created are relevant within a single table and therefore stay within those tables in the Data pane.

### Analyze related data

Let's do some comparisons of how analysis looks between relationships and joins. We recommend that you download the companion workbooks for [Question 1](#) and [Question 2](#) rather than continue with your own data source from above. If you identify issues with the data source configuration or steps for Question 1, note that they are intentional for the purposes of the scenario.

### Question 1: How many editions are there for each book?

**Important:** The video for Question 1 was recorded on beta software. The released version of 2020.2 correctly handles our attempt to introduce an error in the related data source. If you follow along, your workbook will not match the video—the relationships values will be correct. Please bear with us while we attempt to outsmart our product and force an error for educational purposes.

We'll set this up by doing some basic analysis with both data sources. We'll build a bar chart with each one, looking at the number of editions by title.

#### Related

Using the related data source:

1. Bring Title to Rows
2. Bring Edition (Count) to Columns
3. Click the Label icon in the toolbar to turn on labels

#### Joined

Using the joined data source:

1. Bring Title to Rows
2. Bring ISBN to Columns
3. Right Click on the pill and select Measure > Count

4. Click the Sort Descending icon in the toolbar
4. Click the Label icon in the toolbar to turn on labels
5. Click the Sort Descending icon in the toolbar

It's immediately clear that Count is not the right aggregation for the joined data. However, something isn't right with the related data, either. Let's view the data and see what's going on and how to fix it. Watch the video (or read its transcript) to see how.

Video: Data validation and fixing the data model

## Question 1 video transcript

### Joined

Here we're looking at our joined data. On the joined viz, we'll take a look at a mark's underlying data.

This view data dialog has two tabs, Summary and Full Data.

- There are tons of rows for the same book—this is likely duplicated because of all the joins.

To handle the duplication, we'll change the aggregation on the ISBN field in the view to Count Distinct. Remember that we'll need to think about this duplication in almost every analytic scenario and address it with the correct aggregation, filtering, or how we structure the viz.

### Related

Let's take a look at the structure of our related data source, and we'll take a peek at what's going on with our join as well. On the related viz, we'll take a look at a mark's underlying data.

And we see that the view data dialog again has two tabs, but this time it's the Edition tab instead of Full Data. Every table used in the viz will have its own tab.

- There's a doubling of rows for this book—and we know that joins can cause duplication, and that the Book table in this data source is really the Book table joined with Info and Award.

We can create a viz with Title and Award Name and scroll down to investigate. And sure enough, The Mallemaroking has won two awards. It would be better to relate these tables than to join them.

We'll go back to the Data Source tab and remove the Awards table from the join and relate it instead. And now we don't have to worry about the duplication issue any more for this data source.

Question 2: For authors with books in a series, who is has the most book tour events?

Video: Work with different levels of details

## Question 2 video transcript

Let's look at which authors we'll be working with. Using the related data source, we'll bring **Author Name** and **Series Name** to Rows.

Because related data sources pare down unmatched data in tables that only contain dimensions, we're focusing on the data that is relevant to us. We can see that there are seven authors, two of whom have written for two series. If you don't want to see only matched values, you can restore

those unmatched values (which is more like the legacy behavior) by going to the Analysis menu > Table Layout and checking Show Empty Rows.

### Related

Using the related data source:

1. Bring the set **In a series** from the Book table to the filter shelf. The default is to filter only to members in the set.
2. Bring **Author Name** to Rows.
3. Bring **Book Tour Events** to Columns.

### Joined

Using the joined data source:

1. Bring the set **In a series** to the filter shelf.
2. Bring **Author Name** to Rows.
3. Bring **Book Tour Events** to Columns.

Our numbers here look a bit off.

For the joined data, we know there's duplication because of the join, and we also know some authors span series. Because of this, we can't just change the aggregation to, say, MIN or MAX, because we lose information for authors with works in multiple series.

What we really want is the number of events per series, visualized by author. This is a classic case for Level of Detail (LOD) expressions. We'll create a calculation **Series Events**:

```
{FIXED [Series Name] : MIN ([Book Tour Events])}
```

Note that the MIN is to handle duplication of events for a single series.

Now if we bring this new field to Columns instead of the original events field, we'll get the correct values.

For the related data, we didn't need to do any of that. Relationships are smart enough to understand the native level of detail and the way the Author table relates through the Book and

Info tables through to the Series table, and to correctly join and aggregate the Events measure back to Author Name—all without having to write LOD calculations.

So don't be scared of relating your data. See for yourself! You can [download the Bookshop data](#) or use some of your own. Try filtering, using table calculations, building a variety of chart types, configuring performance options, and pushing relationships as far as you can.

### Tips when working with related data

- [View Underlying Data on page 2610](#) often to verify what data a mark represents.
- If you aren't required to join—and there are [reasons](#) you may need to—using a relationship provides more flexibility.
- If you don't want to see only matched values, you can restore those unmatched values by going to the Analysis menu > Table Layout > Show Empty Rows.

### Don't Be Scared of Calculations in Relationships

Calculations can be intimidating. Calculations in a data source that uses relationships can seem more intimidating. But there's no reason to be scared of calculations in relationships.

**Note:** if you aren't yet comfortable with the principles behind data sources that use relationships, it might help to read [Don't Be Scared of Relationships on page 715](#) before diving into this topic.

## Calculation types

A **row-level calculation** is something that is computed for each record in the data. For example, each sale transaction has a sales amount, the price, potentially adjusted by the discount percentage: `Price * (1 - ZN([Discount]))`. This is computed row-by-row for each transaction—the results can be thought of as adding a new column in the data source for Sales Amount.

There are also **aggregate calculations**. Aggregate calculations are computed at the level of detail of the visualization and their value depends on the structure of the view. Counts are an example of an aggregate calculation. The value of `Count([Title])` depends on whether we're looking at the count by format, author, or sales day.

See [our blog](#) for more information about types of calculations.

## Table level of detail

Because each table in the Tableau data source can have its own level of detail, which table a calculation is associated with has a large impact. For example, historically in Tableau (pre 2020.2, before relationships), it was possible to count the number of records in the data source by creating a calculation with the constant value 1 and summing it. 1 was assigned to each row in the data source so the sum was equal to the number of rows.

Now, however, that calculation would have a value of 1. There is no global level of detail for the entire data source, and a constant calculation lives in the unassigned area at the bottom of the Data pane. It has its own level of detail. Summing 1 is simply 1.

As mentioned previously, calculations that have the same level of detail as a table—usually because they contain a field from the table—belong in that table in the Data pane. For example, the concatenation of First Name and Last Name to get the full name of each author (that is, `[First Name] + " " + [Last Name]`) is placed in the Author table.

However, if we were to use fields from multiple tables in one calculation, the calculation would go to the unassigned area at the bottom of the Data pane. This is called a cross-table row-level calculation; it requires a row-level join of the tables involved, which can impact performance. (Make sure the correct cardinality is set in the Performance Options of the relationship).

## Assigning the level of detail

Because the level of detail of a table controls what a calculation's results represent, it's important to have calculations in the appropriate tables. A FIXED Level of Detail expression can be used to pull a calculation into a specific table. The field the expression is fixed to (the [dimension declaration](#)) determines the level of detail of the results.

## Example: Author book tours

**Q:** How many book tour events is each author participating in?

**A:** This number should “belong” to each author, so it should go in the author table.

- **Author Book Tour Events** = {FIXED [Author Name] : SUM([Book Tour Events])}
- (This can be thought of in plain language as “for each author, total the number of book tour events associated with them”)

**Q:** How many authors are not doing any book tours?

**A:** It’s tempting to try a calculation like

- COUNTD(IF ISNULL([Book Tour Events]) THEN ([Author Name]) END).
- (This can be thought of in plain language as “if Book Tour Events is null, then return the author’s name. Count each unique author name”)

However, this is a cross-table row-level calculation because Book Tour Events is from the Series table and Author Name is from the Author table. And cross-table calculations like that use inner joins, which means when there’s no corresponding value from both tables, the row is dropped from the join results. Which in turn means we’re asking Tableau to count something that doesn’t exist. Note that if the two fields were in the same table, however, this would be a fine way to do it. There’s nothing wrong with the calculation as it stands other than the fact it doesn’t play well with the structure of the data source.

Instead, we need to indicate the presence or absence of book tour events for each author—and keep those results in the Author table. Once each author is flagged as “participating in a book tour” or not, we can count the number who aren’t doing book tours.

- **Book tour participant?** = IF {FIXED [Author Name] : COUNT([Book Tour Events])} = 0 THEN "No" ELSE "Yes" END
- (This can be thought of in plain language as “For each author, count the number of book tour events. If that count is zero, label the author ‘No’, otherwise label them ‘Yes’”. By naming the field “Book tour participant?” the no’s and yes’s will line up.)

Now we can count the number of Nos and answer the original question.

If our calculation is **Authors without book tours** = IF [Book tour participant?] = "No" THEN ([Author Name]) END, we’ll get a list of authors who aren’t doing book tours. (This can be thought of as “for every author where Book tour participant? is no, list the author’s name.”)

If our calculation is `COUNTD(IF [Book tour participant?]= "No" THEN ([Author Name]) END)`, we'll get a numeric answer that will live in the unassigned area at the bottom of the data pane. Why? Because this calculation is aggregated.

### Bonus Question:

It's also possible to use the structure of the Book tour participant? calculation directly to return the list of author names. `IF {FIXED [Author Name]: COUNT([Book Tour Events])} = 0 THEN ([Author Name]) END`. Where would this calculation go in the Data Pane? Why? Try it in your own copy of Tableau Desktop, or [download this workbook](#) to see. (Requires Tableau Desktop 2020.2 or higher. Once in the workbooks, right click the calculation in the Data pane and select Edit to open the calculation editor and see an explanation in the calculation comments.)

### Don't Be Scared of Deeper Relationships

Because of the nature of relationships, understanding where fields come from, their domain, and what nulls represent is more important than ever. Remember that anyone viewing the viz without access to the Data source page or the Data pane will be reliant on the title or other information presented by the author to interpret the viz correctly.

**Note:** if you aren't yet comfortable with the principles behind data sources that use relationships, it might help to read [Don't Be Scared of Relationships on page 715](#) before diving into this topic.

## Why aren't all date fields equal?

It's important to remember that just because two field names contains the word "Date" doesn't mean the contents of those fields are identical. Let's look at an example that sticks with the level of Year. That is, we don't care about the values for months and days, we're only interested in what years the fields cover.

There are multiple fields in [The Bookshop data set on page 189](#) with a data type of Date.

- Birthday
- Publication Date
- Sales Date
- And Year Won and Year Established also contain date information, though they are numeric fields.
  - NB: If the icon in the data pane is green, this field is continuous. Right click on the field name in the Data pane and choose **Convert to Discrete**. The icon should turn blue. Do this for both "Year Won" and "Year Established" if necessary.

But the domain—the values in each field—vary. Bring each field in turn to the rows shelf and look at the number of marks in the bottom left corner, removing each field before bringing out the next.

- YEAR(Birthday) has 27 marks, meaning the domain contains 27 different years.
- YEAR([Publication Date]) has 15 marks, so its domain consists of 15 years.
- Year Won has 11 marks
- Year Established has four marks
- YEAR([Sales Date]) has one mark

This difference in domain is very important to keep in mind. If we related the Edition and Award table on YEAR([Publication Date]) to Year Won, we could wind up with analyses that use an inner join and are therefore trimmed down to just the years when an award was won—thus dropping all books from years without awards. (Note that this is not the same thing as filtering out books without awards. Non-award winning books that were published in the same year as an award-winning book will be preserved. All books from years with no awards will be dropped entirely. The filtering action from the join is at the level of year, not book.)

### **Example: Publication Date and Birthday**

If we bring Publication Date to Columns and Birthday to Rows, we get a table of Abcs. You can [download the workbook](#) and explore this table on your own. (Requires Tableau Desktop 2020.2 or later.)

Year of Birthday	2178	2179	2180	2181	2182	2183	2184	2185	2186	2187	2188	2189	2190	2191	2192
2120										Abc	Abc		Abc		
2122								Abc							
2129		Abc			Abc	Abc				Abc	Abc			Abc	
2130						Abc		Abc							
2133				Abc	Abc		Abc	Abc							
2141				Abc					Abc	Abc	Abc				
2143														Abc	Abc
2145	Abc	Abc						Abc	Abc	Abc					
2146					Abc	Abc									
2147	Abc	Abc	Abc	Abc											
2148															Abc
2149	Abc	Abc	Abc				Abc	Abc						Abc	Abc
2150	Abc					Abc	Abc	Abc	Abc	Abc	Abc				Abc
2151		Abc			Abc									Abc	Abc
2153					Abc										
2154									Abc	Abc					
2155				Abc	Abc	Abc		Abc	Abc	Abc	Abc	Abc	Abc	Abc	
2156		Abc		Abc		Abc	Abc	Abc	Abc	Abc	Abc	Abc			Abc
2157														Abc	Abc
2160												Abc	Abc		
2161													Abc		
2163												Abc			
2169							Abc	Abc							

Abc is simply a placeholder because there is no data other than the years. Tableau has no values to make marks with, but the Abc shows where marks could go.

Notice that there is a lot of blank space in this table. There is no placeholder for the Publication year 2180 and the Birthday 2133. This means the author born in 2133 did not publish in the year 2180.

Sure. But why do we care?

Imagine you wanted to do some analysis over time. Are Hardcover sales increasing over time? You might imagine your graph as a timeline that filters Format to only Hardcover with Sales (Count) on Rows and date on Columns. But which date field? Publication Date? Birthday? Sales Date? These fields are well named and it's fairly obvious that if we have a question about sales we should use Sales Date. Not all data sets have clear names, though. If the fields were something like "Date1" and "Date3" it would be much harder to tell. Especially if the analytical question isn't clearly thought through.

**What table a field comes from and what the domain of the field represents have a crucial impact on analysis.**

By changing the date field, we can change the analysis entirely. Consider these two vizzes:

The first could be interpreted as “How many books were written by authors born in each year?”. It answers questions like “Have older authors written more books?” (No) or “Author(s) born in which year are the most prolific?” (2155).

The second could be interpreted as “How many books were published each year?”. It answers questions like “Which year had the most published books?” (2188) or “Is book publication steady over time?” (No).

It’s awkward to phrase the question for the viz that uses birthday because it’s an awkward combination of concepts. But Tableau doesn’t judge and will let you ask whatever question you like—whether you mean to or not. That’s a vital takeaway. If you bring out Date3 when you should have used Date1, Tableau will give you a viz. But not all date fields mean the same thing and it’s up to the author to know which field to use for the correct analysis.

For more information about the importance of what table a field comes from, check out [this blog post](#).

### What does missing data mean?

There’s a difference between zero and null.

**Zero** means we measured and something isn’t there. We know the value and it is zero. If I have zero speeding tickets, I probably don’t speed much.

- NB: 0 and 1 are often used interchangeably with True/False, or other binomial values like Yes/No or Pass/Fail. In this case, zero is being used as a label, not a numeric value.

**Null** means we don’t know: we haven’t measured or we didn’t record the data. If my driving record is simply blank for speeding tickets, we have no idea if I speed or not.

Nulls can represent either missing data or nonexistent data.

- For my driving record, if the speeding tickets value is null, it's conceivable that I could have a speeding ticket that wasn't recorded. We should assume that data is missing.
- Nonexistent data could be recorded as N/A, but is often simply not recorded because we don't need to track impossible things. How many speeding tickets did I get while riding a bus? That data likely won't be present in the data set. In a matrix of "Modes of transportation" and "speeding tickets", there are combinations that simply don't make sense. We may assume that data is nonexistent.

## When nulls carry meaning

It takes knowledge of the data to be able to recognize if a null is truly unknown (lack of information for number of speeding tickets) or if it represents nonexistent data (lack of information about speeding tickets as a bus passenger). Is the data trustworthy enough that a lack of information can be taken as nonexistent data rather than missing data? When subject matter expertise is applied, nulls can be meaningful.

Looking again at the table of Abcs, we can analyze the spaces without placeholders. We'll assume this data is reliable and a null means the data is nonexistent rather than incomplete.

Year of Birthday	Publication Date														
	2178	2179	2180	2181	2182	2183	2184	2185	2186	2187	2188	2189	2190	2191	2192
2120										Abc	Abc		Abc		
2122								Abc							
2129		Abc			Abc	Abc				Abc	Abc				Abc
2130						Abc		Abc							
2133				Abc	Abc		Abc	Abc							
2141				Abc					Abc	Abc	Abc				
2143														Abc	Abc
2145	Abc	Abc						Abc	Abc	Abc					
2146					Abc	Abc									
2147	Abc	Abc	Abc	Abc											
2148		Abc													Abc
2149	Abc	Abc	Abc				Abc	Abc						Abc	Abc
2150	Abc					Abc		Abc	Abc	Abc	Abc				Abc
2151		Abc			Abc									Abc	Abc
2153					Abc										
2154										Abc	Abc				
2155				Abc	Abc	Abc		Abc	Abc	Abc	Abc	Abc	Abc		
2156		Abc		Abc		Abc	Abc		Abc	Abc	Abc	Abc			Abc
2157														Abc	Abc
2160												Abc	Abc		
2161													Abc		
2163											Abc				
2169							Abc	Abc							

The lack of a placeholder means an author was born that year (so the row exists), and a book was published that year (so the column exists), but the published book was not written by an author born in that year (so the cell is empty). We can meaningfully assign a label to that empty space: Nothing Published. We could even do analysis on those nulls—for example, for the dates present in the data, how many years went by for each author without publishing a book?

**Note:** There are also gaps in the domain of Birthdays. No authors were born in 2131 or 2132, so Year goes from 2130 to 2133 (the rows for 2131 and 2132 do not exist). These missing years can be interpreted as “no books in this data set had authors born in those years”. However, as pointed out above when talking about the domain of the date fields, the fact there are missing values in the domain is important information to consider when building relationships or choosing which field to use for a header or axis in a viz.

For more information about working with nulls in relationships, check out [this blog post](#).

## Hands-on exercises

Write a title for each viz. Can you describe what is happening in plain language? [Download the workbook](#) to explore the live vizzes. (This workbook uses a slightly tweaked version of [The Bookshop data set on page 189](#) and uses only two tables. The date fields have been adjusted so they can be used as the related field.)

To read the matrix of vizzes:

- The bars show the number of editions (purple) and number of awards (green) per year.
- Each column has a different date field for the axis. The left-hand column is Publication Year from the Edition table, the center column is Year Won from the Award table, and the right-hand column is a calculated field that used publication date but if that field is null uses Year won (this calculation is used to ensure that both domains are fully represented).
- Each row is a different relationship for how the Award and Edition table are combined. The top row relates the tables on Book ID, the middle row relates them on Year, and the bottom row relates them on both Book ID and Year.
- The bars for the year 2183 are thicker to make comparison easier. In the solution below, that is the year whose values are looked at in detail.
- Note that the two vizzes that are shaded have identical values.

## If you get stuck

Walk through each part of the viz step-by-step. Look at the data source structure, the axis and headers, and the fields used for the marks (and which tables they come from). Think about nulls and why they might be there. View the data for a specific mark or two to see which records it contains.

# Tableau Desktop and Web Authoring Help

- The data source is Awards related to Editions on Book ID.
- The date axis is Publication Year
- The values are Count of Awards and Count of Editions.

Try to pick a single mark in the viz and define it. For the year 2183, the viz shows there are seven editions and three awards. Use [View Underlying Data](#) on page 2610 to investigate which records are represented in each mark.

## Editions

Publication Year	Book ID
2183	WG715
2183	DY800
2183	TM925
2183	QQ737
2183	IA439
2183	WO506
2183	DE571

## Awards

Publication Year	Award	Book ID (Awards)	Year Won
2183	Nebula Award	TM925	2179
2183	Hugo Award	TM925	2179
2183	Pulitzer	WO506	2183

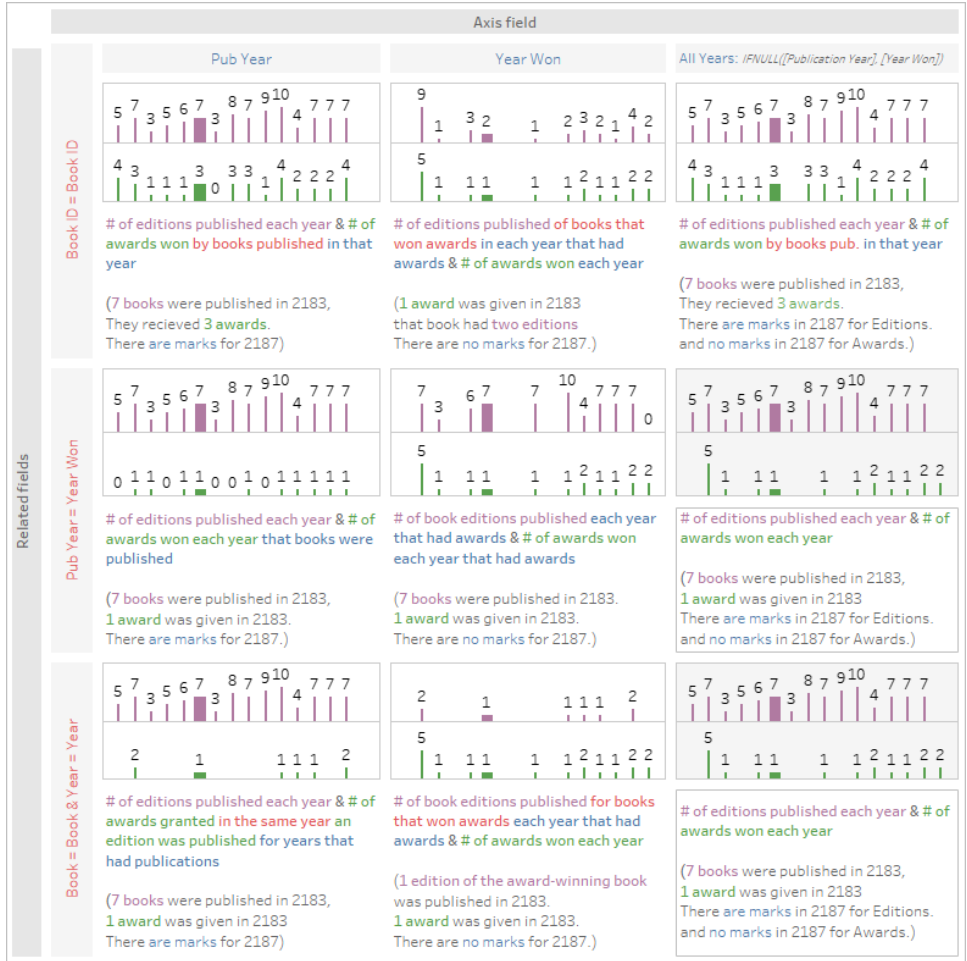

Together, this can be interpreted as “return the seven books published in 2183, then for those books, list any awards they won *regardless of when they won the award*”. TM925 was originally published in 2179 and the hardcover edition won two awards in that year. In 2183, a different edition of the book was published, perhaps in paperback. The value for Count of Award is tied to the book, not the year.

So the viz overall could be interpreted as “the number of editions published each year, and how many awards were won by books published in that year” or “the number of editions published each year and the number of awards won by those books”.

## Solution to the hands-on exercise

The year 2183—the thicker bars—is the year focused on for interpretation. Information about editions is in purple and information about awards is in green. The year 2187 is also called out in the descriptions because it is a year when no awards were won but books were published. As such, it is a good illustration of the power of which date field is used for the axis. This nuance is addressed in blue in the description. The importance of the field(s) used to set up the relationship is called out in pink.

This visual is provided for your convenience, but a better experience may be to [download the workbook](#) and open it in Tableau Desktop 2020.2 or later so you can make use of interactivity such as tooltips and View Data. If you prefer to look at the sheets more closely, you can right click on either dashboard tab at the bottom and choose Unhide all Sheets. This will make all the individual vizs available, and from each sheet you can see the Data pane and the authoring environment, including which fields are on which shelves. Note that in order to achieve the three different relationships (the rows of the matrix above), there are three different data sources.

## Join Your Data

It is often necessary to combine data from multiple places—different tables or even data sources—to perform a desired analysis. Depending on the structure of the data and the needs of the analysis, there are several ways to combine the tables.

## Relationships vs Joins

The default method in Tableau Desktop is to use relationships. Relationships preserve the original tables' level of detail when combining information. Relationships also allow for context-based joins to be performed on a sheet-by-sheet basis, making each data source more flexible. Relationships are the recommended method of combining data in most instances. For more information, see [How Relationships Differ from Joins on page 675](#).

However, there may be times when you want to directly establish a join, either for control or for desired aspects of a join compared to a relationship, such as deliberate filtering or duplication.

**Note:** Relationships eventually leverage joins (just behind the scenes). For example, a relationship across data sources will produce a cross-database join when the viz uses fields from tables in different data sources. As such, [Improve Performance for Cross-Database Joins on page 756](#) may be relevant.

## Common issues

- To view, edit, or create joins, you must open a logical table in the relationship canvas—the area you see when you first open or create a data source—and access the join canvas.

- **Published Tableau data sources cannot be used in joins.** To combine published data sources, you must edit the original data sources to natively contain the join or use a data blend.
- When joining tables, the fields that you join on must be the same data type. If you change the data type after you join the tables, the join will break.
- Fields used in the join clause cannot be removed without breaking the join. To join data and be able to clean up duplicate fields, use Tableau Prep Builder instead of Desktop

**Tip:** While Tableau Desktop has the capability to create joins and do some basic data shaping, Tableau Prep Builder is designed for data preparation. If you need to do multiple joins, clean up field names, change data types, perform multiple pivots, or other sorts of involved data prep, consider using [Tableau Prep Builder](#).

## Create a join

1. To create a join, connect to the relevant data source or sources. See [Connect to Your Data on page 233](#).

These can be in the same data source (such as tables in a database or sheets in an Excel spreadsheet) or different data sources (this is known as a cross-database join). If you combined tables using a cross-database join, Tableau colors the tables in the canvas and the columns in the data grid to show you which connection the data comes from.

**Note:** Not all data sources support cross-database joins, including published Tableau data sources. To combine published data sources, edit the original data sources to natively contain the join or use a data blend.

2. Drag the first table to the canvas.

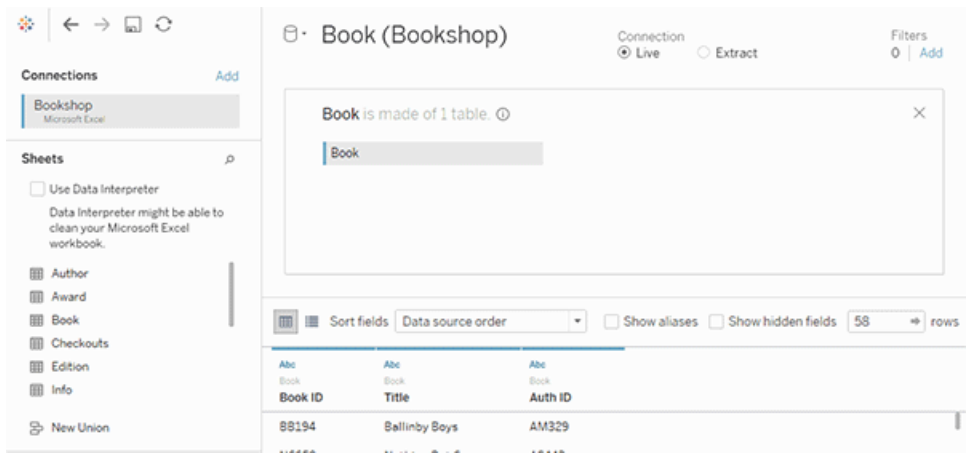

Note that if you drag out a second table at this point a relationship will form.

3. Select Open from the menu or double-click the first table to open the join canvas (physical layer).

Double-clicking a table on the relationship canvas opens the join canvas

4. Double-click or drag another table to the join canvas.

If your next table is from another data source entirely, in the left pane, under **Connections**, click the **Add** button (⊕ in web authoring) to add a new connection to the Tableau data source. With that connection selected, drag the desired table to the join canvas.

5. Click the join icon to configure the join. Add one or more join clauses by selecting a field from one of the available tables used in the data source, choosing a join operator, and a field from the added table.

**Note:** You can delete an unwanted join clauses by clicking the "x" that displays when you hover over the right side of the join clause.

6. When finished, close the join dialog and join canvas.

After you've created a join, [Join Your Data on page 738](#). To troubleshoot your join, see [Join Your Data on page 738](#).

## Anatomy of a join

Joins are defined by their type as well as the join clause.

### Join types

In general, there are four types of joins that you can use in Tableau: inner, left, right, and full outer. If you aren't sure what join type you want to use to combine data from multiple tables, you should use relationships.

Join Type	Result
Inner 	<p>When you use an inner join to combine tables, the result is a table that contains values that have matches in both tables.</p> <p>When a value doesn't match across both tables, it is dropped entirely.</p>
Left 	<p>When you use a left join to combine tables, the result is a table that contains all values from the left table and corresponding matches from the right table.</p> <p>When a value in the left table doesn't have a corresponding match in the right table, you see a null value in the data grid.</p>
Right 	<p>When you use a right join to combine tables, the result is a table that contains all values from the right table and corresponding matches from the left table.</p> <p>When a value in the right table doesn't have a corresponding match in the left table, you see a null value in the data grid.</p>
Full outer 	<p>When you use a full outer join to combine tables, the result is a table that contains all values from both tables.</p> <p>When a value from either table doesn't have a match with the other table, you see a null value in the data grid.</p>
Union 	<p>Though union is not a type of join, union is another method for combining two or more tables by appending rows of data from one table to another. Ideally, the tables that you union have the same number of fields, and those fields have matching names and data types. For more information about union, see <a href="#">Union Your Data</a> on page 795.</p>

Not all databases support all join types. If an option is unavailable in the join dialog, it is likely due to a constraint from your data source.

## Join Clauses

A join is performed by setting up one or more join clauses. The join clause tells Tableau which fields are shared between the tables and how to match the corresponding rows. For example, rows with the same ID are aligned in the results table.

Join clauses most often use the equality operator (=) which matches rows with the same values. It is also possible to perform non-equi joins, such as less than (<) and not equal (<>).

A join can also have multiple join clauses. For example, if First name and Last name are stored in separate columns, it may be beneficial to join only if “First name = First name” and “Last name = Last name”. Both conditions will have to be true for rows to be joined. Alternatively, if the goal was to return results when the last name is shared but the first name is not, the join clauses could be “First name <> First name” and “Last name = Last name”.

Join clauses can also contain calculations. For example, the join clause could be the concatenation of the name fields “[First name] + [Last name] = [First name] + [Last name]”. Note that not all data source connections support calculations in join clauses.

## About null values in join keys

In general, joins are performed at the database level. If the fields used to join tables contain null values, most databases return data without the rows that contain the null values. However, for certain single-connection data sources, Tableau provides an additional option to allow you to join fields that contain null values with other fields that contain null values.

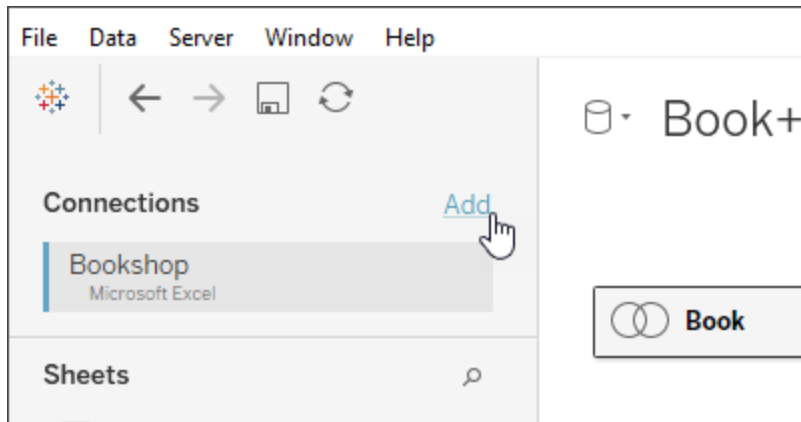

After you've set up your data source, on the data source page, select **Data > Join null values to null values**.

If the option is greyed out, it is not available for your data source. Note that if you add a second connection to a data source that uses this option, the join reverts back to the default behavior of excluding rows with null values.

## Cross-database joins

Tableau allows joins from tables in different data sources, albeit with some limitations from the database side on which platforms are compatible. Cross-database joins require a multi-connection data source—that is, you create a new *connection* to each database before you join the tables.

1. Once you've connected to the first source of data, use the Add option in the data pane to add another connection.

**Note:** If the connector you want is not available from the **Connect** list when you're trying to add another connection, cross-database joins are not supported for the combination of sources that you want to join. This includes connections to cube data (e.g., Microsoft Analysis Services), most extract-only data (e.g., Google Analytics and OData), and published Tableau Server data sources.

2. This creates a second connection rather than an entirely different data source. You can switch between the two (or more) connections while on the data source tab.

3. Once you move to a worksheet and begin analysis, the data source functions as a single, combined data source. This is in contrast to two independent data sources that can be toggled between on a worksheet.

The **Book+** data source contains two connections with a cross-database join. It functions as a single data source. The **Movie adaptations** data source is an independent data source.

**Note:** Typically, joining tables from the same database yields better performance. This is because querying data that is stored on the same database takes less time and leverages the native capabilities of the database to perform the join. For more information on cross-database join performance, see [Improve Performance for Cross-Database Joins on page 756](#).

## Review Join Results in the Data Grid

After you have created a join on the canvas, review the data grid to make sure the join produces the results that you expect. If the data grid displays data that you don't expect, you might need to modify the join.

### Results in the data grid

- **No data:** If no data displays in the data grid, you might need to change the join type or a join field used in the join condition. If you suspect a mismatch between fields in the join, use a calculation instead. For more information, see [Use calculations to resolve mismatches between fields in a join on the next page](#).
- **Duplicate data:** If you see duplicate data, there are a few things you can do. Consider relating the tables instead of joining. For more information, see [Relate Your Data](#).

- **Missing data:** If some data is missing from the data grid, you might need to change the join type or a join field used in the join condition. Again, if you suspect a mismatch between fields in the join, use a calculation instead. For more information, see [Use calculations to resolve mismatches between fields in a join](#) below.
- **Many null values:** If you see many null values that you do not expect, you might need to change the join type from the full outer type to the inner type.
- **All null values for one table:** If all values for one table is null, there are no matches between the tables that you are joining. If this is not expected, consider changing the join type.

## Use calculations to resolve mismatches between fields in a join

When the fields in a join condition don't match—that is a mismatch between the values in the fields used in a join condition, the data grid can show little or no data at all. A mismatch between fields can occur for several reasons but often caused by the differences in format of the string values or date values in the fields. In many cases, you can resolve mismatches between the fields in your join by using a calculation.

Most functions are available for you to use in a calculation to create and replace a field in the join condition, with the exception of aggregate functions and table calculation functions.

**Note:** Join calculations are not supported for QuickBooks Online, Marketo, Oracle Eloqua, Anaplan, ServiceNow ITSM, and web data connectors.

### String mismatch

A common mismatch scenario when working with string data occurs when one of the fields on one side of the join condition is equivalent to two or more fields on the other side of the join condition. In this case, you can use a calculation to combine the two fields so that its format matches the other field in the join condition.

For example, suppose you want to join two tables that contain the following data:

Patron

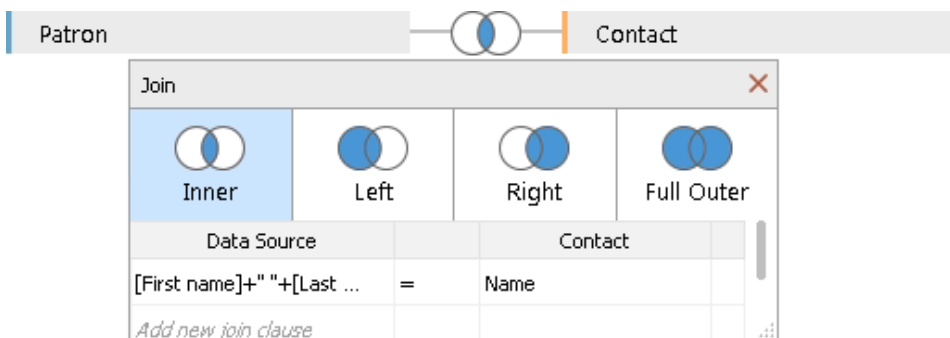

Contact

First name	Last name	Branch	Member since	Units borrowed	Fees	Suggested limit	Name	Member number	Emergency contact	Relationship	Emergency number
Alan	Wang	North	200-0	1	0	15	Adam Davis	555-032-4	Ellen Davis	Partner	555-0884
John	Smith	North	200-0	36	3.50	15	Alan Wang	555-035-6	Jean Wilson	Mother	555-0327
Ashley	Garcia	South	200-0	243	11.30	15	Fred Suzuki	555-018-8	Jim Suzuki	Brother	555-3188
Fred	Suzuki	North	200-0	52	.90	15	Henry Wilson	555-010-0	Laura Rodriguez	Partner	555-0103
							Michelle Kim	555-019-9	Steven Kim	Partner	555-0125

The common fields between the two tables appear to be name. However, in the Patron table the first and last names are in separate columns and in the Contact table the first and last names are in the same column. To join the tables on names, you can use a calculation in the left side of the join condition to merge the first name and last name columns together.

The result is a calculated field on the left side of the join condition that is accessible only from the join dialog. This calculation converts the field in the Patron table into a format that now matches the format of the field in the Contact table on the right side of the join condition.

Using the calculation in the join produces the following combined table:

First name	Last name	Branch	Member since	Units borrowed	Fees	Suggested limit	Name	Phone number
Alan	Wang	North	2000	1	0	15	Alan Wang	555-0356
Fred	Suzuki	North	2000	52	.90	15	Fred Suzuki	555-0188

### Date mismatch

A common mismatch scenario when working with date data occurs when the date values in one field of the join condition are captured at a different level of detail than the other field in the join

condition. In this case you can use a calculation in the join condition to change the format of the field on one side of the join condition so that its format matches the other field in the join condition.

For example, suppose you have the following two tables of data:

Projector rental

Date	Reservation type	Requester ID
1/1/2000	Individual	23344-5589
1/28/2002	K-12	36594-8999
1/29/2002	Non-profit	23344-8888
12/5/2002	K-12	36594-8999
5/5/2003	Non-profit	33401-5476
3/12/2004	Non-profit	33401-5476
3/15/2006	City	21189-6980
7/8/2007	K-12	33401-5476
1/4/2008	Individual	56049-5523
3/8/2009	Non-profit	23344-5566

Patron

ID	First name	Last name	Branch	Member since	Units borrowed	Fees	Suggested limit
45461-3981	Adam	Davis	West	2012	25	0	10
23250-2870	Alan	Wang	North	2000	1	0	15
29800-0916	Amanda	Smith	North	2001	54	6.4	15
23344-5566	Ashley	Garcia	South	2000	243	11.30	15
90000-5122	Brian	Frank	East	2011	12	.10	10
92149-1769	Elizabeth	Johnson	West	2010	19	.5	10
23344-5589	Fred	Suzuki	North	2000	52	.90	15
34455-6677	Henry	Wilson	South	2005	3	.2	15
93950-2870	Jane	Johnson	West	2017	0	0	10
23344-	John	Smith	North	2000	36	3.5-	15

Date	Reservation type	Requester ID	ID	First name	Last name	Branch	Member since	Units borrowed	Fees	Suggested limit
2/14/2014	Non-profit	23344-5566								
			8978		h	h			0	
12/21/2015	Non-profit	23344-5566								
2/10/2016	Non-profit	23344-5566								

To find out more information about new patron behavior, joining the Patron table to the Projector Rental table might provide some insight about which library services motivate new memberships. The common fields between the two tables appear to be "Date" and "Member since." However, the date values in each field are captured at different levels of detail. To join these tables on their respective date fields, use a combination of DATE functions in a calculation on each side of the join condition to make the level of detail in each field match.

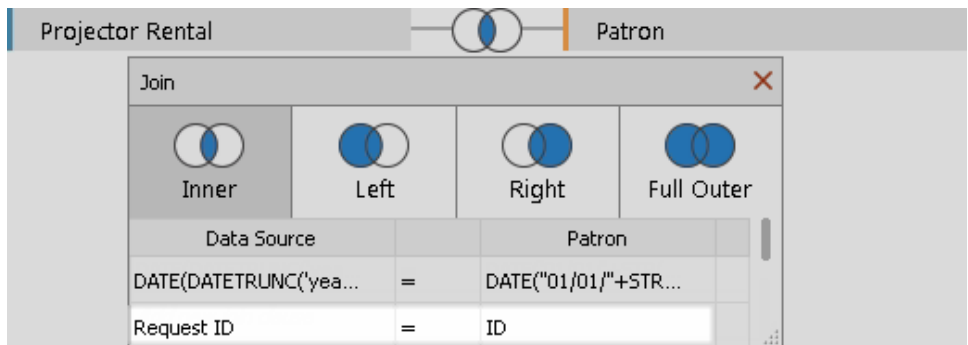

```
DATE (DATETRUNC ('year', [Date])) = DATE ('01/01/' + STR ([Member since]))
```

Using the calculation in the join produces the following combined table:

Date	Reservation type	Requester ID	ID	First name	Last name	Branch	Member since	Units borrowed	Fees	Suggested limit
1/1/2000	Individual	23344-5589	23250-2870	Alan	Wang	North	2000	1	0.0-0	15
1/1/2000	Individual	23344-5589	23344-5589	Fred	Suzuki	North	2000	52	0.9-0	15
1/1/2000	Individual	23344-5589	23344-5566	Ashley	Garcia	South	2000	243	11.-30	15
1/1/2000	Individual	23344-5589	23344-5566	Joh	Smit	North	2000	36	3.5-	15

Date	Reser- vation type	Reque- ster ID	ID	Firs- t na- me	Last na- me	Bran- ch	Mem- ber since	Units bor- rowed	Fe- es	Sugge- sted limit
000	vidual	5589	8978	n	h	h			0	

To determine if a patron rented the projector in the same year he or she started his or her membership, add one more clause to the join based on ID.

The result of the additional join condition shows that only one patron might have started his membership to rent a projector.

Date	Reser- vation type	Reque- ster ID	ID	Firs- t na- me	Last nam- e	Bran- ch	Join- ed	Units bor- rowed	Fe- es	Sugge- sted limit
1/1/2- 000	Indi- vidual	233445- 589	233445- 589	Fre- d	Suz- uki	North	2000	52	0.9- 0	15

### Troubleshoot Joins

**Note:** If your join is mis-counting data, it could be a sign you should be using a relationships instead. For more information about relationships, see [Relate Your Data on page 622](#). For information about how Tableau handles combining data from different levels of detail (such as many-to-many relationships), see [Cardinality and Referential Integrity](#).

## Over-counting values or duplicated data

When you connect to and join multiple tables together, you set up a *denormalized* version of the data. In some cases, Tableau treats the multiple tables as one table. When multiple tables are treated as one table, after the tables are joined, *all* tables are queried. This can cause values to be over-counted.

For example, suppose you have two tables. The first table contains employee information, such as employee ID and salary. The second table contains organizational information, such as department names.

**Table 1**

Employee ID	Name	Salary
20106	Kim, Michelle	63,000
20107	Wilson, Henry	61,000
20108	Smith, John	65,000

**Table 2**

Department	Hire Date	Employee ID	Organization
Development	6/16/2016	20289	Strategy
Support	7/28/2015	20107	Operations
Support	8/05/2016	20299	Operations
Sales	8/25/2016	20107	Operations

If you join these tables on **Employee ID**, an employee's salary is counted more than once because the employee is associated with multiple departments.

Employee ID	Name	Salary	Department	Hire Date	Organization
20107	Wilson, Henry	61,000	Support	7/28/2015	Operations
20107	Wilson, Henry	61,000	Sales	8/25/2016	Operations

This is an example of one-to-many cardinality (one employee ID in Table 1 has multiple results in Table 2). For more information on cardinality between tables, see [Optimize Relationship Queries Using Performance Options](#) on page 679.

To help resolve this issue, you can do one of the following:

- **Relate the data:** Instead of creating a join, which might duplicate your data, you can use relationships. For more information, see [Relate Your Data on page 622](#).

**Change the aggregation:** Depending on your analysis, you can use the **MIN** or **AVG** aggregation to remove over-counting.

For example, if you change the aggregation of **Salary** from SUM to MIN or from SUM to AVG.

- **Create a calculated field that removes the duplicate values:** You can create a calculation that divides the sum of the field being duplicated by the number of instances of the field that is causing the duplication.

For example, the Salary values are being duplicated by the number of instances of Employee ID for Wilson, Henry. In this case, in the view replace Salary with a calculated field that uses the following formula: `SUM ([Salary]) / COUNT ([Employee ID])`.

You could also use a Level of Detail Expression to delete the duplicate data. For more information, see [Removing Duplicate Data with LOD Calculations](#) in the Tableau Knowledge Base.

- **Use custom SQL:** Tableau supports using custom SQL for connecting to multiple tables in a data source. You can pre-aggregate the tables before joining them with a GROUP BY clause. This option requires some knowledge about writing SQL queries and assistance from a database expert if possible. For more information about how to connect to a custom SQL query from Tableau, see [Connect to a Custom SQL Query on page 811](#).

## Broken table joins and cross-database joins

Before you join tables (from the same data source or using a cross-database join), make sure that the data types of the join keys match. If the data types of the join keys don't match, the join breaks, which is indicated by a red exclamation point and the error text "type mismatch between join fields". To fix a broken join, use one of the following suggestions:

- You can change the format of a field (including its data type) in the join dialog to make the join keys match by creating a join calculation. A join calculation supports a subset of calculations that lets you modify the format of the join key in one or more tables that you want to combine. To create a join calculation, click the join icon between the tables that have a broken join, click the field whose format needs to be modified, and then select **Create Join Calculation**. For more information, see [Troubleshoot Joins on page 751](#).

- For text or Excel-based data, modify the data type of one of the text or Excel fields in the join key using the data type menu in the data grid.
- **Tableau Desktop only:** For most connections, you can use the **Convert to custom SQL** option to change the data type of one of the fields in the join key, using a function like CAST (). The **Convert to custom SQL** option is available only when the data source contains only one connection. In this case, remove the second connection and then select **Data > Convert to custom SQL**.

## Assuming Referential Integrity for Joins

In some cases, you can improve query performance for joins by selecting the option to **Assume Referential Integrity** from the **Data** menu. When you use this option, Tableau will include the joined table in the query only if it is specifically referenced by fields in the view.

Using this setting is appropriate when you know that your data has referential integrity (see definition below) but your database is not enforcing or cannot enforce referential integrity. If you have the option of configuring referential integrity in your database that is a better option than using this setting because it can improve performance both in the database and in Tableau. The **Assume Referential Integrity** option in Tableau can only affect performance on Tableau's end. If your data does not have referential integrity and you turn on this setting, query results may not be reliable.

To understand what referential integrity is, imagine connecting to sales data that has two tables: Sales and Product Catalog. These two tables are shown below:

**Sales**

**Product Catalog**

Product ID (Foreign Key)	Sale Amount	Transaction Date	Product ID (Primary Key)	Product Name
1	100	10/1/2012	1	10 Inch Tablet
1	2000	10/2/2012		
2	50	9/30/2012	2	Smart Phone
3	10	8/21/2012	3	Desk Lamp
			4	Memory Stick

Because all products that are sold must have a listing in the Product Catalog, every row in the Sales table has a matching row in the Product Catalog table. When these two tables are joined on Product ID, you end up with a table that looks like this:

Product ID	Product Name	Product ID	Sale Amount	Transaction Date
1	10 Inch Tablet	1	100	10/1/2012
1	10 Inch Tablet	1	2000	10/2/2012
2	Smart Phone	2	50	9/30/2012
3	Desk Lamp	3	10	8/21/2012

Now let's say you build a view to look at Sale Amount by Region. By default, dragging the Sale Amount field to the view may create a query like this:

```
SELECT SUM([Sales Amount]) FROM [Sales] S INNER JOIN [Product Catalog]
P ON S.ProductID = P.ProductID
```

By selecting **Assume Referential Integrity**, you tell Tableau that the joined tables have referential integrity. In other words, you are confirming that the Sales table will always have a matching row in the Product Catalog table. Because that is true, Tableau doesn't need any information from the Product Catalog table in order to return these results. When you drag the Sales Amount field into the view, Tableau can simplify the query to:

```
SELECT SUM([Sales Amount]) FROM [Sales]
```

This simplified query can often return quicker results because it removes the join operation. This option impacts only inner joins and does not affect data sources with a single table.

## Improve Performance for Cross-Database Joins

**Important:** This feature temporarily moves data outside of Tableau. Be sure that the database you're connected to is from a trusted source.

You can improve performance when joining data from a single file and a single database by allowing Tableau to perform the join using the database instead of Hyper. When this option is enabled, Tableau chooses the fastest option (Hyper or the connected database). If Tableau uses the connected database, the data from the file connection is moved into temporary tables in the database and the join is performed there.

### Feature conditions

This option is only available if the following conditions are met:

- The data source consists of one or more file-based connections and a single SQL-based connection.
- The file is a Microsoft Excel, PDF, or Text (.csv, .txt, .tsv or .tab) file type.
- The connected database is one of the following:
  - Microsoft SQL Server
  - Oracle
  - PostgreSQL
  - Vertica
  - Teradata
- The join type is an inner join.
- In **web authoring**: The **Allow users to use web authoring** option is enabled.

### Overriding feature conditions

As an administrator, you can override the file size, join type, and single file connection limitations and force Tableau to use the live database to perform the join. This enables you to experiment and determine optimal performance configurations. The single database connection requirement still applies.

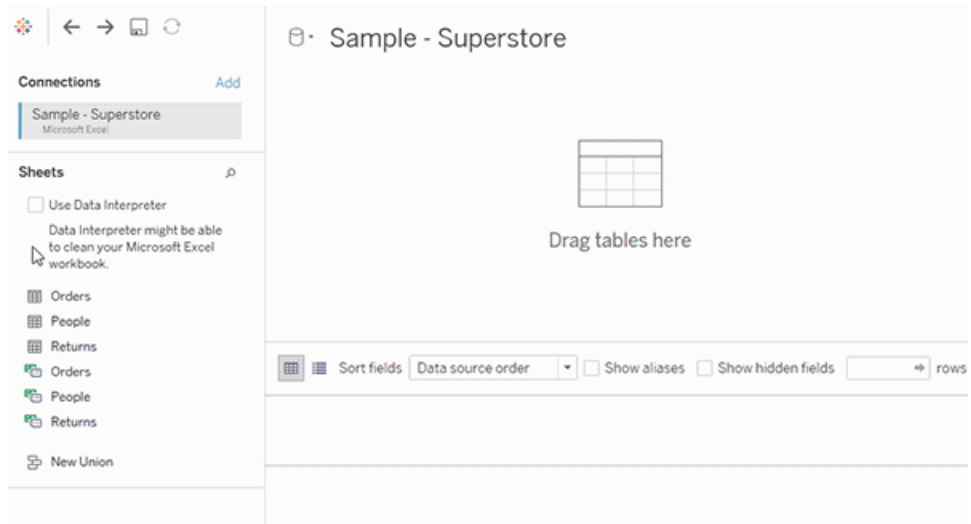

To enable this option enter the following information from the command line:

- **Tableau Desktop:** Enter the command `tableau.exe -DForceAlternativeFederationEngine=true`
- **Tableau Server:** Enter the tsm configuration command `tsm configuration set -k native_api.force_alternative_federation_engine -v true`

For more information about setting configuration values in Tableau Server, see [tsm configuration set Options](#) in the Tableau Server help.

### Enable the performance option for cross-database joins

1. Connect to the first data source.
  - In **Tableau Desktop:** On the Start page, under **Connect**, connect to a supported file type or supported database type. This step creates the first connection in the Tableau data source.
  - In **web authoring:** From the **Home** or **Explore** page, click **Create> Workbook** to start a new workbook and then connect to your data. This step creates the first connection in the Tableau data source.
2. Select the file or database that you want to connect to, then double-click or drag a table to the canvas.

3. In the left pane, under **Connections**, click the **Add** button (⊕ in web authoring) to add your second connection to the Tableau data source.

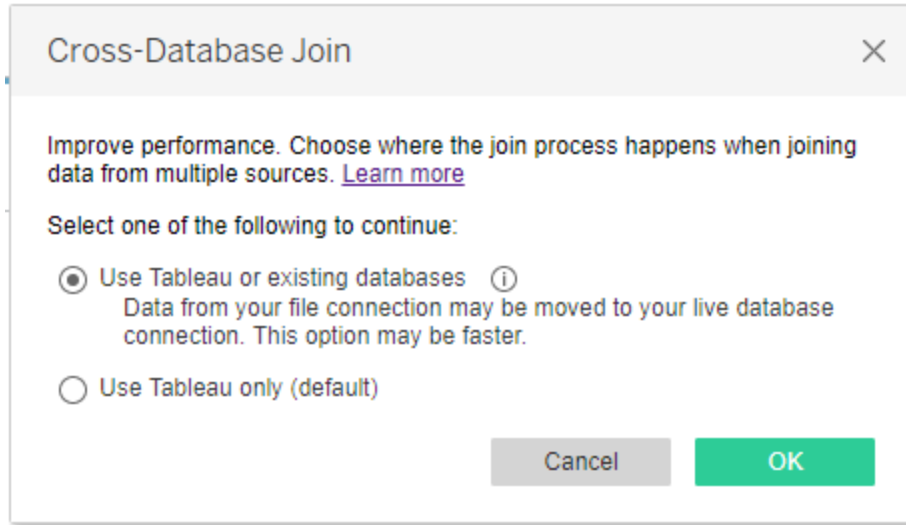

The **Cross-database join** option is displayed.

**Note:** If you don't see this option, check that you're using only supported data sources and that you have only two data sources (one file and one database type). Otherwise, the Site Administrator may have set the **Cross-Database Joins** configuration option to **Tableau only**.

4. To change how Tableau performs the join, next to the **Cross-database join** option, click **Edit**.
5. In the **Cross-Database Join** dialog, select one of the following options, then click **OK**:
  - **Use Tableau or existing databases.** This option allows Tableau to choose the fastest option to perform the join - either Hyper or the database you're connected to.
  - **Use Tableau only.** This option is the default and always uses Hyper to perform the

join.

The **Cross-database join** option changes from the default option, **Using Tableau** (using Hyper), to the new option **Using your database**, depending on what you choose.

**Important:** If you select **Use Tableau or existing databases**, Tableau chooses the fastest option when performing the join. This behavior is pre-determined by a set of criteria including join types. For instance, Tableau always chooses Hyper for non-inner joins.

If Tableau uses Hyper to perform the join, this process happens in the background and no indicator is shown to identify where the join was performed.

6. Add one or more join clauses by selecting a field from one data source, a join operator, and a field from the added table. Inspect the join clause to make sure it reflects how you want to connect the tables.

### About working with multi-connection data sources

Working with multi-connection data sources is just like working with any other data source, with a few caveats, discussed in this section.

### Union data from within a connection

To union data, you must use text tables or Excel tables from the same connection. That is, you can't union tables from different databases. In Tableau Desktop, you can union tables across different Excel workbooks and files in different directories. For more information, see the [Union tables using wildcard search \(Tableau Desktop\)](#) on page 798.

If you need to union data from different databases, use [Tableau Prep](#).

## Collation

Collation refers to the rules of a database that determine how string values should be compared and sorted. Usually, the collation is handled by the database. However, when you work with cross-database joins, you might join columns that have different collations.

For example, suppose your cross-database join used a join key comprised of a case-sensitive column from SQL Server and a case-insensitive column from Oracle. In cases like this, Tableau maps certain collations to others to minimize interpreting values incorrectly.

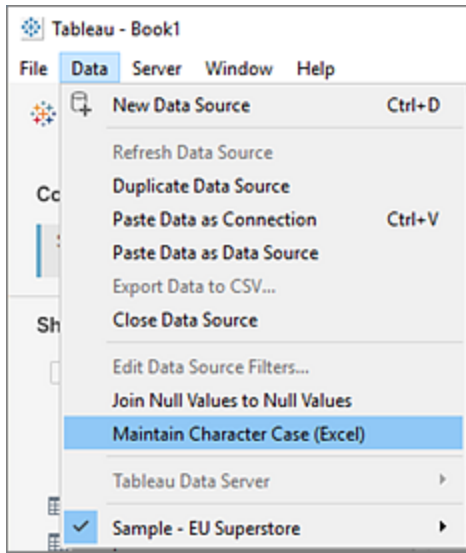

The following rules are used in cross-database joins:

- If a column uses collation standards of the International Components for Unicode (ICU), Tableau uses the collation of the other column.
- If all columns use collation standards of the ICU, Tableau uses the collation of the column of the left table.
- If no columns use collation standards of the ICU, Tableau uses a binary collation. A binary collation means the locale of the database and data type of the columns determine how string values should be compared and sorted.

## Maintain case sensitivity for Excel data

If you need to maintain case sensitivity for your Excel data when performing joins, enable the **Maintain Character Case (Excel)** option from the Data menu.

When this option is selected, Tableau maintains the casing and uniquely identifies values with different casing instead of combining them, resulting in a different number of rows.

For example, consider one worksheet with "House" and another with "house" and "HOUSE". By default, Tableau ignores the casing and considers all three variations of "house" as the same. With the **Maintain Character Case (Excel)** option enabled, when you join your tables, Tableau preserves the character casing differences. "House", "house", and "HOUSE" are treated as different values.

**Note:** This option is available for all Tableau supported languages and isn't dependent on the locale of your operating system. This option is only available for Microsoft Excel data sources.

## Calculations and multi-connection data sources

Only a subset of calculations can be used in a multi-connection data source.

- **In Tableau Desktop:** You can use a specific calculation if it's both:
  - Supported by all the connections in the multi-connection data source
  - Supported by Tableau extracts.
- **In web authoring (Tableau Cloud and Tableau Server):** You can use a specific calculation if it's supported by all the connections in the multi-connection data source.

## Stored procedures

Stored procedures aren't available for multi-connection data sources.

## Pivot data from within a connection

To pivot data, you must use text columns or Excel columns from the same connection. That is, you can't include columns from different databases in a pivot.

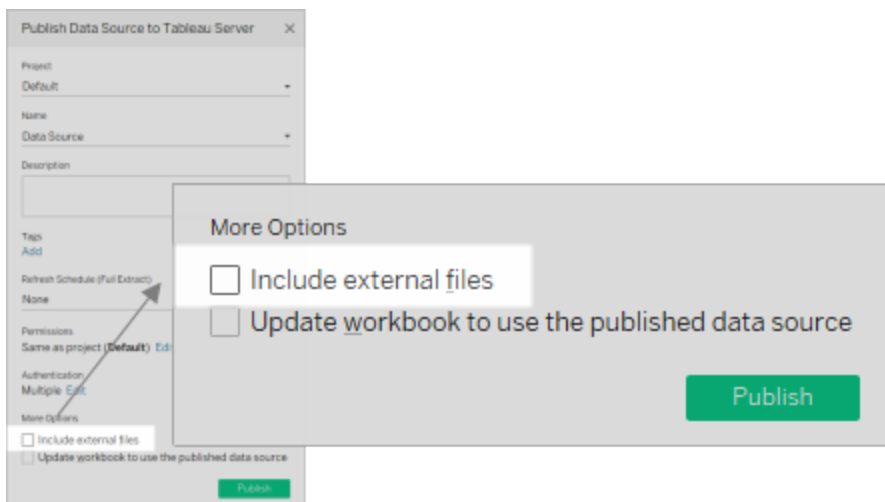

## Make extract files the first connection (Tableau Desktop only)

When connecting to extract files in a multi-connection data source, make sure that the connection to the extract (.hyper) file is the first connection. This preserves any customizations that might be a part of the extract, including changes to default properties, calculated fields, groups, aliases, and so on.

**Note:** If you must connect to multiple extract files in your multi-connection data source, only the customizations in the extract in the first connection are preserved.

## Extracts of multi-connection data sources that contain connections to file-based data (Tableau Desktop only)

If you're publishing an extract of a multi-connection data source with file-based data such as Excel, selecting the **Include external files** option copies the file-based data as part of the data source. In this case, a copy of your file-based data can be downloaded and its contents accessed by other users. If there's sensitive information in the file-based data that you've intentionally excluded from your extract, *don't* select **Include external files** when you publish the data source.

For more information about publishing data sources, see [Publish a Data Source on page 3076](#).

### About queries and cross-database joins

For each connection, Tableau sends independent queries to the databases in the join. The results are stored in a temporary table, in the format of an extract file.

**Important:** Cross-database joins may move data between databases. Be sure the databases you're joining are trusted sources.

For example, suppose you create connections to two tables, `dbo.listings` and `reviews$`. These tables are stored in two different databases, SQL Server and Excel. Tableau queries the database in each connection independently. The database performs the query and applies customizations such as filters and calculations, and Tableau stores the results for each connection in a temporary table. In this example, `FQ_Temp_1` is the temporary table for the connection to SQL Server and `FQ_Temp_2` is the temporary table for the connection to Excel.

#### SQL Server table    Excel table

When you perform a cross-database join, the temporary tables are joined by Tableau Desktop. These temporary tables are necessary for Tableau to perform cross-database joins.

After the tables have been joined, a Top N filter is applied to limit the number of values shown in the data grid to the first 1,000 rows. This filter is applied to help maintain responsiveness of the data grid and the overall performance of the Data Source page.

#### Joined tables

## Blend Your Data

Data blending is a method for combining data from multiple sources. Data blending brings in additional information from a secondary data source and displays it with data from the primary data source directly in the view.

Data blending is particularly useful when the blend relationship—the linking fields—need to vary on a sheet-by-sheet basis, or when combining published data sources.

### Options to combine data

There are several ways to combine data, each with their own strengths and weaknesses.

**Relationships** are the default method and can be used in most instances, including across tables with different levels of detail. Relationships are flexible and adapt to the structure of the analysis on a sheet by sheet basis. However, you can't create relationships between tables from published data sources.

**Joins** combine tables by adding more columns of data across similar row structures. This can cause data loss or duplication if tables are at different levels of detail, and joins must be established before analysis can begin. You can't use a published data source in a join.

**Blends**, unlike relationships or joins, never combine the data directly. Instead, blends query each data source independently, aggregate the results to the appropriate level, then present the results together visually in the view. Because of this, blends can handle different levels of detail and also work with published data sources. Blends don't create a new, blended data source (and therefore can't be published as a "blended data source"). Instead, they are simply blended results visualized per sheet.

### Steps for blending data

Data blending is performed on a sheet-by-sheet basis and is established when a field from a second data source is used in the view.

To create a blend in a workbook, you need to connect to at least two data sources. Then bring a field from one data source to the sheet—it becomes the primary data source. Switch to the other data source and use a field on the same sheet—it becomes a secondary data source. A linking icon will appear in the data pane, indicating which field(s) are being used to blend the data sources.

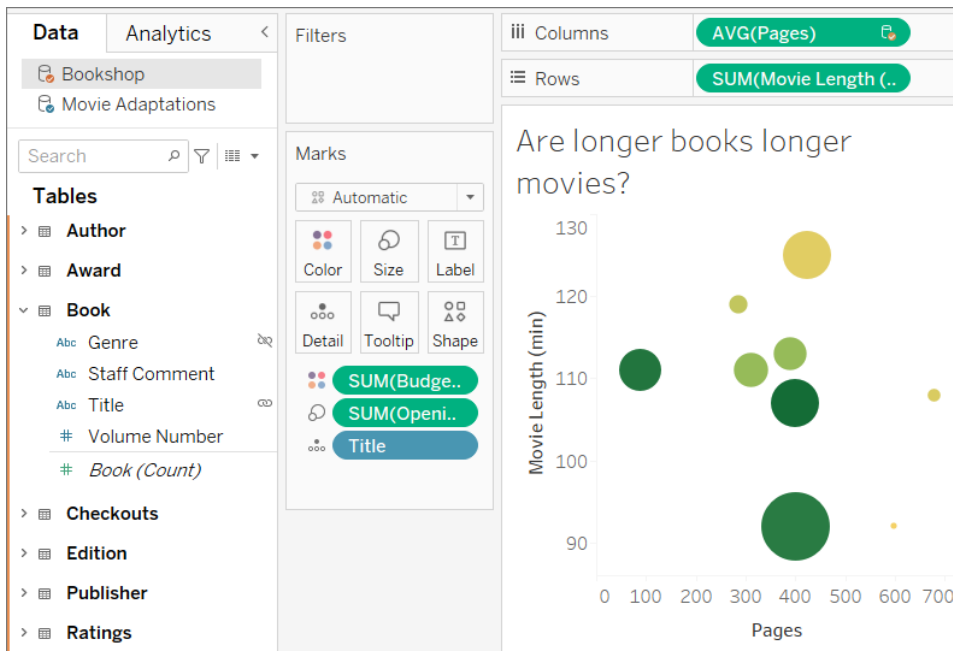

1. Ensure that the workbook has multiple data sources. The second data source should be added by going to **Data > New data source**.

**Tip:** Blending requires two or more distinct data sources, listed independently in the Data pane. Adding another *connection* to the first data source enables relationships and joins on the Data Source page.

2. Drag a field to the view. This data source will be the primary data source.
3. Switch to another data source and verify there is a blend relationship to the primary data source.
  - If there is a linking field icon (  ), the data sources are automatically linked. As long as there is at least one active link, the data can be blended.
  - If there are broken link icons (  ), click the icon next to the field that should link the two data sources. The slash will go away, representing an active link.
  - If a link icon does not appear next to the desired field, see [Define blend relationships for blending on page 769](#).
4. Drag a field into the view from the secondary data source.

As soon as this second data source is used in the same view, a blend is established. In the example below, our primary data source is **Movie Adaptations** and the secondary data source is **Bookshop**.

- The primary data source is indicated with a blue check mark on the data source. Fields from the primary data source used in the view have no indication.
- The secondary data source is indicated with an orange check mark on the data source and an orange bar down the side of the Data pane. Fields from the secondary data source used in the view have an orange check mark.

## Understand primary and secondary data sources

Data blending requires a primary data source and at least one secondary data source. The first data source used in the view becomes the primary data source and defines the view. This can restrict values from the secondary data source—only values that have corresponding matches in the primary data source appear in the view. This is comparable to a left join.

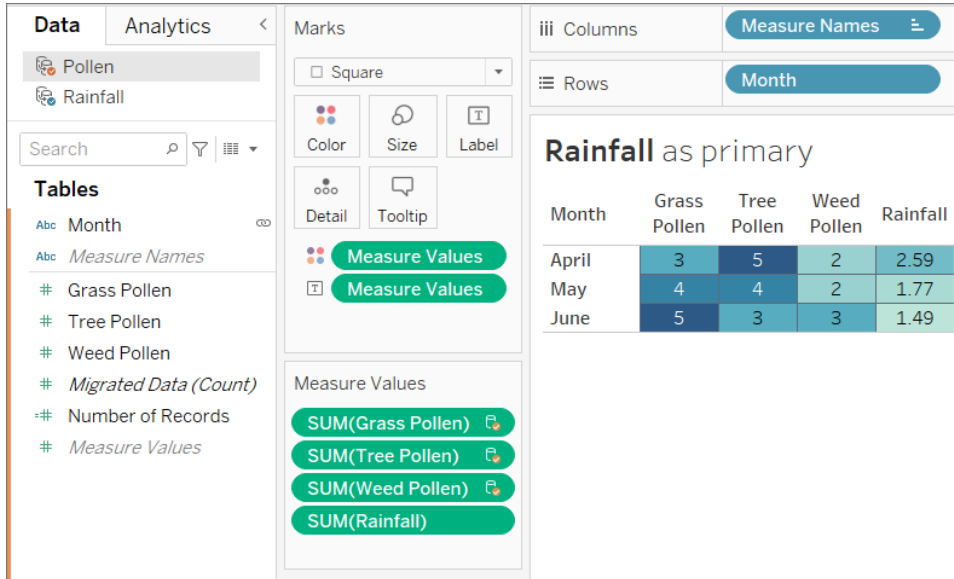

For example, if the primary data source has a Month field that only contains April, May, and June, any view built around months will only display April, May, and June, even if the secondary data source has values for twelve months. If the desired analysis involves all twelve months, try switching which data source is primary by rebuilding the sheet and using the other data source first.

## Learn more: the effects of data source order

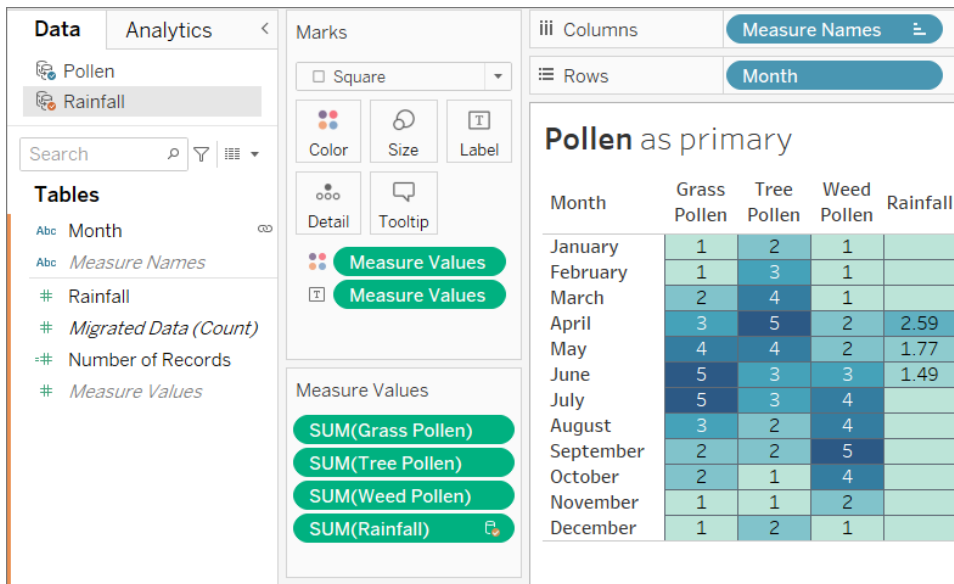

The following examples below use the same data sources linked on the same field, and the viz is built the same way both times. The difference between the results is due to which data source is designated as the primary.

1. Here, the Month field from the **Rainfall** data source is brought into the view first. Because **Rainfall** only contains three months, when the **Pollen** data set is added as a secondary,

only three months are brought into the view.

2. On another sheet, the Month field from the **Pollen** data set is brought into the view first. All twelve months are displayed. When the **Rainfall** data set is added as a secondary, **Rainfall** is only available for the three months in that data set.

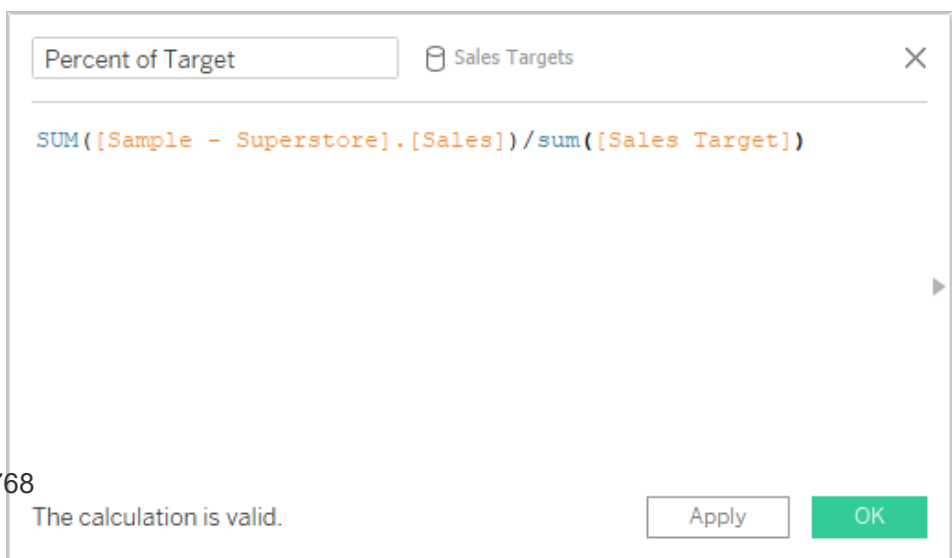

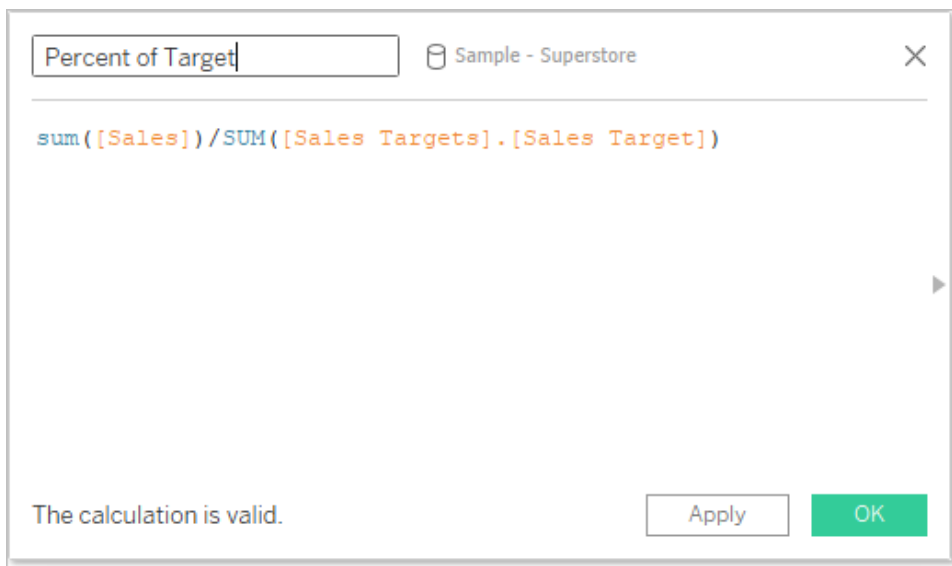

### Work across blended data sources

Due to the nature of a data blend, there are some things to keep in mind when working across blended data sources.

Performing calculations with fields from more than one data source can be slightly different than an ordinary calculation. A calculation must be created in a single data source; the top of the calculation editor indicates which data source the calculation is in.

- **Aggregation.** Any fields used from another data source will come in with an aggregation—by default, SUM, but this can be changed. Because calculations cannot mix aggregate and non-aggregate arguments, fields from the calculation's host data source must also be aggregated. (In the images below, the **SUM** aggregation was added automatically and the **sum** aggregation was added manually.)
- **Dot notation.** Any field referenced in the calculation that belong to another data source refers to its data source using dot notation. (In the images below, for the calculation built in **Sample - Superstore**, the Sales Target field becomes **[Sales.Targets].[Sales Target]**. When the calculation is built in **Sales Targets**, the Sales field becomes **[Sample - Superstore].[Sales]**.)
- These are equivalent versions of the same calculation built in each data source. In both cases, this is  $SUM(Sales) / SUM(Sales Target)$ .

In addition to handling calculations slightly differently, there are some limitations on secondary data sources. You may not be able to sort by a field from a secondary data source, and action filters may not work as expected with blended data. For more information, see [Other data blending issues on page 790](#).

## Define blend relationships for blending

In order for Tableau to know how to combine the data from multiple sources, there must be a common dimension or dimensions between the data sources. This common dimension is called the linking field. Active linking fields are identified in the Data pane for the secondary data source

with an active link icon (  ) and potential linking fields are identified with a broken link icon (  ). Linking fields are not indicated on the primary data source.

For example, in a blend of transactional and quota data, a geographic field might be the desired the linking field so you can analyze both quota and performance towards that quota for the same region.

**Note:** In order for the blend to function, the linking fields must also share values or members. Tableau builds the view of blended data based on the shared values. For example, if **Color** is the linking field in both data sources, Tableau will match data on "Purple" from the primary and "Purple" from the secondary. But "Lt. Blue" will not map correctly to "Light Blue", so one of them would need to be realiaised. Like renaming fields to help Tableau identify linking fields, you can edit aliases for members in those fields. For more information, see [Create Aliases to Rename Members in the View on page 1015](#).

## Establish a link

If the linking field in the primary and secondary data sources have the same name, Tableau automatically creates the relationship. When a primary data source is established (that is, a field is in use in the view) and the secondary data source is selected in the Data pane, any fields with

the same name between the two data sources will display a link icon (  or  ) in the *secondary* data source. If the related field from the primary data source is used in the view, the link becomes active automatically.

If there are no link icons on the secondary data source, you may need to help Tableau establish the link in one of two ways:

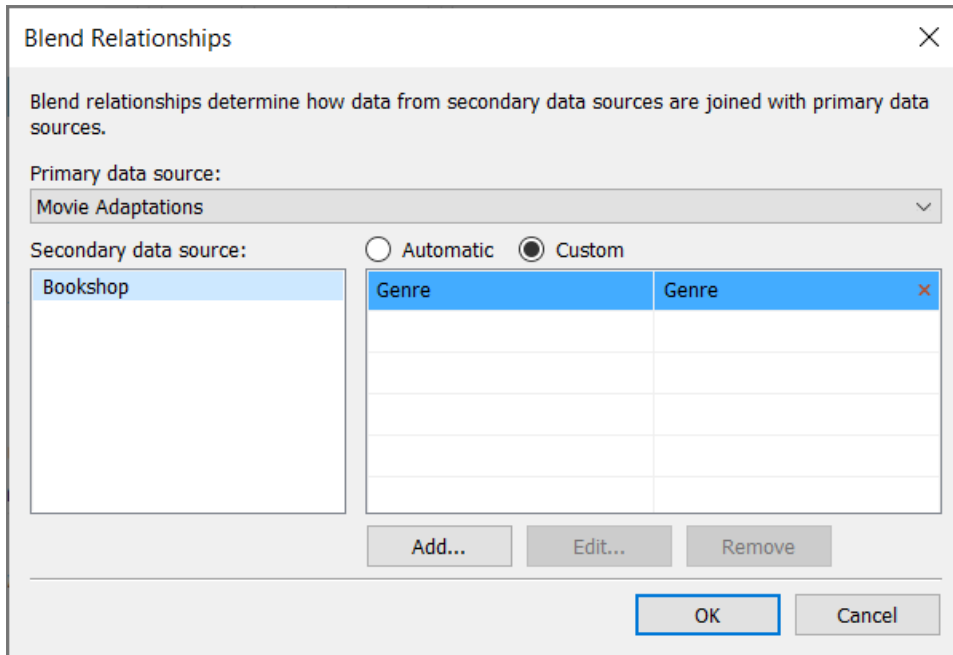

1. If common dimensions don't have the same name (such as "Title" and "Book Title"), renaming one will let Tableau identify them as common dimensions and establish the link.
2. Alternatively, you can manually define a relationship between the fields in the primary and secondary data sources. See below for more information on creating manual link relationship

There can be as many active or potential linking fields as necessary. Click the broken link icon (  ) in the data pane to make the relationship active.

## Manually define a link relationship

If your common dimensions do not share the same name, you can map the relationship between them manually.

1. Select **Data > Edit Blend Relationships....**
2. In the Blend Relationships dialog box, verify that the primary data source is selected from the **Primary data source** drop-down list.
3. Select the secondary data source in the **Secondary data source** pane. Any existing, automatic blend relationships are visible (and can be deleted by hovering over the row and clicking the x). Select **Custom** in the relationships list, and then click **Add**.

4. In the Add/Edit Field Mapping dialog box, do the following:
  - a. Select a field from the primary data source.
  - b. Select the comparable field from the secondary data source.
  - c. Click **OK**.

In this example, **Segment** is mapped to **Cust Segment**.

**Tip:** For dates, the relationship can be specified precisely. Expand the date field and select the desired aspect of the date, such as exact date, month, year, etc.

5. Create as many field mappings as desired, then click **OK**.

## Multiple links

As with relationships or joins, there are times when the links between the data sources are defined by more than one field. For example, if regional sales quotas are monthly, a blend between transactional sales data and quota data needs to be established on both region and month for the correct data to be brought together in the view. Multiple links can be active at the same time.

## Learn more: the impact of multiple linking fields

When data is blended based on multiple fields, values are included in the view only where the combination of data from those fields matches across both data sets. Let's look at an example to

understand this.

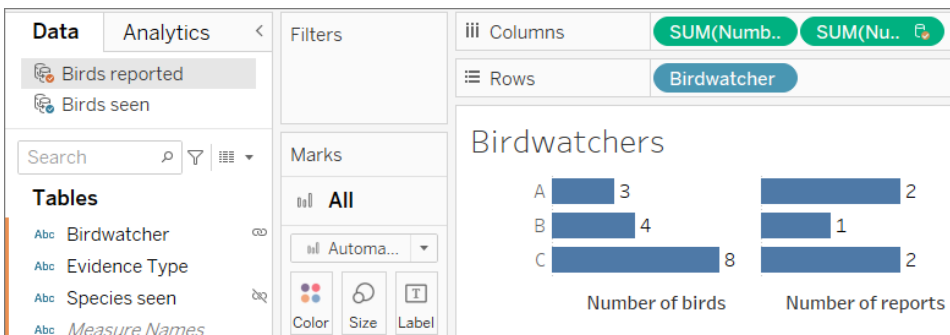

We have two tables, one for birds that were actually seen by birdwatchers, and one for birds that were reported as seen.

Birdwatcher	Species seen	Location	Number of birds
A	Grackle	Beach	1
	Oriole	Pier	2
B	Kiskadee	Beach	4
C	Kiskadee	Beach	5
	Oriole	Tree	3

and

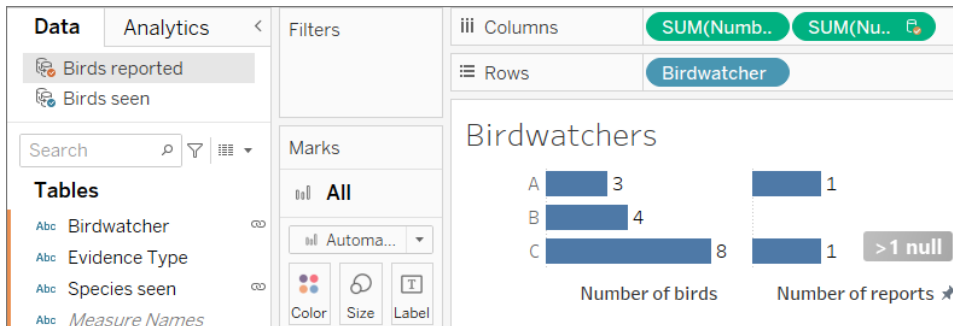

Birdwatcher	Species seen	Evidence Type	Number of reports
A	Kiskadee	journal entry	1
	Oriole	photograph	1
B	Grackle	journal entry	1
C	Grackle	journal entry	1
	Kiskadee	photograph	1

If we set up a blended view with the fields **Birdwatchers** and **Number of birds** from the primary data source (**Birds seen**) and bring in the field **Number of reports** from the secondary data source (**Birds reported**), Tableau automatically blends on **Birdwatcher**.

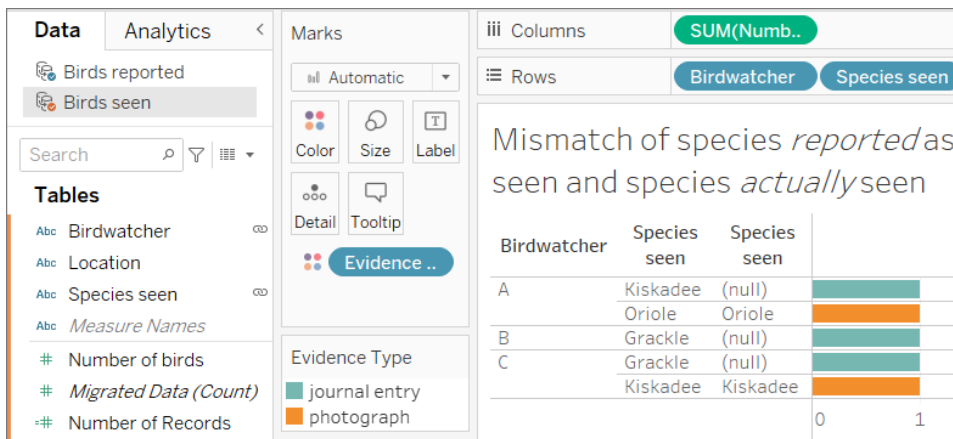

We see that birdwatcher A saw three birds and made two reports, B saw four birds and made one report, and C saw 8 birds and made two reports.

But there's another possible linking field, **Species seen**. Why not blend on this, too? Will it make a difference?

It makes quite a dramatic difference. Now we see that there is only one report each for birdwatchers A and C, and B has a null. What's going on?

It turns out that these birdwatchers aren't very honest. When they only reported their sightings based on a journal entry (blue bars in the image above), the species they reported seeing didn't match what they actually saw (note the nulls in the second column, from the **Birds seen** secondary data source). When they backed up the report with a photograph (orange bars), they were honest (both columns of **Species seen** match).

Because three reports didn't match on species, those rows of data were dropped when **Species seen** was used as a linking field. The view only shows data where values for both linking fields match.

## Takeaway

Be careful when linking on multiple fields. Although it can be very easy to click the icon and establish an active link, over-linking or linking on undesired fields can have a serious impact on

the analysis.

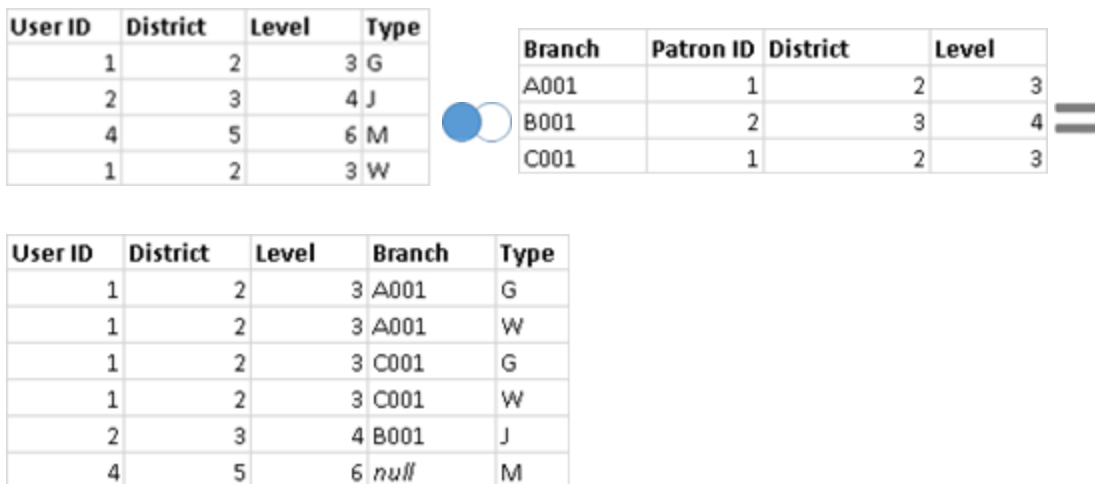

## Differences between joins and data blending

Data blending simulates a traditional left join. The main difference between the two is when the aggregation is performed. A join combines the data and then aggregates. A blend aggregates and then combines the data.

### Left join

When you use a left join to combine data, a query is sent to the database where the join is performed. A left join returns all rows from the left table and any corresponding rows from the right table. The results of the join are then sent back to Tableau and aggregated for display in the visualization.

A left join takes all rows from the left table. The common columns are **User ID** and **Patron ID**; where there is corresponding information from the right table, that data is returned. Otherwise, there is a null.

Suppose you have the same tables, but flip the order. This new left join produces different results. Again, a left join takes all the data from the new left table, but essentially ignores a row from the right table. The row of data for User ID = 4 is not included because there is no row for Patron ID = 4 in the left table.

Branch	Patron ID	District	Level
A001	1	2	3
B001	2	3	4
C001	1	2	3

User ID	District	Level	Type
1	2	3	G
2	3	4	J
4	5	6	M
1	2	3	W

User ID	District	Level	Branch	Type
1	2	3	A001	G
1	2	3	A001	W
1	2	3	C001	G
1	2	3	C001	W
2	3	4	B001	J

## Data blending

When you use data blending to combine data, a query is sent to the database for each data source that is used on the sheet. The results of the queries are sent back to Tableau as aggregated data and presented together in the visualization.

**Note:** Aggregating measures is straightforward—we can take the sum, average, maximum, or other aggregation of a number with ease. Measure values are aggregated based on how the field is aggregated in the view. However, all fields from a secondary data source must be aggregated. How does that work for dimensions? Dimension values are aggregated using the **ATTR** aggregate function, which returns a single value for all rows in the secondary data source. If there are multiple values contained in those rows, an asterisk (\*) is shown. This can be interpreted as "there are multiple values in the secondary data source for this mark in the view".

The view uses all values from the primary data source (functioning as the left table) and the corresponding rows from the secondary data source (the right table) based on the linking field (s).

Suppose you have the following tables. If the linking fields are **User ID** and **Patron ID**, not all values can be a part of the resulting table because of the following:

- A row in the left table does not have a corresponding row match in the right table, as indicated by the null value in the results.
- There are multiple corresponding values in the rows in the right table, as indicated by the asterisk (\*) in the results.

User ID	District	Level	Type
1	2	3	G
2	3	4	J
4	5	6	M
1	2	3	W

Branch	Patron ID	District	Level
A001	1	2	3
B001	2	3	4
C001	1	2	3

User ID	District	Level	Branch	Type
1	2	3	*	G
2	3	4	B001	J
4	5	6	<i>null</i>	M
1	2	3	*	W

When measures are involved, they are also aggregated, as seen below:

Branch	Patron ID	District	Level	Fines
A001	1	2	3	10.00
B001	2	3	4	20.00
C001	1	2	3	30.00

↓

User ID	District	Level	Type
1	2	3	G
2	3	4	J
4	5	6	M
1	2	3	W

Branch	Patron ID	District	Level	Fines
*	1	2	3	40.00
B001	2	3	4	20.00
*	1	2	3	40.00

User ID	District	Level	Type	Branch	Fines
1	2	3	G	*	40.00
2	3	4	J	B001	20.00
4	5	6	M	<i>null</i>	<i>null</i>
1	2	3	W	*	40.00

Important: an asterisk (\*) in a view with blended data indicates multiple values. This can be resolved by ensuring there is only one matching value in the secondary data source for each mark in the primary data source, potentially by swapping the primary and secondary data sources. For more information, see [Troubleshoot Data Blending on page 784](#).

### Data blending at a glance

- Data blending occurs on a sheet-by sheet basis.
- The order in which fields are used determines which data source is the primary versus the secondary data source.

- The primary data source is indicated with a blue check mark, any secondary data sources and fields from secondary data sources have an orange check mark.
- Linking fields can be automatically determined based on shared field names or the blend relationship can be manually created.
- Data blending behaves similarly to a left join, which may result in missing data from the secondary data source.
- Asterisks (\*) may appear. This indicates multiple dimension values in a single mark, because data blending takes aggregated results and combines them in the view.
- A secondary data source can be used to re-alias the field values in a primary data source. For more information, see [Alias Field Values Using Data Blending](#) below.

### Data blending limitations

- There are some data blending limitations around non-additive aggregates, such as COUNTD, MEDIAN, and RAWSQLAGG. For more information, see [Troubleshoot Data Blending on page 784](#)
- Blended data sources cannot be published as a unit. Instead, publish each data source separately (to the same server) and then blend the published data sources.
- Data from secondary data sources must always be aggregated in calculations.
- If you are blending a cube data source, it must be the primary data source.

### Alias Field Values Using Data Blending

Data blending is a method for combining data. Data blending works by supplementing the data in the primary data source with the data in the secondary data source.

Aliasing is the alternative name that you can assign to a value in a dimension field. You can use aliases to rename specific values within a dimension. This can be useful when you want to show more relevant or descriptive dimension values in your view than what the original data provides.

You can use data blending as a method for re-aliasing values in a data source by using field values from another data source. To do this, there must be a field in the secondary data source that contains aliases for a field in the primary data source.

For example, suppose you have a primary data source that contains information on fruit, including fruit names and code values that the fruit are associated with. A secondary data source contains a field with more descriptive code values.

**Primary data source      Secondary data source**

<b>Fruit</b>	<b>Fruit ID</b>	<b>Alternate ID</b>
Apple	A	APP
Banana	B	BAN

When you re-alias a field in your primary data source, you can create a view that replaces the original code values with the more descriptive code values.

**Note:** After you have used the secondary data source to provide aliases for the primary data source, you no longer need the secondary data source and can close it.

To alias field values

1. Set up the primary and secondary data sources and establish a relationship between the data sources. For more information, see [Blend Your Data on page 764](#). The data sources used in this example are Fruit Stand and Alternate ID.

2. Select the primary data source in the **Data** pane, and then drag the field that you want to alias to the view.

For this example, Fruit Stand is the primary data source.

3. Select the secondary data source in the **Data** pane, and drag the field that contains the alias information to the view.

For this example, Alternate ID is the secondary data source. **Note:** The field you are using to alias the field values in the primary data source cannot be the linking field you are using to link the primary and secondary data sources.

In this example, Alternate ID field in the secondary data source contains the aliasing information needed by the Fruit Stand field in the primary data source.

Columns		
Rows		
Fruit ID	Alternate ID	
A	APP	Abc
B	BAN	Abc
C	CAN	Abc
D	DUR	Abc
E	EMB	Abc

4. Right-click (control-click on a Mac) the field from the secondary data source and select **Edit Primary Aliases**.

Values in the primary data source must have corresponding alias values in the secondary data source. An asterisk under **Has Alias** confirms that the data sources have corresponding alias values .

**Note:** If asterisks don't appear under **Has Alias**, then either the secondary data source doesn't have the corresponding aliases to match the field values in the primary data source, or there is more than one field value in the primary data source that has the same

alias in the secondary data source. In cases like this, aliasing field values in the primary data source with data from the secondary data source is not possible.

5. Click **OK**. The alias values in the secondary data source replace the field values in the primary data source. In this example, the more descriptive code values from Alternate ID field replaces the values in the Fruit ID field.

The screenshot shows the Tableau interface with a table view. The 'Columns' shelf is empty. The 'Rows' shelf contains two fields: 'Fruit ID' and 'Alternate ID'. The table below shows the following data:

Fruit ID	Alternate ID	
APP	APP	Abc
BAN	BAN	Abc
CAN	CAN	Abc
DUR	DUR	Abc
EMB	EMB	Abc

6. (Optional) Select the secondary data source from the **Data** menu, and select **Close**.

## Bring a Field into the Primary Data Source

Data blending is a method for combining data. Data blending works by supplementing the data in the primary data source with the data in the secondary data source.

In cases where you might only need just *some* of the data in the secondary data source, you can create a primary group to bring only the fields that you need into the primary data source. This eliminates the need for the secondary data source, which reduces the size of the workbook and can improve workbook performance.

For example, suppose you have two data sources: Superstore and Population. The Superstore data source contains lots of data, but most importantly, it contains data about states and the region each of the states is associated with. The Population data source contains state and population data, but doesn't contain any data about regions. In this case, you can blend the Population and Superstore data sources to create a primary group. Then so that you can pull in the Region field from the Superstore data source into the Population data source, thereby eliminating the need for the Superstore data source all together.

## To blend two data sources and create a primary group

1. Download and open the following workbook from Tableau Public.
  - a. Go to <https://public.tableau.com/profile/tableau.docs.team#!/vizhome/BringaFieldintothePrimaryDataSource/Sheet1>.
  - b. Click **Download Workbook** in the upper-right corner and then open the workbook.

In the workbook, the **State** dimension is already on the **Rows** shelf, making it the first field in the view and establishing the Population data source as the primary data source for the sheet. The Superstore data source is also included in the workbook and functions as the secondary data source.

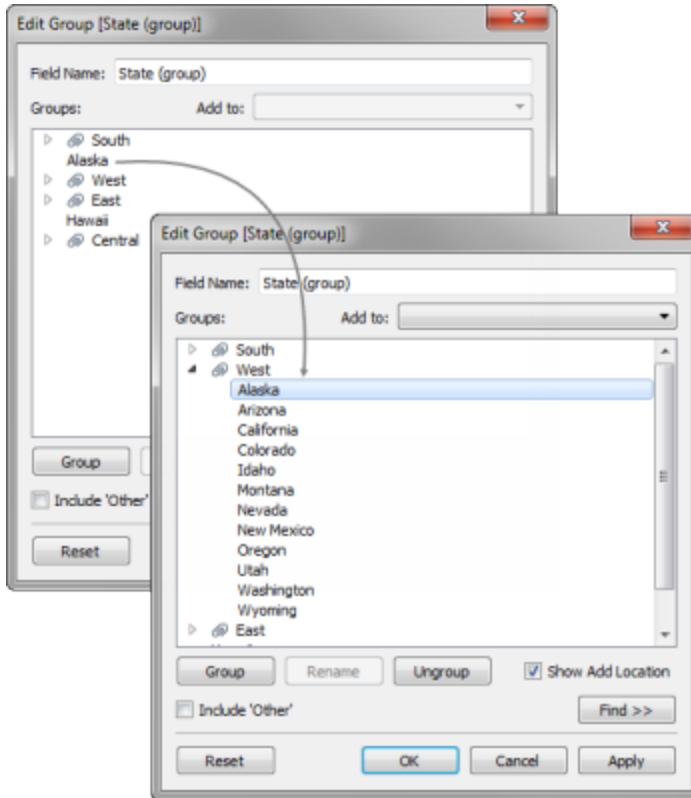

2. In the **Data** pane, select Superstore, and then drag the **Region** dimension to the **Rows** shelf and place it in front of **State**.

The view shows the regions from the Superstore data source (secondary) and the states in the Population data source (primary) that are associated with those regions. There are two states, Alaska and Hawaii, from Population data source (primary) that are not associated with a specific region. These two states are assigned to a "null" region.

Region	State	
Null	Alaska	Abc
	Hawaii	Abc
Central	Illinois	Abc
	Indiana	Abc
	Iowa	Abc
	Kansas	Abc
	Michigan	Abc
	Minnesota	Abc
	Missouri	Abc
	Nebraska	Abc
	North Dakota	Abc
	Oklahoma	Abc
	South Dakota	Abc
East	Connecticut	Abc

3. Right-click the **Region** field in the **Rows** shelf from the Superstore data source (secondary), and select **Create Primary Group**.
4. In the Edit Group dialog box, drag Alaska and Hawaii (from the "null" region) to the **West** region. This task assigns the states in the Population data source (primary) in the "null" region into a region.

5. Click **OK** to close the Edit Group dialog box.
6. In the **Data** pane, select the State data source (secondary). Now you see a new group field listed in the Population data source (primary) called **State (group)**.
7. Drag the **State (group)** dimension over the Region dimension on the **Rows** shelf to replace it.
8. Drag the **2016 Population** measure to the **Columns** shelf to see Population based on the regions from the Superstore (secondary) data source.
9. (Optional) You can close the Superstore data source (secondary), and then continue with your analysis. You can also publish the data source or workbook without the secondary

data source. This is because the field you were using from the secondary data source, **Region**, is replaced by the primary group field that you created in the primary data source.

## Troubleshoot Data Blending

When you use data blending to combine your data from different data sources, there are a few common issues that might arise. This topic lists them and describes how you can respond to each situation.

### Common warnings and errors when blending data sources

#### No relationship to the primary data source

When you drag a field from a secondary data source to the view, you might see a warning that says:

*Fields cannot be used from the [name of secondary data source] data source, because there is no blend relationship to the primary data source. In the Data pane, switch to the [name of secondary data source] data source, and click at least one link icon to blend these data sources.*

This warning occurs when you have no active links in the secondary data source

For example, suppose you have two data sources that are related by the **State** and **Date** fields.

At least one of these fields must have the active link icon (  ) next to it in the secondary data source. You can make the link active by clicking a broken link icon (  ) in the **Data** pane or by using the linking field from the primary data source in the view.

The secondary data source may not have any links to the primary data source. Look in the **Data** pane for the link icon. Tableau automatically links fields that have the same name. If your fields do not have the same name, you must define a link between them. For more information, see [Blend Your Data on page 764](#).

#### Primary and secondary connections are from tables in the same data source

When you drag a field from a secondary data source to the view, you might see a warning that says:

*The primary and secondary connections are from tables in the same data source. Instead of linking the connections, use the Data menu to join the data. Joins can integrate data from many tables and may improve performance and filtering.*

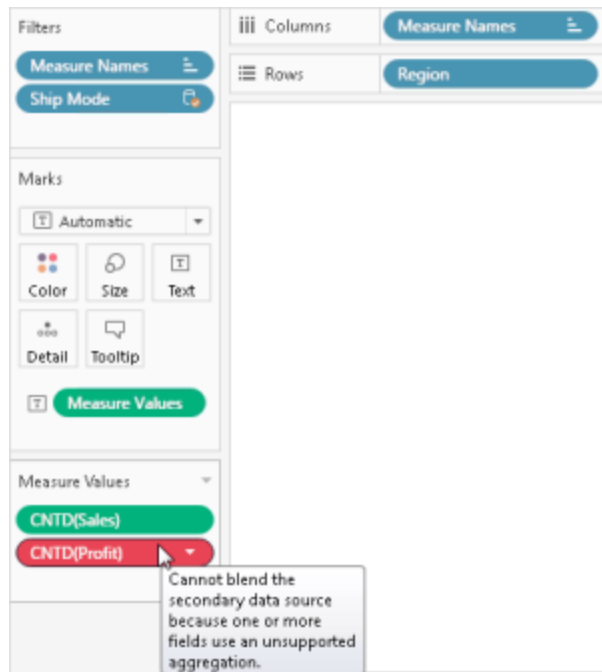

This warning occurs when the workbook contains separate data sources that connect to the same database. Though you can combine data in this way, Tableau recommends that you use a join or relationship to combine data from the same database instead, as they can leverage some of the database's native optimizations in ways blending can't.

### Cannot blend the secondary data source because one or more fields use an unsupported aggregation

Data blending has some limitations regarding non-additive aggregates such as COUNTD, MEDIAN, and RAWSQLAGG. Non-additive aggregates are aggregate functions that produce results that cannot be aggregated along a dimension. Instead, the values have to be calculated individually. All Number functions, except for MAX and MIN, are non-additive aggregates. For more information, see [Tableau Functions \(by Category\)](#) on page 2320.

These limitations cause certain fields in the view to become invalid under certain circumstances. If you hover your mouse cursor over one of these invalid fields, you see the following error:

*Cannot blend the secondary data source because one or more fields use an unsupported aggregation.*

This error can occur for one of the following reasons:

- **Non-additive aggregates from the primary data source:** Non-additive aggregates are only supported in the primary data source if the data in the data source comes from a relational database that allows the use of temporary tables. To work around this issue, consider creating an extract of your data source. Extracts support temporary tables.
- **Non-additive aggregates from the secondary data source:** Non-additive aggregates are only supported in the secondary data source if the linking field from the primary data source is included in the view and no non-aggregated dimensions from the secondary data source is included in the view. Some number functions can still be used if they include an additive aggregation. For example, use `ROUND(SUM([Sales]),1)` instead of `ROUND([Sales],1)`.
- **Non-additive aggregates from a multi-connection data source that uses a live connection:** Multi-connection data sources that connect to data using a live connection do not support temporary tables. Therefore, using a multi-connection data source that connects to data using a live connection prohibits the use of blending functionality with non-additive aggregates. To work around this issue, consider creating an extract of your multi-connection data source. Extracts support temporary tables.
- **LOD expressions from the secondary data source:** This error can also appear when you use a level of detail expression in a view that uses data blending. To resolve the error, make sure the linking field in the primary data source is in the view before you use an LOD expression from the secondary data source and remove any dimensions, including dimension filters, from the secondary data source.

## Data sources that contain logical tables cannot be used as secondary data sources for data blending

The secondary data source can use logical joins as long as the following conditions are satisfied:

- All active linking fields from the primary data source must be included in the view on a shelf other than the Filters shelf
- All fields from the secondary data source are aggregated, including dimensions

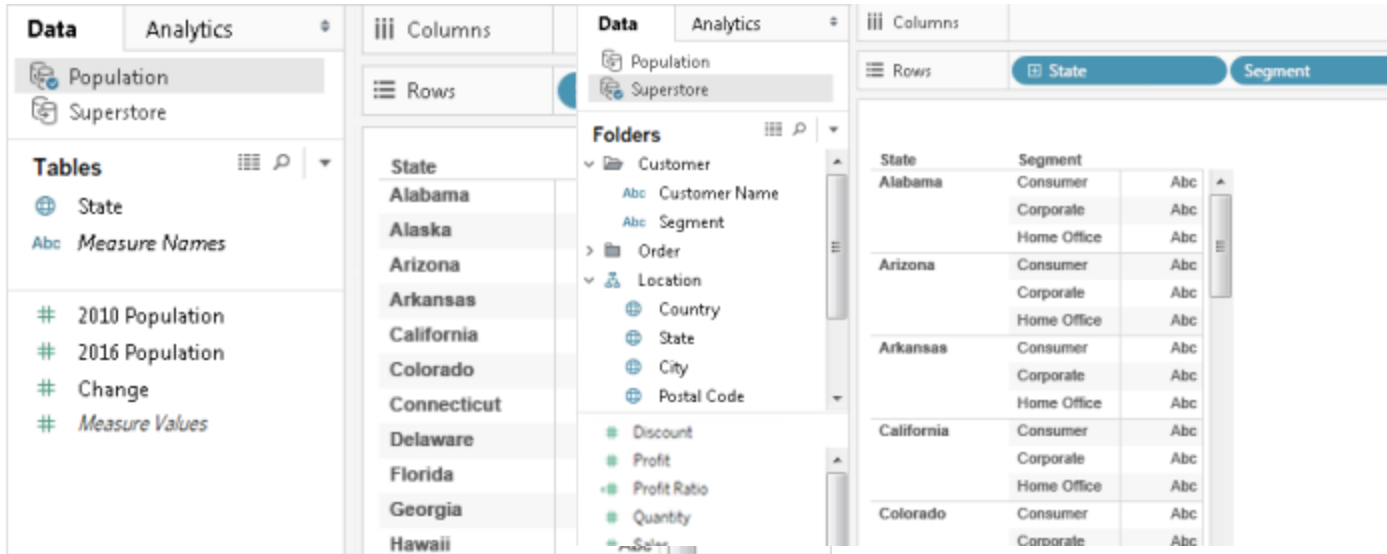

## Asterisks show in the sheet

When you blend data, make sure that there is only *one* matching value in the secondary data source for each mark in the primary data source. If there are multiple matching values, you see an asterisk in the view that results after you blend data.

For example, suppose you have two data sources: Population and Superstore. The primary data source, Population, has a field called **State**. The secondary data source, Superstore, contains fields called **State** and **Segment**. In the secondary data source, each state has multiple segments. Alabama, for example, has three segments: Consumer, Corporate, and Home Office.

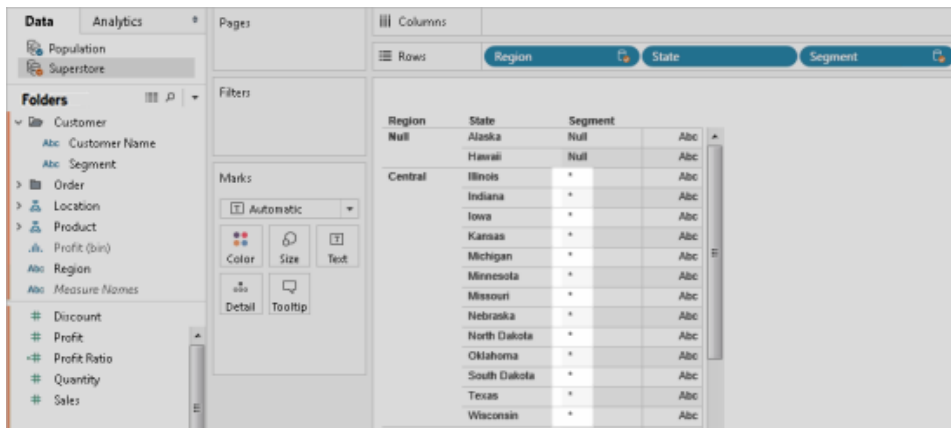

**Primary data source**

**Secondary data source**

When you blend the two data sources on the **State** field, you create a link where individual state values (in the primary data source) can have multiple segment values (in the secondary data source). In this case, multiple values for segments in the secondary data source for each corresponding state value in the primary data source cause asterisks to appear in the view, as demonstrated by the images below.

**Blended data**

## Resolve asterisks in the sheet

Avoid asterisks in the sheet by making sure that there is only *one* matching value in the secondary data source for each mark in the primary data source. Though the way you ensure this depends on the data and the view you're trying to create, consider one of the following suggestions to resolve asterisks in the sheet.

- Add field with a higher level of granularity from the primary data source to the sheet.

For example, suppose you have a view similar to the example used above. Consider adding a field such as City into the sheet because its values are at a higher level of granularity than a field like State.

- Rebuild the view to switch the primary and secondary data sources with each other. In general, you should make the data source whose values have a higher level of granularity the primary data source.

For example, suppose you have a view similar to the example used above. Consider making Superstore the primary data source and Population the secondary data source.

## Null values appear after blending data sources

Null values can sometimes appear in place of the data you want in the view when you use data blending. Null values can appear for a few reasons:

- The secondary data source does not contain values for the corresponding values in the primary data source.
- The data types of the fields you are blending on are different.
- The values in the primary and secondary data sources use different casing.

Data blending works by supplementing the data in the primary data source with data from the secondary data source based on the linking field. This means Tableau takes all the data in the primary data source, and only the corresponding matches in the secondary data source. If Tableau cannot identify at least one matching value in the secondary data source for the corresponding value in the primary data source, null values appear.

You can resolve this issue by doing the following:

- **Insert data in the secondary data source:** Insert missing data in the secondary data source so that all records in the primary data source have a match. For example, suppose your primary data source contains values for all 50 U.S. states, but your secondary data

source only has values for 30 U.S. states. To resolve this issue, you can add values for the remaining 20 U.S. states to the underlying data set of the secondary data source.

Alternatively, you might be able to [Bring a Field into the Primary Data Source](#) on page 781 or [Alias Field Values Using Data Blending](#) on page 778 to work around null values if you cannot modify the underlying data.

- **Verify data types in the primary and secondary data sources match:** For example, both data sources should use string data for the fields you are blending on, or both fields should contain numbers. You can't blend fields where one field contains numbers and the other contains strings.
- **Verify the casing of the values in the primary and secondary data sources match:** If one data source uses a mix of upper- and lowercase names, and the other uses only uppercase, you'll see null values. For more information, see [Nulls Show When Data Blending](#).

## Blending issues after publishing data sources

When you make a field-level customization that blends two data sources, the customization is based on one of the data sources, the primary data source. Then, when the primary and secondary data sources are published to Tableau Server or Tableau Cloud, the primary data source, which contains the customization (i.e., the reference to the secondary data source) no longer works. The customization no longer works because the blend relationship between the primary and secondary data sources is lost. This is because the blend relationship between the primary and secondary data sources is defined at the workbook level.

For example, suppose you have two data sources: Store - Main and Store - West. You create a field-level customization, like a calculation, that combines the sales totals from the primary data source, Store - Main, with the sales totals from the secondary data source, Store - West. As soon as you publish the data sources to Tableau Server or Tableau Cloud, the calculation in Store - Main no longer works. This is because the calculation refers to the secondary data source, Store - West, whose location is now undetermined.

To work around this scenario, do the following:

1. Before creating any field-level customizations, publish each data source first.
2. Connect to each data source.
3. Create a workbook that contains the field-level customizations that you need.
4. Publish the workbook to Tableau Server.

You can use this workbook as a "template" that can be shared and downloaded by you and others.

## Blending with a cube (multidimensional) data source

Cube data sources can only be used as the primary data source for blending data in Tableau. They cannot be used as secondary data sources.

## Other data blending issues

For other issues that emerge while blending data, see the following links.

## Sort is not available

- For issues sorting on a calculated field, see [Sorting by Fields is Unavailable for Data Blended Measures](#).
- For issues with a computed sort, see [Sort Options Not Available from Toolbar When Data Blending](#).

## Actions do not behave as expected

- Fields from the secondary data source cannot be added to a URL action. See [Fields from Blended Data Source Unavailable for URL Actions](#).
- Action filters are not behaving as expected. See [Action Filters with Blended Data Not Working as Expected](#).

## Unexpected values and field changes

- Duplicate totals after every date value in the view. See [Issues with Blending on Date Fields](#).
- Underlying data shows different values than blended data. See [Underlying Data from Secondary Data Source Not Displayed or Consistent with Blended Data](#).

## Blend on Summary Data

Data blending is a method for combining data. Data blending works by supplementing the data in the primary data source with the data in the secondary data source.

When one of the data sources that you're working with is large, you can reduce query time by using data blending to combine data in the primary data source with summary data from the secondary (large data source).

For example, suppose you have two data sources: Store - North and Store - South. Store - North is the primary data source and Store - South is the large secondary data source. To reduce query times when working with a large data source like Store - South, you can use data blending to blend only on the summary data of the large secondary data source (Store - South) with the data in the smaller and presumably faster primary data source (Store - North).

To blend on summary data, you can do the following:

1. Create a relationship between data sources.
2. Bring summary data from the secondary data source into the primary data source.
3. Compare primary data source data to summary data in the secondary data source.

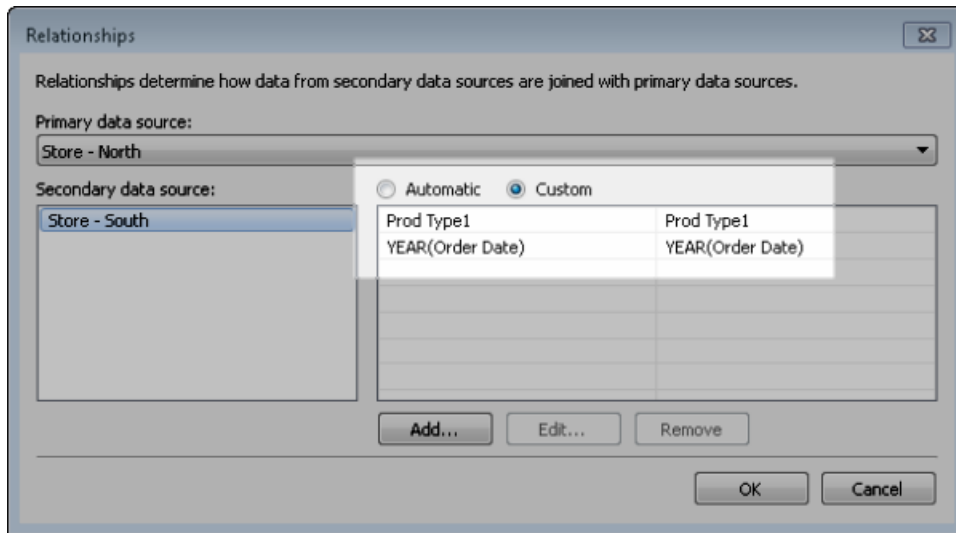

### Step 1: Create a relationship between the primary and secondary data sources

1. Download and open the following from Tableau Public.
  - a. Go to <https://public.tableau.com/profile/tableau.docs.team#!/vizhome/BlendonSummaryData/Sheet1>.
  - b. Click **Download Workbook** in the upper-right corner.

In the workbook, the Order Date dimension is already on the Columns shelf, making it the first field in the view and establishing *Store - North* as the primary data source for the sheet. The *Store - South* data source is also included in the workbook and functions as the large secondary data source.

2. Select **Data > Edit Relationships**.
3. In the Relationships dialog box, select **Custom**, and then click **Add**.
4. In the Add/Edit Field Mapping dialog box, in both lists, click the arrow next to Order Date, select **Year(Order Data)**, and then click **OK**.
5. In the Relationships dialog box, click **Add** again.
6. In the Add/Edit Field Mapping dialog box, in both lists, click **Prod Type 1**, and then click

OK.

Step 2: Bring summary data from the secondary data source into the primary data source

1. In the Data pane, select the Store - North data source.
2. Select **Analysis > Create Calculated Field**.
3. In the calculation dialog box, do the following:
  - a. In the name text box, enter **Sales for Store - South**.
  - b. In the formula text box, type the ZN function, the SUM function, and the Sales Totals field from the Store - South data source.

Your formula should look like the following: `ZN(SUM([Store - South].[Sales Total]))`

This formula pulls in just the sales data from the large secondary data source.

4. Select **Analysis > Create Calculated Field**.

5. In the calculation dialog box, do the following:

- a. In the name text box, enter **Total Sales (North and South)**.
- b. In the formula text box, type the following:

```
IF ISNULL([Sales for Store - South]) THEN 0 ELSE [Sales for Store - South]END
```

+

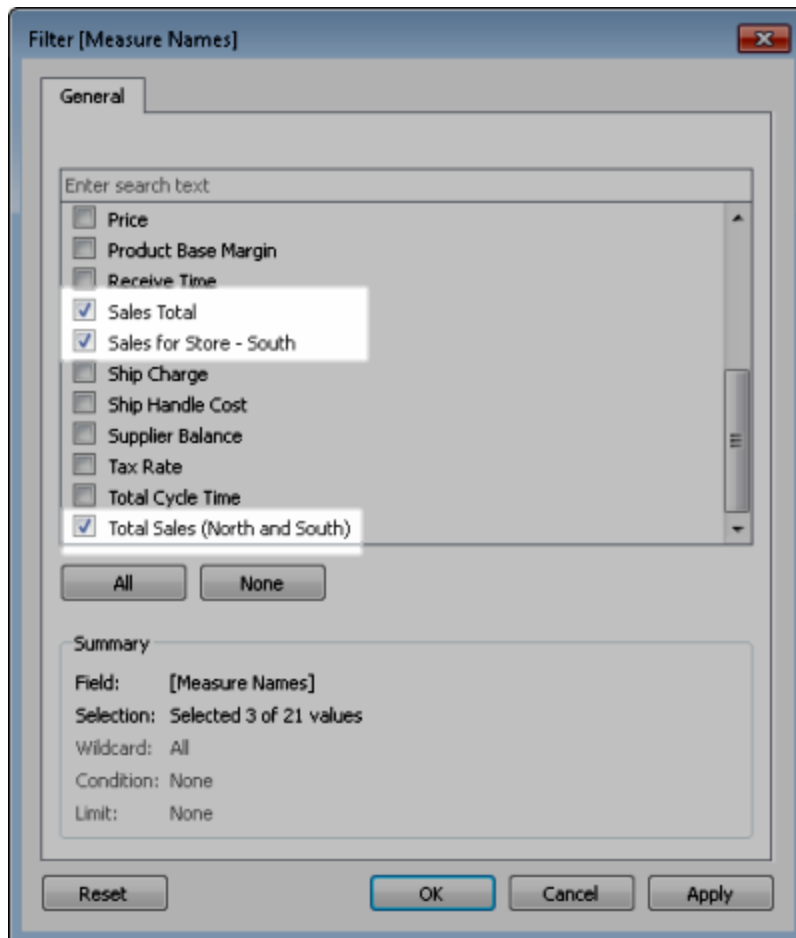

```
IF ISNULL (SUM([Sales Total])) THEN 0 ELSE SUM([Sales Total]) END
```

This formula adds the sales data from the large secondary data source to the sales data in the primary data source to get combined sales for Store - South and Store - North.

### Step 3: Compare primary data source data to summary data of secondary data source

1. From the Data pane, drag **Order Date** to the Columns shelf and **Prod 1** to Rows shelf.
2. Drag **Measure Names** to the Rows shelf, and then to the Filters shelf.
3. In the Filter dialog box, click **None**, and then select **Sales Total**, **Sales for Store - South**, **Total Sales (North and South)** check boxes.

4. From the Data pane, drag **Measure Values** to Text.

The final result is a view that summarizes primary data source and secondary data source data on the Order Year and product category.

The screenshot shows the Tableau Desktop interface with a pivot table. The Columns shelf contains 'YEAR(Order Date)' and the Rows shelf contains 'Measure Names' and 'Prod Type1'. The view is titled 'Sheet 1' and displays a table with sales data for Furniture, Office Supplies, and Technology from 1997 to 2002. The table is organized into three main sections: Sales Total, Sales for Store - South, and Total Sales (North and South). Each section lists the product type and its sales values for each year.

		Order Date					
Prod Type1		1997	1998	1999	2000	2001	2002
Sales Total	FURNITURE	5,537,544	5,661,287	5,678,312	5,938,958	5,966,809	5,226,176
	OFFICE SUPPLIES	4,154,015	4,225,035	4,141,064	3,760,214	3,907,569	3,826,844
	TECHNOLOGY	6,722,790	7,629,904	6,863,829	6,477,433	6,420,297	6,549,857
Sales for Store - South	FURNITURE	5,537,544	5,661,287	5,678,312	5,938,958	5,966,809	5,226,176
	OFFICE SUPPLIES	4,154,015	4,225,035	4,141,064	3,760,214	3,907,569	3,826,844
	TECHNOLOGY	6,722,790	7,629,904	6,863,829	6,477,433	6,420,297	6,549,857
Total Sales (North and South)	FURNITURE	11,075,088	11,322,574	11,356,624	11,877,915	11,933,619	10,452,352
	OFFICE SUPPLIES	8,308,030	8,450,070	8,282,127	7,520,427	7,815,138	7,653,688
	TECHNOLOGY	13,445,581	15,259,809	13,727,659	12,954,865	12,840,595	13,099,715

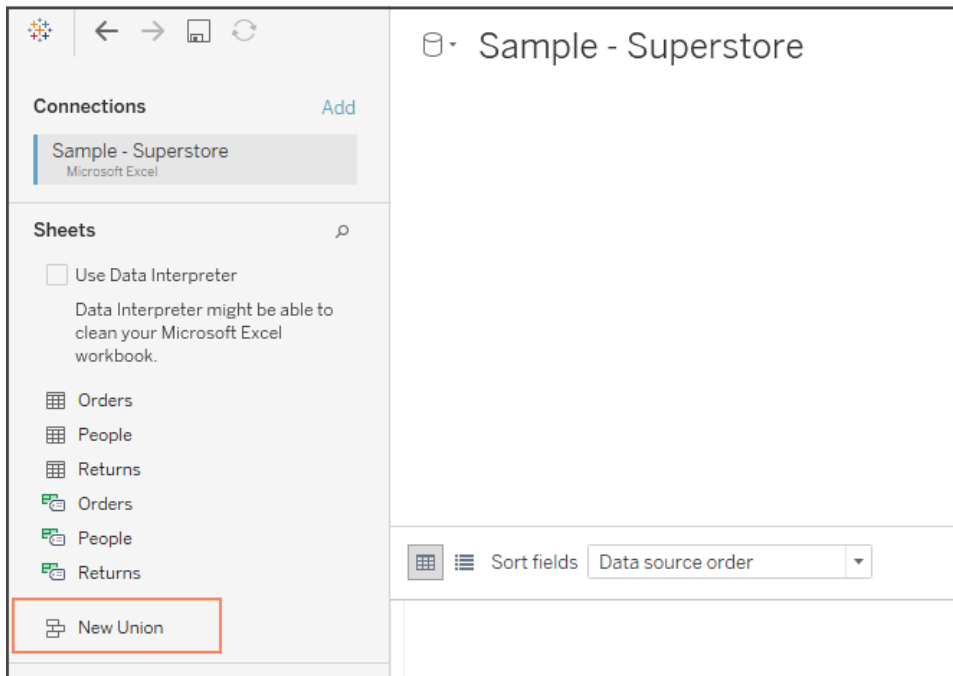

**Note:** The example sales data in both Store - North and Store - South are identical and therefore yield same results for both **Sales Total** and **Sales for Store - South** fields.

## Union Your Data

You can union your data to combine two or more tables by appending values (rows) from one table to another. To union your data in Tableau data source, the tables must come from the same connection.

### Supported connectors

If your data source supports union, the **New Union** option displays in the left pane of the data source page after you connect to your data. Supported connectors may vary between Tableau Desktop and Tableau Server and Tableau Cloud.

For best results, the tables that you combine using a union must have the same structure. That is, each table must have the same number of fields, and related fields must have matching field names and data types.

For example, suppose you have the following customer purchase information stored in three tables, separated by month. The table names are "May2016," "June2016," and "July2016."

#### May2016

D-ay	Cus-tomer	Purch-ases	Ty-pe
4	Lane	5	Cre-dit
10	Chris	6	Cre-dit
28	Juan	1	Cre-dit

#### June2016

D-ay	Cus-tomer	Purch-ases	Ty-pe
1	Lisa	3	Cre-dit
28	Isaac	4	Ca-sh
28	Sam	2	Cre-dit

#### July2016

D-ay	Cus-tomer	Purch-ases	Ty-pe
2	Mario	2	Cre-dit
15	Wei	1	Ca-sh
21	Jim	7	Ca-sh

A union of these tables creates the following single table that contains all rows from all tables.

#### Union

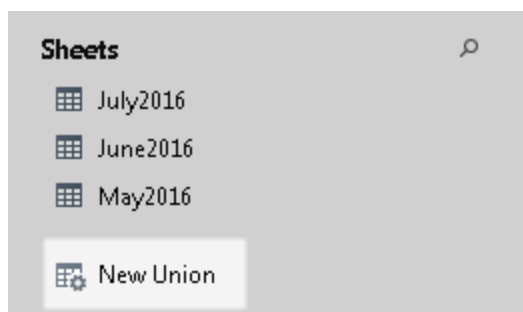

Day	Customer	Purchases	Type
4	Lane	5	Credit
10	Chris	6	Credit
28	Juan	1	Credit
1	Lisa	3	Credit
28	Isaac	4	Cash
28	Sam	2	Credit
2	Mario	2	Credit
15	Wei	1	Cash
21	Jim	7	Cash

## Union tables manually

Use this method to manually union distinct tables. This method allows you to drag individual tables from the left pane of the Data Source page and into the Union dialog box.

### To union tables manually

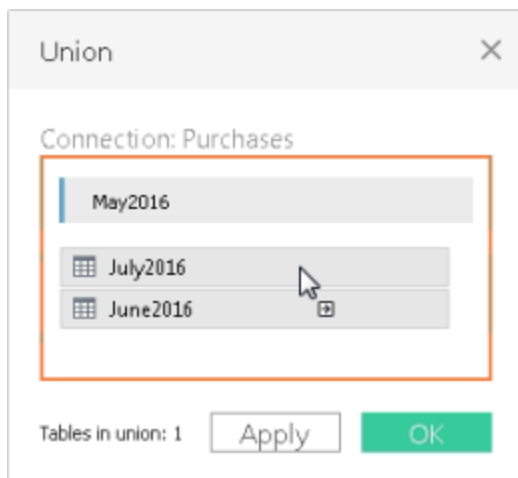

1. On the data source page, double-click **New Union** to set up the union.

2. Drag a table from the left pane to the Union dialog box.

3. Select another table from the left pane and drag it directly below the first table.

**Tip:** To add multiple tables to a union at the same time, press **Shift** or **Ctrl** (**Shift** or **Command** on a Mac), select the tables you want to union in the left pane, and then drag them directly below the first table.

4. Click **Apply** or **OK** to union.

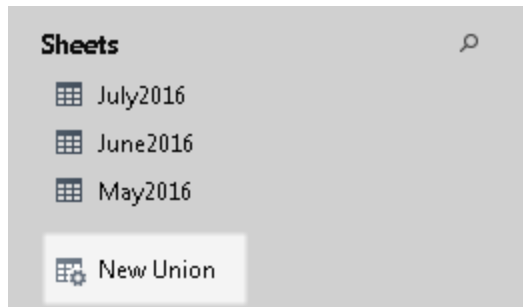

## Union tables using wildcard search (Tableau Desktop)

Use this method to set up search criteria to automatically include tables in your union. Use the wildcard character, which is an asterisk (\*), to match a sequence or pattern of characters in the Excel workbook and worksheet names, Google Sheets workbook and worksheet names, text file names, JSON file names, .pdf file names, and database table names.

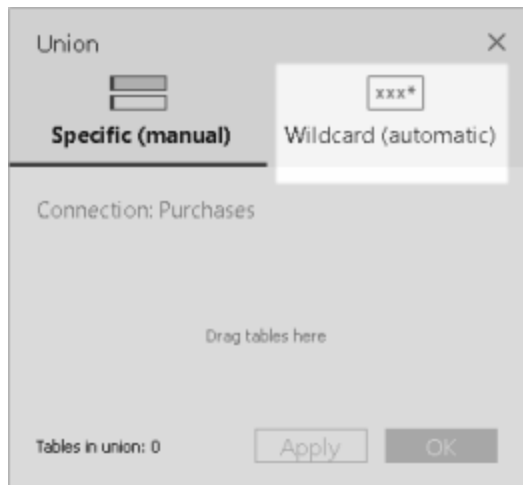

When working with Excel, text file data, JSON file, .pdf file data, you can also use this method to union files across folders, and worksheets across workbooks. Search is scoped to the selected connection. The connection and the tables available in a connection are shown on the left pane of the Data source page.

### To union tables using wildcard search

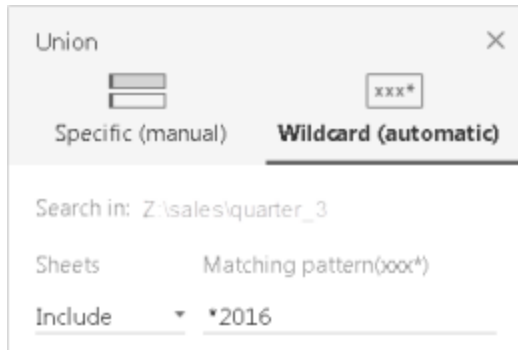

1. On the data source page, double-click **New Union** to set up the union.

2. Click **Wildcard (automatic)** in the Union dialog box.

3. Enter the search criteria that you want Tableau to use to find tables to include in the union.

For example, you can enter **\*2016** in the **Include** text box to union tables in Excel worksheets that end with "2016" in their names. Search criteria like this will result in the union of May2016, June2016, and July2016 tables (Excel worksheets), from the selected connection. In this case, the connection is called Sales, and the connection made to the Excel workbook containing the worksheets you wanted was in the quarter\_3 folder in the sales directory (e.g., Z:\sales\quarter\_3).

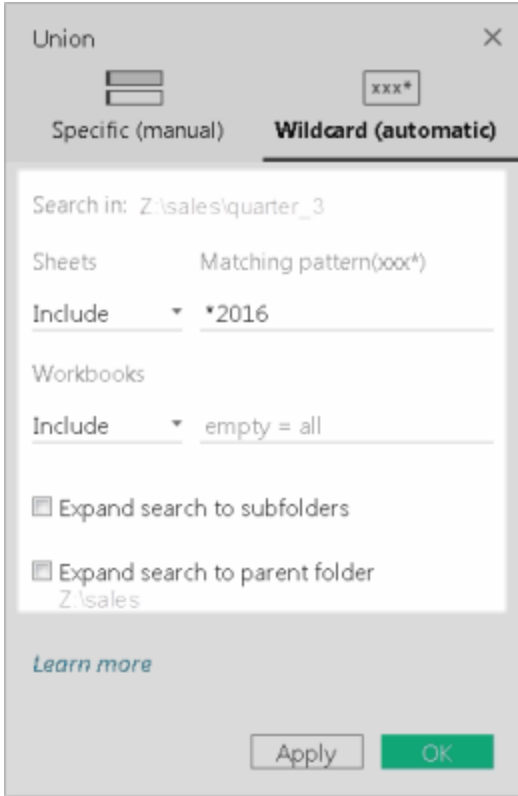

4. Click **Apply** or **OK** to union.

### Expand search to find more Excel, text, JSON, .pdf data

The tables initially available to union are scoped to the connection you've selected. If you want to union more tables that are located outside of the current folder (for Excel, text, JSON, .pdf files) or in a different workbook (for Excel worksheets), select one or both check boxes in the Union dialog box to expand your search.

For example, suppose you want to union all Excel worksheets that end with "2016" in its name outside of the current folder. The initial connection is made to an Excel workbook located in the same directory in the above example, Z:\sales\quarter\_3.

- **Include:** If you enter **\*2016** in the **Include** text box and leave the remaining search criteria of the dialog as is, Tableau looks for all Excel worksheets that end with "2016" in its name inside the current folder.

In the diagram below, the yellow highlighted item represents the current location, that is, the Excel workbook that you created a connection to in the "quarter\_3". The green box represents the tables belonging to workbooks and sheets that are unioned as result of this search criteria.

- **Include + Expand search to subfolders:** If you enter **\*2016** in the **Include** text box and select the **Expand search to subfolders** check box, Tableau does the following:

- Looks for all Excel worksheets that end with "2016" in their names inside the current folder.
- Looks for additional Excel worksheets that end with "2016" in their names that are located in Excel workbooks in subfolders of the "quarter\_3" folder.

In the diagram below, the yellow highlighted item represents the current location, that is, the Excel workbook that you created a connection to in the "quarter\_3" folder. The green box represents the tables belonging to workbooks and worksheets that are unioned as a result of this search criteria.

- **Include + Expand search to parent folder:** If you enter \*2016 in the **Include** text box and select the **Expand search to parent folder** check box, Tableau does the following:
  - Looks for all Excel worksheets that end with "2016" in their names inside the current folder, "quarter\_3."
  - Looks for additional Excel worksheets that end with "2016" in their names that are located in parallel folders of the "quarter\_3" folder. In this example, "quarter\_4" is the parallel folder.

In the diagram below, the yellow highlighted item represents current location, that is, the Excel workbook that you created a connection to in the "quarter\_3" folder. The green boxes represent the tables belonging to the workbook and worksheets that are unioned as a result of this search criteria.

- **Include + Expand search to subfolders + Expand search to parent folder:** If you enter **\*2016** in the **Include** text box and select both the **Expand search to subfolders** and **Expand search to parent folder** check boxes, Tableau does the following:
  - Looks for all Excel worksheets that end with "2016" in their names inside the current folder, "quarter\_3."
  - Looks for additional Excel workbooks that are located in the subfolders of the current folder, "quarter\_3."
  - Looks for additional Excel workbooks that are located in parallel folders and subfolders of the "quarter\_3" folder. In this example, "quarter\_4" is the parallel folder.

In the diagram below, the yellow highlighted item represents the current location, that is, the Excel workbook that you created a connection to. The green box represents the tables belonging to the workbook and worksheets that are unioned as a result of this search criteria.

**Note:** When working with Excel data, wildcard search includes named ranges but excludes tables found by Data Interpreter.

## Rename, modify, or remove unions

Perform basic union tasks directly in the canvas of the Data Source page.

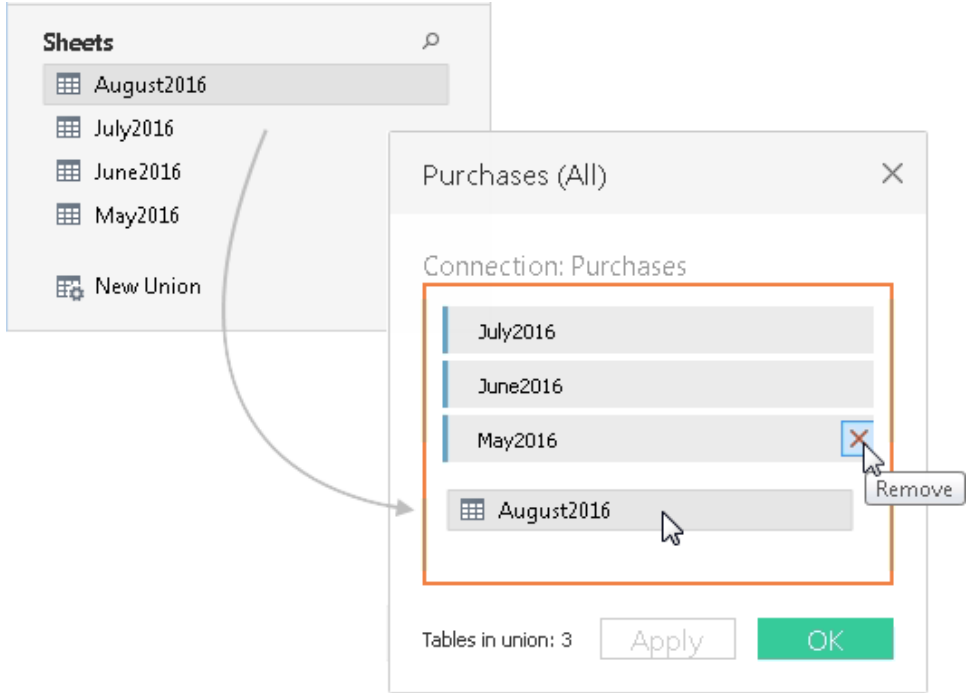

### To rename a union

1. Double-click the logical table that contains unioned physical tables.
2. Double-click the union table on the physical layer canvas.
3. Enter a new name for the union.

### To add or remove tables in the union

1. Double-click the logical table that contains unioned physical tables.
2. Click the union drop-down arrow and then select **Edit Union**.
3. You can drag additional tables that you want to union from the left pane, or hover over a table until the remove icon displays and then click the icon to remove the table.

4. Click **Apply** or **OK** to complete the task.

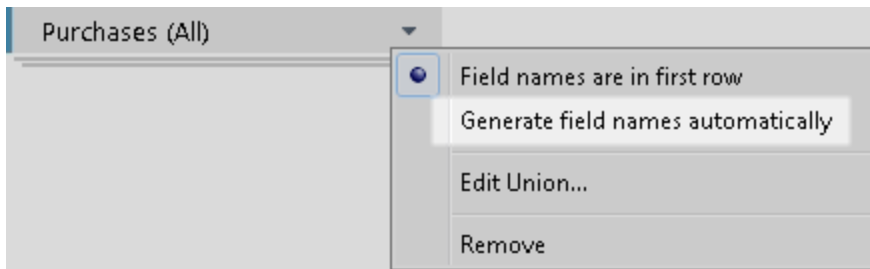

## To remove a union

- Double-click the logical table that contains unioned physical tables, and then click the union drop-down arrow and select **Remove**.

## Matching field names or field ordering

Tables in a union are combined by matching field names. When working with Excel, Google Sheets, text file, JSON file or .pdf file data, if there are no matching field names (or your tables do not contain column headers), you can tell Tableau to combine tables based on the order of the fields in the underlying data by creating the union and then selecting **Generate field names automatically** option from the union drop-down menu.

## Metadata about unions

After you create a union, additional fields about the union are generated and added to the grid. The new fields provide information about where the original values in the union come from, including the sheet and table names. These fields are useful when unique information that is critical to your analysis is embedded in the sheet or table name.

For example, the tables used in the example above have unique month and year information stored in the table name instead of in the data itself. In this case, you can use the **Table Name** field that is generated by the union to access this information and use it in your analysis.

Project Customer & Cust.	# Purchases (All) Purchases	Type	Sheet	Table Name
Lee	1	Credit	August2016	August2016
Philip	1	Credit	August2016	August2016
Wei	5	Cash	August2016	August2016
Maria	2	Cash	August2016	August2016
Max	2	Credit	July2016	
Wendy	1	Cash	July2016	
Jim	7	Cash	July2016	
Lisa	3	Credit	June2016	
Isaac	4	Cash	June2016	
Sam	2	Credit	June2016	
Arnold	5	Credit	June2016	
Lane	5	Credit	May2016	
Chris	6	Credit	May2016	
Juan	1	Credit	May2016	

Sheet	Table Name
Purchases (All)	Purchases (All)
August2016	August2016
August2016	August2016
August2016	August2016
August2016	August2016
August2016	August2016
August2016	August2016
July2016	July2016
July2016	July2016

If a named range is used in a union, null values display under the **Sheet** field.

**Note:** You can use the fields generated by a union, such as **Sheet or Table Name**, as join keys. You can use a unioned table in a join with another table or unioned table.

### Merge mismatched fields in the union

When field names in the union do not match, fields in the union contain null values. You can merge the non-matching fields into a single field using the merge option to remove the null values. When you use the merge option, the original fields are replaced by a new field that displays the first non-null value for each row in the non-matching fields.

You can also create your own calculation or, if possible, modify the underlying data to combine the non-matching fields.

For example, suppose a fourth table, "August2016", is added to the underlying data. Instead of the standard "Customer" field name, it contains an abbreviated version called "Cust."

#### August2016

Day	Cust.	Purchases	Type
7	Maria	2	Credit
9	Kathy	1	Credit
18	Vijay	7	Cash

A union of these tables creates a single table that contains all rows from tables, with several null values. You can use the merge option to combine the related customer fields into a single field.

#### Union (with null values)

Da- y	Cus- tomer	Purcha- ses	Typ- e	Cus- t.
4	Lane	5	Cre- dit	null
10	Chris	6	Cre- dit	null

#### Union (with columns that have been merged)

Da- y	Purcha- ses	Typ- e	Cus- tomer, Cust.
4	5	Cre- dit	Lane

Da- y	Cus- tomer	Purcha- ses	Typ- e	Cus- t.
28	Juan	1	Cre- dit	null
1	Lisa	3	Cre- dit	null
28	Isaac	4	Cas- h	null
28	Sam	2	Cre- dit	null
2	Mario	2	Cre- dit	null
15	Wei	1	Cas- h	null
21	Jim	7	Cas- h	null
7	null	2	Cre- dit	Mari- a
9	null	1	Cre- dit	Kat- hy
18	null	7	Cas- h	Vija- y

Da- y	Purcha- ses	Typ- e	Cus- tomer, Cust.
10	6	Cre- dit	Chris
28	1	Cre- dit	Juan
1	3	Cre- dit	Lisa
28	4	Cas- h	Isaac
28	2	Cre- dit	Sam
2	2	Cre- dit	Mario
15	1	Cas- h	Wei
21	7	Cas- h	Jim
7	2	Cre- dit	Maria
9	1	Cre- dit	Kathy
18	7	Cas- h	Vijay

After you merge fields, you can use the field generated from the merge in a pivot or split, or use the field as a join key. You can also change the data type of the field generated from a merge.

## To merge mismatched fields

1. Select two or more columns in the grid.
2. Click the column drop-down arrow, and then select **Merge mismatched fields**.

## To remove a merge

- Click the column drop-down arrow of the merged field and select **Remove merge**.

## At a glance: Working with unions

### Tableau Desktop and web authoring (Tableau Cloud and Tableau Server)

- A unioned table can be used in a join.
- A unioned table can be used in a join with another unioned table.
- The fields generated by a union, **Sheet** and **Table name**, can be used as the join key.
- If a named range is used in union, null values display under the **Sheet** field.
- The field generated from a merge can be used in a pivot.
- The field generated from a merge can be used as a join key.
- The data type of the field generated from a merge can be changed.
- Union tables from within the same connection. That is, you cannot union tables from different databases.

### Tableau Desktop only

- When working with Excel data, wildcard search includes named ranges but excludes tables found by Data Interpreter.
- The field generated from a merge can be used in a pivot or split.
- To union a JSON file, it must have a .json, .txt, or .log extension. For more information about working with JSON data, see [JSON File on page 251](#).
- When using wildcard search to union tables in a .pdf file, the result of the union is scoped to the pages that were scanned in the initial .pdf file you connected to. For more information about working with data in .pdf files, see [PDF File on page 257](#).
- Stored procedures cannot be unioned.
- When working with database data, you can convert your union into custom SQL.

## Create a Data Source or Add a New Connection with Clipboard Data

Sometimes you want to pull in data from an outside source for some quick analysis. Rather than create a whole data source and then connect in Tableau, you can copy and paste the data directly into your workbook. Tableau automatically creates a data source that you can begin analyzing.

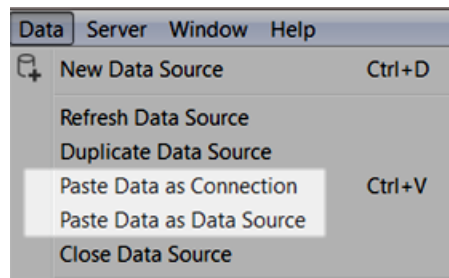

When you paste data on the data source page, Tableau creates a new connection in the existing data source.

When you paste data on the sheet, Tableau creates a new data source that you can begin analyzing. When you paste the data as a data source, the data source is saved as a text file to your Tableau Repository when you save the workbook.

You can copy and paste data from a variety of office applications including Microsoft Excel and Microsoft Word. You can also copy and paste HTML tables from web pages. Tables that are copied as comma separated values or tab delimited can be pasted into Tableau.

**Note:** Not all applications use these formats when copying.

1. Select the data you want and copy it to the clipboard.
2. Open Tableau Desktop and do one of the following:
  1. On the data source page, select **Data > Paste Data as Connection** or **Paste Data as Data Source**.

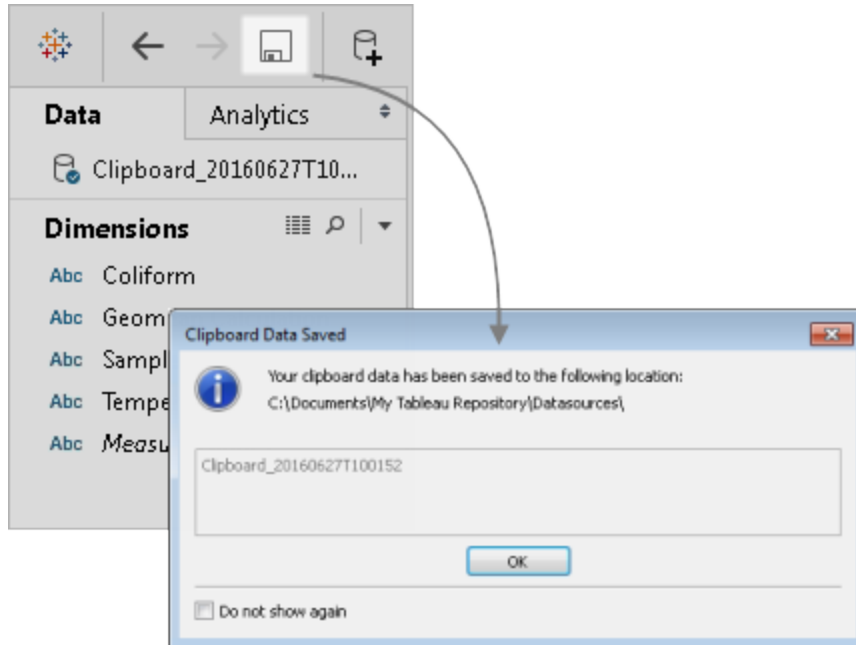

2. On the sheet, select **Data > Paste** to paste the data as a data source.

3. Select **File > Save** to save the data source.

When you save the workbook, the data source either becomes a part of the existing data source or is added to your repository, depending on which of the methods you choose. If you paste the data as a data source, the data source is saved with the workbook when you save the workbook as a packaged workbook (.twbx).

## Connect to a Custom SQL Query

**Note:** Using custom SQL can affect performance of a workbook. Working with your DBA will ensure the best possible custom SQL query. In order to perform the operations necessary for building views in Tableau Desktop, Tableau must be able to control WHERE, GROUP BY and other SQL clauses. Because a custom SQL query may contain those elements, and Tableau cannot inject them into the existing SQL, Tableau must wrap the custom SQL statement within a select statement. When a custom SQL connection is performing slowly, or produces an error, it is often the result of the custom SQL wrapping that Tableau Desktop performs.

For most databases, you can connect to a specific query rather than the entire data set. Because databases have slightly different SQL syntax from each other, the custom SQL you use to connect to one database might be different from the custom SQL you might use to connect to

another. However, using custom SQL can be useful when you know exactly the information you need and understand how to write SQL queries.

Though there are several common reasons why you might use custom SQL, you can use custom SQL to union your data across tables, recast fields to perform cross-database joins, restructure or reduce the size of your data for analysis, etc.

For Excel and text file data sources, this option is available only in workbooks that were created before Tableau Desktop 8.2 or when using Tableau Desktop on Windows with the legacy connection. To connect to Excel or text files using the legacy connection, connect to the file, and in the Open dialog box, click the **Open** drop-down menu, and then select **Open with Legacy Connection**.

**NOTE:** Beginning with Tableau 2020.2, legacy Excel and Text connections are no longer supported. See the [Legacy Connection Alternatives](#) document in Tableau Community for alternatives to using the legacy connection.

## Connect to a custom SQL query

1. After connecting to your data, double-click the **New Custom SQL** option on the Data Source page.

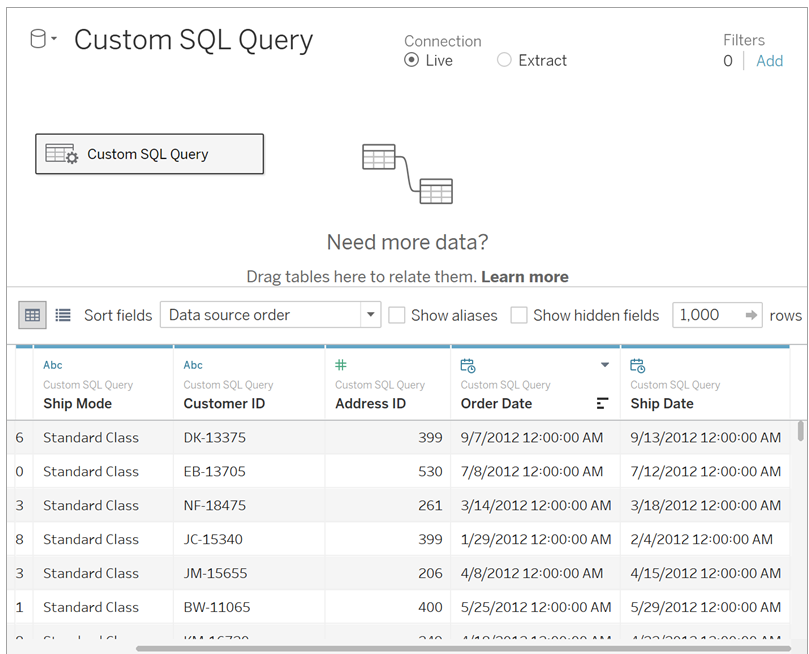

2. Type or paste the query into the text box. The query must be a single SELECT\* statement.

3. When finished, click **OK**.

When you click OK, the query runs and the custom SQL query table appears in the logical layer of the canvas. Only relevant fields from the custom SQL query display in the data grid on the Data Source page.

For more information about the logical and physical layers of the canvas, see [The Tableau Data Model](#) on page 664.

## Examples of custom SQL queries

### Combine your tables vertically (union)

If you need to append data to each other, you can use the union option in the physical layer of the canvas in Tableau. In some cases your database does not support this option, so you can use custom SQL instead.

For example, suppose you have the following two tables: November and December.

November		December	
Guest ID	Party Size	Guest ID	Party Size
3005	4	3009	2
3006	2	3010	2
3007	2	3011	4
3008	2	3012	5
		3013	3
		3014	4
		3015	2

You can use the following custom SQL query to append the second table, December, to the first table, November:

```
SELECT * FROM November UNION ALL SELECT * FROM December
```

The result of the query looks like this in the data grid:

Abc Custom SQL Query <b>Guest ID</b>	# Custom SQL Query <b>Party Size</b>
3005	4.00000
3006	2.00000
3007	2.00000
3008	2.00000
3009	2.00000
3010	2.00000
3011	4.00000
3012	5.00000
3013	3.00000
3014	4.00000
3015	2.00000

For more information about the union option, see [Union Your Data](#) on page 795.

### Change the data type of a field to do a cross-database join

When you want to perform a join between two tables in the physical layer of the canvas, the data type of the fields you join on must be the same. In cases when the data type of the fields are not the same, you can use custom SQL to change the data type (cast) the field before performing the join.

For example, suppose you want to join two tables, Main and Sub, using the Root and ID fields, respectively. The Root field is a number type and the ID field is a string type. You can use the following custom SQL query to change the data type of Root from a number to a string so that you can join the Main and Sub tables using the Root and ID fields.

```
SELECT [Main].[Root] AS [Root_Number]
CAST([Main].[Root] AS INT) AS [Root_String]
FROM [Main]
```

The result of this query shows the original Root field and the Root field cast as a string.

#	Abc
Custom SQL Query Root_Number	Custom SQL Query Root_String
7,981.00	7981
740.00	740
741.00	741
742.00	742
1,760.00	1760

For more information about joins and cross-database joins, see [Join Your Data](#) on page 738.

### Reduce the size of your data

When working with very large data sets, sometimes you can save time while working with your data if you reduce its size first.

For example, suppose you have a large table called FischerIris. You can use the following custom SQL query to retrieve the specified columns and records thereby reducing the size of the data set that you connect to from Tableau.

```
SELECT
  [FischerIris].[Species] AS [Species],
  [FischerIris].[Width] AS [Petal Width],
  COUNT([FischerIris].[ID]) AS [Num of Species]
FROM [FischerIris]
WHERE [FischerIris].[Organ] = 'Petal'
AND [FischerIris].[Width] > 15.0000
GROUP BY [FischerIris].[Species], [FischerIris].[Width]
```

### Restructure your data (pivot)

In some cases, you might be working with a table that needs to be restructured before analysis. Though this type of task can be done in the physical layer of the canvas in Tableau by using options like pivot, your database might not support it. In this case, you can use custom SQL instead.

For example, suppose you have the following table:

Season ID	Items - Don't like	Items - Defective	Items - Too small	Items - Too big
R000151493		1	3	20
R000151493		2	44	1
R000151495		0	0	0
R000151495		0	17	1
R000151497		1	0	0
R000151497		0	15	0
R000151789		0	0	0
R000151789		0	12	4
R000151813	3	0	0	3
R000151813	3	0	53	1
R000151815	0	0	0	0
R000151815	0	0	0	0
R000151855	0	0	0	3
R000151855	59	0	22	0
R000151857	4	0	14	18
R000151857	0	0	0	33
R000153013	0	0	21	0
R000153013	9	1	19	0

To change its structure and optimize your data for analysis in Tableau, you can use the following custom SQL query:

```
SELECT Table1.Season ID AS [Season ID],
Table1.Items - Don't like AS [Quantity],
"Don't Like" AS [Reason]
FROM Table1
UNION ALL
SELECT Table1.Season ID AS [Season ID],
Table1.Items - Defective AS [Quantity],
"Defective" AS [Reason]
FROM Table1
UNION ALL
SELECT Table1.Season ID AS [Season ID],
Table1.Items - Too big AS [Quantity],
"Too Big" AS [Reason]
FROM Table1
UNION ALL
SELECT Table1.Season ID AS Season ID,
Table1.Items - Too small AS [Quantity]
"Too Small" AS [Reason]
FROM Table1
```

The result of the query looks like this in the data grid:

Abc Custom SQL Query <b>Season ID</b>	Abc Custom SQL Query <b>Quantity</b>	Abc Custom SQL Query <b>Reason</b>
R000151493	<i>null</i>	Don't Like
R000151493	<i>null</i>	Don't Like
R000151495	<i>null</i>	Don't Like
R000151495	<i>null</i>	Don't Like
R000151497	<i>null</i>	Don't Like
R000151497	<i>null</i>	Don't Like
R000151789	<i>null</i>	Don't Like
R000151789	<i>null</i>	Don't Like
R000151813	3	Don't Like
R000151813	3	Don't Like
R000151815	0	Don't Like
R000151815	0	Don't Like
R000151855	0	Don't Like
R000151855	59	Don't Like

For more information about the pivot option, see [Pivot Data from Columns to Rows on page 840](#).

### Combine (join) and aggregate your data

If you need to combine tables and aggregate your data, you can use both a join and default aggregation type options in the physical layer of the canvas in Tableau. In some cases you might need to use custom SQL instead.

For example, suppose you have the following two tables: Orders and Vendors.

**Orders**

Order	CustomerID	VendorID
10248	32	1
10249	90	3
10250	81	2

**Vendors**

VendorID	Name
1	Tminus Shipping
2	Packing You
3	ShipWise Express

You can use the following custom SQL query to find a count on the number of orders and do a left join on the Orders and Vendors tables:

```
SELECT Vendors.Name, COUNT(Orders.Order) AS Number Of Orders
FROM Orders
LEFT JOIN Vendors
ON Orders.VendorID=Vendors.VendorID
GROUP BY Name;
```

The result of the query looks like this:

Abc Custom SQL Query Name	# Custom SQL Query Number Of Orders
Packing You	1
ShipWise Express	1
Tminus Shipping	1

For more information about joins, see [Join Your Data](#) on page 738.

**Errors when duplicate columns are referenced**

If your custom SQL query references duplicate columns, you may get errors when trying to use one of the columns in your analysis in Tableau. This will happen even if the query is valid. For example, consider the following query:

```
SELECT * FROM authors, titleauthor WHERE authors.au_id =
titleauthor.au_id
```

The query is valid, but the **au\_id** field is ambiguous because in this case it exists in both the “authors” table and the “titleauthor” table. Tableau will connect to the query but you will get an error anytime you try to use the **au\_id** field. This is because Tableau doesn’t know which table you are referring to.

**Note:** It is a best practice to define column aliases with an AS clause whenever possible in a Custom SQL Query. This is because each database has its own rules when it comes to automatically generating a column name whenever an alias is not used.

## Edit a custom SQL query

### To edit a custom SQL query

1. On the data source page, in the canvas, double-click the custom SQL query in the logical layer.
2. Hover over the custom SQL table in the physical layer until the arrow displays.

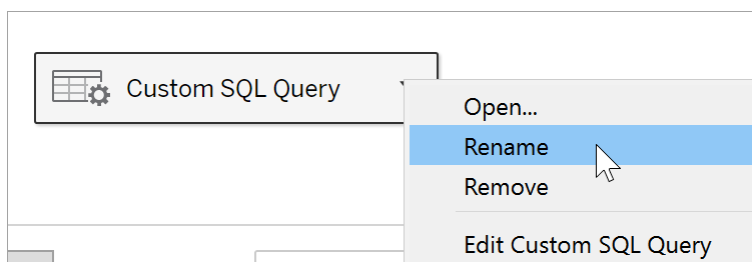

3. Click the arrow and then select **Edit Custom SQL Query**.
4. In the dialog box, edit the custom SQL query.

### To change a custom SQL query name

When you drag a custom SQL query to the logical layer of the canvas, Tableau gives it a default name: Custom SQL Query, Custom SQL Query1, and so on. You can change the default name to something more meaningful.

1. On the data source page, in the logical layer of the canvas, select the drop-down arrow in the custom SQL query table and select **Rename**.

2. Enter the name you want to use for your custom SQL query.

## Use parameters in a custom SQL query

You can use parameters in a custom SQL query statement to replace a constant value with a dynamic value. You can then update the parameter in the workbook to modify the connection. For example, you may connect to a custom SQL query that provides web traffic data for a particular page that is specified by a pageID. Instead of using a constant value for the pageID value in the SQL query, you can insert a parameter. Then after finishing the connection, you can show a parameter control in the workbook. Use the parameter control to switch out the pageID and pull in data for each page of interest without having to edit or duplicate the connection.

In **Tableau Desktop**, you can create a parameter directly from the Custom SQL dialog box or use any parameters that are part of the workbook. If you create a new parameter, it becomes available for use in the workbook just like any other parameter. See [Create Parameters on page 1070](#) to learn more.

For **web authoring (in Tableau Cloud or Tableau Server)**, you can use an existing parameter published from Tableau Desktop. You cannot create a new parameter in web authoring.

### To add a parameter to a custom SQL query

1. On the data source page, in the canvas, hover over the table until the edit icon displays, and then click the edit button.
2. At the bottom of the dialog box, click **Insert Parameter**.
3. Select a constant value in the SQL statement and then, from the **Insert Parameter** drop-down menu select the parameter you want to use instead. If you have not created a parameter yet, select **Create a new parameter**. Follow the instructions in [Create Parameters on page 1070](#) to create a parameter.

**Note:** Parameters can only replace literal values. They cannot replace expressions or identifiers such as table names.

In the example below, the custom SQL query returns all orders that are marked as Urgent priority. In the custom SQL statement, the order priority is the constant value. If you want to change the connection to see the High priority orders, you would have to edit the data source.

Instead of creating and maintaining many variations of the same query, you can replace the constant order priority value with a parameter. The parameter should contain all of the possible values for Order Priority.

After you create a parameter, you can insert it into the SQL statement to replace the constant value.

## Tableau Desktop and Web Authoring Help

After you finish editing the connection, the new parameter is listed in the Parameters area at the bottom of the Data pane and the parameter control displays on the right side of the view. As you select different values, the connection updates.

**Note:** If you are using an extract, you must refresh the extract in order to reflect changes to the parameter. Publishing a data source that uses Custom SQL parameters includes the parameters. The parameters are transferred to any workbooks that connect to the data source.

## Tableau Catalog support for custom SQL

Support for custom SQL in Tableau Catalog depends on the custom SQL query.

Tableau Catalog is available as part of the Data Management offering for Tableau Server and Tableau Cloud. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

### Supported queries

Catalog supports custom SQL queries that meet the ANSI SQL-2003 standard, with three known exceptions:

- Time zone expressions
- Multiset expressions
- Tableau parameters

Starting in 2021.4, Tableau Catalog also supports use of the Transact-SQL (T-SQL) dialect in Custom SQL, with the following exceptions:

- Hints
- FOR clauses
- OPENROWSET, OPENXML, and OPENJSON functions
- ODBC scalar functions
- FOR SYSTEM\_TIME
- TABLESAMPLE
- MATCH expression
- CONTAINS expression
- FREETEXT expression

Starting in Tableau Cloud October 2023 and Tableau Server 2023.3, Tableau Catalog also offers support for custom SQL queries that use PostgreSQL, with the following exceptions:

- XML function
- JSON functions and operators

## Supported features and functions

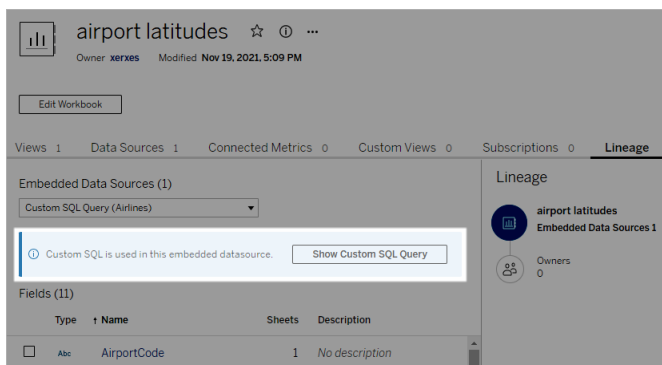

Catalog supports the following additional functionality for data sources, workbooks, and flows with connections that use the MySQL or PostgreSQL drivers, for example, Amazon Aurora for MySQL, Amazon RedShift, Pivotal Greenplum Database, MemSQL, Denodo, and others.

- MySQL GROUP\_CONCAT function
- PostgreSQL arrays
- PostgreSQL EXTRACT() function

Other custom SQL scenarios and functionality might work, but Tableau doesn't specifically test for or support them.

## Supported lineage

When an asset uses custom SQL, a message with a **Show Custom SQL Query** button appears on the **Lineage** tab of the asset page. Click the button to see the custom SQL used in the connection. Then, if you would like to copy the custom SQL to your clipboard, click **Copy**.

Some types of custom SQL can cause the upstream lineage to be incomplete. When this happens, a message appears with that information. Field details cards might not contain links to connected columns, or might not show any connected columns at all. Column details cards might not contain links to fields that use the column, or might not show any fields at all.

If you are examining a table's lineage, note that Catalog doesn't support showing column information in the lineage for table metadata gathered using custom SQL. However, if other assets use the same table and don't use custom SQL, Tableau Catalog might be able to display information about the columns that it has discovered through these other assets.

In the following screenshot, the factAccountOpportunityByQuarter table was indexed because it's used by a data source. However, because it's referenced by a custom SQL query, the column information isn't available.

In a case where more than one data source, workbook, or flow uses a table, any of the assets downstream from that table that uses a custom SQL query are excluded when column-level filters are applied. As a result, fewer downstream assets show in the lineage than are actually used.

For more information about using the lineage, see "Use Lineage for Impact Analysis" in the [Tableau Server](#) or [Tableau Cloud](#) Help.

## Use a Stored Procedure

A stored procedure is a subroutine available to applications that access a relational database system. When you connect to a SAP Sybase ASE, Microsoft SQL Server, or Teradata database with Tableau, you can use a stored procedure to define the connection.

For Oracle, you can use a table function to define the connection. Oracle table functions act similarly to stored procedures and are listed under **Stored Procedures** on the Data Source page.

When you create a data source using one of these data types, available procedures are listed under **Stored Procedures**, as shown in the Microsoft SQL Server example:

From the left pane, drag the procedure to the canvas or double-click one of the listed procedures. If parameters are available in the procedure, the Parameters dialog box automatically displays.

Instead of entering a value, you can use an existing Tableau parameter, or create a new Tableau parameter for the value:

If you then expose the Tableau parameter in the view, users are able to change the value of the parameter in the procedure interactively.

Stored procedures don't support federation, relating, or joining. They are represented in a single logical table in the logical layer, and don't allow opening the Join/Union canvas (physical layer).

## Notes on Stored Procedures

If you use stored procedures to define a data source for Tableau, keep the following in mind:

- If a stored procedure returns more than one result set, Tableau reads the first one and ignores the rest.
- If a stored procedure has output parameters, Tableau filters out the stored procedure.
- Stored procedures that have parameters of a non-scalar type are excluded.
- Result set columns that don't have matching types in Tableau (such as varbinary, geometry, and hierarchyid) are logged. If all result set columns map to unknown data types, Tableau displays a message:  
"The result set... has no usable columns."
- Stored procedures that return no result sets are listed on the data source page but fail if selected.
- If no value is provided for a parameter that the stored procedure requires, an error occurs. Tableau cannot determine in advance whether parameters are required.
- Tableau does not perform any transaction management for stored procedures. That is, stored procedure writers must not depend on Tableau to start transactions before invoking stored procedures, or to commit them afterward.

- Column names must be unique for stored procedures to work. If two columns have the same name, or if no name is provided, the procedure can result in an error.
- If there are multiple queries in a stored procedure (for example, to read values from another table or to hold temporary combinations) each of the queries must return the same sets of columns in the same order (same names and data types). To ensure that column order and names match in the query results, you may need to explicitly `CAST` to ensure the data type is correct, for example `CAST(Username as VARCHAR(20))`, and explicitly name the columns. If a stored procedure does not follow these guidelines, an error message can result:

"InsertData: unbound column error"

- If there are multiple queries in a stored procedure (for example, to read values from another table or to hold temporary combinations) and the procedure is generating an error, try adding `SET NOCOUNT ON` to the top of the procedure. This prevents the message which shows the count of number of rows affected by a Transact-SQL statement from being returned as part of the result set for a query.

In addition, the following constraints apply for specific databases.

### Stored Procedure Constraints for Teradata Databases

The following constraints apply for stored procedures on Teradata databases.

- Values must be provided for every parameter. If the user does not provide a value for one or more parameters, Tableau displays a Teradata database error stating there are too few values provided for the stored procedure.

### Stored Procedure Constraints for SQL Server Databases

The following constraints apply for stored procedures on SQL Server databases.

- If the result set for a stored procedure contains columns of type `IMAGE` or `TEXT`, the stored procedure will fail with an "Incorrect syntax" error message.
- If the total width of the result set (number of bytes in each row) exceeds 8060, the stored procedure fails. This can occur with very wide tables (hundreds of columns) or with tables having large text columns, intended to hold thousands of characters of text.
- Tableau does not display stored procedures from schema "sys".
- If the user does not provide a value for one or more parameters that the procedure requires, Tableau displays a SQL Server database error in the form "The procedure

requires a value for parameter @x but one was not provided."

- Stored procedures that contain multiple queries should follow the guidelines listed in Notes on Stored Procedures (above).
- Tableau Desktop does not support the Microsoft SQL Server TIME data type. When fields of this type are included in a stored procedure on a Microsoft SQL Server database Tableau Desktop will not import them.

## Stored Procedure Constraints for SAP Sybase ASE Databases

The following constraints apply for stored procedures on SAP Sybase ASE databases (Windows only).

- The database must have a properly configured remote server.
- If the user does not provide a value for one or more parameters that the procedure requires, Tableau displays a Sybase ASE database error in the form "The procedure requires a value for parameter @x but one was not provided."

## Use Certified Data Sources

To speed up the process of validating and setting up data, use certified data sources. Certified data sources are carefully chosen by site administrators and project leaders.

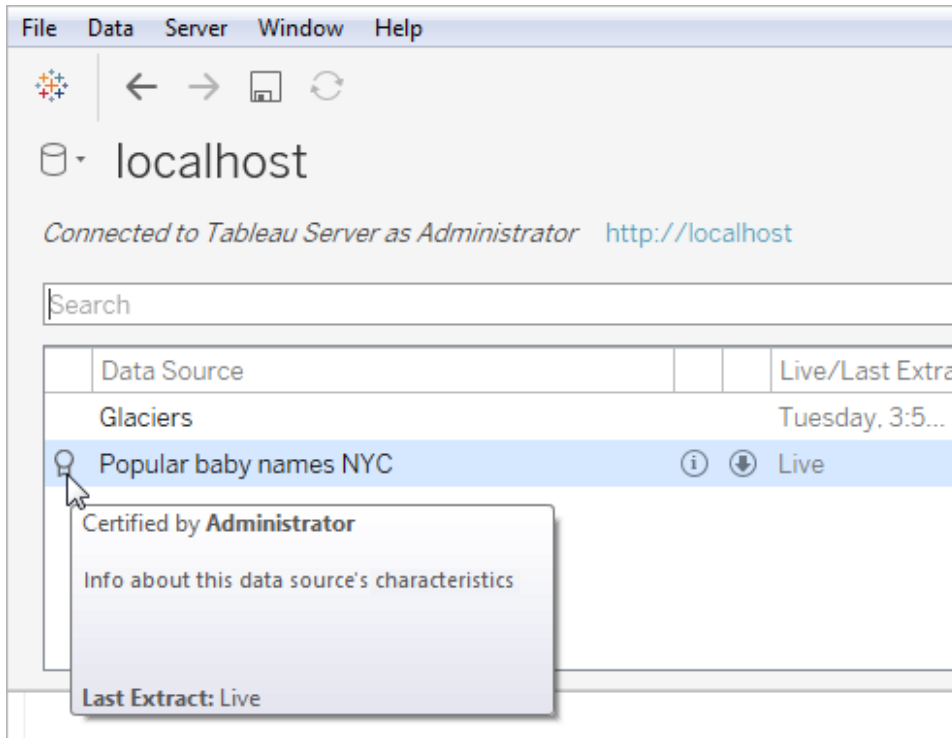

By taking advantage of relevant content that's already available, you can avoid duplicating work and spend more time on your analysis.

**Note:** To access these features in Tableau Desktop, you need to sign in to Tableau Server or Tableau Cloud from the **Server** menu.

## Certified data sources published to Tableau Server or Tableau Cloud

Certified data sources appear with a unique certification badge. Hover over the badge to learn who certified the data source, read any descriptive notes they've provided, and confirm the connection type.

Here's how certified data sources look when you connect to data in Tableau Desktop.

And here's how you can identify certified data sources in Tableau Server or Tableau Cloud.

## Convert a Field to a Date Field

Each database stores Date fields in slightly different ways. Tableau does its best in interpreting the date fields, but sometimes a field will be imported to Tableau as a text string or numerical field. If this happens, there are a few steps we can take to resolve the issue.

### Verifying Date Fields

A date field might appear as a string  
in the Data Source page

Or as a string in the Data pane

When dates are interpreted as strings, you will lose all of the features and conveniences of working with date fields, such as drilling down, using date calculations, and switching between Continuous and Discrete measures.

If your dates aren't interpreted correctly, take the following steps in order:

1. **Change the data type of the field** below
2. **Create a calculation using the DATEPARSE function** on the next page
3. **Create a calculation using the DATE function** on page 838

## Change the data type of the field

The first step in resolving a date field interpretation issue is to make sure the data type is set to **Date** or **Date & Time**.

1. In the **Data Source** or **Data** pane, click the data type icon and change the data type to **Date** or **Date & Time**

2. Inspect the data in the view or **Data Source** pane. If you see many Null values, return the data type to **String** and proceed to [Create a calculation using the DATEPARSE function below](#) to correct the issue.

parseddates.tsv
Original Date
11/1/2013 12:09:00 A...
<i>null</i>
<i>null</i>
<i>null</i>
<i>null</i>
<i>null</i>
<i>null</i>
<i>null</i>
<i>null</i>

## Create a calculation using the DATEPARSE function

Dates are stored in a nearly infinite array of formats. Some date fields have years before months, others separate the parts of the date with periods, and still others use a combination of formats. When Tableau cannot interpret a date field, it might be because the particular format cannot be translated.

The DATEPARSE function lets you clearly define which parts of your field are which parts of a date. In essence, you are creating a map that Tableau can use to translate the string into a date field. This map is referred to as the **format**.

**Note:** This function is available through the following connectors: non-legacy Excel and text file connections, Amazon EMR Hadoop Hive, Cloudera Hadoop, Google Sheets, Hortonworks Hadoop Hive, MapR Hadoop Hive, MySQL, Oracle, PostgreSQL, and Tableau extracts. Some formats may not be available for all connections.

**Note:** DATEPARSE is not supported on Hive variants. Only Denodo, Drill, and Snowflake are supported.

### Creating the DATEPARSE calculation

1. Inspect the current format of your date field. Note where months, years, hours, and days are displayed in your field. You will need this information for the DATEPARSE function.

A	B	C	D	
				Abc
01-APR-14	01	00	10.000000000 PM	Abc
01-APR-14	01	01	51.000000000 PM	Abc
01-APR-14	01	02	55.000000000 PM	Abc
01-APR-14	01	18	14.000000000 PM	Abc

**A.** Day of month

**B.** Month

**C.** Year

**D.** Hour, minute, second, millisecond, period

2. Right click your date field in the Dimensions pane and select **Create > Calculated Field**.
3. In the dialog, write the DATEPARSE function. The DATEPARSE function has two parts: the **format** and the **string**. The **string** is field you wish to convert, which must be a string data type.

Dateparse
×

```
DATEPARSE('dd-MMM-YY HH.mm.ss.AAAAAAAAA aa', [Original Date])
```

A

B

**A.** Format

**B.** String

The **format** is the guide Tableau will use to interpret the string as a date. Each part of a date or time string has a matching symbol, as seen in the table below. The format must exactly duplicate the way that the date is displayed. For example, if a single year code ("Y") is used when the string has a 2-digit year code ("97"), the calculation might return null values.

**Note:** The exception to the format exactly duplicating the displayed string is that long form parts of dates ("September") can be formatted with four symbols ("September" = "MMMM").

The format must include all spaces, hyphens, and other non-alphanumeric symbols in order to interpret the string correctly.

### Date Field Symbols

Date Part	Symbol	Example String	Example Format
Year	y	97, 2017	yy, y or yyyy
Year of "Week of year"	Y	1997	Y
Time Zone	Z, z	-0800, PST-08:00, PST	Z, ZZZZ, zzz
Month	M	9, 09, Sep, September	M, MM, MMM, MMMM
Week of year (1-52)	w	8, 27	w, ww
Quarter of year	Q	Q2, 2nd quarter	QQQ, QQQQ
Day of week	E	Mon, Monday	EEE, EEEE
Day of month	d	1, 15	d, dd
Day of year (1-365)	D	23, 143	D, DD, DDD
Period (am/pm)	a	AM, am, PM	aa, aaaa

marker)			
Hour (1-12), Hour (0-23)	h, H	1, 10, 16	h, hh, HH
Minute	m	8, 59	m, mm
Second in a minute	s	5, 05	s, ss
Fractional second	S	2, 23, 235, 2350	S, SS, SSS, SSSS
Milliseconds in day	A	34532	AAAAA

For a more complete list of date symbols, please see the [Formatting Date and Times Overview on the International Components](#) for Unicode page.

**Note:** Some date formats are not supported by all databases and file types.

4. Check your format against the string displayed in Tableau. If the symbols and formatting is correct, select OK to create the new calculated field. The calculated field will act as a date field in your view.

### Hyper extracts

For .hyper extract data sources, the symbols are defined by the Unicode Consortium. For more information, go to [Format syntax in DATEPARSE function for extract data sources on page 1122](#) to see a the subset of field types and symbols that can be used with the DATEPARSE function in .hyper extracts.

### Locale considerations

The DATEPARSE function relies on the locale specified by your computer settings to interpret and then display the strings that you want to convert. More specifically, the locale will affect

whether a certain format can be recognized. This means that if a format is not supported by the locale, then you might see a null value or no value returned. For example, suppose you have the following string in your data:

```
12Sep2016:9:8:8.6546
```

The values returned from the DATEPARSE function for this string are different based on locale. In the English locale you will get a certain value, but for the Japanese locale you will get no value. In this case, no value is returned because the Japanese locale does not recognize “Sep.”

### Datetime value

English locale	Japanese locale
#9/12/2016 9:08:09 AM#	-

As with all dates, after you have used the DATEPARSE function to convert a string to a datetime type, by default Tableau will display the datetime value in the default format of your locale. If the locale changes, the result of the DATEPARSE function might display your new datetime value in a different format.

**Note:** Because of a Jet limitation, the DATEPARSE function cannot correctly identify locale information specified by your computer settings in extracts created from Access data sources. To resolve this issue, consider exporting your Access data to Excel.

## Create a calculation using the DATE function

If the DATEPARSE function is not available for the data that you're working with, or the field you are trying to convert is a number data type, you can use the DATE function instead.

The DATE function converts a number, string or date expression to a date type. When you create a calculation that uses the DATE function, Tableau creates a new field in your Tableau data source that allows you to interact with your date data as a date. To successfully produce date values from a number, string, or date expression using the DATE function, Tableau needs to be able to interpret the components of the string into date parts. After the components of the date are identified, Tableau uses the computer locale to determine the default format of the date.

For example, suppose the table you're working with contains a column of date data that is called "Original Date." The "Original Date" column is a string type.

Original Date
03Jan2017
05Jan2017
07Mar2017
19Mar2017
30Apr2017

In this case, you can create a calculated field called "New Date" that uses an expression in a DATE function to convert the string values in the "Original Date" field into date values.

For this example, the date expression is comprised of the LEFT function to isolate the day component, the MID function to isolate the month component, and the RIGHT function to isolate the year component.

```
DATE (LEFT([Original Date], 2) + "/" + MID([Original Date],3,3) + "/"
+ RIGHT([Original Date],4))
```

The "New Date" calculation produces the following column:

New Date
1/3/2017
1/5/2017
3/7/2017
3/19/2017
4/30/2017

In this example, the new date values are based on an English locale and default formatting.

[All Functions \(by Category\): Date](#)

[STR\(\) Function Ignores the Default Date and Number Formatting](#) (Tableau Knowledge Base)

## Pivot Data from Columns to Rows

Sometimes, analyzing data that is stored in a crosstab format can be difficult in Tableau. When working with Microsoft Excel, text file, Google Sheets, and .pdf data sources, you can pivot your data from crosstab format into columnar format. If you are working with other data sources, you can [Pivot using custom SQL \(Tableau Desktop\)](#) on page 842.

For example, suppose you have the number of devices sold by quarter for three vendors in three separate fields. You can pivot your data so that the vendor is in one field and the number of devices sold is in another field.

Quarter	Samsung	Nokia	Apple
Q1 '12	89.2800	83.1600	33.1200
Q2 '12	90.4300	83.4200	28.9400
Q3 '12	97.9600	82.3000	24.6200
Q4 '12	106.9600	85.0500	43.4600
Q1 '13	100.6600	63.2200	38.3300
Q2 '13	107.5300	60.9500	31.9000
Q3 '13	117.0500	63.0500	30.3300
Q4 '13	119.2100	63.5800	50.2200

Quarter	Pivot Field Names	Pivot Field Values
Q4 '12	Apple	43.460
Q1 '13	Apple	38.330
Q2 '13	Apple	31.900
Q3 '13	Apple	30.330
Q4 '13	Apple	50.220
Q1 '10	Nokia	110.110
Q2 '10	Nokia	111.470
Q3 '10	Nokia	117.460
Q4 '10	Nokia	122.280

### Pivot the data

After you have set up the data source, in the grid, select two or more columns. Click the drop-down arrow next to the column name, and then select **Pivot**. New columns called "Pivot field names" and "Pivot field values" are created and added to the data source. The new columns replace the original columns that you selected to create the pivot.

Quarter	Samsung	Nokia	Apple
Q4 '11	93.8300	111.7000	35.46
Q1 '12	89.2800	83.1600	33.12
Q2 '12	90.4300	83.4200	28.94
Q3 '12	97.9600	82.3000	24.62
Q4 '12	106.9600	85.0500	43.4600
Q1 '13	100.6600	63.2200	38.3300
Q2 '13	107.5300	60.9500	31.9000
Q3 '13	117.0500	63.0500	30.3300
Q4 '13	119.2100	63.5800	50.2200

### Add to the pivot

To add more data to the pivot, select another column, click the drop-down arrow next to the column name, and then select **Add Data to Pivot**. Make sure that the pivot columns and values look as expected before you begin your analysis.

Quarter	LG	Pivot Field Values
Q1 '10	27.19	8.270
Q2 '10	29.37	8.740
Q3 '10	27.48	13.480
Q4 '10	30.12	16.010
Q1 '11	24.00	16.880
Q2 '11	24.42	19.630
Q3 '11	21.0100	17.300
Q4 '11	16.9400	35.460

To remove a pivot, click the drop-down arrow next to the name of a pivot column, and then select **Remove Pivot**.

## Troubleshooting pivots

- **Red fields in the view and fields with exclamation points in the Data pane:**  
Because the original fields are replaced with new pivot fields, any references to the original fields in the view will no longer work. They cause fields to become red in the view or show a red exclamation point next to the field in the **Data** pane.
- **Null values in the grid:** If all of the original fields used in the pivot are removed, for example in an extract refresh, null values display in the pivot fields.
- **No pivot option:** Pivot appears when you select two or more columns in a single Microsoft Excel, text file, Google Sheets, and .pdf data source. If using a different data source in Tableau Desktop, you can use custom SQL to pivot.

## Pivot using custom SQL (Tableau Desktop)

You can also use custom SQL to pivot your data, even if you aren't working Excel, text file, Google Sheets, and .pdf data sources. When you use the UNION ALL operator in a custom SQL query, you can take values from distinct columns and put them into a new column.

For example, suppose you have a table called **Contest**.

### Contest

Runner	Start Time	End Time
Amanda	9/3/2016 3:04 PM	9/3/2016 3:25 PM
Oscar	9/3/2016 3:04 PM	9/3/2016 3:21 PM
William	9/3/2016 3:04 PM	9/3/2016 3:16 PM

To optimize your analysis of this data in Tableau, you can use the following custom SQL query to pivot the "Start Time" and "End Time" columns so that their values are in a single column.

```
Select [Runner]
, 'Start' as [Action]
, [Start Time] as [Time]
From [Contest]
Union ALL
```

```
Select [Runner]
, 'End' as [Action]
, [End Time] as [Time]
From [Contest]
```

The above custom SQL query does the following:

- Pivots the **Start Time** column header into a string value called **Start** and adds that value to a new column called **Action**.
- Pivots the **End Time** column header into a string value called **End** and adds that value to a new column called **Action**.
- Pivots the **Start Time** and **End Time** columns so that their values are in a new column called **Time**.

The following table shows the results of this custom SQL query.

Runner	Action	Time
Amanda	Start	9/3/2016 3:04 PM
Oscar	Start	9/3/2016 3:04 PM
William	Start	9/3/2016 3:04 PM
Amanda	End	9/3/2016 3:25 PM
Oscar	End	9/3/2016 3:21 PM
William	End	9/3/2016 3:16 PM

To pivot data using custom SQL

1. Connect to your data.
2. Double-click the **New Custom SQL** option in the left pane. For more information, see [Connect to a Custom SQL Query on page 811](#).
3. In the **Edit Custom SQL** dialog box, copy and paste the following custom SQL query and replace the contents with information about your table:

```

Select [Static Column]
, 'New Value (from Column Header 1)' as [New Column Header]
, [Pivot Column Values 1] as [New Values]

From [Table]

Union ALL

Select [Static Column]
, 'New Value (from Column Header 2)' as [New Column Header]
, [Pivot Column Values 2] as [New Values]

From [Table]

Union ALL

Select [Static Column]
, 'New Value (from Column Header 3)' as [New Column Header]
, [Pivot Column Values 3] as [New Values]

From [Table]

```

Where the following is true:

- ***Static Column***: A comma-delimited list of the columns from *Table*, both dimensions and measures, which should not be included in the pivot.
- ***New Value (from Column Header 1-3)***: New names that you give to the original column headers, which are used as row values in the pivot.
- ***Pivot Column Values 1-3***: The columns whose values need to be pivoted into a single column.
- ***New Column Header***: The name you give the new column that contains the new row values from *New Value (from Column Header 1-3)*.
- ***New Values***: The name give the new column that contains the original values from *Pivot Column Values 1-3*.
- ***Table***: The table that you connected to.

4. Click **OK**.

## Clean Data from Excel, CSV, PDF, and Google Sheets with Data Interpreter

When you track data in Excel spreadsheets, you create them with the human interface in mind. To make your spreadsheets easy to read, you might include things like titles, stacked headers, notes, maybe empty rows and columns to add white space, and you probably have multiple tabs of data too.

When you want to analyze this data in Tableau, these aesthetically pleasing attributes make it very difficult for Tableau to interpret your data. That's where Data Interpreter can help.

**Tip:** Though Tableau's Excel add-in is no longer supported, Data Interpreter can help you reshape your data for analysis in Tableau.

### What does Data Interpreter do?

Data Interpreter can give you a head start when cleaning your data. It can detect things like titles, notes, footers, empty cells, and so on and bypass them to identify the actual fields and values in your data set.

It can even detect additional tables and sub-tables so that you can work with a subset of your data independently of the other data.

After Data Interpreter has done its magic, you can check its work to make sure it captured the data that you wanted and identified it correctly. Then, you can make any necessary adjustments.

After you select the data that you want to work with, you might also need to do some additional cleaning steps like pivoting your data, splitting fields, or adding filters to get the data in the shape you want before starting your analysis.

**Note:** If your data needs more cleaning than what Data Interpreter can help you with, try [Tableau Prep](#).

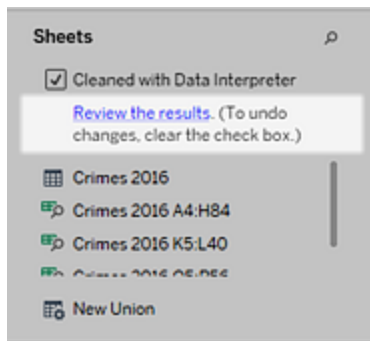

## Turn on Data Interpreter and review results

1. From the **Connect** pane, connect to an Excel spreadsheet or other connector that supports Data Interpreter such as Text (.csv) files, PDF files or Google sheets.
2. Drag a table to the canvas (if needed), then on the **Data Source** page, in the left pane, select the **Use Data Interpreter** check box to see if Data Interpreter can help clean up your data.

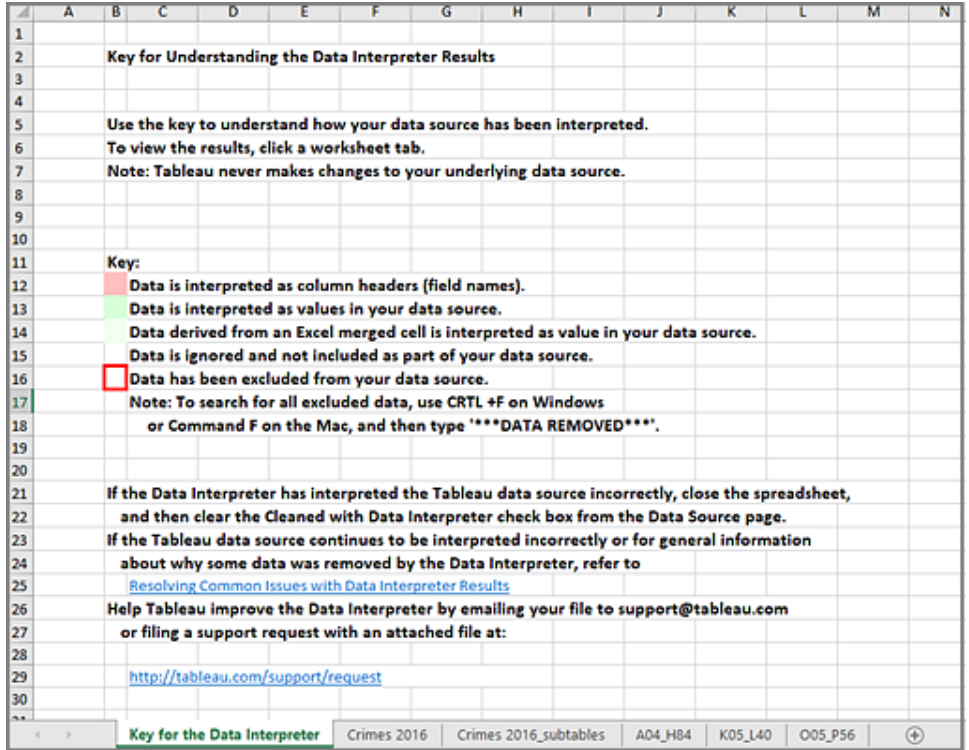

**Note:** When you clean your data with Data Interpreter, Data Interpreter cleans all the data associated with a connection in the data source. Data Interpreter does not change the underlying data.

3. In the Data pane, click the **Review the results** link to review the results of the Data Interpreter.

A copy of your data source opens in Excel on the **Key for the Data Interpreter** tab. Review the key to find out how to read the results.

- Click each tab to review how Data Interpreter interpreted the data source.

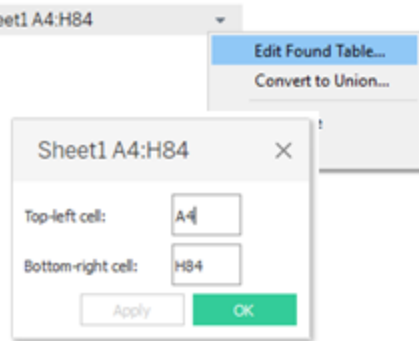

If Data Interpreter found additional tables, also called found tables or sub-tables, they are identified in the <sheet name>\_subtables tab by outlining their cell ranges. A separate tab is also included for each sub-table, color coded to identify the header and data rows.

If Data Interpreter does not provide the expected results, clear the **Cleaned with Data Interpreter** check box to use the original data source.

- To replace the current table with any of the found tables, drag the current table off the canvas and then drag the found table that you want to use to the canvas.

If Data Interpreter has misidentified the range of the found table, after you drag the found table to the canvas, click the drop-down arrow on that table, and then select **Edit Found Table** to adjust the corners of the found table (the top-left cell and bottom-right cell of the table).

6. After you have the data that you want to work with, you can apply any additional cleaning operations to your data so that you can analyze it.

### Data Interpreter Example

In this example we are connecting to an Excel spreadsheet with violent crime data by city and state for the year 2016. This spreadsheet includes multiple tables on one sheet and some extra formatting.

Violent Crimes in 2016 in the United States by City and State									
Location		Months							
city	state	Apr	Jun	Jul	Aug	Sep	Oct		
Albuquerque	New Mexico							46	
Anaheim	California								26
Anchorage	Alaska	1							17

- A. Title
- B. Merged header cells
- C. Extra white space
- D. Sub-tables

## Tableau Desktop and Web Authoring Help

The extra formatting in this spreadsheet makes it difficult for Tableau to determine what the field headers and values are.

Instead, it reads the data vertically and assigns each column the default value F1, F2, F3 (Field 1, Field 2, Field 3) and so on. Blank cells are read as null values.

Row	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11	F12	F13	F14	F15	F16	F17	F18	F19	F20	F21	F22	F23	F24	F25	F26	F27	F28	F29	F30	F31	F32	F33	F34	F35	F36
Valent Crimes in 2011																																				
Location		Months																																		
city	state	Apr	Jun	Jul	Aug	Sep	Oct	state	Total Crimes 2016	State	Population 2016																									
Albuquerque	New Mexico					46		Alabama	12	Alabama	4860545																									
Anahem	California		4					Alaska	26	Alaska	741522																									
Anchorage	Alaska	1				26		Arizona	132	Arizona	6908642																									
Arlington	Texas					17		California	616	Arkansas	2988231																									
Atlanta	Georgia					85		Colorado	64	California	39296476																									

To see if Data Interpreter can help clean this data set, we select **Use Data Interpreter**.

Data Interpreter detected the proper headings for the fields, removed the extra formatting and found several sub-tables. The sub-tables are listed in the **Sheets** section in the Data pane and are named using the original sheet name and the cell ranges for each sub-table.

In this example there are three sub-tables: **Crimes 2016 A4:H84**, **Crimes 2016 K5:L40**, and **Crimes 2016 O5:P56**.

Row	Location	state	Months	Months	Months	Months	Months	Months	Months	state	Total Crimes 2016	State	Population 2016
Albuquerque	New Mexico							46		Alabama	12	Alabama	4,860,545
Anahem	California		4						Alaska	26	Alaska	741,522	
Anchorage	Alaska	1					26		Arizona	132	Arizona	6,908,642	
Arlington	Texas					17			California	616	Arkansas	2,988,231	
Atlanta	Georgia					85			Colorado	64	California	39,296,476	
Aurora	Colorado						26		D.C.	106	Colorado	5,630,106	
Austin	Texas						29		Florida	210	Connecticut	3,687,685	
Bakersfield	California		22						Georgia	85	Delaware	952,699	
Baltimore	Maryland							220	Hawaii	9	District of Columbia	684,336	

To examine the results of the Data Interpreter more closely, we click the **Review the results** link in the Data pane to view an annotated copy of the spreadsheet.

Here we see a copy of the original data, color coded to identify which data was identified as header data and which data was identified as field values.

Location	Location	Months	Months	Months	Months	Months	Months	state	Total Crimes 2016	State	Population	Header
city	state	Apr	Jun	Jul	Aug	Sep	Oct					
Albuquerque	New Mexico						46	Alabama	12	Alabama	4860545	Data
Anaheim	California			4				Alaska	26	Alaska	741522	Data
Anchorage	Alaska	1					26	Arizona	132	Arizona	6908642	Data
Arlington	Texas					17		California	515	Arkansas	2988231	Data
Atlanta	Georgia						85	Colorado	64	California	39296476	Data
Aurora	Colorado						16	D.C.	105	Colorado	5530105	Data
Austin	Texas					28		Florida	210	Connectic	3587685	Data
Bakersfiel	California		22					Georgia	85	Delaware	952698	Data
Baltimore	Maryland							Hawaii	9	District of	684336	Data
Boston	Massachusetts						28	Illinois	536	Florida	20656589	Data
Buffalo	New York						38	Indiana	151	Georgia	10313620	Data
Chandler	Arizona						3	Kansas	10	Hawaii	1428683	Data

The next tab shows us the sub-tables that Data Interpreter found, outlined by the cell ranges.

Location	Location	Months	Months	Months	Months	Months	Months	state	Total Crimes 2016	State	Population 2016
city	state	Apr	Jun	Jul	Aug	Sep	Oct				
Albuquerque	New Mexico						46	Alabama	12	Alabama	4860545
Anaheim	California			4				Alaska	26	Alaska	741522
Anchorage	Alaska	1					26	Arizona	132	Arizona	6908642
Arlington	Texas					17		California	515	Arkansas	2988231

Aurora	Colorado						16	D.C.	105	Colorado	5530105
Austin	Texas					28		Florida	210	Connectic	3587685
Bakersfiel	California		22					Georgia	85	Delaware	952698
Baltimore	Maryland							Hawaii	9	District of	684336
Boston	Massachusetts						28	Illinois	536	Florida	20656589
Buffalo	New York						38	Indiana	151	Georgia	10313620
Chandler	Arizona						3	Kansas	10	Hawaii	1428683
Charlotte	North Carolina			25				Kentucky	95	Idaho	1680026
Chicago	Illinois							Louisiana	127	Illinois	12835726
Chula Vista	California		2			1		Maryland	230	Indiana	6634007
Cincinnati	Ohio						50	Massachu	28	Iowa	3130869
Cleveland	Ohio						89	Michigan	221	Kansas	2907731
Colorado	Colorado					15		Minnesota	26	Kentucky	4436113
Columbus	Ohio						70	Missouri	223	Louisiana	4686157
Corpus Ch Texas	Texas			9				Nebraska	29	Maine	1330232
Dallas	Texas						118	Nevada	128	Maryland	6024752
Denver	Colorado					33		New Jersey	86	Massachu	6823721
Detroit	Michigan		5					New Mexi	46	Michigan	9933445
Durham	North Carolina							New York	290	Minnesota	5525050
El Paso	Texas						14	North Car	82	Mississip	2985415
Fort Wayr	Indiana						34	Ohio	217	Missouri	6091176

In this example the first sub-table, **Crimes 2016 A4:H84**, has the main data that we want to work with. To use this table as our data table, we can simply drag the original table off the canvas and then drag the new table to the canvas.

## Tableau Desktop and Web Authoring Help

Crimes 2016 A4:H84	Crimes 2016 A4:H84	Crimes 2016 A4:H84	Crimes 2016 A4:H84	Crimes 2016 A4:H84	Crimes 2016 A4:H84	Crimes 2016 A4:H84	Crimes 2016 A4:H84
Location city	Location state	Months Apr	Months Jun	Months Jul	Months Aug	Months Sep	Months Oct
Albuquerque	New Mexico	null	null	null	null	45	null
Anaheim	California	null	4	null	null	null	null
Anchorage	Alaska	1	null	null	null	26	null
Arlington	Texas	null	null	null	17	null	null
Atlanta	Georgia	null	null	null	null	85	null
Aurora	Colorado	null	null	null	null	16	null
Austin	Texas	null	null	null	28	null	null
Bakersfield	California	null	22	null	null	null	null
Baltimore	Maryland	null	null	null	null	null	230
Boston	Massachusetts	null	null	null	null	28	null
Buffalo	New York	null	null	null	null	38	null
Chandler	Arizona	null	null	null	null	3	null

Once we have the data that we want to work with in the canvas, we can do some additional clean up on the data. For example we can:

- Change the field names so that they represent city, state, and month names.
- Pivot the months fields.
- Drag in the third sub-table **Crimes 2016 o5:P56** and join it to our first sub-table on the **State** field to include state populations for our analysis.
- Hide any duplicate fields that were added as a result of the join.

The results might look something like this:

Sort fields Data source order				
Crimes 2016 A4:HB4 City	Crimes 2016 A4:HB4 State	Crimes 2016 O5:P56 Population 2016	Abc Pivot Months	# Pivot Crimes
Phoenix	Arizona	6,908,642	August	111
Pittsburgh	Pennsylvania	12,787,085	August	<i>null</i>
Plano	Texas	27,904,862	August	5
Portland	Oregon	4,085,989	August	<i>null</i>
Raleigh	North Carolina	10,156,689	August	<i>null</i>
Riverside	California	39,296,476	August	7
Sacramento	California	39,296,476	August	<i>null</i>
San Antonio	Texas	27,904,862	August	<i>null</i>
San Diego	California	39,296,476	August	30
San Francisco	California	39,296,476	August	<i>null</i>
San Jose	California	39,296,476	August	35
Santa Ana	California	39,296,476	August	<i>null</i>
Seattle	Washington	7,280,934	August	14
St. Louis	Missouri	6,091,176	August	133
St. Petersburg	Florida	20,656,589	August	14

Now we are ready to start analyzing our data in Tableau.

## When Data Interpreter is not available

The Data Interpreter option might not be available for the following reasons:

- **The data source is already in a format that Tableau can interpret:** If Tableau Desktop doesn't need extra help from Data Interpreter to handle unique formatting or extraneous information, the Data Interpreter option is not available.
- **Many rows or many columns:** The Data Interpreter option is not available when your data has the following attributes:
  - Data contains more than 2000 columns.
  - Data contains more than 3000 rows and more than 150 columns.
- **The data source is not supported:** Data Interpreter is only available for Microsoft Excel, Text (.csv) files, PDF files and Google Sheets. For Excel, your data must be in the .xls or .xlsx format.

## Split a Field into Multiple Fields

If you have string fields in your data that contain multiple distinct pieces of information (for example, the first and last name of a customer) you may be able to split the values into separate fields.

Customer Name	Customer Name - ...	Customer Name - ...
Claire Gute	Claire	Gute
Claire Gute	Claire	Gute
Darrin Van Huff	Darrin	Van
Sean O'Donnell	Sean	O'Donnell
Sean O'Donnell	Sean	O'Donnell
Brosina Hoffman	Brosina	Hoffman
Brosina Hoffman	Brosina	Hoffman
Brosina Hoffman	Brosina	Hoffman

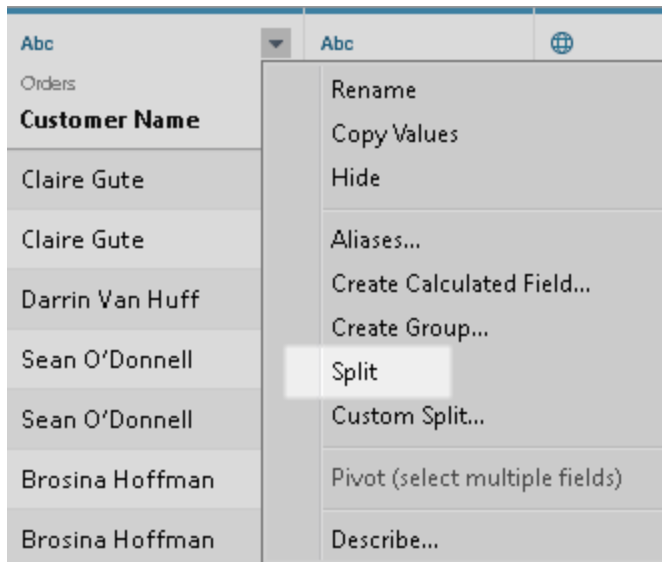

You can use split options in Tableau Desktop to separate the values based on a separator (delimiter) or a repeated pattern of values present in each row. In the example of Customer Name, the common separator is a space (" ") between first and last name.

### Find the Split option

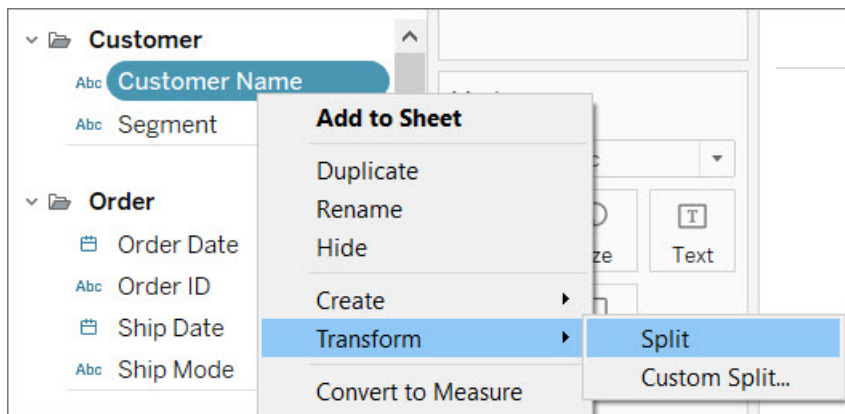

Tableau Desktop—but not web editing in the browser—has a menu option for automatic or custom splits. These are based on the SPLIT string function, which can also be used manually in a calculation for complete control over the split.

Not all data sources support SPLIT. You can tell if your data supports the **SPLIT function** by checking for the Split and Custom Split menu options:

- On the Data Source page, check the menu for **Split** and **Custom Split**.

- From the Data pane on a sheet, check the menu for **Transform > Split** and **Custom Split**.

### Split on the web

Web authoring doesn't support splitting from a menu. To split data while working in the browser, you can manually create a SPLIT calculation. See [Alternatives to splitting from the menu](#) on page 856.

## Split fields

A string field can be split automatically based on a common separator that Tableau detects in the field. You can also manually define the split

Depending on the connection type, a split can automatically separate a field's values in up to ten new fields.

### Split a field automatically

**On the Data Source page**, in the grid, click the drop-down arrow next to the field name, then select **Split**.

**In the Data pane**, right-click the field you want to split, and then select **Transform > Split**.

The results of the split are standard calculated fields that can be edited or deleted like any other calculated field. The data type of the new fields generated by the split can vary depending on the pattern combination that Tableau detects.

### Split a field with custom split

Use the custom split option for more control over the split. You can specify the separator and choose to split the values at the first N occurrences of the separator, the last N occurrences, or at all occurrences.

**On the Data Source page**, in the grid, click the drop-down arrow next to the field name. Select **Custom Split**.

**From the Data pane**, in the Data pane, right-click the field you want to split, and then select **Transform > Custom Split**.

The new fields generated by the custom split always result in a string data type.

**Note:** In some cases, if the automatic split takes too long to generate new fields or Tableau can't find a common separator, the custom split dialog box displays.

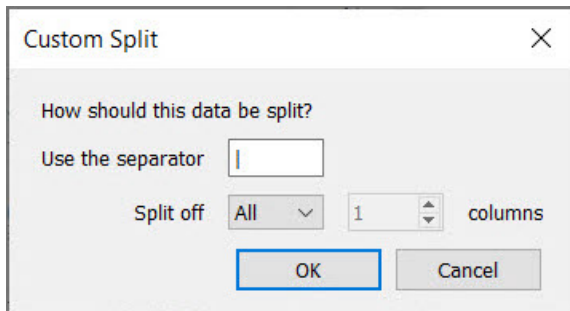

Custom split is useful when the number of separators varies from value to value. Automatic split can't be used in these cases.

For example, suppose a field Employee Info has the following values:

- jsmith| accounting | north
- dnguyen | humanresources

- lscott | recruiting | west
- karnold |recruiting |west

The custom split could be configured to split on the pipe character ( "|") and split off all columns. For the value without a region, the third result field will be null for that row.

## Alternatives to splitting from the menu

### Split manually using the SPLIT function

The SPLIT function works similarly to a custom split, but only one result field is returned per calculation. You define the separator and specify which value to return by providing a token number.

For example, to split Customer Name into First Name and Last Name, create two calculated fields:

- First Name: `SPLIT([Customer Name], " ", 1)`
- Last Name: `SPLIT([Customer Name], " ", 2)`

The Employee Info example (such as "jsmith| accounting | north") would use three calculated fields:

- Username: `SPLIT([Employee Info], |, 1)`
- Department: `SPLIT([Employee Info], |, 2)`
- Region: `SPLIT([Employee Info], |, 3)`

For more information, see the [SPLIT function](#).

### Split manually using LEFT and RIGHT functions

If your use case is more to extract a specific part of a string than to split it based on a separator, you can use the LEFT and RIGHT functions. These return only a portion of the string based on a specified number of characters.

For example, if the value of a row is IGW8892:

Calculation	Result
<code>RIGHT([Value], 4)</code>	8892
<code>LEFT([Value], 4)</code>	IGW8
<code>LEFT(RIGHT([Value], 2) , 1)</code>	9

For more information, see LEFT and RIGHT in [String Functions on page 2186](#).

### Use regular expressions for fields contain mixed separators

Fields can't be split automatically if the separator types are different. For example, suppose a field includes the following values:

- smith.accounting
- dnguyen-humanresources
- lscott\_recruiting
- karnold\_recruiting

In cases like this, consider using regular expressions to extract the desired information. For more information, see [Additional Functions on page 2314](#).

## Working with splits and custom splits

Things to keep in mind when working with splits and custom splits.

- New fields can't be used as keys to join tables, but can be used to blend data sources.
- New fields can't be used in a pivot.
- Split and custom split options aren't supported for sets, groups, parameters, and bins.
- Microsoft SQL Server only allows up to four split fields.
- To generate more than ten new fields, consider splitting multiple times. You can use split again on a field from the first split that still includes multiple pieces of information.

## Troubleshooting splits and custom splits

Known issues you might experience when using splits and custom splits:

- **Split and custom split options missing for a supported data source type:** Split and custom split options are available only for fields that are a string data type.

- **Null values:** After creating a split or a custom split, new fields might contain null values or no values at all. Null values or empty cells happen when there are no values for the expected new fields.
- **Data has been removed:** Tableau might use portions of the field's values as a separator. If a portion of a field's value is used as a separator, those values no longer appear in the new fields.

For example:

Original value	Split field values
Zip-98102	98102
Zip-98109	98109
Zip-98119	98199
Zip-98195	98195

The split doesn't create a separate field for "Zip-" because that entire string is used as the separator.

## Filter Data from Data Sources

You can create filters on a data source, thereby reducing the amount of data in the data source. This feature is available to Creators when authoring in Tableau Cloud and Tableau Server.

If you create an extract from a data source that already has data source filters in place, those filters are automatically recommended as extract filters, and will appear in the Extract dialog. Those recommended filters are not required to be part of the Extract filter list, and can safely be removed without affecting the existing set of data source filters.

Data source filters can be useful for restricting the data users can see when you publish a workbook or data source. When you publish a data source to Tableau Server, the data source and any associated files or extracts are transported in entirety to the Server. As you publish a data source you can define access permissions for downloading or modifying the data source, and you can also choose the users and groups who can remotely issue queries through Tableau Server against that data source. When users have query permission and no download permission, you can share a rich data model having calculated fields, aliases, groups, sets and more—but only for querying.

Furthermore, users who query published data source will never be able to see or modify any data source filters present on the originally published data source, but all of the users' queries will be subject to those data source filters. This is a great way to offer a restricted subset of your data, for example by filtering dimensions for specific users and groups, or by defining data source filters based on a fixed or relative date range. This is often useful for data security, and it also allows you to manage performance of the remote database which Tableau Server will ultimately query on a user's behalf. For systems that rely heavily on partitions or indexing, data source filters may yield tremendous control over the performance of queries issued by Tableau.

## Create a data source filter

The primary way to create a data source filter is from the data source page.

To create a data source filter

1. On the data source page, click **Add** in the Filters section in the upper-right corner of the page.

To create a data source filter on a worksheet, right-click (control-click on a Mac) the data source and choose **Edit Data Source Filters**.

Whether you start from the Data Source page or from a worksheet, you see an Edit Data Source Filter dialog box, listing any existing data source filters.

2. Click **Add** to open an Add Filter dialog box listing all fields in the data source.
3. Click to select a field to filter; then specify how the field should be filtered, just as you would for a field on the Filters shelf.

To add an additional data source filter, repeat this procedure.

## Global filters and data source filters

When you create a data source filter, any global filters that use that data source are displayed automatically in the **Edit Data Source Filters** dialog box.

In Tableau Desktop, you can promote a global filter to be a data source filter. To promote the global filter to be a data source filter, click **OK**.

If you promote a global filter to be a data source filter in Tableau Desktop, that global filter will no longer be visible in worksheets of the workbook (because it becomes a data source filter).

**Important:** Be aware that you do not need to select a global filter in the **Edit Data Source Filters** dialog box to promote it. When you click **OK**, all global filters in the list will be promoted.

To prevent a global filter from being promoted to a data source filter, select the global filter in the **Edit Data Source Filters** dialog box, and then click **Remove**.

## Understand Field Type Detection and Naming Improvements

Tableau uses a collection of commonly used patterns to detect and transform your data to make it easier for you to interact with. For example, when you work with fields in the Data pane, Tableau takes the data from your data source, detects its type, and divides it into dimensions and measures.

**Note:** Tableau never changes your underlying data.

Tableau can also detect fields that should be treated as dimensions and clean up field names by making them more readable. You see these improvements only when the field names, which come from column headers in your data source, meet the patterns or conditions described below.

### New fields added to underlying data

If you add new fields to your underlying data, and then refresh the data source in Tableau, the newly added fields will retain their original database names. If you would like Tableau to automatically rename those fields, you will need to create a new connection to that same data source.

If you prefer to maintain the field types and field names from the underlying data, see the [Undo changes made by Tableau](#) section at the bottom of this article.

### Fields that are treated as a dimension

Field names that contain certain keywords are treated as dimensions, even if the values for those fields are numeric.

#### Keywords Code, Key, and ID

Field names that contain the following keywords and meet the conditions listed are treated as dimensions instead of measures.

**Conditions:**

- Contains keywords Code, ID, or Key.
- Keywords are either separated from other text in the field name by non-letter characters, all capitalized, or the first letter is capitalized in a field name that otherwise has mixed casing.
- Keywords are at the beginning or end of the field name, with leading or trailing non-letter characters. In Chinese, Japanese, and Korean, the key word must be located at the end of the field name.

Language	Keywords
English (UK and US)	Code, Id, Key
Chinese (Simplified)	代码, ID, 键
Chinese (Traditional)	代碼, ID, 金鑰
French (Canada and France)	Code, ID, clé
German	Code, ID, Schlüssel
Italian	Codice, ID, chiave
Japanese	コード, ID, キー
Korean	코드, ID, 키
Portuguese	Código, ID, chave
Spanish	Código, ID, clave
Swedish	Kod, ID, nyckel
Thai	รหัส, ID, คีย์

### Keywords Number, Num, and Nbr

Field names that end with Number, Num, or Nbr are treated as a dimension instead of a measure. For example, “Record Number” is treated as a dimension but “Number of Records” is not. In addition, the Korean field name must be four or fewer characters long.

Language	Keywords
English (UK and US)	Number, Num, Nbr
Chinese (Simplified)	数字
Chinese (Traditional)	數字
French (Canada and France)	Nombre
German	Nr, Nummer

Language	Keywords
Italian	Numero, N°
Japanese	数值
Korean	숫자
Portuguese	Número
Spanish	Número
Swedish	Nummer
Thai	ตัวเลข

### Keywords related to dates

Field names containing keywords that are recognized as date parts are treated as dimensions. These field names can only contain only one additional word unrelated to dates to qualify. For example, “Fiscal Year” is treated as a dimension but “Fiscal Year Information” is not. In addition, Chinese field names must be four or fewer characters long and cannot contain digits. Japanese and Korean field names must be four or fewer characters long.

Language	Keywords
English (UK and US)	Year, Yr, Day, Day of Week, Week, Wk, Month, Quarter, Qtr, FY
Chinese (Simplified)	年, 天, 周中某天, 周, 月, 季度, 会计年度
Chinese (Traditional)	年, 天, 週中某天, 週, 月, 季, 會計年度
French (Canada and France)	Année, Jour, Jour de la Semaine, Semaine, Mois, Trimestre, AF
German	Jahr, Tag, Wochentag, Woche, Monat, Quartal, GJ
Italian	Anno, Giorno, Giorno della Settimana, Settimana, Sett, Mese, Trimestre, Trim, AF

Japanese	年, 日, 曜日, 週, 月, 四半期, 年度
Korean	년, 일, 요일, 주, 월, 분기, 회계 연도
Portuguese	Ano, Dia, Dia da Semana, Semana, Mês, Trimestre, AF
Spanish	Año, Día, Día de la Semana, Semana, Mes, Trimestre, AF
Swedish	År, Dag, Veckodag, Vecka, Månad, Kvartal, Räkenskapsåret
Thai	ปี, วัน, วันของสัปดาห์, สัปดาห์, เดือน, ไตรมาส, FY

## Field name clean-up

Field names that contain specific characters or capitalized in a certain way are renamed. Field values that include square brackets are automatically converted to parentheses.

### Field names with underscore, space, or tab characters

Non-leading and trailing underscore ( ) characters in field names are converted into space ( ) characters. Carriage return or line feed characters in a field name are removed. However, field names that contain leading underscore characters remain unchanged. In addition, leading and trailing spaces in field names are removed. This type of field name clean up applies only to English, French, German, Portuguese, and Spanish languages.

**Example 1:** The field name “Country\_Name” is converted to “Country Name”.

**Example 2:** The field name “\_Days\_On\_Market” is converted to “\_Days On Market”.

Field names with multiple underscore characters in a row remain unchanged. For example, “Country\_\_Name” remains as “Country\_\_Name”.

If a field name contains multiple tab characters, the tabs are converted to underscores.

### Field names and capitalization

Field names that use all capital letters with non-letter characters are converted to all lower-case letters except for the characters immediately after the non-letter character.

Additionally, field names that use all lower-case letters are converted so the first letter in the field name is capitalized.

This type of field name clean up applies only to English, French, German, Portuguese, and Spanish languages.

**Example 1:** The field name “PC1” is converted to “Pc1.” The field name “COUNTRY\_NAME” is converted to “Country Name”. However, “Budget COGS” remains as “Budget COGS” .

**Example 2:** The field name “FDA” does not change. However, the field name “FDA\_Sales” is converted to “Fda Sales”.

**Example 3:** The field name “age” is converted to “Age”.

Space characters are added to the case boundaries of field names that contain mixed casing with non-letter characters.

**Example:** The field name “ThisCase” is converted to “This Case”.

### Field names that are two or three letters long

Field names that are two or three letters long that are part of a multiple word phrase are converted so that each letter in the word is capitalized, unless the two or three letter word contains a vowel (i.e., a, e, i, o, or u).

**Example:** The field name "Unit Qty" is converted to "Unit QTY". However, the field name "Sales Amt" remains as "Sales Amt".

Several three-letter acronyms are converted to all uppercase. Examples of three-letter acronyms include the following:

CIF	FDA	MPI
DMA	FOB	MSA
DOB	FTE	SKU
EIN	KPI	UPC
ESP	LOB	URL
		USD

The following field names are converted to all lowercase letters unless the name occurs at the beginning of the field name:

1st	as	down	of	th (suffix following a number)
2nd	at	for	on	than
3rd	but	in	off	the
a	by	inclu.	or	to
an	de	into	over	vs
and	da	la	per	with

**Note:** The casing of field names that are one letter long remain unchanged.

## Undo changes made by Tableau

If you prefer to maintain the field types and field names specified by the underlying data, you can undo changes made by Tableau either manually, at the data source level, or automatically, at the application level.

### To undo changes manually

1. Open your workbook and go to the Data Source page.
2. Click the drop-down arrow for the field with changes you want to undo and select **Reset name**.

### If there are multiple fields you wish to change

1. Open your workbook and go to the Data Source page.
2. Optionally, click the metadata grid button.
3. **Ctrl+Click** (Windows) or **Command+Click** (Mac) to select the fields with changes you want to undo.
4. Click the drop-down arrow for any of the fields selected and select **Reset name**.

To automatically undo changes made by Tableau at the application level, follow the procedure in the [Overriding Automatic Field Renaming](#) article. This method affects all data sources that you access from Tableau Desktop.

## Extract Your Data

A data extract is a subset of information that is saved separately from the original dataset. It serves two purposes: to enhance performance and to utilize Tableau features that may not be available or supported in the original data. By creating a data extract, you can effectively reduce the overall data volume by applying filters and setting other limitations.

Once a data extract is created, it can be refreshed with the latest data from the original source. During the refresh process, you have the flexibility to choose between a full refresh, which replaces all existing content in the extract, or an incremental refresh, which only includes new rows since the previous refresh.

**Note:** Starting from version 2024.1, Tableau introduces a feature that enables users to perform incremental refreshes on extracts using a non-unique key column.

### Benefits of Extracts

- **Handling large datasets:** Extracts can handle massive amounts of data, even reaching billions of rows. This allows users to work with extensive datasets efficiently.
- **Improved performance:** Interacting with views that utilize extract data sources results in better performance compared to views connected directly to the original data. Extracts optimize query performance, resulting in faster data analysis and visualization.
- **Enhanced functionality:** Extracts provide access to additional Tableau functionality that may not be available or supported by the original data source.

For instance, users can leverage extracts to compute Count Distinct, enabling more advanced calculations and analysis.

- **Offline data access (Tableau Desktop):** Extracts allow for offline access to data. This means that even when the original data source isn't available, users can still save, manipulate, and work with the data locally.

## Create an extract

There are multiple options available within your Tableau workflow to create an extract, but the main approach is explained below.

1. After you connect to your data and set up the data source on the Data Source page, in the upper-right corner, select **Extract**, and then select the **Edit** link to open the Extract Data dialog box.

2. Under Data Storage, select either **Logical Tables** or **Physical Tables**. For assistance with this step see the [Data Storage](#) section.
3. Expand **Filters** to set up filters to limit how much data gets extracted based on fields and their values.

4. Select **Aggregate data for visible dimensions** to aggregate the measures using their default aggregation.
5. (Optional) Select **Roll up dates** to a specified date level such as Year, Month, etc.

6. Select the number of rows you want to extract. You can extract **All rows**, **Sample**, or the **Top N** rows.
7. Select the **Incremental refresh** box, and then specify the table to refresh and a column in the database that will be used to identify new rows.
8. When finished, choose **Save Settings**.
9. Select the sheet tab. This initiates the creation of the extract.

10. Next, select a location to save the extract.
11. Enter an extract file name.
12. Select **Save**. If the Save dialog box doesn't display, see the [Troubleshoot extracts section](#).

## Extract field descriptions

You can configure numerous fields when creating an extract. This section walks you through each field.

### Data Storage

Under Data Storage you can select either Logical or Physical tables. Logical tables store data in one extract table for each logical table in the data source. On the other hand, physical tables store data in one extract table for each physical table in the data source.

#### Logical tables

If you want to limit the amount of data in your extract and use additional extract properties like filters, aggregation, or Top N, you should select Logical Tables.

- This option also works well when your data includes pass-through functions (RAWSQL).
- Tableau uses Logical Tables as the default structure for storing extract data.
- If you choose this option and your extract includes joins, the joins will be applied when the extract is created.

#### Physical tables

If your extract consists of tables combined with equality joins and meets the Conditions for using the Physical Tables option, you should select Physical Tables. This option performs joins at query time and can potentially improve performance and reduce the size of the extract file.

Considerations for using the Physical Tables option. To store your extract using the Physical Tables option, the data in your extract must meet all of the following conditions.

- All joins between physical tables are equality (=) joins.
- Data types of the columns used for relationships or joins are identical.
- No pass-through functions (RAWSQL) used.
- No incremental refresh configured.
- No extract filters configured.

- No Top N or sampling configured.
- When the extract is stored as physical tables, you can't append data to it.
- For logical tables, you can't append data to extracts that have more than one logical table.

### Tips for using the physical tables option

Tableau generally recommends that you use the default data storage option, Logical Tables, when setting up and working with extracts. In many cases, some of the features you need for your extract, like extract filters, are only available to you if you use the Logical Tables option.

#### **Physical Tables option for extracts that are larger than expected**

The Physical Tables option should be used sparingly to help with specific situations such as when your data source meets the Conditions for using the Physical Tables option and the size of your extract is larger than expected. To determine if the extract is larger than it should be, the sum of rows in the extract using the Logical Tables option must be higher than the sum of rows of all the combined tables before the extract has been created. If you encounter this scenario, try using the Physical Tables option instead.

#### **Alternative filtering suggestions when using the physical tables option**

When using the Physical Tables option, other options to help reduce the data in your extract, like extract filters, aggregation, Top N and Sampling are disabled. If you need to reduce the data in an extract that uses the Physical Tables option, consider filtering the data before it is brought into Tableau Desktop using one of the following suggestions:

#### **Connect to your data and define filters using custom SQL**

Instead of connecting to a database table, connect to your data using custom SQL instead. When creating your custom SQL query, make sure that it contains the appropriate level of filtering that you need to reduce the data in your extract. For more information about custom SQL in Tableau Desktop, see [Connect to a Custom SQL Query](#).

#### **Define a view in the database**

If you have write access to your database, consider defining a database view that contains just the data you need for your extract and then connect to the database view from Tableau Desktop.

#### **Row-level security with extracts**

If you want to secure extract data at the row level, using the Physical Tables option is the recommended way to achieve this scenario. For more information about row-level security in Tableau, see [Restrict Access at the Data Row Level](#).

### General table considerations

Both the Logical Tables and Physical Tables options only affect how the data in your extract is stored. The options don't affect how tables in your extract are displayed on the Data Source page.

For example, suppose your extract consists of one logical table that contains three physical tables.

If you directly open the extract (.hyper) file that has been configured to use the default option, Logical Tables, you see one table listed on the Data Source page.

However, if you open the extract using the packaged data source (.tdsx) file or the data source (.tdsx) file with its corresponding extract (.hyper) file, you see all three tables that comprise the extract on the Data Source page.

### Filters

Use filters to set up filters to limit how much data gets extracted based on fields and their values.

### Aggregation

Aggregation allows you to aggregate measures. You can also select **Roll up dates** to a specified date level such as Year, Month, etc. The examples below show how the data will be extracted for each aggregation option you can choose.

<p><b>Original data</b></p>	 <table border="1"> <thead> <tr> <th></th> <th>A</th> <th>B</th> <th>C</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Date</td> <td>Region</td> <td>Sales</td> </tr> <tr> <td>2</td> <td>1/1/2009</td> <td>South</td> <td>\$500</td> </tr> <tr> <td>3</td> <td>1/1/2009</td> <td>West</td> <td>\$200</td> </tr> <tr> <td>4</td> <td>1/1/2009</td> <td>West</td> <td>\$100</td> </tr> <tr> <td>5</td> <td>1/1/2009</td> <td>East</td> <td>\$300</td> </tr> <tr> <td>6</td> <td>1/2/2009</td> <td>South</td> <td>\$600</td> </tr> <tr> <td>7</td> <td>1/2/2009</td> <td>South</td> <td>\$400</td> </tr> <tr> <td>8</td> <td>1/2/2009</td> <td>East</td> <td>\$100</td> </tr> </tbody> </table>		A	B	C	1	Date	Region	Sales	2	1/1/2009	South	\$500	3	1/1/2009	West	\$200	4	1/1/2009	West	\$100	5	1/1/2009	East	\$300	6	1/2/2009	South	\$600	7	1/2/2009	South	\$400	8	1/2/2009	East	\$100	<p>Each record is shown as a separate row. There are seven rows in your data.</p>
	A	B	C																																			
1	Date	Region	Sales																																			
2	1/1/2009	South	\$500																																			
3	1/1/2009	West	\$200																																			
4	1/1/2009	West	\$100																																			
5	1/1/2009	East	\$300																																			
6	1/2/2009	South	\$600																																			
7	1/2/2009	South	\$400																																			
8	1/2/2009	East	\$100																																			
<p><b>Aggregate data for visible dimensions</b> <i>(no roll up)</i></p>	 <table border="1"> <thead> <tr> <th></th> <th>A</th> <th>B</th> <th>C</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Date</td> <td>Region</td> <td>Sales</td> </tr> <tr> <td>2</td> <td>1/1/2009</td> <td>East</td> <td>\$300</td> </tr> <tr> <td>3</td> <td>1/1/2009</td> <td>South</td> <td>\$500</td> </tr> <tr> <td>4</td> <td>1/1/2009</td> <td>West</td> <td>\$300</td> </tr> <tr> <td>5</td> <td>1/2/2009</td> <td>East</td> <td>\$100</td> </tr> <tr> <td>6</td> <td>1/2/2009</td> <td>South</td> <td>\$1,000</td> </tr> </tbody> </table>		A	B	C	1	Date	Region	Sales	2	1/1/2009	East	\$300	3	1/1/2009	South	\$500	4	1/1/2009	West	\$300	5	1/2/2009	East	\$100	6	1/2/2009	South	\$1,000	<p>Records with the same date and region have been aggregated into a single row. There are five rows in the extract.</p>								
	A	B	C																																			
1	Date	Region	Sales																																			
2	1/1/2009	East	\$300																																			
3	1/1/2009	South	\$500																																			
4	1/1/2009	West	\$300																																			
5	1/2/2009	East	\$100																																			
6	1/2/2009	South	\$1,000																																			
<p><b>Aggregate data for visible dimensions</b> <i>(roll up dates to Month)</i></p>	 <table border="1"> <thead> <tr> <th></th> <th>A</th> <th>B</th> <th>C</th> <th>D</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Date</td> <td>Region</td> <td>Sales</td> <td></td> </tr> <tr> <td>2</td> <td>1/1/2009</td> <td>East</td> <td>\$400</td> <td></td> </tr> <tr> <td>3</td> <td>1/1/2009</td> <td>South</td> <td>\$1,500</td> <td></td> </tr> <tr> <td>4</td> <td>1/1/2009</td> <td>West</td> <td>\$300</td> <td></td> </tr> </tbody> </table>		A	B	C	D	1	Date	Region	Sales		2	1/1/2009	East	\$400		3	1/1/2009	South	\$1,500		4	1/1/2009	West	\$300		<p>Dates have been rolled up to the Month level and records with the same region have been aggregated into a single row. There are three rows in the extract.</p>											
	A	B	C	D																																		
1	Date	Region	Sales																																			
2	1/1/2009	East	\$400																																			
3	1/1/2009	South	\$1,500																																			
4	1/1/2009	West	\$300																																			

## Number of rows

You can extract All rows or the Top N rows. Tableau first applies any filters and aggregation and then extracts the number of rows from the filtered and aggregated results. The number of rows options depend on the type of data source you are extracting from. You might not see the Sampling option in the Extract Data dialog box because some data sources don't support sampling.

**Note(s):** Any fields that you hide first in the Data Source page or on the sheet tab will be excluded from the extract. Click the **Hide All Unused Fields** button to remove the hidden fields from the extract.

## Incremental Refresh

Most data sources support an incremental refresh. Rather than refreshing the entire extract, you can configure a refresh to add only the rows that are new since the previous time you extracted the data.

For example, you may have a data source that is updated daily with new sales transactions. Rather than rebuild the entire extract each day, you can just add the new transactions that occurred that day.

## Incremental Refresh and Advanced Settings tips

This section will help you with tips to prevent errors you can encounter when setting up these features.

Incremental Refresh:

- In Number of Rows, you need to select **All Rows**.
- Incremental Refresh isn't available if you enable Aggregation.

Advanced Settings:

- Advanced Settings aren't compatible with Filters.

## Extract tips

### Save your workbook to preserve the connection to the extract

After you create an extract, the workbook begins to use the extract version of your data. However, the connection to the extract version of your data isn't saved until you save the workbook. This means if you close the workbook without saving the workbook first, the workbook will connect to the original data source the next time you open it.

### Toggle between sampled data and entire extract

When you're working with a large extract, it can be helpful to create a smaller sample of the data. This allows you to set up your view without having to run lengthy queries every time you add a field to your analysis. You can easily switch between using the sample data and the complete data source by selecting the appropriate option in the Data menu.

### Don't connect directly to the extract

When you save extracts to your computer, you can directly connect to them using a new Tableau Desktop. However, it isn't recommended for a few of the following reasons:

#### The names of the tables may be different.

Extracts use special naming to ensure that each table has a unique name, which might be hard to understand.

#### You can't update or refresh the extract.

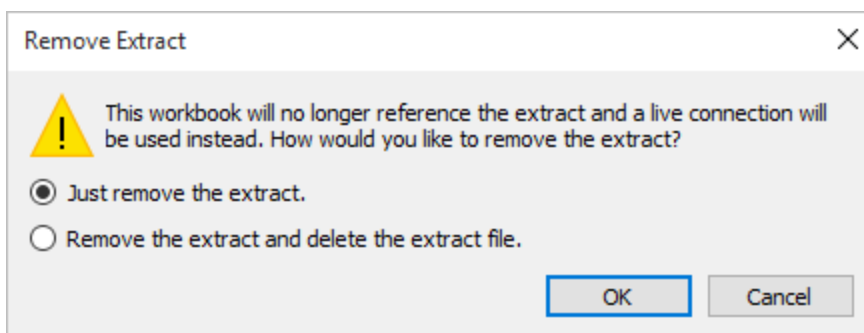

When you connect directly to an extract, Tableau considers it as the original source of data, rather than a copy. This means you can't link it back to your original data source.

#### The structure and relationships between tables will be lost.

The arrangement and connections between tables are stored in the .tds file, not in the .hyper file. Therefore, when you connect directly to the .hyper file, you lose this information. If you use logical tables storage for the extract, you won't see any references to the original physical tables.

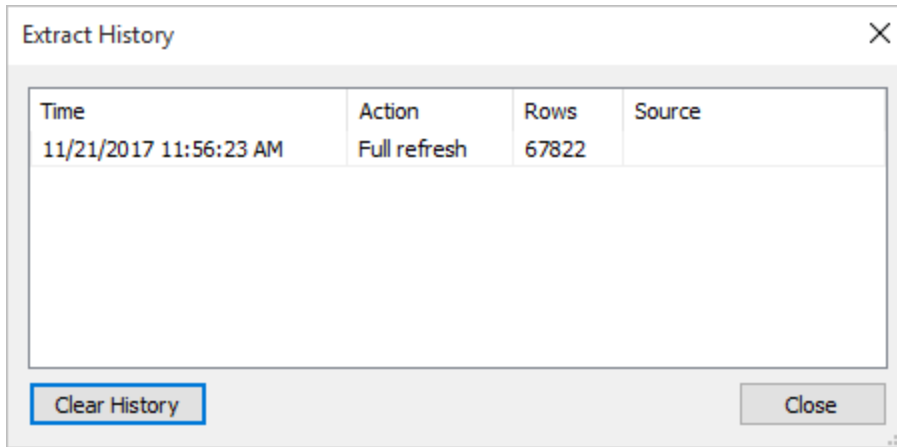

### Remove the extract from the workbook

You can remove an extract at anytime by selecting the extract data source on the **Data** menu and then selecting **Extract > Remove**. When you remove an extract, you can choose to **Remove the extract from the workbook only** or **Remove and delete the extract file**. The latter option will delete the extract from your hard drive.

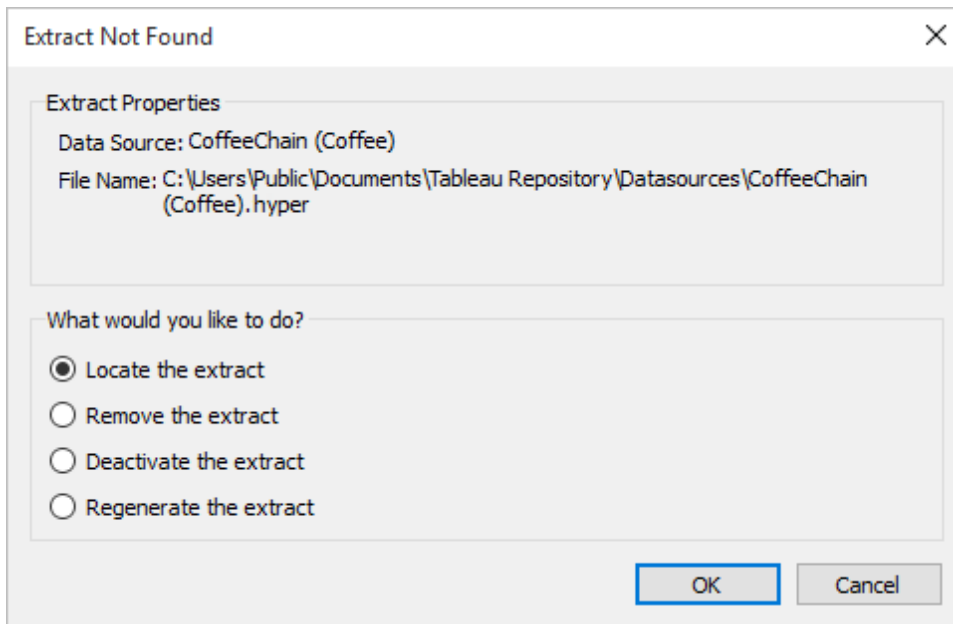

### See extract history (Tableau Desktop)

You can see when the extract was last updated and other details by selecting a data source on the **Data** menu and then selecting **Extract > History**.

If you open a workbook that is saved with an extract and Tableau can't locate the extract, select one of the following options in the Extract Not Found dialog box when prompted:

- **Locate the extract:** Select this option if the extract exists but not in the location where Tableau originally saved it. Click **OK** to open an Open File dialog box where you can specify the new location for the extract file.
- **Remove the extract:** Select this option if you have no further need for the extract. This is equivalent to closing the data source. All open worksheets that reference the data source are deleted.
- **Deactivate the extract:** Use the original data source from which the extract was created, instead of the extract.
- **Regenerate the extract:** Recreates the extract. All filters and other customizations you specified when you originally created the extract are automatically applied.

## Troubleshoot extracts

- **Creating an extract takes a long time:** Depending on the size of your data set, creating an extract can take a long time. However, after you have extracted the data and saved it to your computer, performance can improve.
- **Extract is not created:** If your data set contains a really large number of columns (e.g., in the thousands), in some cases Tableau might not be able to create the extract. If you encounter problems, consider extracting fewer columns or restructuring the underlying data.
- **Save dialog does not display or extract is not created from a .twbx:** If you follow the above procedure to extract data from a packaged workbook, the Save dialog doesn't display. When an extract is created from a packaged workbook (.twbx), the extract file is automatically stored in the package of files associated with the packaged workbook. To access the extract file that you created from the packaged workbook, you must unpackage the workbook. For more information, see [Packaged Workbooks on page 3018](#).

## Extract feature updates

### Incremental Refresh

Starting from version 2024.1, Tableau introduces a feature that enables users to perform incremental refreshes on extracts using a non-unique key column. There is a new UI that supports these advanced settings.

This update introduces an additional step in the process. During an incremental refresh, Tableau first removes rows from the extract that match the previously recorded highest value.

Subsequently, Tableau queries for all rows that have a value higher than or equal to the previous highest value. This approach ensures that any deleted rows are accounted for, along with any newly added ones.

### Extracts in the web

Beginning with version 2020.4, extracts are available in web authoring and content server. Now, you no longer have to use Tableau Desktop to extract your data sources. For more information, see [Create Extracts on the Web](#).

### Logical and physical table extracts

With the introduction of logical tables and physical tables in the Tableau data model in version 2020.2, extract storage options have changed from Single Table and Multiple Tables, to Logical Tables and Physical Tables. These options better describe how extracts will be stored. For more information, see [Extract Your Data on page 867](#).

### Deprecation of .tde format

**Note:** Beginning in March 2023, extracts using the .tde format are deprecated in Tableau Cloud, Tableau Public, and Tableau Server (version 2023.1.0). For more information, see [Extract Upgrade to .hyper Format on page 884](#).

Beginning with version 10.5, when you create a new extract it uses the .hyper format. Extracts in the .hyper format take advantage of the improved data engine, which supports faster analytical and query performance for larger data sets.

Similarly, when an extract-related task is performed on a .tde extract using version 10.5 and later, the extract is upgraded to a .hyper extract. After a .tde extract is upgraded to a .hyper extract, it can't be reverted back to .tde extract. For more information, see [Extract Upgrade to .hyper Format on page 884](#).

## Changes to values and marks in the view

To improve extract efficiency and scalability, values in extracts can be computed differently in versions 10.5 and later compared to versions 10.4 and earlier. Changes to how the values are computed can affect the way marks in your view are populated. In some rare cases, the changes can cause your view to change shape or become blank. These changes can also apply to multi-connection data sources, data sources that use live connections to file-based data, data sources that connect to Google Sheets data, cloud-based data sources, extract-only data sources, and WDC data sources.

To get an idea of some of the differences you might see in your view using version 2022.4, see the sections below.

### Format of date and date time values

In versions 10.5 and later, extracts are subject to more consistent and stricter rules around how date strings are interpreted through the DATE, DATETIME, and DATEPARSE functions. This affects how dates are parsed, or the date formats and patterns that are allowed for these functions. More specifically, the rules can be generalized as the following:

1. Dates are evaluated and then parsed by column, not by row.
2. Dates are evaluated and then parsed based on the locale of where the workbook was created, not on locale of the computer where the workbook is opened.

These new rules allow extracts to be more efficient and to produce results that are consistent with commercial databases.

However, because of these rules, particularly in international scenarios where the workbook is created in a locale different from the locale that the workbook is opened in or the server that the workbook is published to, you might see that 1.) date and datetime values change to different date and datetime values or 2.) date and datetime values change to *Null*. When your date and datetime values change to different date and datetime values or become *Null*, it's often an indication that there are issues with the underlying data.

Here are some common reasons why you might see changes to your date and datetime values in your extract data source using version 10.5 and later.

<b>Common causes of changes to date/datetime values</b>	<b>Common causes of null values</b>
<ul style="list-style-type: none"> <li>• When a function has to parse multiple date formats in a single</li> </ul>	<ul style="list-style-type: none"> <li>• When a function has to parse multiple date</li> </ul>

<b>Common causes of changes to date/datetime values</b>	<b>Common causes of null values</b>
<p>column. Where the date is ambiguous and can be interpreted in several different ways, the date will be interpreted based on the format Tableau has determined for that column. For some examples, see <a href="#">Date scenario 1 on the next page</a> and <a href="#">Date scenario 2 on page 881</a> below.</p> <ul style="list-style-type: none"> <li>• When a function has to parse a YYYY-MM-DD (ISO) format. For an example, see <a href="#">Date scenario 3 on page 882</a>.</li> <li>• When a function doesn't have enough information to derive the time, it can interpret a value as "00:00:00.0", using "0" for hour, minute, second, and millisecond.</li> <li>• When a function doesn't have enough information to derive the day, it can interpret a value as "1" or "January" for month.</li> <li>• When a function parses years, it is interpreted as the following:             <ul style="list-style-type: none"> <li>• Year "07" is interpreted as "2007"</li> <li>• Year "17" is interpreted as "2017."</li> <li>• Year "30" is interpreted as "2030."</li> <li>• Year "69" interpreted as "2069."</li> </ul> </li> </ul>	<p>formats in a single column. After Tableau determines the date format, all other dates in the column that deviate from the format become null values. For some examples, see <a href="#">Date scenario 1 on the next page</a> and <a href="#">Date scenario 2 on page 881</a> below.</p> <ul style="list-style-type: none"> <li>• When a function has to parse a YYYY-MM-DD (ISO) format. Values that exceed what is allowed for "YYYY," or "MM," or "DD" cause null values. For an example, see <a href="#">Date scenario 3 on page 882</a>.</li> <li>• When a function has to parse date values that contain trailing characters. For example, time zone and daylight savings suffixes and keywords, such as "midnight" cause null values.</li> <li>• When a function has to parse an invalid date or time. For example, 32/3/2012 causes a null value. In another example, 25:01:61 causes a null value.</li> </ul>

Common causes of changes to date/datetime values	Common causes of null values
<ul style="list-style-type: none"> <li>Year "70" is interpreted as "1970."</li> </ul>	<ul style="list-style-type: none"> <li>When a function has to parse contradicting inputs. For example, suppose the pattern is 'dd.MM (MMMM) y' and the input string is '1.09 (August) 2017', where both "9" and "August" are months. The result is a null value because the month values aren't the same.</li> <li>When a function has to parse contradicting patterns. For example, a pattern that specifies a mix of Gregorian year (y) and ISO week (ww) causes null values.</li> </ul>

### Date scenario 1

Suppose you have a workbook created in an English locale that uses .tde extract data source. The table below shows a column of string data contained in the extract data source.

10/31/2018
31/10/2018
12/10/2018

Based on the particular English locale, the format of the date column was determined to follow the MDY (month, day, and year) format. The following tables show what Tableau displays based on this locale when the DATE function is used to convert string values into date values.

October 31, 2018
---------------------

October 31, 2018
December 10, 2018

If the extract is opened in a German locale, you see the following:

31 Oktober 2018
31 Oktober 2018
12 Oktober 2018

However, after the extract is opened in a German locale using version 10.5 and later, the DMY (day, month, and year) format of the German locale is strictly enforced and causes a *Null* value because one of the values doesn't follow DMY format.

Null
October 31, 2018
October 12, 2018

## Date scenario 2

Suppose you have another workbook created in an English locale that uses a .tde extract data source. The table below shows a column of numeric date data contained in the extract data source.

1112018
1212018
1312018
1412018

Based on the particular English locale, the format of the date column was determined to follow the MDY (month, day, and year) format. The following tables show what Tableau displays based on this locale when the DATE function is used to convert the numeric values into date values.

11/1/2018
12/1/2018
Null
Null

### Date scenario 3

Suppose you have a workbook that uses a .tde extract data source. The table below shows a column of string data contained in the extract data source.

2018-10-31
2018-31-10
2018-12-10
2018-10-12

Because the date uses the ISO format, the date column always follows the YYYY-MM-DD format. The following tables show what Tableau displays when the DATE function is used to convert string values into date values.

October 10, 2018
Null
December 10, 2018
October 12, 2018

**Note:** In versions 10.4 (and earlier), ISO format and other date formats could have produced differing results depending on the locale of where the workbook was created. In an English locale for example, both 2018-12-10 and 2018/12/10 could produce December 12, 2018.

However, in a German locale 2018-12-10 could produce December 12, 2018 and 2018/12/10 could produce October 12, 2018.

### **Sort order and case sensitivity**

Extracts have collation support and therefore can more appropriately sort string values that have accents or are cased differently.

For example, suppose you have a table of string values. In terms of sort order, this means that a string value like Égypte is now appropriately listed after Estonie and before Fidji.

#### *About Excel data:*

With regard to casing, this means that how Tableau stores values have changed between version 10.4 (and earlier) and version 10.5 (and later). However, the rules for sorting and comparing values haven't. In version 10.4 (and earlier), string values like "House," "HOUSE," and "houSe" are treated the same and stored with one representative value. In version 10.5 (and later), the same string values are considered unique and therefore stored as individual values. For more information, see [Changes to the way values are computed](#) on page 238.

### **Breaking ties in Top N queries**

When a Top N query in your extract produces duplicate values for a specific position in a rank, the position that breaks the tie can be different when using version 10.5 and later. For example, suppose you create a top 3 filter. Positions 3, 4, and 5 have the same values. When using version 10.4 and earlier, the top filter can return 1, 2, and 3 positions. However, when using version 10.5 and later, the top filter can return 1, 2, and 5 positions.

### **Precision of floating-point values**

Extracts are better at taking advantage of the available hardware resources on a computer and therefore able to perform mathematical operations in a highly parallel way. Because of this, real numbers can be aggregated by .hyper extracts in different order. When numbers are aggregated in different order, you might see different values in your view after the decimal point each time the aggregation is computed. This is because floating-point addition and multiplication is not necessarily associative. That is,  $(a + b) + c$  isn't necessarily the same as  $a + (b + c)$ . Also, real numbers can be aggregated in different order because floating-point multiplication isn't necessarily distributive. That is,  $(a \times b) \times c$  isn't necessarily the same as  $a \times b \times c$ . This type of floating-point rounding behavior in .hyper extracts resemble that of floating-point rounding behavior in commercial databases.

For example, suppose your workbook contains a slider filter on an aggregated field comprised of floating point values. Because the precision of floating-point values have changed, the filter might now exclude a mark that defines the upper or lower bound of the filter range. The absence of these numbers could cause a blank view. To resolve this issue, move the slider on the filter or remove and add the filter again.

### Accuracy of aggregations

Extracts optimize for large data sets by taking better advantage of the available hardware resources on a computer and therefore able to compute aggregations in a highly parallel way. Because of this, aggregations performed by .hyper extracts can resemble the results from commercial databases more than the results from software that specializes in statistical computations. If you're working with a small data set or need a higher level of accuracy, consider performing aggregations through reference lines, summary card statistics, or table calculation functions like variance, standard deviation, correlation, or covariance.

### About the Compute Calculations Now option for extracts

If the **Compute Calculations Now** option was used in a .tde extract using an earlier version of Tableau Desktop, certain calculated fields were materialized and therefore computed in advance and stored in the extract. If you upgrade the extract from a .tde extract to a .hyper extract, the previously materialized calculations in your extract aren't included. You must use the **Compute Calculations Now** option again to ensure that materialized calculations are a part of the extract after the extract upgrade. For more information, see [Materialize Calculations in Your Extracts on page 891](#).

### New Extract API

You can use the Extract API 2.0 to create .hyper extracts. For tasks that you previously performed using the Tableau SDK, such as publishing extracts, you can use the Tableau Server REST API or the Tableau Server Client (Python) library. For refresh tasks, you can use the Tableau Server REST API as well. For more information, see [Tableau Hyper API on page 903](#).

### Extract Upgrade to .hyper Format

In Tableau version 2018, we introduced the .hyper format for Tableau extracts to replace the old .tde format. The .hyper format has been the standard format used by Tableau to create extracts since 2018, and the large majority of extracts are now .hyper files. Beginning in early 2023, Tableau is discontinuing support for the .tde format on Tableau Cloud and Tableau Public. For more details, see this [Tableau Community post](#).

## Discontinuation of support for TDE extract files

Beginning in 2023, the `.tde` format for Tableau extracts is deprecated. This format was replaced by the `.hyper` format in 2018 but continued to be valid for uploaded files until March 2023.

- This change takes place for Tableau Cloud and Tableau Public as of March 2023.
- Beginning with version 2023.1.0 of Tableau Server, the uploading of `.tde` format files is disabled by default.

It is unusual to have existing `.tde` files because these were replaced by `.hyper` format files in 2018 and several common actions on the files automatically and permanently convert them to the supported `.hyper` format. For details see below.

## Tasks that cause an extract upgrade

There are three distinct ways a `.tde` extract can get upgraded to a `.hyper` extract: 1.) during an extract refresh (full or incremental), 2.) when appending data to an extract, and 3.) when an extract is upgraded manually. After an extract has been upgraded using Tableau Desktop, it's not automatically removed in case the `.tde` extract is being referenced by other workbooks.

In addition to the tasks that upgrade an extract, extract tasks performed outside of Tableau Desktop can cause an extract upgrade to the `.tde` extract you interact with. This includes the following tasks:

- Manual refresh (Tableau Server and Tableau Cloud)
- Incremental refresh on a published extract data source from Tableau Bridge (Tableau Cloud)
- A scheduled full or incremental extract refresh data source (Tableau Server and Tableau Cloud)
- A scheduled incremental extract refresh from Tableau Bridge (Tableau Cloud)

## Manually upgrade your extract

If you manage extracts locally, you can manually upgrade your `.tde` extract to a `.hyper` extract using Tableau Desktop.

1. In Tableau Desktop, open a workbook that uses a `.tde` extract.
2. Select the extract data source from the **Data** menu and then select **Extract > Upgrade**
3. Select **File > Save**, which saves the workbook and also completes the extract upgrade.

## Refresh Extracts

When the original data changes, you can refresh the extract using Desktop by selecting a data source on the **Data** menu, and then selecting **Extract** and **Refresh**. Extracts can be set up in two ways: fully refreshed or incrementally refreshed.

With a full refresh, all the data in the extract is replaced with the latest information from the original data source. An incremental refresh only adds the new rows since the last refresh. If you want more details on how to extract your data, you can visit the [Extract Your Data Page](#).

**Note:** You can also automate extract refreshes using the Tableau Data Extract Command Line Utility. For more information, see [Tableau Data Extract Command-Line Utility on page 894](#).

### Before you refresh extracts

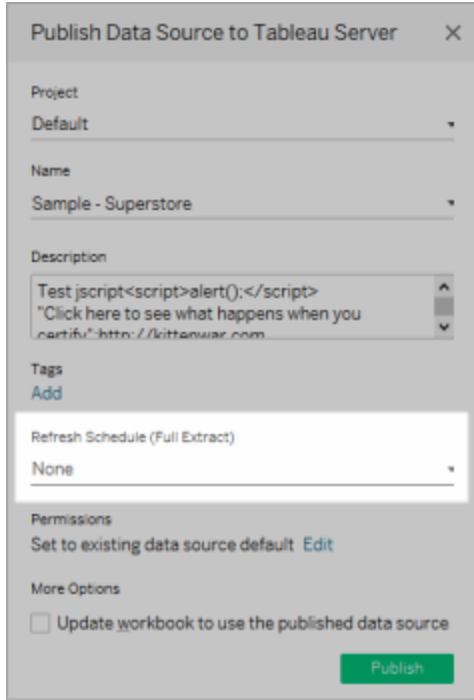

If you want to refresh an extract, make note of the file format of the extract before you perform an extract refresh. If you perform a refresh on an `.tde` extract using version 2022.4, the extract is upgraded to `.hyper` extract automatically. While there are many benefits of upgrading to a `.hyper` extract, you will be unable to open the extract with previous versions of Tableau Desktop. For more information, see [Extract Upgrade to .hyper Format on page 884](#).

### Configure a full extract refresh

By default, extracts are configured to fully refresh. This means that every time you refresh the extract, all of the rows are replaced with the data in the original data source. While this kind of refresh ensures that you have an exact copy of what is in the original data, depending on the size of the extract, a full refresh can sometimes take a long time and be expensive on the database. If an extract is not configured for an incremental refresh, selecting to refresh the extract will perform a full refresh of the extract.

### Publish to Tableau Server

If you plan to publish the extract as a data source to Tableau Server, you can specify a schedule for the extract refresh during publishing.

Similarly, if you are publishing the extract in a workbook to Tableau Server, you can also specify a schedule for the extract refresh during publishing. For more information, see [Schedule Extract Refreshes as You Publish a Workbook](#) on page 3093.

## Publish to Tableau Cloud

If you plan to publish the extract as a data source to Tableau Cloud, your options for refreshing your data depend on the characteristics of your data sources. For more information on refreshing data from specific data sources, see [Extract refresh options by data source](#).

## Configure an incremental extract refresh

Most data sources support an incremental refresh. Rather than refreshing the entire extract, you can configure a refresh to add only the rows that are new since the previous time you extracted the data.

For example, you may have a data source that is updated daily with new sales transactions. Rather than rebuild the entire extract each day, you can just add the new transactions that occurred that day. Then once a week you might want to do a full refresh just to be sure you have the most up to date data.

Starting from version 2024.1, Tableau introduces a feature that enables users to perform incremental refreshes on extracts using a non-unique key column. This update introduces an additional step in the process. During an incremental refresh, Tableau first removes rows from

the extract that match the previously recorded highest value. Subsequently, Tableau queries for all rows that have a value higher than or equal to the previous highest value. This approach ensures that any deleted rows are accounted for, along with any newly added ones.

The Advanced Settings feature provides two options for managing data updates. You can choose to replace the last rows added by refreshing values that are equal to or greater than the last recorded value. Or you can opt to keep the last rows added by only refreshing the extract with values greater than the last recorded value.

**Note:** If the data structure of the source data changes (for example, a new column is added), you will need to do a full extract refresh before you can start doing incremental refreshes again.

You can follow the steps below to set up an extract to be refreshed incrementally.

1. Select a data source on the **Data** menu, and then select **Extract Data**.
2. In the Extract Data dialog box, select **All rows** as the number of Rows to extract. Incremental refresh can only be defined when you are extracting all rows in the database.

**Note:** You can't increment a sample extract.

3. Select **Incremental refresh**.

**Note:** Incremental Refresh isn't available if you enable Aggregation.

4. Specify a column in the database that will be used to identify new rows.

For example, you can select a Date field or an ID column that monotonically increases as rows are added to the database.

5. Expand Advanced Settings to establish how new rows are retrieved. You can choose to replace the last rows added by refreshing values that are equal to or greater than the last recorded value. Or you can opt to keep the last rows added by only refreshing the extract with values greater than the last recorded value.

**Note:** When filters are added, the Advanced Settings for Incremental Refresh will appear greyed out and the default setting of "Don't replace the last rows added" will be enforced. The purpose of this is to avoid any conflicts that may arise between certain filter criteria and the advanced incremental refresh logic that will "Replace the last rows added".

6. To finish, select **Save Settings**.

The steps above can be used to define a new extract or edit an existing extract for an incremental refresh.

## Considerations when doing a Incremental refresh

### Editing an extract

If you are editing an existing extract, the last refresh is shown so you can be sure you are updating the extract with the correct data.

### Full Refresh

A Full Refresh replaces all of the rows with the data in the original data source every time you refresh the extract. A Full Refresh can take longer and be expensive on the database.

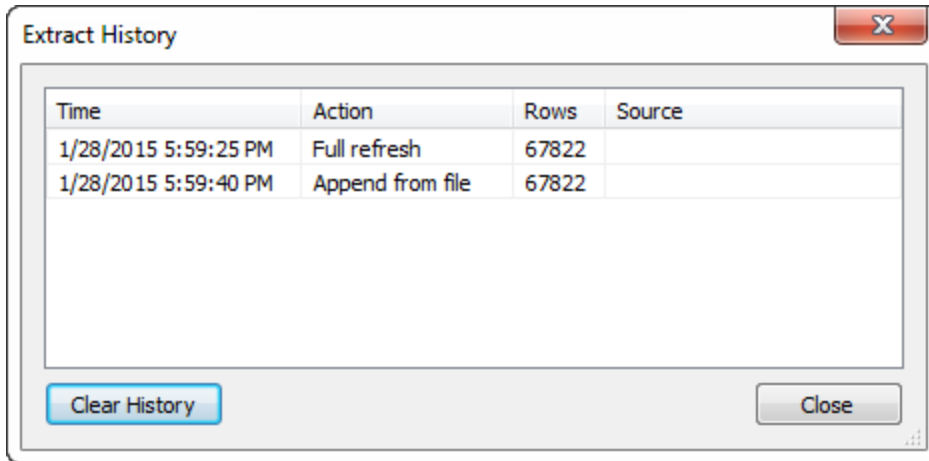

### Data Engine

The data engine, which is the underlying mechanism that Tableau uses to create extracts, stores time values with a precision of up to 3 decimal places. If you specify a datetime or timestamp column for **Identify new rows using column**, and your database uses a higher precision than Tableau, you can end up with duplicate rows after an incremental refresh. For example, if the database has two rows, one with a datetime value of 2015-03-13 17:30:56.502352 and one with a datetime value of 2015-03-13 17:30:56.502852, Tableau will store both rows using a datetime value of 2015-03-13 17:30:56.502 thereby creating duplicate rows.

### See extract history (Tableau Desktop)

You can see a history of when the extract was refreshed by selecting a data source on the **Data** menu and then select **Extract > History**.

The Extract History dialog box shows the date and time for each refresh, whether it was full or incremental, and the number of rows that were added. If the refresh was from a file, it also shows the source file name.

## Add Data to Extracts

There are two ways you can add new data to an extract: from a file or from a data source. However, to add new data, you must first connect to data and create a new data source, and the columns in the file or data source must match the columns in the extract.

### Add data from a file

You can add new data to an extract from a file-based data source. Use this option when the file type of the extract is the same as the file type of the data that you want to add. Alternatively, you can add data from an extract (.hyper) file. For example, you may have text files that are generated for a task that is performed every day. To add each day's worth of information to your extract whose original data source is also a text file, use the **Append Data from File** command.

1. On the **Data** menu, select a data source, and then select **Extract > Append Data from File**.
2. Browse to and select the file that has the new data.

**Note:** By default, the file format of the extract's original data source is used. To add data from a Tableau data extract, click the file format drop-down list, and then select **Hyper Extracts (\*.hyper)**.

3. When finished, click **OK**.

## Add data from a data source

You can also add new data to an extract from another data source that's already open in the workbook. Use this option when the data from the data source that you want to add matches the extract data source before it was extracted. For example, you created an extract from a SQL Server database that has the past ten years worth of data. However, the maintained version of that data is stored on a different SQL Server database. You can add new data to the extract by using the **Append Data from Data Source** command.

**Note:** Joins or custom SQL should be specified in the data source before adding data to the extract.

1. On the **Data** menu, select a data source, and then select **Extract > Append Data from Data Source**.
2. In the dialog box, select the data source that you want to append.
3. When finished, click **OK**.

Using either option will add new rows to the extract. To see a summary of the number of rows that were added, select a data source on the **Data** menu and then select **Extract > History**.

**Note:** When you refresh this extract, the data will be replaced with the data from the original data.

## Materialize Calculations in Your Extracts

You can use the **Compute Calculations Now** option to materialize calculations in your extract. When calculations are materialized, certain calculations are computed in advance and its values stored in the extract. Depending on the complexity of the calculations used in your extract, this can potentially speed up future queries by allowing Tableau to compute certain calculations in advance. Tableau can then use the precomputed value rather than computing the value each time a query against a calculation is made.

If the formula for a calculation that Tableau has already materialized changes or the calculation is deleted from the data source, the materialized calculation is removed from the extract until you use the **Compute Calculations Now** option again.

## When to materialize calculations

You should not use the **Compute Calculations Now** option for all your extracts. Instead, try this option only when the query performance of your extract is slow as a result of complex calculations, such as string manipulations and regular expressions.

## Materialize calculations

To materialize calculations in your extract, do the following:

1. In Tableau Desktop, select the extract data source from the **Data** menu.
2. Select **Extract > Compute Calculations Now**.

## Materialize calculations in extracts already published to Tableau Cloud or Tableau Server

If you need to retroactively materialize calculations in extracts that are already published to Tableau Cloud or Tableau Server, you have the following options:

- You can download the extract, open the extract in Tableau Desktop, use the **Compute Calculations Now** option (as described above), and then republish the extract.
- As a site administrator or data source owner, you can use `tabcmd` to refresh the published extract with the `--addcalculations` option to materialize the calculations. For more information about the `tabcmd` command option, see [refreshextracts](#) in the Tableau Cloud Help or [refreshextracts](#) in the Tableau Server Help.

**Note:** Materializing calculations can increase the size of the extract.

## Calculations that cannot be materialized

The following calculations cannot be materialized:

- Calculations that use unstable functions such as `NOW()` and `TODAY()`
- Calculations that use external functions such as `RAWSQL` and `R`
- Table calculations
- Level of detail (LOD) calculations
- Calculations that use column groups, until the dependent column group is materialized with an extract refresh

## Update Server Data Sources That Are Using Extracts

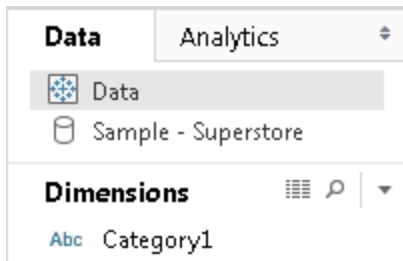

You have the following options for updating extract data sources that are published to Tableau Server or Tableau Cloud:

- **Option 1:** You can add the data source or a workbook that connects to it to a refresh schedule in Tableau Server or Tableau Cloud (cloud-based data sources only).
- **Option 2:** You can update the data source in Tableau Desktop and then republish it.
- **Option 3:** You can add to or refresh the data source on Tableau Server or Tableau Cloud, from Tableau Desktop, without first adding to or refreshing the extract in Tableau Desktop.

The remainder of this topic describes option 3.

## Update Tableau Server or Tableau Cloud extracts from Tableau Desktop

Before you attempt to update an extract data source on Tableau Server or Tableau Cloud, verify first that Tableau Desktop is connected to a published data source. You can verify that Tableau Desktop is connected to a published data source by the Tableau Server icon next to the data source name in the Data pane:

To update the published data source, do the following:

1. In Tableau Desktop, right-click (control-click on a Mac) the data source in the Data pane
2. Select **Tableau Data Server**, and choose one of the following options:

- **Edit Server and Site Path**

If you have changed the location of the data source in Tableau Server or Tableau Cloud, choose this option to point Tableau Desktop to the new, correct location.

- **Refresh from Source**

Refreshes the extract (full or incremental) using the original data.

This command is available only for extracts that include a connection to the original data. If you connected directly to an extract file (.hyper) and then published it, the connection to the original data is not included and this option is therefore unavailable.

- **Append from Data Source**

Updates the extract from another open (and compatible) data source. If you connected directly to an extract file (.hyper) and then published it, the connection to the original data is not included and this option is therefore unavailable.

**Note:** If you see the Tableau Data Server option, but the commands in the submenu are unavailable, the data source exists on the server, but is not an extract.

It is also possible to update an extract on Tableau Server using a command-line utility. For more information, see [Tableau Data Extract Command-Line Utility](#) below.

## Tableau Data Extract Command-Line Utility

You can automate extract refresh tasks using the Tableau Data Extract Command-Line Utility. This is a command-line utility that comes with Tableau Desktop, through which you can refresh published extract data sources or append data to them from a file.

Requirements for using the Tableau Data Extract Command-Line Utility include the following:

- It is available with Tableau Desktop on Windows and can run only on a Windows system.
- It is not available with the trial version of Tableau Desktop.
- You can use it for extract data sources that don't use OAuth.
- You can use it to refresh single-connection data sources only. It does not work for multi-connection data sources.

**Deprecated October 2022:** This utility isn't available in later releases due to the [multi-factor authentication](#) requirement in Tableau Cloud. To refresh data sources or virtual connections data that Tableau Cloud can't reach directly, use Tableau Bridge instead. For more information, see [Set Up a Bridge Refresh Schedule](#).

To initiate refresh jobs using a script, use tabcmd [refreshextracts](#) or REST API [Run Extract Refresh Task](#).

### Run the utility

1. Open the Command Prompt as an administrator and change to the Tableau Desktop bin directory. For example:

```
cd C:\Program Files\Tableau\Tableau 2022.4\bin
```

2. Use either of the following commands, adding parameters described in the tables below.

- `tableau refreshextract`
- `tableau addfiletoextract`

**Note:** When using the utility, always specify `tableau` on the command line or in scripts, never `tableau.exe`.

**Note:** To troubleshoot, check the logs in the `tableaucom.txt` file in the `\My Tableau Repository\Logs` folder.

**Note:** In a multiple-site environment, specify the site to which the command applies.

### Syntax and parameters for the `tableau refreshextract` command

Use `tableau refreshextract` to refresh an extract on Tableau Server or Tableau Cloud. Refreshing an extract updates an existing extract with any modifications that have been made to the data source since the last refresh.

To see help for this command, at the Windows command prompt, type the following command:

```
tableau help refreshextract
```

### Using parameters

- All options have a full form that you use with a double hyphen (for example, `--server`).
- Some options also have a short form that you use with a single hyphen (for example, `-s`).
- If the value for an option contains spaces, enclose it in quotation marks.
- The source being refreshed must be the original data source, not an extract (`.hyper`).

### `tableau refreshextract` command options

Short Form	Full Form	Description
	<code>--source-user-name &lt;user name&gt;</code>	A valid user name for the data source connection. Use this option with <code>--source-password</code> , or use

`--original-file` instead of the user name and password options.

**Note:** You must provide the user name and password when refreshing a published extract, even if the data source was originally published with embedded credentials.

<code>--source-password "&lt;password&gt;"</code>	The password for the data source user.
<code>--original-file &lt;path and file name&gt;</code>	Path and file name for the data source to be refreshed on the server. For example: <code>--original-file c:\folder\file.csv</code>
or	To refresh a multi-file data source, pass the path to a folder that contains the data files. For example: <code>--original-file c:\folder.</code>
<code>--original-file &lt;path and folder name&gt;</code>	If the file is on a network share, use the UNC format for the path: <code>\\server\path\filename.csv</code>
<code>--force-full-refresh</code>	If the data source is set up for incremental refreshes, use this option to force a full extract refresh. If this option is not included, an incremental refresh is performed. Not all data sources support incremental refresh.
<code>-s &lt;server http address&gt;</code>	<code>--server &lt;URL&gt;</code> The URL for the Tableau server on which the data is published.  For Tableau Cloud, specify <code>https://online.tableau.com.</code>
<code>-t &lt;site id&gt;</code>	<code>--site &lt;siteid&gt;</code> In a multiple-site environment, specifies the site to which the command applies. For Tableau Cloud, use this argument if your user name is associated with more than one site. For Tableau Server, if you do not

specify a site, the default site is assumed.

The site id is independent of the site name, and it is indicated in the URL when you view the site in a browser. For example, if the URL for the page you see after signing in to Tableau Cloud is

```
https://online.tableau.com/t/vernazza/views
```

the site id is *vernazza*.

`--datasource <datasource>` The name of the data source, as published to Tableau Server or Tableau Cloud.

`--project <projectname>` The project to which the data source belongs. If this option is not included, the default project is assumed.

If the project you want to specify is a child project nested within a project hierarchy, you must use this parameter along with the `--parent-project-path` parameter.

`--parent-project-path/to/project` If a project to which the data source is published is not at the top level of a project hierarchy, use this parameter along with the `--project` parameter to specify the path to a nested project.

Use the forward slash character (/) to delimit project levels in the hierarchy. Use the backward slash (\), to escape instances of forward or backward slash characters in project names.

For example, for a project named Sandbox, in project Social, under top-level Marketing:

```
--project Sandbox --parent-project-path Marketing/Social
```

`-u <username>` `--username <username>`

Valid Tableau Server or Tableau Cloud user.

<code>-p "&lt;password&gt;"</code>	<code>--password "&lt;password&gt;"</code>	The password for the specified Tableau Server or Tableau Cloud user.
	<code>--proxy-user-name &lt;user-name&gt;</code>	The user name for a proxy server.
	<code>--proxy-password "&lt;password&gt;"</code>	The password for a proxy server.
<code>-c "&lt;path and file name&gt;"</code>	<code>--config-file "&lt;path and file name&gt;"</code>	Path and file name information for a file containing configuration options for the command. Always enclose the path in double quotation marks. For more information, see <a href="#">Using a config file on page 902</a> below.

### Sample tableau refreshextract command

The following command refreshes an extract named CurrentYrOverYrStats that has been published to Tableau Server on-premises. This command specifies the following:

- The name of your Tableau Server.
- Server user name and password.
- Project name.
- The name of the data source to refresh, along with the data source username and password.

```
C:\Program Files\Tableau\Tableau 2022.4\bin>tableau
refreshextract --server https://our_server_name --username
OurServerSignIn --password "OurServerPwd" --project "New
Animations" --datasource "CurrentYrOverYrStats" --source-
username OurDatabaseSignIn --source-password
"OurDatabasePassword"
```

The following command refreshes an extract named CurrentYrOverYrStats that has been published to Tableau Cloud. This command specifies the following:

## Tableau Desktop and Web Authoring Help

- Tableau Cloud user and password.
- Tableau Cloud site and project names.
- The data source, which in this case is hosted by a cloud-based data source provider (for example, Salesforce.com), and the username and password to sign in to the hosted data source.

```
C:\Program Files\Tableau\Tableau 2022.4\bin>tableau
refreshextract --server https://online.tableau.com --username
email@domain.com --password "OurServerPwd" --site vernazza --
project "New Animations" --datasource "CurrentYrOverYrStats" --
source-username database_user@hosted_datasource_provider.com --
source-password "db_password"
```

To refresh an extract of file-based data source, provide the path to the original file from which you created the extract. If the file is on a network share, use the UNC format instead of a mapped drive.

```
C:\Program Files\Tableau\Tableau 2022.4\bin>tableau
refreshextract --server https://online.tableau.com --username
email@domain.com --password "OurServerPwd" --site vernazza --
project "New Animations" --datasource "CurrentYrOverYrStats" --
original-file "\\server\path\filename.csv"
```

### Syntax for `tableau addfiletoextract`

Use `tableau addfiletoextract` to append file content to an extract that has been published to Tableau Server or Tableau Cloud. This command combines the two files.

If you want simply to update an existing extract with the latest changes, use the `refreshextract` command instead. Using `addfiletoextract` to update an existing extract will duplicate data instead.

To see help for this command, at the Windows command prompt, type the following command:

```
tableau help addfiletoextract
```

All options have a full form that you use with a double hyphen (for example, `--server`). Some options also have a short form that you use with a single hyphen (for example, `-s`). If the value for an option contains spaces, enclose it in quotation marks.

## tableau addfiletoextract command options

Short Form	Full Form	Description
	<code>--file &lt;path and file name&gt;</code>	Path and file name information for the data file containing data to append. The file can be from Excel, Access, a Tableau data extract, or a delimited text file. It cannot be password protected. Use UNC format if the file is on a network share. For example, <code>\\server\path\filename.csv</code>
<code>-s &lt;server http address&gt;</code>	<code>--server &lt;URL&gt;</code>	The URL for the Tableau server on which the data is published.  For Tableau Cloud, specify <code>https://online.tableau.com.</code>
<code>-t &lt;site id&gt;</code>	<code>--site &lt;site id&gt;</code>	In a multiple-site environment, specifies the site to which the command applies. For Tableau Cloud, you must include this argument if your user name is associated with more than one site. For Tableau Server, if you do not specify a site, the default site is assumed.
	<code>--datasource &lt;datasource&gt;</code>	The name of the data source, as published to Tableau Server or Tableau Cloud.
	<code>--project &lt;projectname&gt;</code>	The project to which the data source belongs. If this option is not included, the default project is assumed.  If the project you want to specify is a child project nested within a project hierarchy, you must use this parameter along with the <code>--parent-project-path</code> parameter.
	<code>--parent-project-path &lt;path/to/project&gt;</code>	If a project to which the data source is published is not at the top level of a project hierarchy, use this parameter along with the <code>--</code>

		<p>project parameter to specify the path to a nested project.</p> <p>Use the forward slash character (/) to delimit project levels in the hierarchy. Use the backward slash (\), to escape instances of forward or backward slash characters in project names.</p> <p>For example, for a project named Sandbox, in project Social, under top-level Marketing:</p> <pre>--project Sandbox --parent-project-path Marketing/Social</pre>
-u <username>	--username <username>	Valid Tableau Server or Tableau Cloud user.
-p "<password>"	--password "<password>"	The password for the specified Tableau Server or Tableau Cloud user.
	--proxy-username <username>	The user name for a proxy server.
	--proxy-password "<password>"	The password for a proxy server.
-c "<path and filename>"	--config-file "<path and filename>"	Path and file name information for a file containing configuration options for the command. Always enclose the path in double quotation marks. For more information, see <a href="#">Using a config file</a> on the next page below.

Sample tableau addfiletoextract command

```
C:\Program Files\Tableau\Tableau 2022.4\bin>tableau
addfiletoextract --server https://our_server_name --username
OurServerSignIn --password "OurServerPwd" --project "New
Animations" --datasource "CurrentYrOverYrStats" --file
"C:\Users\user1\Documents\DataUploadFiles\AprMay.csv"
```

```
C:\Program Files\Tableau\Tableau 2022.4\bin>tableau
addfiletoextract --server https://online.tableau.com --username
email@domain.com --password "OurServerPwd" --site vernazza --
project "New Animations" --datasource "CurrentYrOverYrStats" --
file "C:\Users\user2\Documents\DataUploadFiles\AprMay.csv"
```

## Using a config file

You can use a plain text editor, such as Notepad or Text Edit, to create a config (configuration) file that you can use with `tableau refreshextract` or `tableau addfiletoextract`. A config file can be useful if you expect to update the same data source regularly over time. Instead of having to type the same options each time you run a command, you specify the config file. A config file also has the advantage of not exposing user names and passwords on the command line.

## Create the config file

For example, say you created a file called `config.txt` and saved it to your Documents folder. And in the file, you included the parameter information shown below.

For an extract published to Tableau Server:

```
server=https://our_server_name
username=OurServerSignIn
password=OurServerPwd
project=New Animations
datasource=CurrentYrOverYrStats
```

For an extract from a hosted data source, published to Tableau Cloud, where **server** is **https://online.tableau.com**:

```
server=https://online.tableau.com
site=vernazza
username=email@domain.com
password=OurPassword
project=New Animations
datasource=CurrentYrOverYrStats
source-username=database_user@hosted_datasource_provider.com
source-password=db_password
```

## Reference the Config File from the Command Line

After you create the config file, you run the `tableau refreshextract` or `tableau addfiletoextract` command, pointing to the config file as the only option you use on the command line, and enclosing the config file's path in double quotation marks. The syntax is as follows:

```
tableau refreshextract --config-file "<path>"
```

For example, to refresh the extract specified in the sample in the [Create the config file on the previous page](#) section, you would run the following command (making sure that you are working in the bin directory for your version of Tableau Desktop):

```
C:\Program Files\Tableau\Tableau 2022.4\bin>tableau  
refreshextract --config-file  
"C:\Users\user1\Documents\config.txt"
```

## Syntax Differences for Config Files

The syntax for specifying options inside a config file differs from the syntax you use on the command line in the following ways:

- Option names do not begin with dashes or hyphens.
- You use an equals sign (with no spaces) to separate option names from option values.
- Quotation marks are not necessary (or allowed) around values, even when they include spaces (as for the `project` option in the example shown earlier).

## Use Windows Task Scheduler to Refresh Extracts

You can use Windows Task Scheduler, in combination with the Tableau Data Extract Command-Line Utility, to automate regular updates to Tableau Desktop data sources from within your corporate firewall. You can configure a task to occur once per day, week, or month, or after a specific system event. For example, run the task when the computer starts.

To learn more, see the [Task Scheduler How To...](#) page in the Microsoft TechNet library.

## Tableau Hyper API

You can use the Tableau Hyper API to create `.hyper` extract files (supported in Tableau 10.5 and later). Using the Hyper API you can build applications that can insert, read, update and delete data from those files.

- For more information about the Tableau Hyper API, see the [Hyper API documentation](#).
- For more information about the `.hyper` format, see [Extract Upgrade to .hyper Format on page 884](#).

If you are using Tableau 10.5 and later, you can still use the [Upgrade from the Extract API 2.0 to the Hyper API](#) to create `.hyper` files. However, the Hyper API provides you more options for working with the extract files and offers improved performance.

The Hyper API runs on Windows, Linux, and macOS and supports multiple programming languages, including C++, Java, and Python, and .NET (C#).

## Manage Data Sources

The topics in this section describe the tasks you can perform after you have set up data sources.

### Edit Data Sources

To enhance the functionality of your workbook, you can modify the data source it relies on. By editing your data source, you can accomplish various tasks, such as adding tables through a join operation. For a detailed understanding of common editing tasks, you can refer to the following resources:

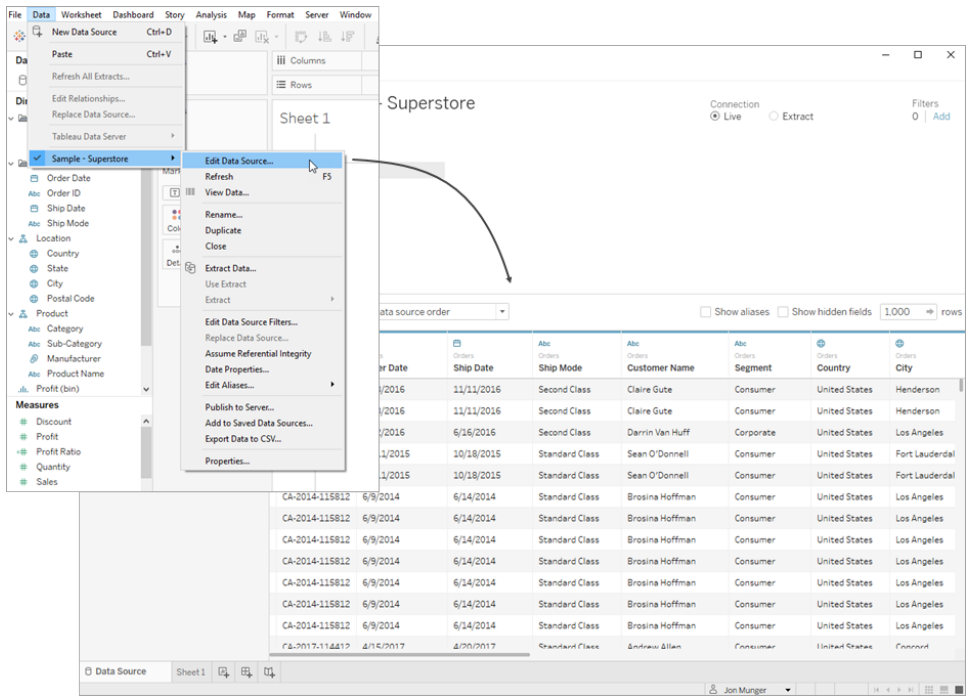

- Adding tables to your data with a Join: Learn how to combine multiple tables in your data source to gain comprehensive insights and make more informed analyses. To explore this topic further, click on the following link: [Join Your Data on page 738](#)
- Connecting to a Custom SQL Query (Tableau Desktop): Discover how to connect Tableau Desktop to a custom SQL query, enabling you to leverage the power of SQL to extract and manipulate data according to your specific requirements. For more information on this topic, please visit: [Connect to a Custom SQL Query on page 811](#)
- Using a Stored Procedure (Tableau Desktop): Gain insights into utilizing stored procedures in Tableau Desktop, empowering you to execute predefined sets of actions or calculations on your data. To delve deeper into this subject, access the following link: [Use a Stored Procedure on page 826 \(Tableau Desktop\)](#)

### How to edit the data source

1. On the **Data** menu, select a data source.
2. Select **Edit Data Source**.

3. On the data source page, make the changes to the data source. The data table updates with the data from the new data source.

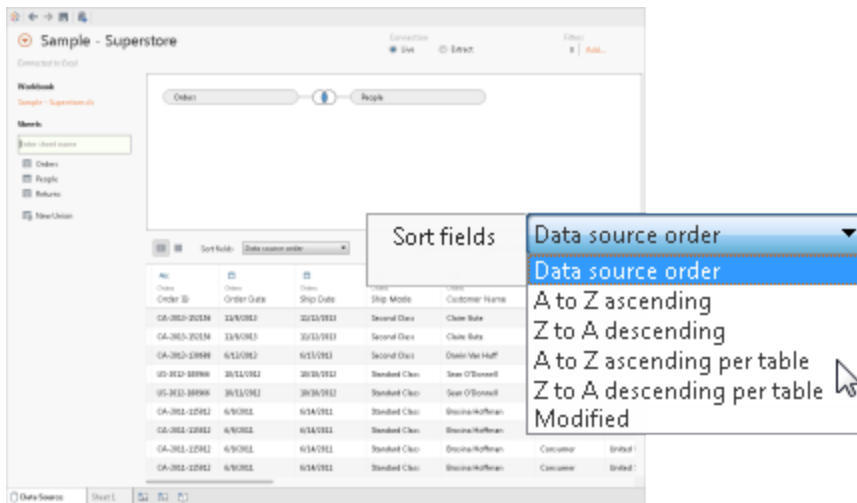

### Navigate the Data Grid

Within the Data Source page, you are provided with options to analyze and visualize your data. One of these options is sorting, which enables you to arrange your data in a structured manner. By sorting columns and rows, you can easily organize and make sense of the information at hand.

### Sort columns

Sorting columns is a simple and efficient way to bring order to your data. Whether you prefer to sort them based on table or data source, the process is straightforward. In the grid, you can sort columns by accessing the Sort fields dropdown list and selecting the desired sorting option.

**Note:** A modified sort state can occur when some tasks cause new columns to be added to the grid.

## Sort rows

To arrange rows in a specific order, simply utilize the sort button. Give it a single click to sort rows in ascending order. For descending order, click the sort button once more. To remove the selection, click the sort button again.

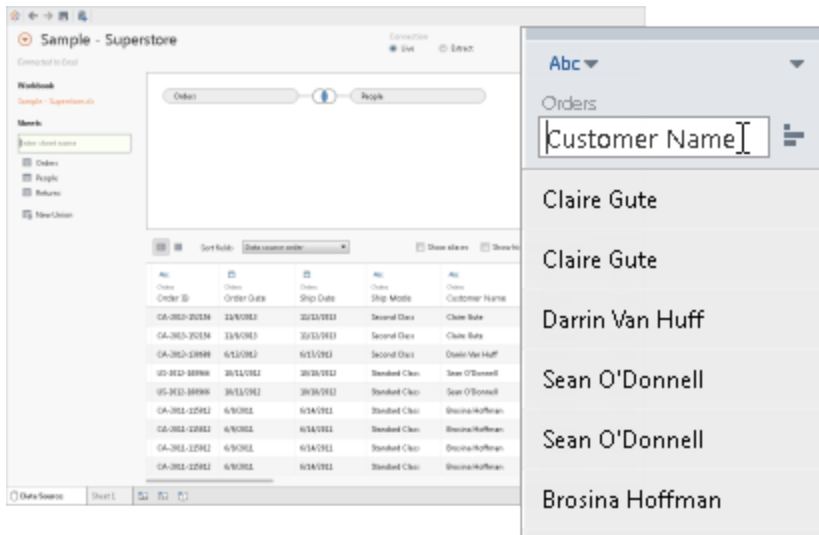

## Change column names and reset field names

In Tableau, it is crucial to have clear and meaningful column names for effective data analysis and visualization.

### Rename a column

To rename a column in Tableau, simply follow these steps:

1. Locate the column whose name you wish to change.
2. Double-click on the current name of the column.
3. Enter the desired new name for the field.
4. Press Enter or click outside the field to save the changes.

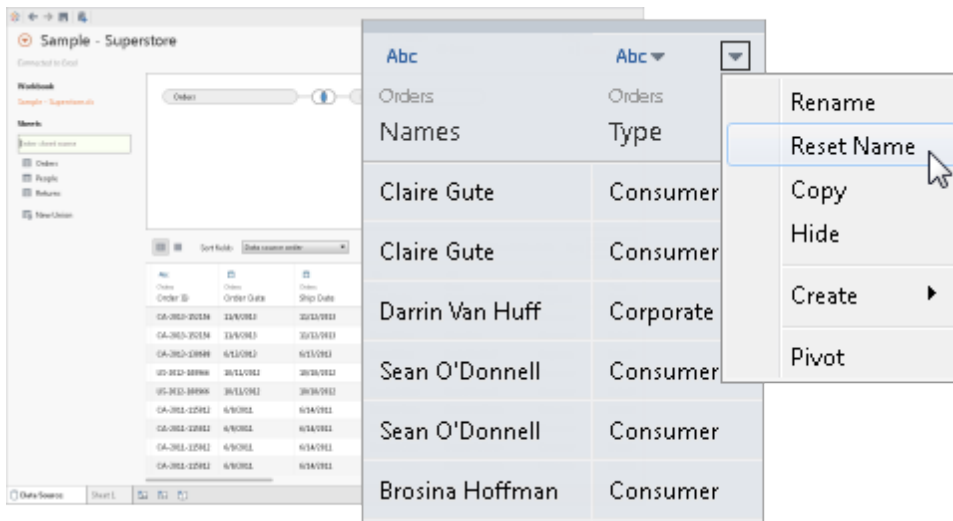

### Reset names

If you have made changes to a field name and want to revert back to the original name, Tableau provides a reset option. Complete the following steps to reset the name.

1. Click on the column dropdown menu.
2. Select the **Reset Name**.

The name will be reset to its original name as specified in the underlying data.

## Revert Tableau's automatic name changes

The Revert command will reset any field names that have been automatically modified by Tableau's naming improvements. For more information, see [Understand Field Type Detection and Naming Improvements](#) on page 861.

## Create calculations

Calculations allow you to perform complex data manipulations and get new insights from your existing dataset. Tableau offers three primary types of calculations:

- Basic expressions
- Level of Detail (LOD) expressions
- Table calculations

For help on choosing which calculation to use, see [Choosing the Right Calculation Type](#).

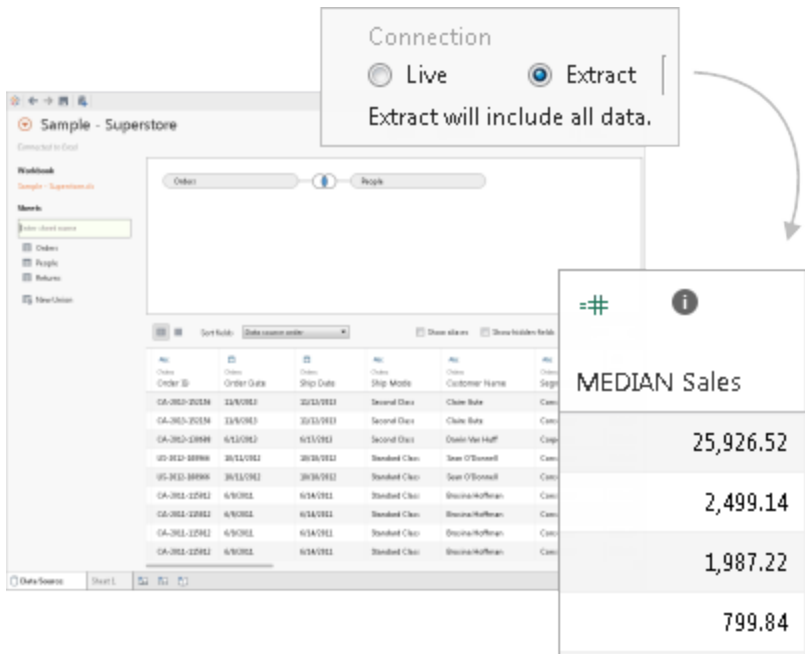

You can create calculations, groups, or bins based on existing fields in the data source. To start, click the column dropdown arrow and select one of the options.

**Note:** If you create an aggregate calculation, the values displayed in the grid aren't meaningful until the calculation is used in the context of the view's level of detail.

### View extract data

When using the Web Data Connector, you can view the extracted data in the grid. This includes extract-only calculations such as MEDIAN. It is important to note that when in Extract mode, the order of rows in the data source may differ from the order of rows in Live mode.

### Copy values

To copy values in the grid, follow these steps.

1. Select the desired values.
2. Right-click on the selected values.
3. Choose **Copy** from the menu.

## Examine your metadata

Utilize the metadata grid within Tableau to efficiently analyze and modify the organization of your data source. The metadata grid offers a way to assess the columns in your data and their respective data types. You can carry out routine management tasks such as column renaming, hiding, altering data types, and modifying the geographical role of a column.

**Note:** When dealing with multi-dimensional data sources, the specific metadata management tasks may differ.

### Default metadata view

After you have successfully configured your data source, the information will be displayed in the grid. In the case of connecting to a cube (multidimensional) data source, the data will be automatically presented. The default view can be different for alternative data source types like Salesforce or Tableau data extracts.

### Review metadata

The metadata grid displays the columns from your data source as rows, providing essential information about each column. For every row, you can find details such as the data type of the column, the field name in the Tableau data source, the name of the physical table in the underlying data source, and the remote field name.

### Manage metadata

Depending on the type of data you're connected to, you can perform routine management tasks like hiding multiple columns at once or quickly renaming columns.

## Change the location of your data source in a workbook

As you work with data in your workbook, there may come a time when you need to change the location of your data source. Whether the name or location of the data source has changed, or you want to apply your analysis to a similar data source, this section will walk you through the process of redirecting your workbook to the correct location without losing any of your work.

## Change the location of a data source

1. Right-click (control-click on a Mac) the data source you wish to edit in the data pane.
2. From the menu, select **Edit Connection**.
3. In the Edit Connection dialog box, you have two options:
  - Navigate to the new location of the data source by browsing your computer's file system.
  - Select a new data source altogether by clicking on the **Browse** button and choosing a different file.
4. After you have selected the new location or data source, select **OK** to save the changes.

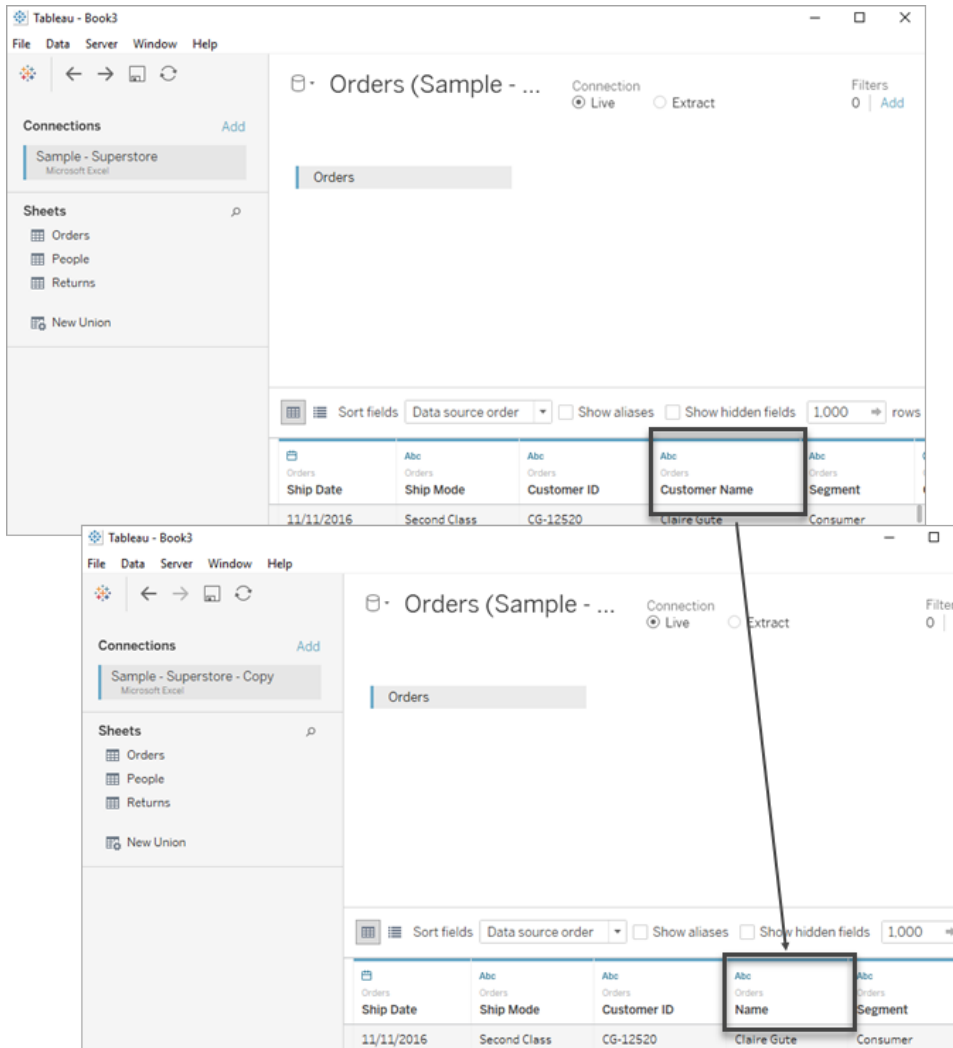

## Replace field references

When you establish a successful connection with a new data source, all worksheets in the workbook that were previously using the original data source will now be linked to the new data source. However, if the new data source doesn't have the same field names as the original workbook, the fields will be considered invalid and marked with an exclamation point. To resolve this issue, you can easily replace the references of these fields.

For instance, let's say you have a workbook connected to a data source that includes a field called "Customer Name." Later, you modify the data source to connect to a new one that contains all the same data, but the field name has been changed to "Name." In this case, the "Customer Name" field will still appear in the Data pane, but it will be marked as invalid.

To make the field valid again, you can replace its references. This means you can map the invalid field to a valid field in the new data source. For example, you can map "Customer Name" to "Name."

## Replace field references

1. Right-click (or control-click on a Mac) the invalid field in the data pane.
2. Select **Replace References**.
3. In the Replace References dialog box, choose a field from the new data source that corresponds to the invalid field.

## Rename the data source

When you establish a connection to a data source in Tableau Desktop, you will be prompted to give it a name. This name is used to identify the data source within Tableau and can be helpful when you have multiple data sources connected to a single workbook. It allows you to keep track of the specific details of each connection.

### Rename a data source

1. Go to the Data menu.
2. Select **Rename**.

By naming your connections appropriately, you can easily distinguish between different data sources and manage them efficiently. You can also review the properties of a connection by selecting the data source on the Data menu and choosing **Properties**.

## Duplicate the data source (Tableau Desktop)

Sometimes you'll want to make changes to a data source such as add more tables, hide and show fields, or set field defaults. When you make these changes it affects all sheets that use the data source. You can duplicate the data source so you can make the changes without affecting the existing sheets. To duplicate a data source in Tableau Desktop, follow these steps:

1. Open your workbook in Tableau Desktop.
2. Go to the Data menu at the top of the screen.
3. Select the data source that you want to duplicate.
4. From the dropdown menu, choose **Duplicate**.

**Note:** After you duplicate a data source, the name of the duplicate will have "copy" appended to it. This ensures that you can differentiate between the original and the duplicate source.

## Refresh Data Sources

If you are connected to a data source that has been modified, you can immediately update Tableau Desktop with the changes by selecting a data source on the **Data** menu and then selecting **Refresh**.

Not every connection will behave in the same way. There are three primary connection types: Live Connection, Extract, and Published Data Source. The type of connection is displayed by the icon next to your data source in the Data Pane.

### Live Connection

A live connection sends queries to the database and updates the view depending on the results. However, the specific fields queried are defined when the connection is initially created. Refreshing the data source will update any new or changed fields. For more information, see [Connect to Your Data on page 233](#).

## Extract

Refreshing an extract will query the data source the extract was created from and rebuild the extract. This process might take some time, depending upon the size of the extract. For more information, see [Extract Your Data on page 867](#).

## Published Data Source

When connected to a Published Data Source, the data source can be either a live connection or an extract. Selecting the **Data Source** tab will display whether the Published Data Source is a live connection or an extract. If the data source is an Extract, all refreshes of the extract are managed by Tableau Server and can only be refreshed by the server.

For more information, see [Best Practices for Published Data Sources on page 3070](#).

## Changes to underlying data

If a field that is used in a Tableau worksheet is removed from the underlying data of the data source and then the data source is refreshed, a warning message displays indicating that the field will be removed from the view and the worksheet will not display correctly because of the missing field.

If the underlying data changes—for example, if new fields or rows are added, data values or field names are changed, or data is deleted, Tableau will reflect those changes the next time you connect to the data source. However, because Tableau Desktop queries the data and does not import the data, you can immediately update Tableau to reflect the data modifications without disconnecting, provided the changes have been saved in the underlying data first.

**Note about web authoring (Tableau Cloud and Tableau Server):** If you connect to a published **flat file** (Excel or text) directly in Tableau Cloud or Tableau Server, that data will not be refreshed even if it's modified. If your data is in an **on-premises server** and is

published to the web through Tableau Desktop, it will be rendered as an extract and won't be refreshed. If you need to keep data published through Tableau Desktop fresh on the web, you can use Tableau Bridge. To learn more about these requirements, see [Keep Data Fresh](#) and [Use Bridge to Keep Data Fresh on page 3091](#)

## Replace Data Sources

**Note:** Replacing a data source isn't supported by Tableau Cloud or Tableau Server.

Users can update a workbook or sheet with a different data source. Replacing a data source doesn't merge or edit the data sources. It redirects fields used in the worksheet to map to corresponding fields in the new data source. Any fields that the user creates in the *original* data source are copied over to the new data source. Fields that aren't included in the original data source must be manually copied and pasted to the *new* data source before replacing the old one. When you replace a data source, the folder structures aren't copied over.

The two data sources don't have to be identical, any differences between the data sources will affect the sheets in the workbook and the fields in the view. Any fields, groups, sets, and calculated fields that don't exist in the new data source (or have a different name) are removed from the Data pane. For more information about how to replace field references to fix invalid fields, see [Edit Data Sources on page 904](#).

### Replace a Data Source

Complete the following steps to replace a data source.

1. Open a workbook that connects to the *original* data source.
2. Select **Data > New Data Source** and then connect to the *new* data source.
3. On the Data Source page, drag a table to the canvas to set up the data source (if this isn't automatically done for you).
4. Go to the sheet tab and select **Data > Replace Data Source**.

**Note:** You must have at least one field in the view to make the **Replace Data Source** option available.

5. In the Replace Data Source dialog box, select the **Current** data source and the **Replacement** data source.
6. (optional) Under the **Current** field, select the checkbox to replace the current worksheet only.
7. When finished, select **OK**.

All worksheets, dashboards, and stories that used the *original* data source are updated to use the *new* data source. You can click **Undo** on the toolbar to revert the change and return to the original data source.

**Note:** You can only replace one data source with another data source when both data sources are relational data sources, or when both data sources are cube (multidimensional) data sources. In Tableau, cube data sources are supported for Windows only.

### Replace the Data Source for a Single Sheet

All sheets that use the data source will be updated when a data source is replaced. If you wish to replace the data source for a single sheet, you'll need to use the following workaround.

1. Copy the sheet to a new workbook.
2. Delete the sheet from the old workbook.
3. In the new workbook, replace the data source.
4. Copy the sheet back into the original workbook. The data source and all relevant items for the sheet, such as parameters and sets will be copied as well. For more information, see [Copy and paste sheets between workbooks on page 3038](#).

## Published Data Sources

When users publish a data source from a workbook, the current workbook in Tableau Desktop will automatically connect to the published data source and close the local data source. For more information on publishing a data source see [Publish a Data Source on page 3076](#).

## Save Data Sources

If you've created a data connection that you might want to use with other workbooks or share with colleagues, you can export (save) the data source to a file. You might want to do this also if you've added joined tables, default properties, or custom fields—such as groups, sets, calculated fields, and binned fields—to the Data pane.

**Note:** This topic describes how to save a data source that you reuse locally, if you do not publish to Tableau Server or Tableau Cloud. For information about sharing data sources on a server, see [Publish Data Sources and Workbooks](#).

### Options for saving a local data source

You can save a data source to either of the following formats:

**Data Source (.tds)** - contains only the information you need to connect to the data source, including the following:

- Data source type
- Connection information specified on the data source page; for example, database server address, port, location of local files, tables
- Groups, sets, calculated fields, bins
- Default field properties; for example, number formats, aggregation, and sort order

Use this format if everyone who will use the data source has access to the underlying file or database defined in the connection information. For example, the underlying data is a CSV file on your computer, and you are the only person who will use it; or the data is hosted on a cloud platform, and your colleagues all have the same access you do.

**Packaged Data Source (.tdsx)** - contains all information in the data source (.tds) file, as well as a copy of any local file-based data or extracts.

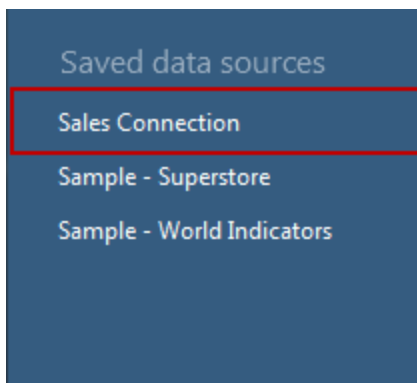

A packaged data source is a single zipped file. Use this format if you want to share your data source with people who do not have access to the underlying data that is defined in the connection information.

## Save a data source

1. In Tableau Desktop, open the workbook that has the connection to the data you want to save as a file.
2. At the top of the **Data** pane, right-click (Control-click on Mac) the name of the data source, and then select **Add to Saved Data Sources**.
3. Enter a file name, select the file type (.tds or .tdsx), and then click **Save**.

## Connect to your data source

By default, Tableau saves .tds and .tdsx files to the **Datasources** folder under your Tableau repository. When you use the default location, you can connect to the data source on the **Connect** pane.

If you specified a different location, you can connect to the data source by selecting **File > Open** and navigating to it.

## Updating a data source after the underlying data location changes

If you move a local data file that a .tds file contains a reference to, when you try to open the data source in Tableau, you will be prompted to locate or replace the original data source. If you

replace the original data source, the replacement data must be of the same type (for example, Excel or MySQL). To avoid saving a specific file path, save the data source as a .tdsx file.

## Upgrade Data Sources

If you have workbooks that were created before Tableau Desktop 8.2 that use Microsoft Excel or text file data sources, or you are using the Excel or text file legacy connection option, you have the option to upgrade the data sources in your workbook. By upgrading your Excel and text file data sources you can take advantage of 1.) better data interpretation, and 2.) compatibility on the Mac. If you are considering upgrading an existing workbook to use the new connection, review the tables below to compare how your data is processed and displayed between the legacy and default connection types.

If there are certain capabilities of the Jet driver that your data relies on, you might need to use the legacy connection to get the expected results. Workbooks that were created before Tableau Desktop 8.2 that use Excel and text file data sources automatically use the legacy connection. To create a new workbook that uses the legacy connection, in Tableau Desktop, navigate to your Excel or text file data, click the drop-down arrow on **Open**, and then select **Open with Legacy Connection**.

**NOTE:** Beginning with Tableau 2020.2, legacy Excel and Text connections are no longer supported. See the [Legacy Connection Alternatives](#) document in Tableau Community for alternatives to using the legacy connection.

## File formats and attributes

The following tables show some examples of the types of Excel and text files, and tables that you can connect to in Tableau when using the legacy and default connections types.

### Excel

Your Data	Legacy Connection	Default Connection
.xlsb file format	Allows connections to Excel data in .xlsb file format.	Does not allow connections to Excel data in .xlsb format. Connections to Excel data in .xls or .xlsx file formats can be used instead.
Excel	Allows connections to built-in	Built-in named ranges are hidden.

<b>Your Data</b>	<b>Legacy Connection</b>	<b>Default Connection</b>
built-in named ranges	named ranges.	
Hidden sheet	Allows connections to a table in a hidden sheet.	Hides a table in a hidden sheet.
Very hidden sheet	Allows connections to a table in a very hidden sheet.	Hides a table in a very hidden sheet.
Table that contain charts	Allows connections to tables that contain Excel charts. However, the table does not contain any values.	Hides tables that contain Excel charts.
Empty table	Allows connections to an empty table.	Hides an empty table.
Table headers	Treats the first row of a table as a header.	Automatically detects whether the first row of a table is a header.
Table width	Limits the table width to 255 columns.	No table width constraints.
Empty columns and rows	Empty columns and rows are visible.	Empty columns and rows are hidden because they do not contain any values.

## Text

<b>Your Data</b>	<b>Legacy Connection</b>	<b>Default Connection</b>
File name length	Does not allow connections to a file whose file name is more than 64 characters long.	No length constraints for file names.
Multiple period in	Does not allow connections to a file whose file name contains mul-	No period constraints for file names.

Your Data	Legacy Connection	Default Connection
the file name	multiple periods.	
Number of columns in the file	Uses the number of fields present in the first row to determine the number of columns in the file.	Scans the entire file and uses the most common number of fields in a row to determine the number of columns in the file.
Headers rows	Does not automatically detect whether the first row in the file is a header.  <b>Note:</b> You can manually specify that the first row in the file is a header.	Automatically detects whether the first row in the file is a header.  <b>Note:</b> You can manually override the detection.
Empty columns	Empty columns are visible.	Empty columns are hidden because they do not contain any values.

## Characters and formatting

The following tables show some examples of how your Excel and text file data might be displayed in Tableau when using the legacy and default connection types.

### Excel

Your Data	Legacy Connection	Default Connection
Number of characters in the field name	Field names are truncated to 64 characters.	No constraint on the number of characters in a field name.
Special characters in field names	Special characters are not allowed in field names. For example, special characters like quotation marks and periods are converted to number signs. Brackets are converted to parentheses.	Special characters are allowed in field names.
Leading and	Leading and trailing spaces in field names are	Leading and trailing

<b>Your Data</b>	<b>Legacy Connection</b>	<b>Default Connection</b>
trailing spaces in field names	allowed.	spaces in field names are automatically removed from column names.
Duplicate field names	For duplicate field names, an index number is appended onto the field name.  For example, Test Scores1.	For duplicate field names, a space and an index number are appended to the field name.  For example, Test Scores 1.
Excel cell formatting	Supports cell formatting configured using the Format Cells option in Excel.	Does not support cell formatting configured using the Format Cells option in Excel.
Precision with currency values	Fields that contain currency values are represented with a maximum precision of four digits	Full precision of currency values is represented.

## Text

<b>Your Data</b>	<b>Legacy Connection</b>	<b>Default Connection</b>
Special characters in file names	Special characters are not allowed in file names.  For example, special characters like periods are converted to number signs.	Special characters are allowed.
Characters in header field names	Automatically removes leading spaces from header field names.	Automatically removes leading and trailing spaces from header field names.
Field sep-	Recognizes only commas as field	Automatically detects the field

Your Data	Legacy Connection	Default Connection
Separators	separators. <b>Note:</b> You can manually override the detection.	separator. <b>Note:</b> You can manually override the detection.
Text enclosed with quotation marks	Quotation marks used to enclose text values remain visible.	Quotation marks used to enclose text values are automatically hidden.
ANSI and OEM code pages	ANSI and OEM code pages are supported.	ANSI and OEM code pages are automatically converted to be cross-platform compatible.
BOM code pages	Inconsistently supports BOM code pages.	Supports BOM code pages.

### Data type detection

The following tables show some examples of how data type is detected and how certain values are displayed in Tableau when using the legacy and default connection types.

#### Excel

Data Type Detection	Legacy Connection	Default Connection
Columns	Data type of a column is determined by the first 8 rows. <b>Note:</b> After the data type of a column in the table has been determined, it cannot be changed.	Data type of a column is determined by the 95% of the first 10000 rows. <b>Note:</b> You can manually override the detection.
Date values without time	Date values are assigned a datetime data type.	Date values without time are assigned a date data type. Date values with time are assigned a datetime data type.

<b>Data Type Detection</b>	<b>Legacy Connection</b>	<b>Default Connection</b>
Number values	All number values are represented as real numbers.	Number values without decimal points are represented as integers.
Null values	If a column contains a null cell, the data type for the column is automatically designated as a string data type.	Null cells do not affect data type detection.
Reference errors or empty cells	If a column contains cells with reference errors or empty cells, the entire column is interpreted as a string data type.	Reference errors or cells with no values do not affect the data type detection.
Overriding data type detection	After the data type of a column in the table has been determined, it cannot be changed.	Data type of a column can be changed after the automatic detection.
Time value precision	The smallest measurement of time values is whole seconds.	The smallest measurement of time values is fractional seconds.
DecimalSymbol and CurrencyDecimalSymbol schema.ini values	Both DecimalSymbol and CurrencyDecimalSymbol schema.ini values are recognized.	DecimalSymbol and CurrencyDecimalSymbol schema.ini values are recognized. However if both values are used, DecimalSymbol takes precedence.
Cells formatted as text	The data type of a column is detected as a string data type when cells are formatted as text using the Format Cells option in Excel.	Does not support cell formatting configured using the Format Cells option in Excel.

Text

<b>Data Type Detection</b>	<b>Legacy Connection</b>	<b>Default Connection (8.2 and later)</b>
Columns	Data type of a column is determined by the first 25 rows.	Data type of a column is determined by the first 1024 rows.
Boolean (True/False) values	Boolean values are assigned the string data type.	Boolean values are assigned the boolean data type.
Values that become null	Spaces in a cell, whether enclosed in quotation marks or not, are treated as null values. Columns with null values are detected as the string data type.	Two field separators in a row are treated as a null value. Null values are ignored during data type detection.

Data source connection properties

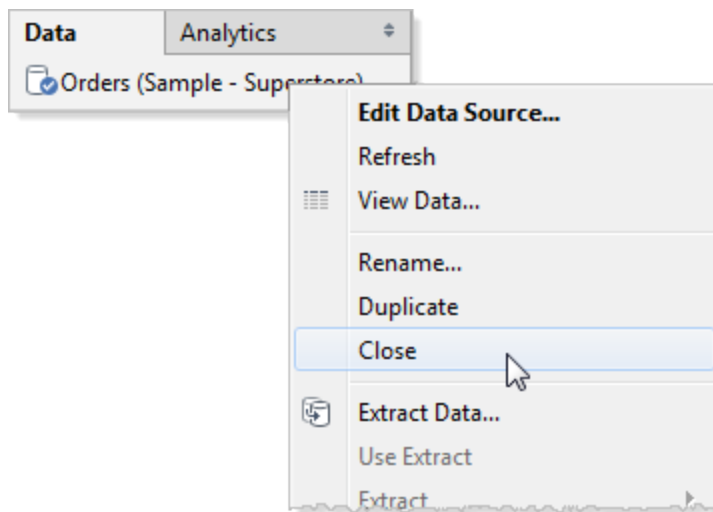

The following table shows examples of the differences in data source connection properties in Tableau when using the legacy and default connection types.

<b>Property</b>	<b>Legacy Connection</b>	<b>Default Connection</b>
Custom SQL	Custom SQL is allowed.	Does not allow the use of Custom SQL.
Join type	Allows left, right, and inner join types.	Allows left, right, inner, and full outer join types.
Join operators	Allows equal to (=), greater than (>), greater than or equal to (>=), less than (<), less than or equal to (<=), and not equal to (<>) join operators.	Allows equal to (=) join operators.

## Close Data Sources

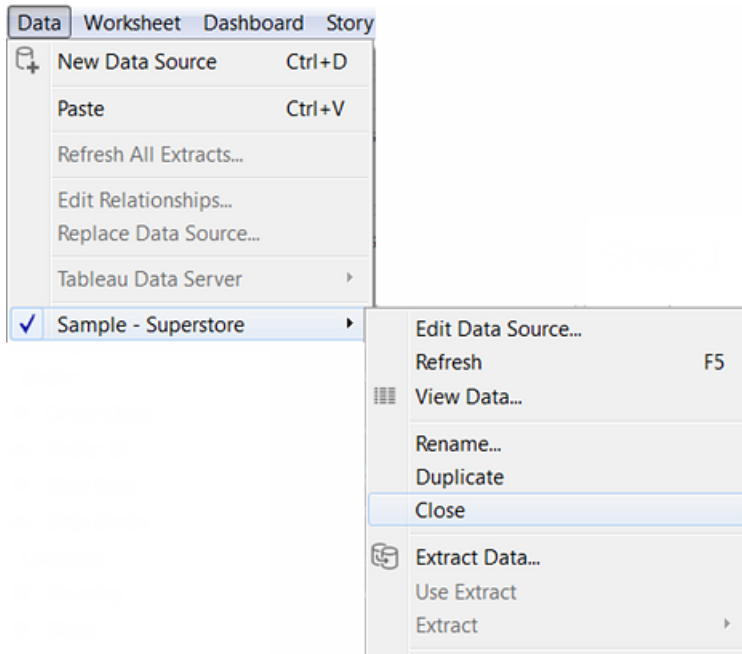

You can close a data source at any time. Doing so does not modify the data source. Instead, it disconnects Tableau from the data so that you can no longer query it. Additionally, the data source is cleared from the Data pane and all open worksheets associated with the data source are cleared. If you accidentally close a data source, use the Undo button to reopen it. Close a data source by doing one of the following:

- Right-click (control-click on a Mac) the data source at the top of the Data pane and select **Close**.

- Select a data source on the **Data** menu and then select **Close**.

**Note:** When authoring on the web, the data source cannot be used by any worksheets for you to be able to close the data source.

## Cube Data Sources

Cube data sources (also known as multidimensional or OLAP data sources) have certain characteristics that differentiate them from relational data sources when you work with them in Tableau. This topic describes these differences, and also identifies some Tableau features that are not available when you connect to a cube data source. In many cases there are alternative approaches that you can use to compensate for the unavailability of these features with cube data sources, but you may also have the option to connect directly to a relational database that was used as the source for a cube data source. Talk to your database administrator to find out if this is an option.

**Note:** Cube data sources are supported only for Tableau Desktop on Windows—not for the Mac.

## What are cube data sources?

A cube data source is a data source in which hierarchies and aggregations have been created by the cube's designer in advance.

Cubes are very powerful and can return information very quickly, often much more quickly than a relational data source. However, the reason for a cube's speed is that all its aggregations and hierarchies are pre-built. These definitions remain static until the cube is rebuilt. Thus, cube data sources are not as flexible as relational data sources if the types of questions you need to ask were not anticipated by the original designer, or if they change after the cube was built.

The cube data sources supported in Tableau are

- Oracle Essbase
- Teradata OLAP
- Microsoft Analysis Services (MSAS)
- SAP NetWeaver Business Warehouse
- Microsoft PowerPivot

## Create calculated members using MDX formulas

When working with a cube data source, you can create calculated members using MDX formulas instead of creating Tableau formulas. MDX, which stands for Multidimensional Expressions, is a query language for OLAP databases. With MDX calculated members, you can create more complex calculations and reference both measures and dimensions. A calculated member can be either a calculated measure, which is a new field in the data source just like a calculated field, or a calculated dimension member, which is a new member within an existing hierarchy. For details, see [How to Create a Calculated Member](#) on page 938.

## Tableau features that are affected when you use a cube data source

When you use a cube data source, not all Tableau features work the same as with relational data sources, or are even available. The following table details the differences.

Feature	Status for Cube Data Sources
Actions	With Microsoft Analysis Services connections, drill-down actions defined in the cube are not available in Tableau.

	<p>Cube data sources do not accept actions from relational or other cube data sources.</p> <p>For example, suppose you have a workbook with a view that uses a MySQL data source, a second view that uses cube data source A, and a third view that uses cube data source B. Actions in the view using the MySQL data source won't affect the views using the cube data sources, and actions in the view for one cube data source won't affect the other. But actions in the views using the cube data sources will affect the view using the MySQL data source.</p>
Advanced analytics features	<p>Level of detail expressions, trend lines, forecasting, and clustering are not supported for cube data sources.</p>
Aggregate calculation functions	<p>Cube data sources are pre-aggregated and thus do not support aggregation functions, such as <code>SUM()</code>, <code>AVG()</code>, and <code>CNT()</code>.</p> <p>It may be possible to use Table Calculations to perform aggregation operations on the cell-level results from the cube in Tableau.</p>
Aliases	<p>Aliases for cube databases are created by the cube's designer and can be activated in Tableau by selecting the data source from the Data menu and then choosing <b>Alias File</b>. Talk to your database administrator to find out whether your database has aliases available. Aliases are not supported by Microsoft Analysis Services databases.</p> <p>By default, the alias for every member of every dimension is initially defined to be the original member name.</p>
Bins	<p>For cube data sources, the <b>Create Bin</b> command is not available for measures.</p> <p>You can, however, write a calculation that takes cube cell results and bins them. For example:</p> <pre>str((INT([Internet Sales Amount]/1000)) * 1000)</pre>
Cube KPI data type	<p>When connected to Microsoft Analysis Services, any KPI calculations defined in the cube are not available.</p> <p>However, you can write your own KPI calculations in Tableau. You can also use Tableau parameters to create highly flexible what-if KPI</p>

	analysis. For more information, see <a href="#">Visualize Key Progress Indicators</a> on page 1521.
Cube lag functions	<p>For cube data sources, you cannot use cube lag functions in the Tableau calculation editor. You can use Tableau Table Calculations to calculate certain percentages and totals instead. For more information, see <a href="#">Transform Values with Table Calculations</a> on page 2484.</p> <p>Alternatively, you can use an MDX Lag function directly in Tableau using a calculated member. For example:</p> <pre>Avg ( { [Date].[Calendar].CurrentMember.Lag(4) : [Date].[Calendar].CurrentMember } , [Measures]. [Internet Sales Amount] )</pre>
Custom multidimensional expression (MDX) statements	When connected to a cube, you cannot make a connection to a custom MDX statement. All sub-cube definitions need to be created on the server by implementing necessary cube perspectives, partitions, dimensions, or cell security.
Data blending	Cube data sources can only be used as the primary data source for blending data in Tableau. They cannot be used as secondary data sources. For details, see <a href="#">Troubleshoot Data Blending</a> on page 784.
Date dimensions	For cube data sources, date dimensions are typically organized into hierarchies that contain levels such as year, quarter, and month. In addition, some multidimensional data sources have time intelligence enabled, which makes it possible to look at data levels different ways, such as Months by Year, Months by Quarter, Weekends, etc. These levels are represented as attributes of the hierarchy. For details, see <a href="#">Dates and Times</a> on page 1097.
Data source filters	Data source filters are not available for cube data sources. All field values must be defined in the cube prior to analysis in Tableau.
Extracts	<p>You cannot create extracts from most cube data sources. Cube and relational data sources have incompatible data structures, which makes extracting data from a cube and storing it in a relational data source, such as the data engine, impossible in most cases.</p> <p>Starting in 10.4, you can create SAP BW extracts without the need for a</p>

	<p>special product key from Tableau. For information about support for and limitations of SAP BW extracts, see <a href="#">SAP NetWeaver Business Warehouse</a> on page 467.</p>
<p>Filters</p>	<p>When you display a filter for a cube dimension, all levels of the hierarchy for that dimension are included in the filter. For example:</p> <div data-bbox="505 491 1070 1318" style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;"> <p>Product</p> <p>0 1 2 3 4</p> <ul style="list-style-type: none"> <li><input checked="" type="checkbox"/> FURNITURE                     <ul style="list-style-type: none"> <li><input type="checkbox"/> BOOKCASES</li> <li><input type="checkbox"/> CHAIRS &amp; CHAIRMATS</li> <li><input type="checkbox"/> OFFICE FURNISHINGS</li> <li><input type="checkbox"/> TABLES</li> </ul> </li> <li><input checked="" type="checkbox"/> OFFICE SUPPLIES                     <ul style="list-style-type: none"> <li><input type="checkbox"/> APPLIANCES</li> <li><input type="checkbox"/> BINDERS AND BINDER ACCESSORIES</li> <li><input type="checkbox"/> ENVELOPES</li> <li><input type="checkbox"/> LABELS</li> <li><input type="checkbox"/> PAPER</li> <li><input type="checkbox"/> PENS &amp; ART SUPPLIES</li> <li><input type="checkbox"/> RUBBER BANDS</li> <li><input type="checkbox"/> SCISSORS, RULERS AND TRIMMERS</li> <li><input type="checkbox"/> STORAGE &amp; ORGANIZATION</li> </ul> </li> <li><input checked="" type="checkbox"/> TECHNOLOGY                     <ul style="list-style-type: none"> <li><input type="checkbox"/> COMPUTER PERIPHERALS</li> <li><input type="checkbox"/> COPIERS AND FAX</li> <li><input type="checkbox"/> OFFICE MACHINES</li> <li><input type="checkbox"/> TELEPHONES AND COMMUNICATION</li> </ul> </li> </ul> </div> <p>You can use cube attributes as filters, to show just a single level instead of a hierarchy. In the Data pane, attributes appear in the Dimensions section and are indicated by this icon: </p> <p>Slicing filters behave differently with a cube data source than with a relational data source. See <a href="#">Create Slicing Filters</a> on page 935 for details.</p> <p>Some dimension filter card options are not available. For example, single value (drop-down), multiple values (custom list), etc. Instead,</p>

	dimensional filters shown in the view retain their hierarchical look and feel, and cannot be changed into specific list types. You can create a Tableau set containing certain values from the hierarchy and then use the set as a filter in the view with the expected filter options (right-click the set in the Data pane, and then click <b>Show Filter</b> ).
Groups	<p>You cannot create groups when working with a cube data source. Any concept of groupings should be pre-defined in the cube as dimensional attributes or cube sets.</p> <p>However, you can write multidimensional expressions (MDX) directly in Tableau using a calculated member to create a group. For example:</p> <pre>[Customer].[Customer Geography].[France] + [Customer].[Customer Geography].[Germany]</pre>
Hierarchies	For cube data sources, hierarchies must be defined in the cube prior to analysis.
Parameters	For cube data sources, you cannot use parameter values to filter dimensions in an MDX calculation.
Publishing	<p>Workbooks using cube data source can be published to Tableau Server, but do not support pass-through connections. This means that you cannot make a connection from Tableau Server using such a data source. It also means you cannot create a workbook using the data source in Tableau Server. For details, see <a href="#">Cube Data Sources</a> in the Tableau Server help.</p> <p>Publishing a cube data source to Tableau Server gives you the ability to store the data source on the server. However, to use the data source, you must download the data source to Tableau Desktop and use it locally.</p> <p>Workbooks that use cube data source cannot be published to Tableau Cloud.</p>
Sets	Cube data sources support hierarchical sets, which filter data to the selected members and all of their descendants. For details, see <a href="#">Examples of sets on page 1052</a> .

<p>Tableau string functions</p>	<p>With cube data sources, dimensions are not available in the calculation editor.</p> <p>However, you can write MDX inside Tableau using a calculated member to manipulate dimensional values. For example:</p> <pre>LEFT([Product].[Product Categories].DataMember.MemberValue, LEN([Product].[Product Categories].DataMember.MemberValue)-5)</pre>
<p>Type conversions</p>	<p>For cube data sources, some type conversion functions are not available in the calculation editor. As a rule, data type conversions should be defined in the cube prior to analysis.</p> <p>In particular, changing the data type of a cube dimension to a date in Tableau sometimes gives incorrect information. This feature is supported for some cube dimensions, depending on how the dates are formatted in the cube.</p> <p>You can write Multidimensional Expressions (MDX) directly in Tableau using a calculated member to change the data type of a cube dimension to a date. For example:</p> <pre>CDATE([Date].[Date].CurrentMember.MemberValue)</pre>

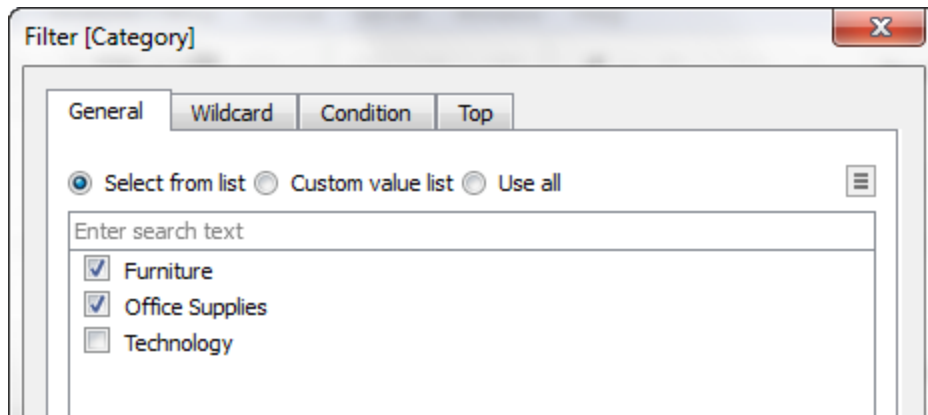

## Create Slicing Filters

Slicing filters, also known as slicers or calculation filters, are dimension filters that behave differently for multidimensional data sources than they do for relational data sources.

In Tableau, multidimensional data sources are supported only in Windows.

A slicing filter exists when:

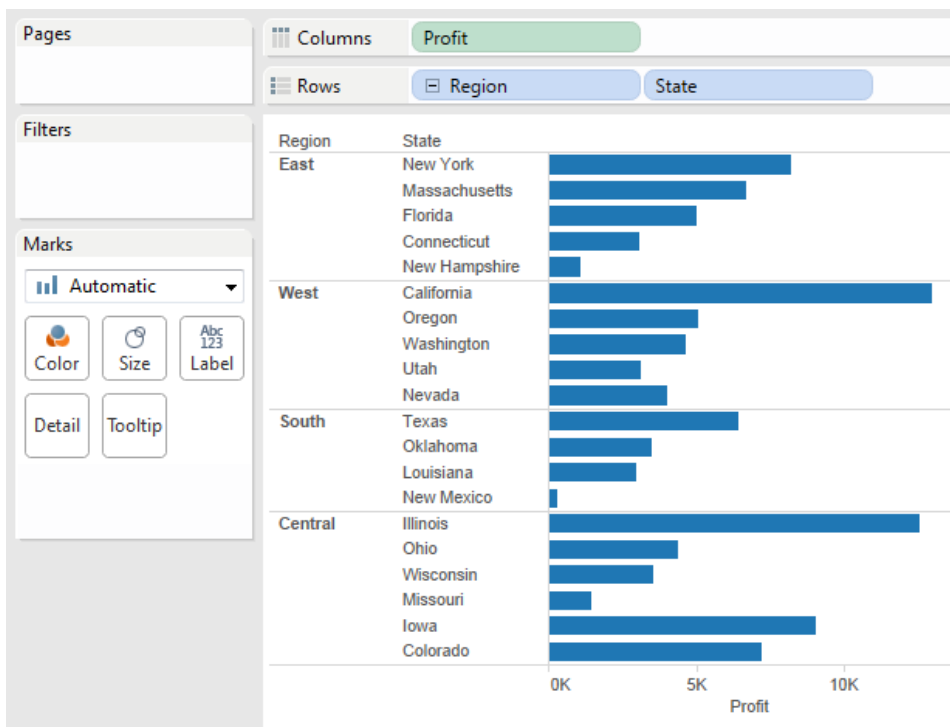

- The dimension that you place on the Filters shelf is not also on any other shelf in the view.
- The filter is defined to include multiple values. For example:

For relational data sources, there is nothing remarkable about a slicing filter. Tableau recalculates values for each measure in the view using the configured aggregations.

But because multidimensional data sources contain data that is aggregated in the data source, no aggregation can be defined for the “slice” that the dimension filter cuts through the values of individual measures. Tableau therefore automatically performs a summation. And because multiple values are defined, the result is the sum of a group of sums.

For example, consider the view shown below, which shows profit by region and state.

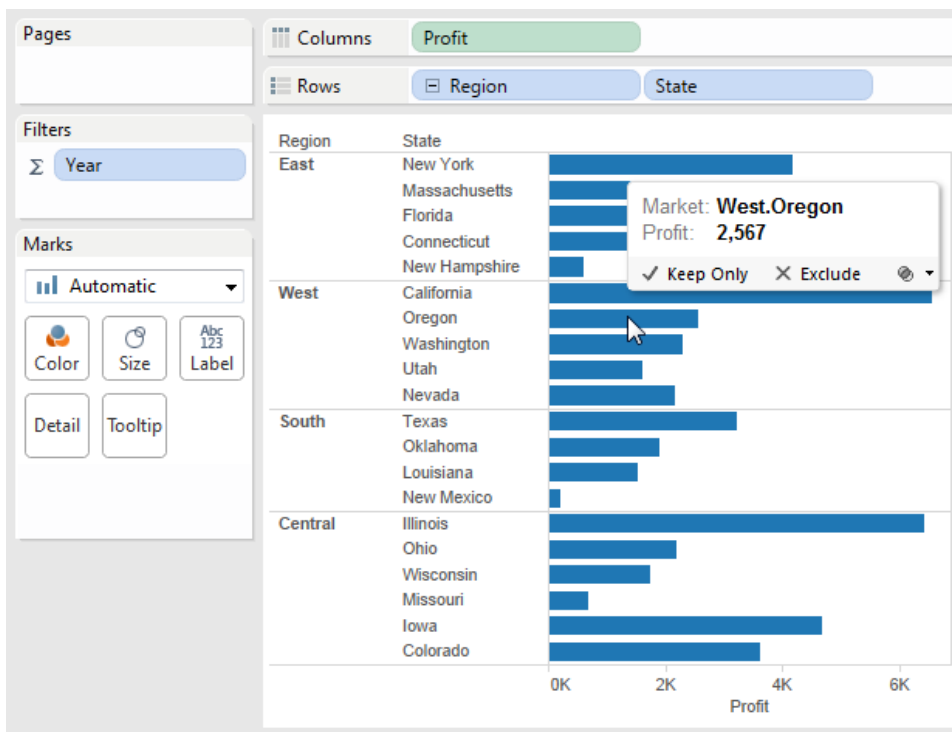

A slicing filter that includes the Q3 and Q4 members of the Quarter dimension is then applied to the data.

In the resulting view, the profit for Oregon in the West region is 2,567. This number was calculated by summing data values for Qtr3 and Qtr4.

The summation symbol ( $\Sigma$ ) you see on the Filters shelf in the view above indicates that this is a slicing filter. If the original aggregation for a field is non-additive (for example, Count Distinct) the values you see after applying a slicing filter may be unexpected.

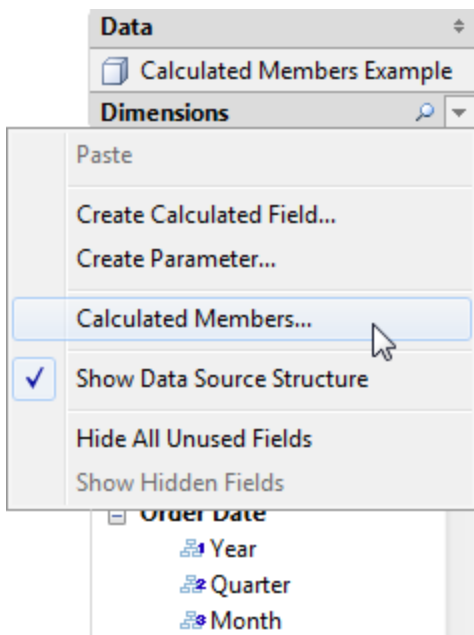

## How to Create a Calculated Member

If you are using a multidimensional data source, you can create calculated members using MDX formulas instead of Tableau formulas. A calculated member can be either a calculated measure, which is a new field in the data source just like a calculated field, or a calculated dimension member, which is a new member within an existing hierarchy. For example, if a dimension Product has three members (Soda, Coffee, and Crackers) you can define a new calculated member Beverages that sums the Soda and Coffee members. When you then place the Products dimension on the **Rows** shelf it displays four rows: Soda, Coffee, Crackers, and Beverages.

**Note:** In Tableau, multidimensional data sources are supported only in Windows.

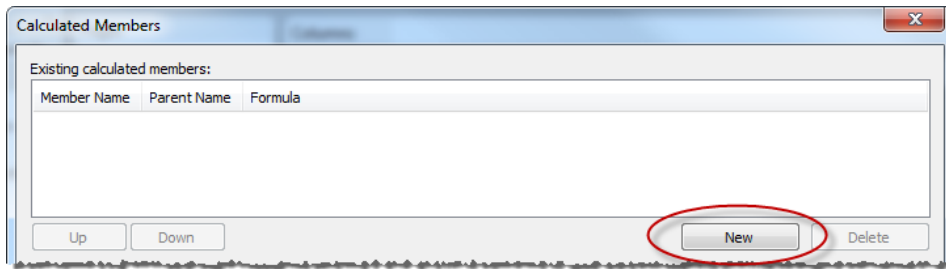

### Defining Calculated Members

You can define a calculated dimension member by selecting **Calculated Members** from the Data pane menu. In the Calculated Members dialog box that opens, you can create, delete, and edit calculated members.

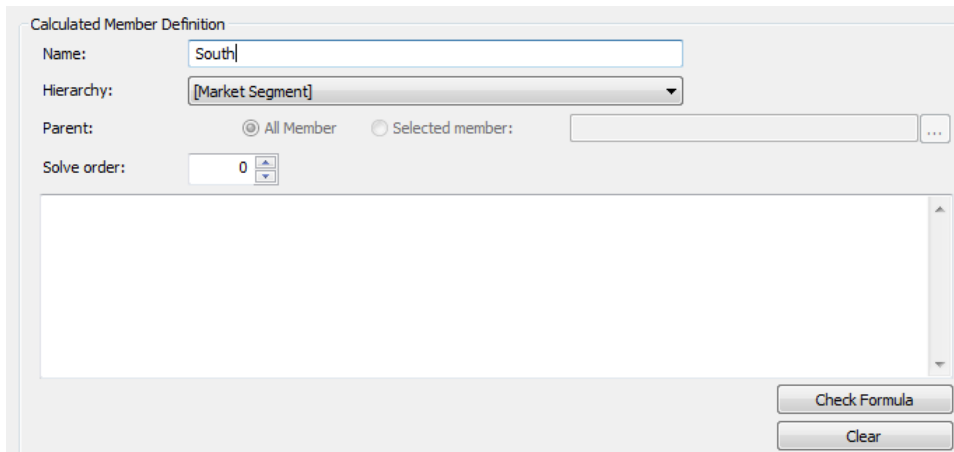

To create a new calculated member do the following:

1. Click New to add a new row to the list of calculated members at the top of the dialog box.

2. Type a Name for the new calculated member in the Member Definition area of the dialog box.

3. Specify the **Parent** member for the new calculated member. **All Member** is selected by default. However, you can choose **Selected Member** to browse the hierarchy and select a specific parent member.

**Note:** Specifying a parent member is not available if you are connected to Oracle Essbase.

4. Give the new member a solve order.

Sometimes a single cell in your data source can be defined by two different formulas. The solve order defines the precedence given to each formula. Formulas with a lower solve order are solved first. The default solve order is zero.

5. If you are connected to a Microsoft Analysis Services data source, the calculation editor contains a **Run before SSAS** check box. Choose this option to execute the Tableau calculation before any Microsoft Analysis Services calculations. For information on connecting to Microsoft Analysis Services data sources, see [Microsoft Analysis Services on page 396](#)
6. Type or paste an MDX expression into the large white text box.
7. Click **Check Formula** to verify that the formula is valid.
8. When finished, click **OK**.

The new member displays in the **Data** pane either in the Measures area, if you chose [Measures] as the parent member, or in the Dimensions area under the specified parent member. You can use the new member just like any other field in the view.

## Multidimensional Hierarchies

Multidimensional data sources contain hierarchies. For example, your database might contain a Product dimension that includes members such as product family, product department, and so on organized into a hierarchy, or you might have a Time dimension that includes years, quarters, and months.

**Note:** In Tableau, multidimensional data sources are supported only in Windows.

## Drilling Down and Up in a Cube Data Source Hierarchy

**Note:** The following applies only to certain multidimensional data sources.

Multidimensional (cube) data sources contain hierarchies. One of the most useful ways to navigate hierarchies is to drill down or drill up. For example, if you are examining the sales totals for various years, you can then drill down and view sales for all of the months within each year. Alternatively, if you are examining sales totals for all months, you can then drill up and view the sales for each year.

### Hierarchies in cube data sources

**When connected to cube data sources, you cannot create or customize hierarchies in Tableau.** Hierarchies must be created in the cube **before** you connect to it in Tableau.

Hierarchies appear with the following icon in the Data pane: 

You can see an example of a hierarchy below:

**Note:** You can only drill up or down in fields that are part of a hierarchy.

### Drill up and down for **all** dimension members in a hierarchy

To drill up or down for all dimension members in a hierarchy:

- On the Columns or Rows shelf, or the Marks card, click the plus sign (+) on a field to drill down, or the minus sign (-) to drill up.

The screenshot shows the Tableau Desktop interface. The Columns shelf is empty, and the Rows shelf contains the 'Category' field. The Marks card is set to 'Automatic' and includes 'Sales Amount'. The Filters shelf contains 'Product Categories'. The main view displays a table with the following data:

Category	Sales Amount
Accessories	\$739,312.49
Bikes	\$62,137,014.43
Clothing	\$1,331,553.75
Components	\$8,210,376.13

Drill up and down for **individual** dimension members in a hierarchy

To drill down and drill up for individual dimension members in a hierarchy:

- Right-click a table header and select **Drill Down** or **Drill Up** .

This screenshot is identical to the one above, showing the same Tableau Desktop interface with the 'Category' field on the Rows shelf and the 'Sales Amount' field on the Marks card. The table data remains the same:

Category	Sales Amount
Accessories	\$739,312.49
Bikes	\$62,137,014.43
Clothing	\$1,331,553.75
Components	\$8,210,376.13

This is often referred to as non-uniform drill down because you expose only the members of interest instead of exposing all the members of a given level.

For example, you can see the difference between drilling down for all dimension members and drilling down for individual dimension members below.

**Individual dimension member: Bikes**

Category	Subcategory	
Accessories		\$739,312.49
Bikes	Mountain Bikes	\$25,419,777.11
	Road Bikes	\$28,885,971.10
	Touring Bikes	\$7,831,266.22
Clothing		\$1,331,553.75
Components		\$8,210,376.13

**All dimension members**

Category	Subcategory	
<b>Accessories</b>	Bike Racks	\$135,667.84
	Bike Stands	\$20,829.00
	Bottles and Cages	\$36,314.58
	Cleaners	\$10,353.42
	Fenders	\$28,617.96
	Helmets	\$291,103.34
	Hydration Packs	\$55,923.42
	Locks	\$11,024.98
	Pumps	\$9,307.96
	Tires and Tubes	\$140,170.00
<b>Bikes</b>	Mountain Bikes	\$25,419,777.11
	Road Bikes	\$28,885,971.10
	Touring Bikes	\$7,831,266.22
<b>Clothing</b>	Bib-Shorts	\$114,307.95
	Caps	\$30,724.64
	Gloves	\$158,190.73
	Jerseys	\$447,551.45
	Shorts	\$272,187.62
	Socks	\$22,400.04
	Tights	\$141,029.15
	Vests	\$145,162.17
<b>Components</b>	Bottom Brackets	\$32,582.84
	Brakes	\$41,645.93
	Chains	\$6,203.66
	Cranksets	\$129,766.15
	Derailleurs	\$42,945.57
	Forks	\$55,917.61
	Handlebars	\$120,580.62
	Headsets	\$43,038.31
	Mountain Frames	\$3,444,986.06
	Pedals	\$102,284.77
	Road Frames	\$2,757,749.72
	Saddles	\$34,773.23
	Touring Frames	\$892,354.49
Wheels	\$505,547.17	

One reason to use a non-uniform drill down is if your data source has a ragged hierarchy (asymmetric layout). You also might want to view the children for just the member of interest.

**Note:** Drilling down and drilling up results in filtering the data.

## Perfect Pivoting

**Note:** The following applies only to certain multidimensional data sources.

In Tableau, perfect pivoting refers to working with hierarchies in these ways:

- Using varying levels of detail including skipping levels (for example, Country and City, but not State).
- Using varying levels of detail on different worksheet shelves simultaneously (for example, Product Family on the Columns shelf and Product Department on Color).
- Using varying levels of detail out of order (for example, Quarter before Year).

For example, in the following view the Market hierarchy is broken up to show the State level as Rows and the Region level as Color.

## Defining Unique Values

**Note:** The following applies only to certain multidimensional (cube) data sources.

Sometimes, when you are building views in Tableau, a field will have multiple members with the same name. For example, you may have a view showing the average profit by month over several years. The month February appears multiple times (once for each year).

While the name, February, is repeated, each instance of February can either be considered similar or unique. If you consider them similar, they will appear in the same column if you decided to move the Year field to the Color. However, if you consider them unique, they will be treated as two different values.

It is generally okay to consider repeated names within date and time fields (like in the previous example) similar but if there are repeated names in the Customer Name field, you won't want to consider the two customers as the same person.

To define how you want Tableau to determine whether repeated values are unique, right-click (control-click on Mac) on the dimension in the **Data** pane and select one of the following on the **Unique Values** context menu:

- **By Key:** each member is considered unique based on the key given to it by the system administrator when the database is set up. Members with the same name but different keys are treated as unique values.
- **By Name:** each member is considered unique based on the member name. Members with the same name (regardless of their keys) are treated as if they are the same.

By default, unique date and time values are determined by name and all other values are determined by key.

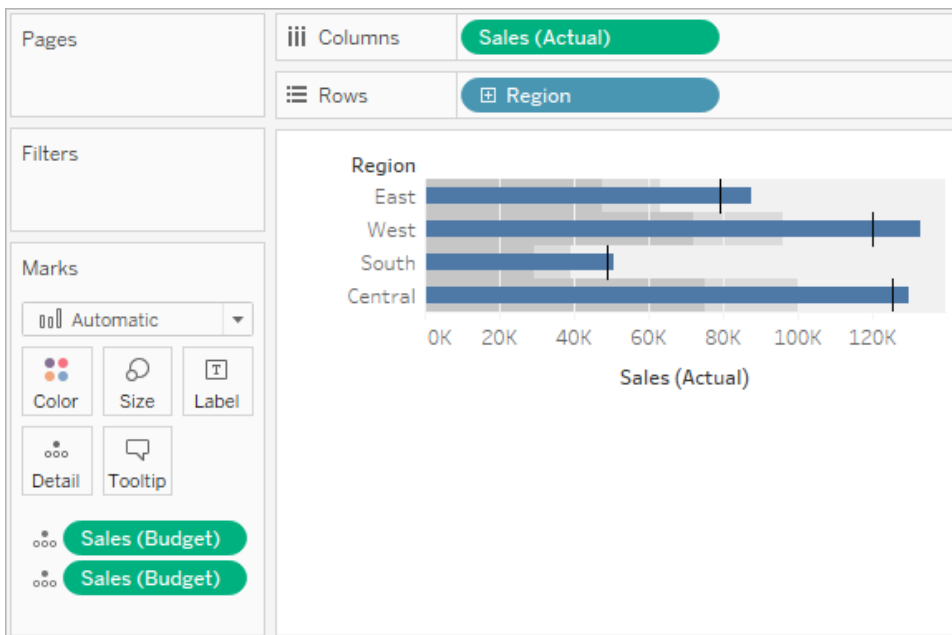

## Utility Dimensions

**Note:** The following applies only to certain multidimensional data sources.

Oracle Essbase databases sometimes have special dimensions used to model comparative values such as Actual vs. Budgeted or Current Year vs. Previous Years. These dimensions are the utility dimensions and are often set up as Scenario or Years. For example, the members of a Scenario dimension are shown below.

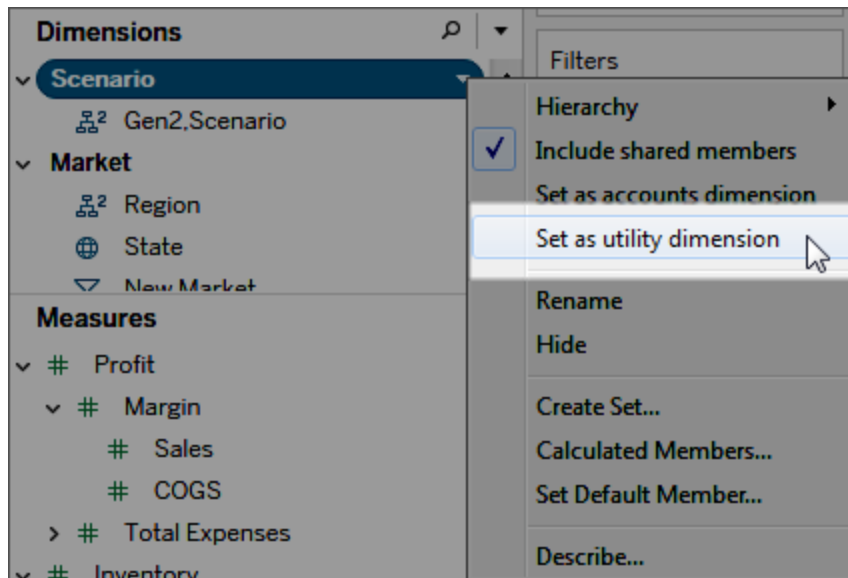

In the above view, you can see Actual Sales, Budgeted Sales, and so on. However, what if you wanted compare Actual Sales to Budgeted Sales in a bullet graph? In that case you need to set the Scenario dimension to be used as the utility dimension. When you set a dimension as the utility dimension you can then specify which member of the utility dimension to use for each measure in the view. For example, below is a bullet graph showing actual sales to budgeted sales by region.

You can see that the Sales measure is used twice in the view: once to show actual and once to show budgeted.

**To use a dimension as the utility dimension:**

1. Right-click the dimension in the Data pane and select **Set as utility dimension**.

The dimension in the Data pane (in this example, Scenario) can no longer be used as a dimension field in the view. The Measures area of the Data pane indicates that there is a utility dimension (in this example, (by Scenario) indicates the utility dimension).

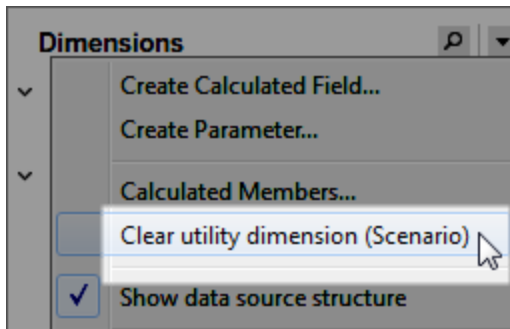

2. Drag a measure to the view.
3. Open the field menu for the measure in the view and select the member of the utility dimension you want to anchor the measure to.

**To remove a utility dimension:**

Open the drop-down menu at the top of the Data pane and select **Clear utility dimension**.

When you remove the utility dimension, measures that reference it in the view are no longer valid.

# Build Charts and Analyze Data

Tableau Desktop is a kind of laboratory in which you can discover the meaning that lies hidden in your data.

In this section you can discover the various features at your disposal as you build views, and learn the basic skills you need to create elegant, insightful views, dashboards, and stories.

## Automatically Build Views with Ask Data

### Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

Ask Data lets you type a question in common language and instantly get a response right in Tableau. Answers come in the form of automatic data visualizations, with no need to manually drag-and-drop fields or understand the nuances of your data's structure.

Ask Data lets you ask sophisticated questions naturally, with support for key analytical concepts such as time series and spatial analysis, and an understanding of conversational phrases such as "last year" and "most popular."

## Navigating to Ask Data lenses

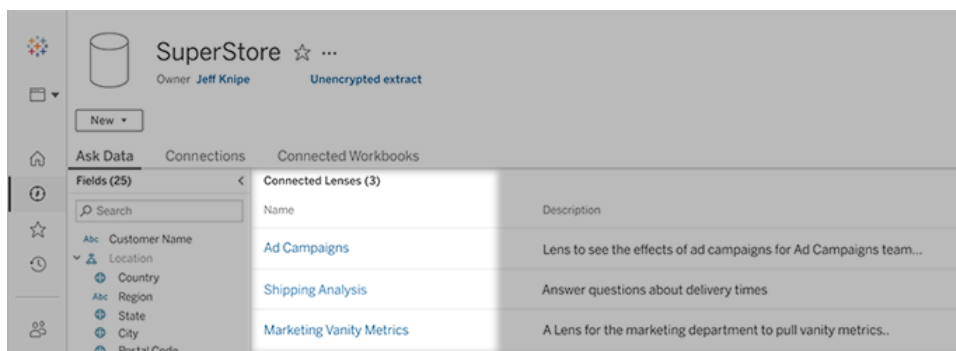

Before you can query a data source with Ask Data, a **Tableau author must first create a lens** that specifies the subset of data fields the lens uses.

In Tableau, here are all the places where you can access an Ask Data lens:

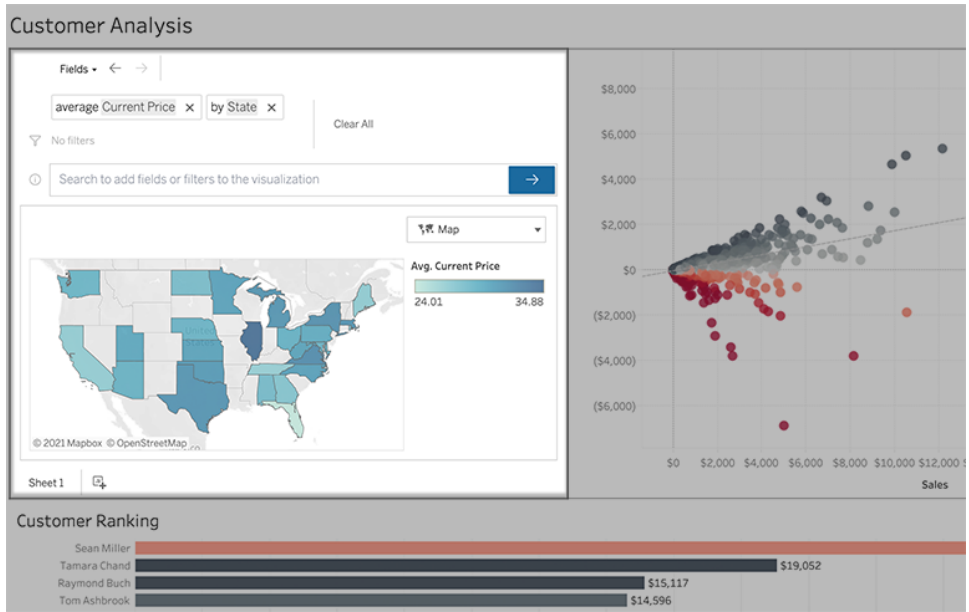

- On the All Lenses page at the top level of your Tableau Cloud or Tableau Server site.

- On the Ask Data tab for a data source for which lenses have been created.

- In an Ask Data object on a dashboard.

## Ask Data from a lens page or dashboard object

### Navigate to a lens and learn more about its data

1. Navigate to a lens via the All Lenses page for your Tableau site, the Ask Data tab for a data source, or an Ask Data object on a dashboard.
2. (Optional) Under **Recommended Visualizations**, click an entry to quickly see visualizations the lens author has created for your organization.

If the recommendations don't address your current data analysis needs, [build a query](#) to create your own question.

3. In the Data pane at left, briefly hover over each field to learn more about the data it contains.

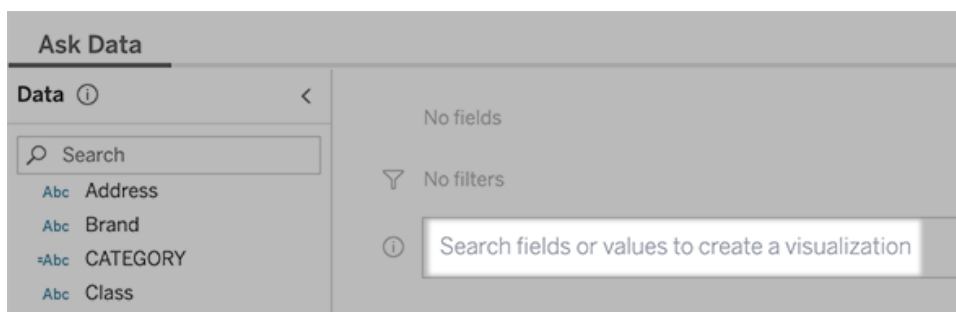

In a narrower dashboard object, the Data pane may be hidden, but you can see the same information by clicking the **Fields** drop-down menu.

## Build queries by entering text

1. Type in the box reading **Search fields or values to create a visualization**.

- As you type, Ask Data searches data fields, functions, and string values and displays results in a drop-down list. Click items in the list to add them to your current entry, shown above the search box. To automatically create a viz using the current entry, press **Enter** at any time.

Modifying a query by searching for fields and analytical functions

A. Current entry B. Current filters C. Search box D. Returned fields E. Returned analytical functions F. Returned field values

## Build queries by adding suggested phrases

Tableau will suggest phrases based on the most common queries asked in your lens and by others in your organization. When you open your lens, you'll notice suggestions that will help you get quick answers to common questions.

You can add these suggestions to your query by clicking them. As you add phrases to your query, the suggestions dynamically update with more relevant phrases. The view automatically builds with each selection.

## Build queries by adding fields and filters

1. Click **Add Field** or **Add Filter**.

2. Click the desired field. (To narrow down a long list, first type in the **Search Fields** box.)

3. Set any sub-options, such as aggregation type for a numeric field, or grouping for string and date fields.
4. To add more fields or filters, click the plus sign.

## See how elements of your query are applied

To see how elements of your query are applied, hover over them in the text box or the interpretation above it. Words that aren't used are grayed out, helping you rephrase your query in a way that's clearer to Ask Data.

## Rephrase your question

You can rephrase questions by clicking options, data fields, and filters in the user interface.

## Change the viz type

If the default viz doesn't fully reveal your data, click the menu at upper right, and choose from these supported viz types:

- Bar Chart
- Gantt Bar
- Heat Map
- Histogram
- Line Chart
- Map
- Pie Chart
- Scatter
- Stacked Bar Chart
- Text Table
- Treemap

**Note:** To automatically create certain viz types, Ask Data sometimes adds fields such as "Number of Records" to your entries.

### Change fields, filters, and displayed data

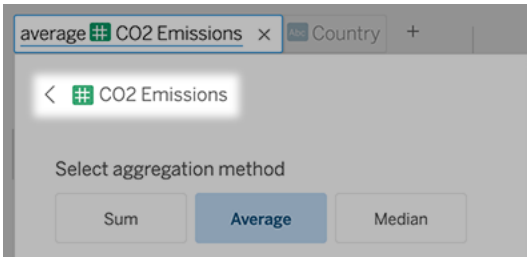

Ask Data gives you several ways to fine-tune how field values are displayed.

- To switch the fields used for the vertical and horizontal axes, click the Swap Axes button

 to the left of the viz selection menu:

- To change a field, first click it in your query entry, and then click the field name below. (To change fields used in difference calculations, see [Compare differences over time on page 964.](#))

- To change a field's aggregation or grouping type (for example, from average to sum), click the field name in the text box, and then choose a different aggregation or grouping.

- For categorical filters, click values (for example, "exclude United States" in the example below) to change specific values or enter wildcard parameters.

- To adjust a numeric range, click words such as "high" or "cheap."

- To delete a field or filter, hover over it and click the **X**.

## Adjust date filters

To adjust a date filter, click words such as "last" or "previous." Then click one of the following:

- **Specific Dates** to enter a specific time period or date value
- **Relative Dates** to show a date range relative to the present day
- **Range of Dates** to enter specific start and end points

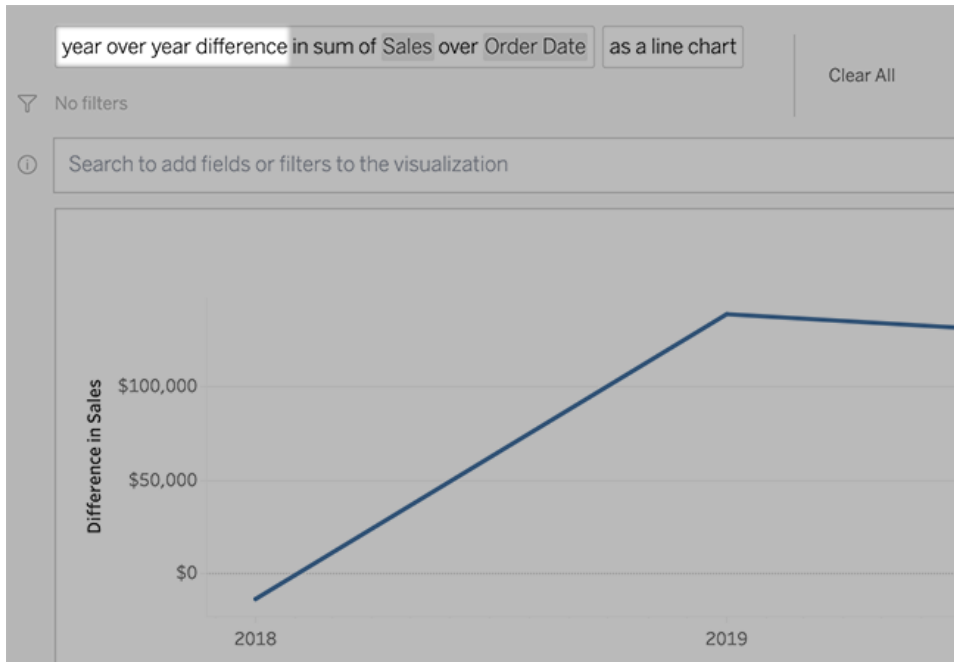

**Specific Dates** offers some unique options in the **Date Detail** menu:

- **Time Period** options show a single continuous date range
- **Date Value** options show ranges that can repeat in multiple time periods. For example, to see combined sales performance for Q1 across multiple years, under Date Value, you would choose Quarters.

## Compare differences over time

Ask Data lets you compare time periods with phrases such as "year over year" or "quarter over quarter." The results appear as difference or percent difference table calculations in workbooks you save from Ask Data.

In the text box, click a difference calculation to choose other fields, aggregation methods, and time periods.

## Apply simple calculations

Ask Data supports simple calculations between two measures, which you can apply using these symbols:

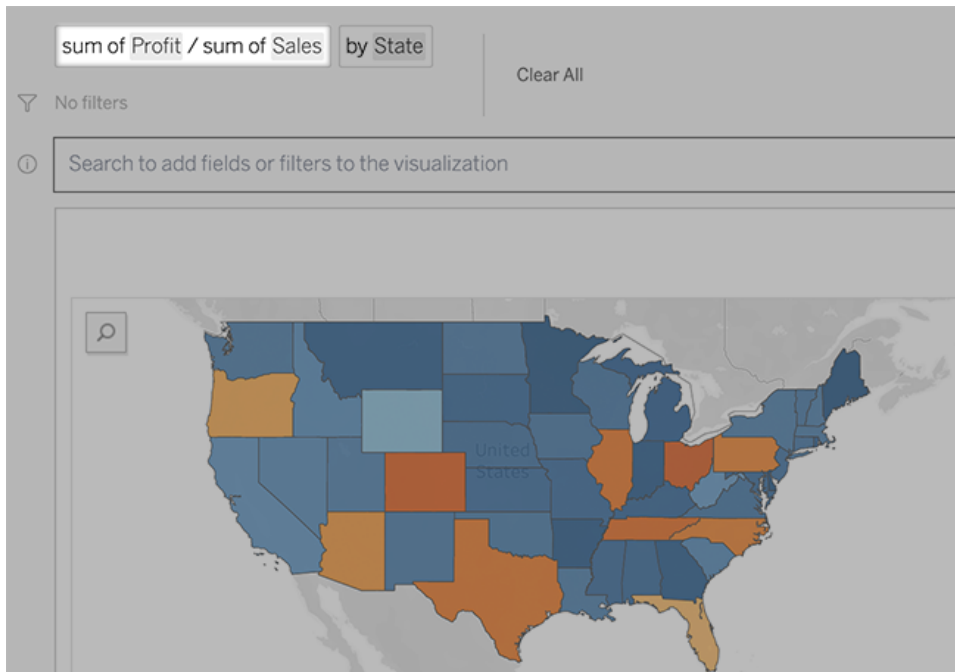

- + sums the measures

- produces the difference between them

\* multiplies

/ divides

In workbooks you save from Ask Data, these calculations don't become calculated fields but instead ad hoc calculations on the Columns, Rows, or Marks shelves. For more information, see [Ad-Hoc Calculations](#) on page 2574.

## Add sheets with other vizzes

To quickly create multiple different vizzes from a lens, add sheets in Ask Data.

At the bottom of the web page, do any of the following:

- Click the **Add Sheet** icon to the right of named sheets.

- Right-click a sheet name, and choose either **Duplicate** or **Delete**.

(To rename sheets from Ask Data, you need to save them in a new workbook.)

## Share Ask Data vizzes via email, Slack, or a link

You can quickly share Ask Data vizzes with anyone who has access to a lens.

1. In the upper right corner of the browser, click the Share icon.

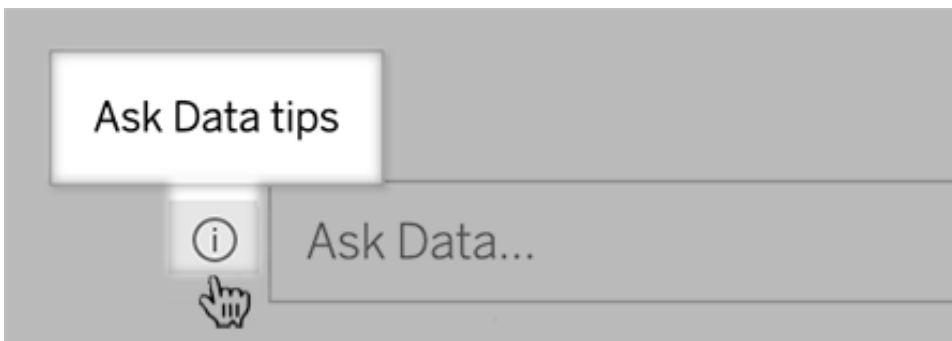

2. Do either of the following:
  - To share the viz via email or Slack, enter specific user names in the text box. (Email and Slack integration must previously be configured by your Tableau administrator.)
  - To copy a URL you can paste into custom emails and other messages, click **Copy Link**.

**Tip:** To find your Slack notifications, read [Receive Notifications, Search, and Share Using the Tableau App for Slack](#) on page 3355.

## Send feedback to the lens owner

If you have questions about the structure of a lens or how best to use it with Ask Data, you can send feedback directly to the author. (This option is enabled by default, but lens authors may disable it.)

1. To the left of the query box for Ask Data, click the **Ask Data tips** icon.

2. At the bottom of the tips dialog, click **Contact the Lens Author**.

## Tips for successful queries

As you structure questions for Ask Data, apply these tips to get better results.

- **Use keywords** — For example, instead of "I want to see all the countries that these airports are in, try "by airport and country."
- **Use exact wording for field names and values** — For example, if your lens includes Airport Code, Airport Name, and Airport Region fields, specify those by name.
- **See a ranked list** — Ask Data maps terms such as "best" and "worst" to Top 1 and Bottom 1, respectively. If you want to see broader rankings, use "high" and "low" instead. For example, enter "houses with low sale prices."
- **Query table calculations** — In query expressions for table calculation fields, note that you can't filter, limit, or include "year over year difference."
- **Surround unusually long values with quotation marks** — To analyze long field values that contain line returns, tabs, or more than ten words, surround them with quotation marks. To improve performance, Ask Data doesn't index fields of that length, or anything beyond the first 200,000 unique field values.

## Embed and Save Vizzes from Ask Data

### Important changes coming for Ask Data and Metrics

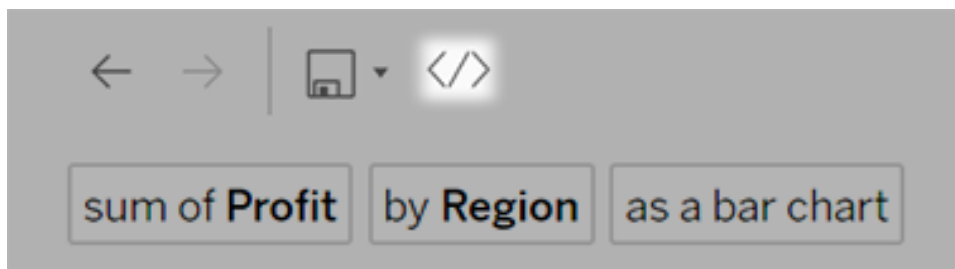

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

If you're a Tableau Creator, after you [create vizzes with Ask Data](#), you can embed and save them.

### Embed an Ask Data lens in a web page

After you ask a question with an Ask Data lens, an **Embed Code** icon appears in the toolbar. Click it to copy code you can incorporate into any web page.

When web pages with a lens embedded in them load, the lens opens without a viz, waiting for users to ask a question.

To see a lens embedded in a web page, users must have a Tableau license and permission to connect to the lens. They can interact with Ask Data just as they would in the Tableau Cloud or Tableau Server interface, but they can't save resulting vizzes.

## Save vizzes in a new workbook

Save vizzes from Ask Data to combine them with other Tableau views and dashboards in a workbook, where you can access Tableau's full range of data analysis and visualization tools.

**Tip:** To incorporate an interactive Ask Data experience into workbooks instead of a finished viz, see [Add an Ask Data lens to a dashboard on page 976](#).

1. Above the viz, click the save icon , and choose **Save as** if you're saving the viz for the first time, or **Save** to overwrite a previously saved version.
2. If you chose **Save as**, select **Embed password for data source** if people who lack access will be viewing the viz.

To quickly navigate to the saved workbook, click the save icon again, and choose **Edit workbook**.

## Supported Analytical Functions for Ask Data

### Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and

stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

Ask Data supports the core analytical functions of Tableau, including aggregations, grouping, sorting, and numeric and categorical filtering.

**Note:** Ask Data requires English analytical phrases but works great with non-English data. For example, you could ask “how many pedidos where fruta is manzanas” if you have Spanish data about orders of fruit for a grocery.

## Aggregations

When using Ask Data, example aggregation phrases include “Sum of Sales”, “Average Profit”, or “Count of Customers”. You can also use common synonyms for these terms, such as “mean” for average or “cnt” for count.

- Sum
- Average
- Median
- Count
- Distinct count
- Minimum
- Maximum

## Grouping

Grouping phrases include the word “by”, with examples like “by Region” and “by Sales”.

This expression is equivalent to placing a dimension or unaggregated measure on the Columns or Rows shelf while authoring a standard Tableau viz.

## Sorting

Examples of sorting phrases include “sort Products in ascending order by sum of Profit” or “sort Customer Name in alphabetical order”. You can also use synonyms like “from smallest” for ascending order and “from largest” for descending.

- Ascending
- Descending

- Alphabetical

### Numerical filters

Ask Data lets you filter data down to the numerical range you're interested in and then **fine-tune that range as needed**. Example phrasing includes “sum of Sales at least \$2,000” or “prices between \$10 and \$20”.

- At least
- At most
- Between

### Numerical limits (top and bottom values)

You can quickly see the top and bottom values of a field with phrases like “top 10 cars sold last year” or “bottom Region by average Profit”.

- Top
- Bottom

Ask Data also supports common terms that people tend to use with their data, like “low”, “high”, “lowest”, and “highest”. With currency-based fields, you can use synonyms for these terms, like “cheap” for low and “expensive” for high (for example, “show me the cheapest houses in Ballard”).

### Categorical filters for text values

Categorical filters let you narrow data down to the specific text values you're interested in.

Examples for each type of filter appear below:

- Is (for example, State is “Ohio”)
- Is not (State is not “Ohio”)
- Starts with (State starts with “O”)
- Ends with (State ends with “O”)
- Contains (State contains “O”)
- Does not contain (State does not contain “hi”)

### Time filtering

Ask Data supports time filtering with phrases like “Sales in the last 10 years” or “Profit between 2012 and 2014”. You can also use synonyms of phrases below, like “starts in” instead of “starting

at”.

- In (followed by specific date)
- Previous
- Last
- Following
- Next
- Between
- Starting at
- Ending at

**Tip:** You can also [compare differences over time](#) with table calculations.

## Create Lenses that Focus Ask Data for Specific Audiences

### Important changes coming for Ask Data and Metrics

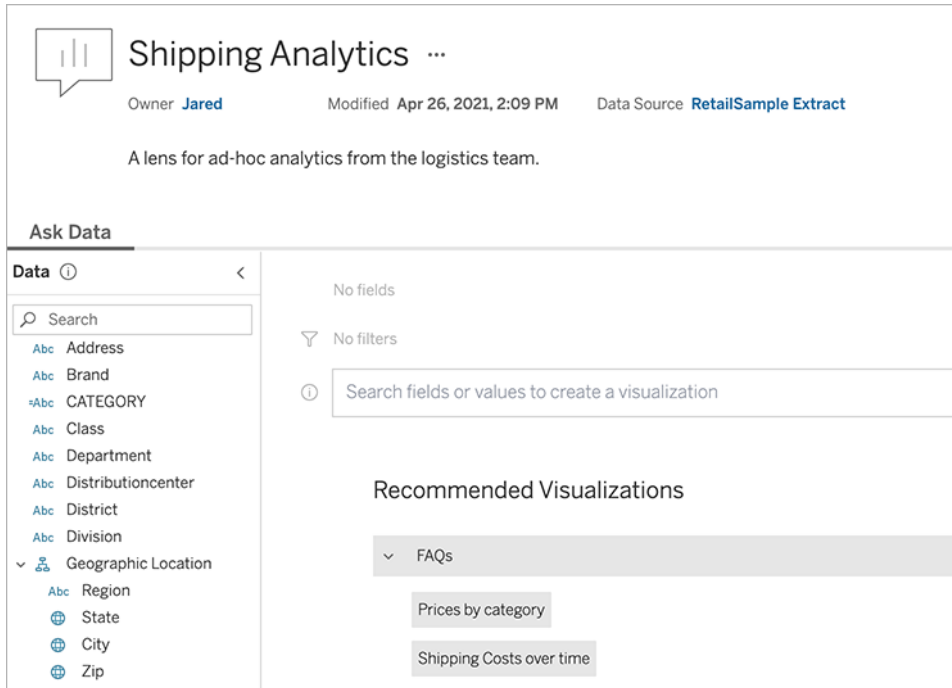

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

Most people don't need information from an entire data source but instead want data visualizations relevant to their job function, like sales, marketing, or support. To optimize Ask Data for different audiences like these, Tableau authors create separate Ask Data *lenses*, which query a selected subset of fields. For the selected fields, authors can specify synonyms for field names and values, reflecting terms the lens audience uses in common language (for example, "SF" for "San Francisco"). Lens authors then customize the recommended visualizations that appear below the Ask Data query box, which provide answers to users with a single click.

**Note:** Ask Data lenses can be created only for data sources published separately to a Tableau site. Lenses can't be created for data sources embedded in workbooks or those with a virtual connection.

## Create or configure a lens page on your Tableau site

On your Tableau site, each lens has a separate page where users can query Ask Data and authors can configure lens fields, synonyms, and suggested questions.

### A lens page on a Tableau site

1. To create a lens page on your Tableau site, go to a data source page, and choose **New > Ask Data Lens**.

To configure an existing lens, go to the lens page on your site. (From an Ask Data object in a dashboard, you can click the pop-up menu in the upper corner and choose **Go to Lens Page**.)

2. If you're creating a new lens, enter a name, description, and project location, and then click **Publish Lens**.
3. At the top of the Fields pane at left, click the pencil icon. Then select the relevant fields for lens users, and click **Save**.

4. At left, hover over individual tables or fields, and click the pencil icon:

Then do any of the following:

- Provide a more representative name by clicking the pencil icon to the right.

- Add common synonyms for field names and values that lens users may enter in their queries. For detailed instructions, see [Add Synonyms for Ask Data](#).
- Edit descriptions that appear when users hover over fields.

## Change the list of recommended visualizations

To address common queries from lens users, you can customize the recommended visualizations that appear below the query box.

### Add or replace a recommended visualization

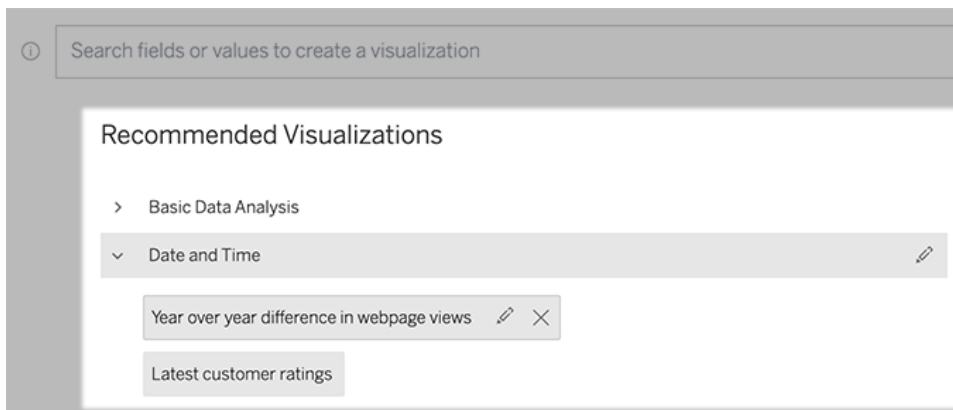

1. Enter a query into the text box, and press Enter or Return.
2. After the visualization appears, from the pin icon in the toolbar, choose either **Pin to Recommended Visualizations** or **Replace Recommendation**.

3. For a new recommendation, enter a name, and choose the section in which you want it to appear. For a replacement recommendation, choose the existing one you want to overwrite.

### Edit section titles and recommendation names, or delete recommendations

- To edit a section title, click the pencil icon  to the right of the title.
- To change the name of a recommendation, hover over it and click the pencil icon . To delete a recommendation, click the X.

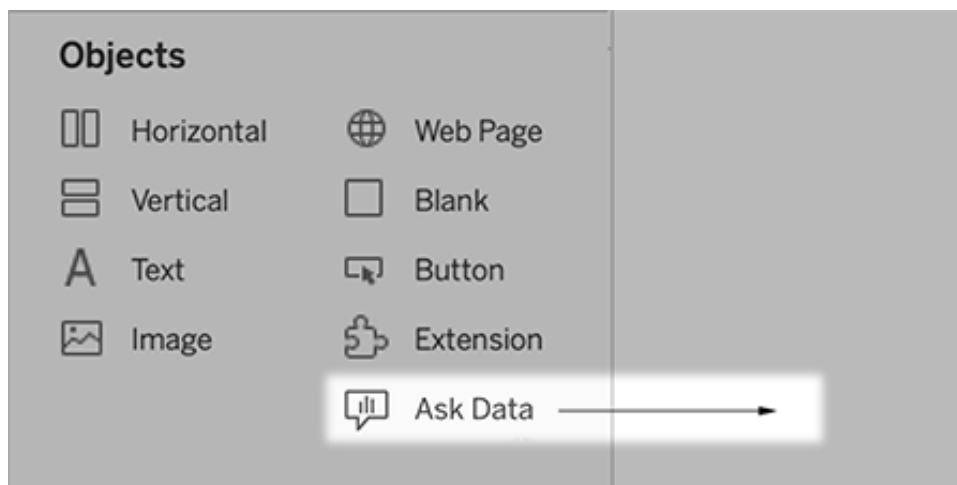

## Add an Ask Data lens to a dashboard

On a dashboard, you can add an Ask Data object that lets users query a published data source via a lens on your Tableau site.

1. While editing a dashboard in Tableau Cloud or Tableau Server, drag the Ask Data object to the canvas.

**Note:** In Tableau Desktop, you can also drag an Ask Data object to the canvas for placement purposes. But to select a lens, you will need publish to Tableau Cloud or Tableau Server and edit the object there.

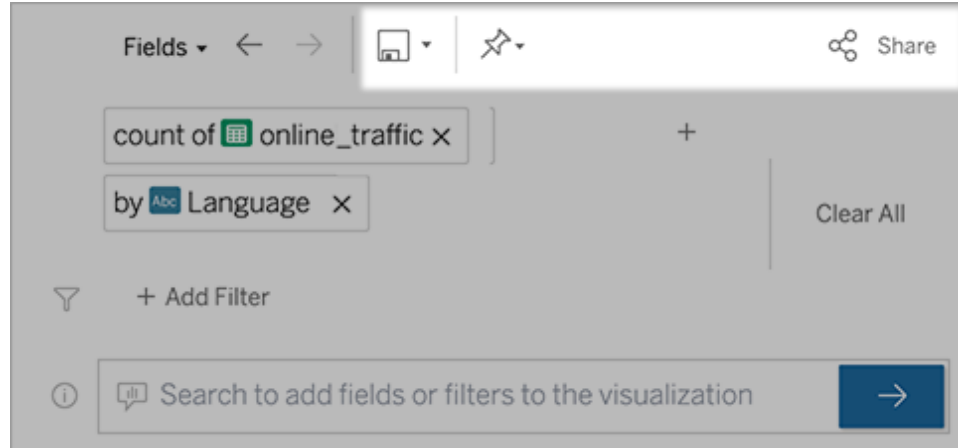

- 2.
3. Select a published data source previously connected to the workbook.
4. To use an existing lens, select it, and click **Use Lens**.  
Or, to create a new lens, do one of the following:
  - If there are no lenses for the data source, click **Go to Data Source Page**.
  - If lenses already exist, click the data source name at the bottom of the dialog.
5. (New lenses only) Complete the steps in [Create or configure a lens page on your Tableau site on page 973](#).
6. Under **Toolbar Options for Lens Users**, select the buttons you want available to users.
  - **Add Visualization to Pins** lets users [add to the Recommended Visualizations list](#), which appears just below the query box.
  - **Publish as Workbook** lets users [save visualizations as workbook sheets](#) to their Tableau site.

- **Share Visualization** lets users [share via email, Slack, or a link](#).

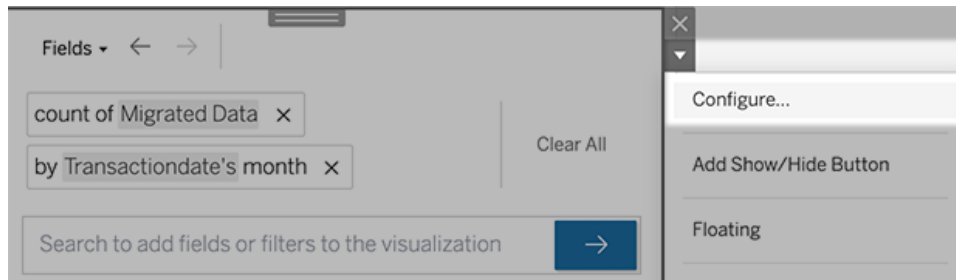

In the lens, the publish (save icon), pin, and share options appear in the upper right corner:

7. (New lenses only) After you finish creating the lens, return to the Lens object in your dashboard, and click **Refresh**. Then select the new lens, and click **Use Lens**.

## Apply a different lens to an Ask Data dashboard object

1. From the pop-up menu at the top of the object, choose **Configure**.

2. Go to [Add an Ask Data lens to a dashboard](#) on the previous page, and repeat steps 2 onward.

## Change a lens name, description, or project location

1. Navigate to the lens page on Tableau Cloud or Tableau Server.
2. To the right of the lens name at the top of the page, click the three dots (...), and choose **Edit Workbook**.
3. Click **Edit Lens Details**.

## See how people use Ask Data with a lens

For data source owners and lens authors, Ask Data provides a dashboard that reveals the most popular queries and fields, the number of visualization results that users clicked, and other helpful information. Filters let you narrow data down to specific users and time ranges. These stats help you further optimize a lens to increase the success of your users.

**Note:** If you use Tableau Server, you can access this data in the Tableau Server Repository to create custom dashboards.

1. In Tableau Server or Tableau Cloud, navigate to a lens page.
2. To the left of the Ask Data text box, click the "Ask Data tips" icon.

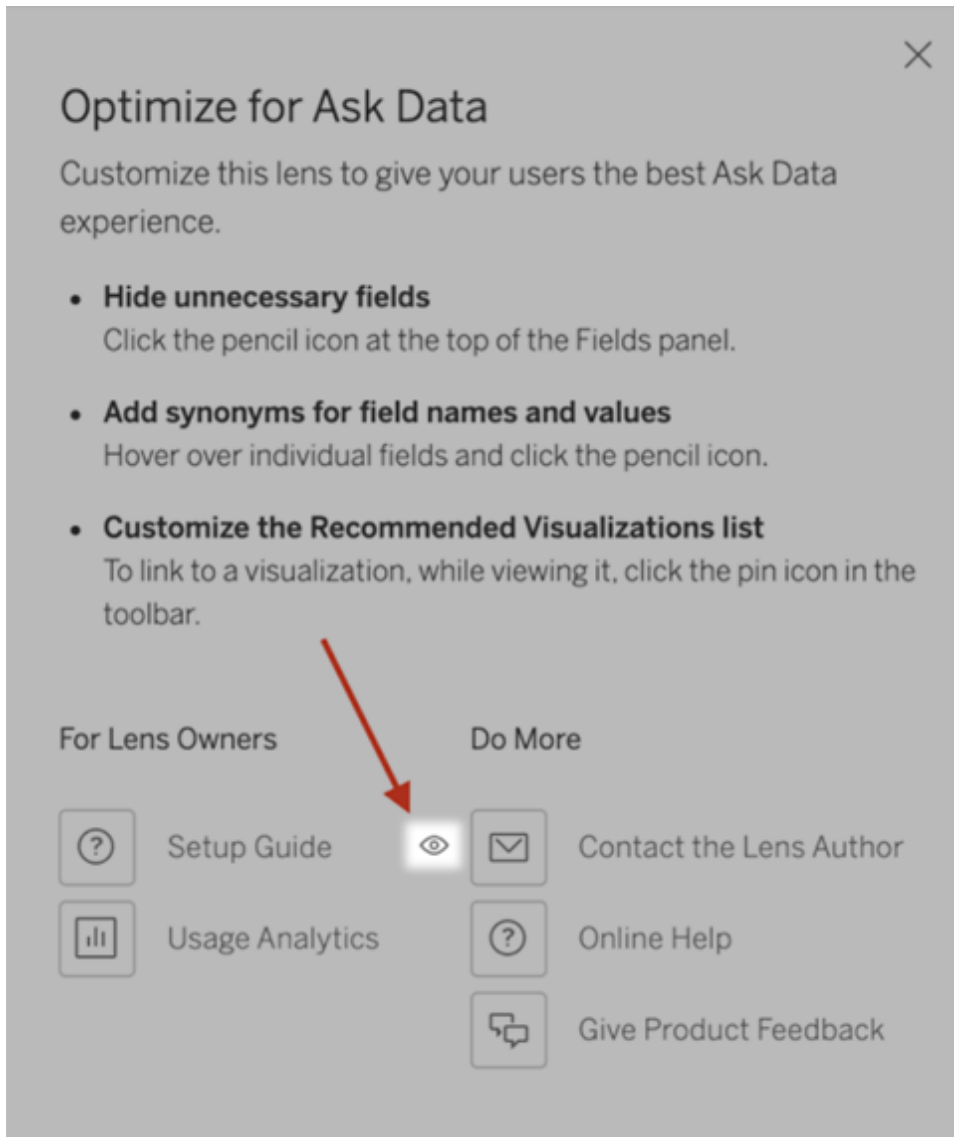

3. In the lower-left corner of the tips dialog, click **Usage Analytics**.

## Let users email you questions about a lens

As a lens owner, you can allow users to email you with questions about data structure, expected results, and more. This option is on by default, but you can turn it off using the steps below.

1. In Tableau Server or Tableau Cloud, navigate to a lens page.
2. To the left of the Ask Data text box, click the "i" shown above in [See how people use Ask Data with a lens above](#).
3. At the bottom of the tips dialog, click the eye icon next to "Contact the Lens Author" to

enable or disable feedback.

## Permissions for publishing and viewing lenses

For Ask Data objects in dashboards, no change to permissions should be required: by default, existing workbook authors can create lenses, and existing dashboard audiences can view them. But for reference, here's a detailed outline of required lens permissions for both dashboards and direct access via a data source page.

To create and publish a lens, a user needs:

- The Creator or Explorer user role
- Lens Creation permission for the data source (inherited by default from the Connect permission)
- Write permission for the parent project to which the lens is published

To access and interact with a published lens, a user needs:

- The Viewer role or above
- Connect permission for the data source
- View permission for the lens

**Note:** By default, lens permissions like View reflect a project's permissions for workbooks. If Tableau administrators want to change default lens permissions, they can do so either individually for each project, or in bulk using the permissions API.

## Optimize Data for Ask Data

### Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

If you manage and publish data sources, here are some tips to help make users of Ask Data more successful. By spending a little extra time on this process, you'll open up data analysis to a wider range of people at your organization, helping them independently answer questions and gain deeper insights.

### Optimize data in Ask Data

In the Data pane on the left of the Ask Data interface, data source owners can add synonyms for fields and exclude irrelevant values.

### Changing settings at the data source or lens level

When changing settings in the Data pane for Ask Data, pay close attention to whether you're at the data source or lens level. (For more information, see [Create Lenses that Focus Ask Data for Specific Audiences](#).)

- At the data source level, you'll see the cylindrical data source icon in the upper left corner. Here, changes you make in the Data pane will apply by default to all subsequently created lenses.

**Note:** For extracts, two cylinders will appear.

- For an individual lens, you'll see the quotation icon in the upper left corner. Here, changes you make in the Data pane will apply to this lens alone.

### Add synonyms for field names and values

People may not use the same terminology found in your data source, so data source owners and Tableau administrators can [add synonyms for specific data field names and values](#). Synonyms you enter are available throughout your organization, making data analysis quicker and easier for everyone.

### Exclude values of specific fields from search results

To improve the usability of search results in Ask Data, you can exclude the values of specific fields from indexing. Though Ask Data doesn't add non-indexed values to search results, the values still appear in visualization results when relevant. For example, if you don't index values from a "Product" field because they add unnecessary detail to search results, Ask Data can still display values such as "iPhone 12" in resulting data visualizations. And users can manually add non-indexed values to queries by surrounding them with quotation marks (for example, "Sales for Product containing "iPhone 12"").

**Note:** This field-level setting is ignored if [the value indexing setting for the data source](#) is set to Disabled. Field names and related synonyms are always indexed.

1. Go to the Ask Data tab for a data source or individual lens.
2. Hover over a data source field at left, and click the **Edit Field Details** icon (the pencil).

3. Deselect **Index field values**.

Either click the text box that appears to reindex the data source now, or let it reindex based on its regular indexing schedule.

## Optimize data sources

To create the best experience for Ask Data users, optimize the original data source.

**Note:** Ask Data doesn't support multidimensional cube data sources, or non-relational data sources like Google Analytics, or data sources with a virtual connection.

## Optimize indexing for Ask Data

Data source owners can change how often field values are indexed for Ask Data, optimizing system performance.

1. At the top of a data source page, click the Details icon:

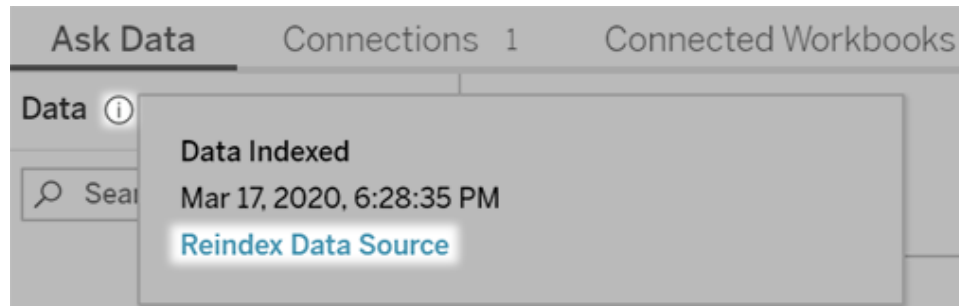

2. In the Ask Data section, click **Edit**.
3. Choose an indexing option for field values:
  - **Automatic** checks for changes every 24 hours and analyzes the data source if it is live, has had an extract refreshed, or has been republished. Choose this option for a

data source frequently used with Ask Data, so it will be ready before users query it.

- **Manual** analyzes the data source only when Tableau creators manually trigger indexing on the data source page. Choose this option if the data source changes frequently but users query it with Ask Data only occasionally.

To trigger manual indexing, go to the data source page, click the circled “i” in the Data pane at left, and then click **Reindex Data Source**.

- **Disabled** analyzes only field names, not values.

#### 4. Click **Save**

### Use data extracts for faster performance

For improved performance and support for large data sets, use Ask Data with published extracts rather than live data sources. For more information, see [Create an extract](#).

### Ensure that users can access the data source

To use Ask Data, users must have permission to connect to the individual data source. If a data source has row-level permissions, those permissions also apply to Ask Data, which won't recognize secure values or make related statistical recommendations.

### Be aware of unsupported data source features

Ask Data supports all Tableau data source features except the following. If your data source contains these, Ask Data users won't be able to query related fields.

- Sets
- Combined fields
- Parameters

## Anticipate user questions

Anticipate the kinds of questions your users will ask, and then optimize your data source for those questions using these techniques:

- Clean and shape data in [Tableau Prep](#) or a similar tool.
- [Join data](#) to include all fields users may have questions about in one table, improving performance.
- Add [calculated fields](#) that answer common user questions.
- Create [bins with appropriate sizes](#) for quantitative variables that users are likely to want to see as a histogram or another binned form.

## Simplify the data

To make data easier to understand by both users and Ask Data, simplify the data source as much as possible during the data prep process.

1. Remove any unnecessary fields to improve performance.
2. Give each field a unique and meaningful name.
  - For example, if there are five field names that start with “Sales ...”, better distinguish them so Ask Data can properly interpret the term “sales”.
  - Rename “Number of records” to something more meaningful. For example, use “Number of earthquakes” in a data source where each record is an earthquake.
  - Avoid field names that are numbers, dates, or boolean (“true” or “false”) values.
  - Avoid names which resemble analytical expressions such as “Sales in 2015” or “Average Products Sold”.
3. Create meaningful [aliases for field values](#), reflecting terms people would use in conversation.

## Set appropriate field defaults

To help Ask Data analyze data correctly, ensure that default field settings reflect the content of each field.

- [Set data types](#) for text, time, date, geographic, and other values.
- [Assign the proper data role](#): dimension or measure, continuous or discrete.
- For each measure, [assign appropriate default settings](#) in Tableau Desktop, such as color, sort order, number format (percentage, currency, etc.), and aggregation function. For example, SUM may be appropriate for “Sales”, but AVERAGE might be a better default for “Test Score”.

**Tip:** It's particularly helpful to set a default comment for each field, because these comments appear as informative descriptions when users hover over fields in Ask Data.

## Create hierarchies for geographic and categorical fields

For time data, Tableau automatically creates hierarchies, which let users quickly drill up and down in vizzes (for example, from day to week to month). For geographic and categorical data, however, we recommend that you [create custom hierarchies](#) to help Ask Data produce visualizations that reflect the relationships between fields. Be aware that Ask Data won't show the hierarchies in the data pane.

Ask Data doesn't index hierarchy names, only names of fields within hierarchies. For example, if a geographic hierarchy named "Location" contains "Country" and "City" fields, users should enter "Country" and "City" in their questions for Ask Data.

## Add Synonyms for Ask Data

### Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

People may not use the same terminology found in your data source, so data source owners and Tableau administrators can add synonyms for specific data field names and values. Synonyms you enter are available throughout your organization, making data analysis quicker and easier for everyone.

**Note:** You can't use synonyms that reflect standard analytical terms like "by" or "max". Likewise, you can't create synonyms for these special types of data: sets, bins, clusters, hierarchies, combined fields, table calculations, or latitude and longitude.

## Add field and value synonyms for a specific data source or lens

1. Go to [the Ask Data tab for a data source or individual lens](#).
2. Hover over a data source field at left, and click the **Edit Field Details** icon (the pencil).

3. To enter synonyms for the field name, use the **Synonyms** text box.
4. To enter synonyms for field values, click the arrow in the lower left corner.

Then use the search box to find specific values, and enter synonyms for them at right.

✕

### Field Details

**Industry**  
Abc String   Data Role ▼

▼ 85 unique values 🔍 Search

Value	Synonyms
Banking	Lenders ✕   Credit Unions ✕
Food & Beverages	
Investment Management	Financial Advisors ✕   Stock Analysts ✕
Insurance	
Pharmaceutical	RX ✕
Supermarkets	Grocers ✕

**Tip:** To help Ask Data better interpret users' questions, make synonyms for field values unique and short.

## Add synonyms for multiple data sources

When a field or value has similar usage throughout your organization, use data roles to apply the same synonyms across multiple data sources. For example, data roles are a great choice if every subsidiary uses the same names for business departments, or if product lines have a consistent set of sub-products.

Using data roles for synonyms saves you a lot of time, because you can manage them centrally in Tableau Cloud or Tableau Server. From Ask Data, you can publish new data roles and apply existing ones created in Ask Data or [Tableau Prep](#).

### Publish synonyms to a new data role

1. Follow the steps for [adding field name and value synonyms](#) for a specific data source.
2. From the **Data Role** menu, choose **Publish Data Role**.
3. Enter a name for the role, and then click **Publish**.

### Apply synonyms from an existing data role

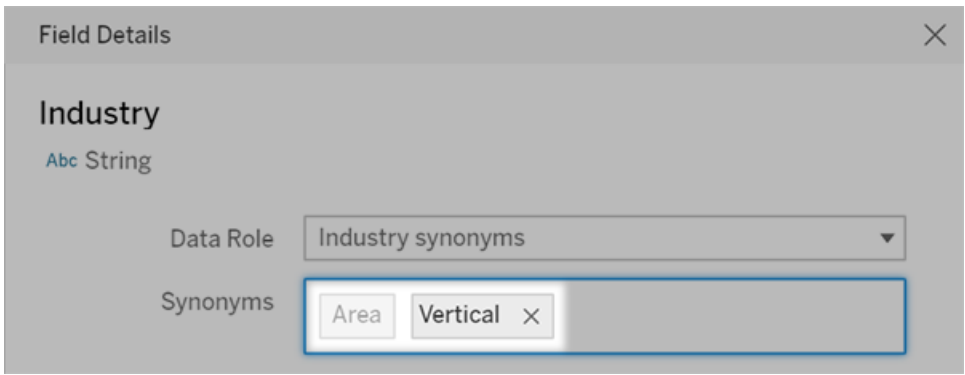

**Note:** When applying existing data roles, you can select only roles you have permission to access.

1. Go to [the Ask Data tab for a data source or individual lens](#).
2. Hover over a data field at left, and click the **Edit Field Details** icon (the pencil).

3. From the **Data Role** menu, choose **Apply Data Role**.
4. Enter search terms to narrow the list of roles. Then select a role from the list, and click **Apply**.

Synonyms from the role appear grayed out, but you can [edit them on the central page for the data role](#).

Grayed-out synonyms must be edited on the data role page. In this example, “Area” comes from a data role, while “Vertical” is specific to the current data source.

## Change or remove an applied data role

**Note:** You cannot change built-in data roles for geographic fields like country, state, province, or city.

1. Go to [the Ask Data tab for a data source or individual lens](#).
2. Hover over a data source field at left, and click the **Edit Field Details** icon .
3. Click the name of the currently applied data role, and choose either **Apply a Different Data Role** or **Remove Data Role**.

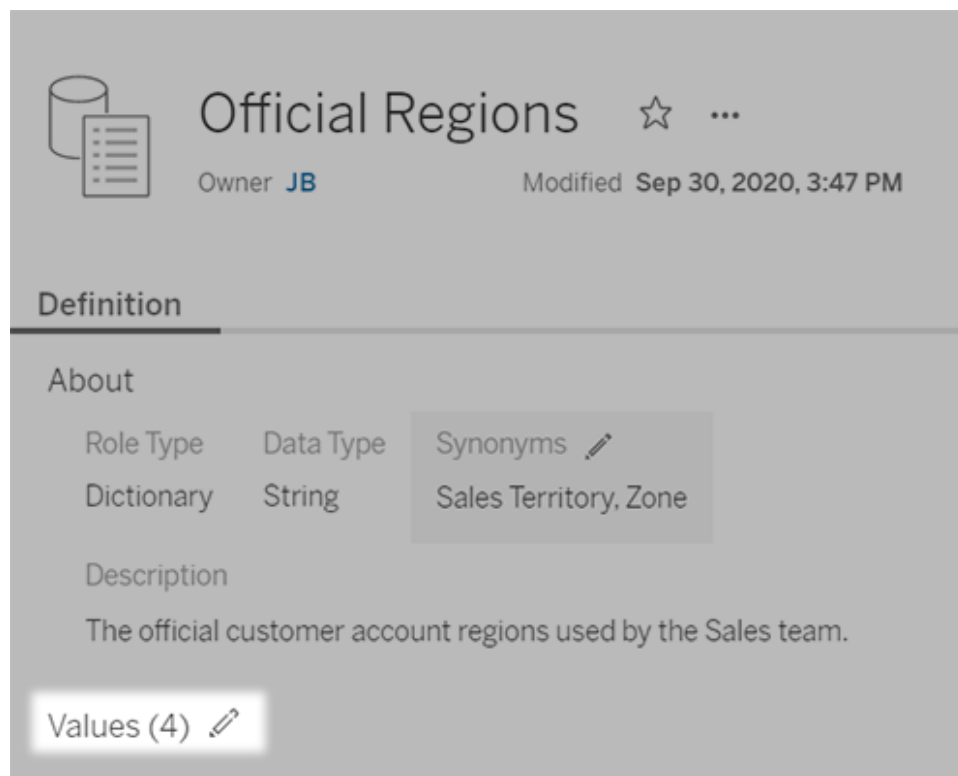

## Edit field name or value synonyms for a data role

1. Go to [the Ask Data tab for a data source or individual lens](#).
2. Hover over a data source field at left, and click the **Edit Field Details** icon .
3. Click the name of the currently applied data role, and choose **View Data Role**.
4. On the central page for the data role, do the following:
  - To edit synonyms for the field name, click the **Synonyms** section at top. Then add or remove synonyms in the text box, and click **Save**.

- To edit synonyms for field values, click the pencil icon next to **Values**.

Then edit values in the **Synonyms** column, and click **Save**. For fields with long lists of values, use the search box at right to narrow things down.

## Disable or Enable Ask Data for a Site

### Important changes coming for Ask Data and Metrics

Tableau's Ask Data and Metrics features were retired in Tableau Cloud in February 2024 and will be retired in Tableau Server version 2024.2. With advances in natural language technologies, we're developing an improved interface that will make it easier to ask questions of your data and stay on top of changes. For more information, see [How Tableau AI and Tableau Pulse are reimagining the data experience](#).

Ask Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Ask Data** section, choose from these options:
  - **Enabled** enables creation of Ask Data lenses for all published data sources.
  - **Disabled** hides Ask Data throughout the site, while preserving information about previously created lenses so they can be restored if Ask Data is re-enabled.

## Add Web Images Dynamically to Worksheets

At Tableau, we know that images are a powerful tool when analyzing data. Imagine that you're looking at a viz of monthly shoe sales. The data is telling you that you sold more high heels than wedges, but you can't picture the difference in the two types of shoe. That's where Image Role comes in. You can dynamically add web images to your worksheets and use them in your headers to add visual detail.

Product Name	Product Image URL	
Flats		12,118
High Heels		15,865
Running Shoes		14,200
Wedges		8,665

## Prepare your data source

Image Role can be assigned to discrete dimension fields that contain URLs that point to web images. To prepare your data, be sure that your image fields meet the requirements set by Tableau to be assigned an image role:

- Make sure your URLs navigate to .png, .jpeg, .jpg, .svg, .webp, .jfif, .ico, or .gif image files.
- Verify that each URL begins with http or https. If a transport protocol isn't included, Tableau assumes https.
- Optimize the number of images used in your data set. Usually, you can load up to 500 images per field.
- Ensure that each image file is smaller than 200 kb.

**Note:** If you're using Tableau 23.1 or earlier, your URLs must navigate to image files with .jpg, .jpeg, or .png file extensions.

In Tableau 23.2 and later, .gif files are supported, but .gif *animations* will only show on Tableau Cloud and Tableau Server with a client-side render. In Tableau Desktop and Tableau Server with a server-side render, the .gif file will show as a static image.

Depending on the complexity of your viz, Tableau may default to a server-side render, which limits the number of images to 100 per field. To learn more about complexity settings and server-side rendering, see [Configure Client-Side Rendering](#).

### Example data set:

Product Name	Product Image URL	Product Sales
--------------	-------------------	---------------

Flats	https://img.example.com/flats.png	12,118
High Heels	https://img.example.com/highheels.png	15,865
Running Shoes	https://img.example.com/runningshoes.png	14,200
Wedges	https://img.example.com/wedges.png	8,665

## Assign an image role to your URLs

After you've connected to your data source, you can assign an Image Role to your URLs from either the Data Source page or on the Data pane in a worksheet.

### From the Data Source page:

1. Locate the column that has image URLs.
2. Right-click (control click on Mac) the icon on the top left of the column and select **Image Role > URL**.

The icon changes to an image icon, and your images are ready to use.

### From a worksheet:

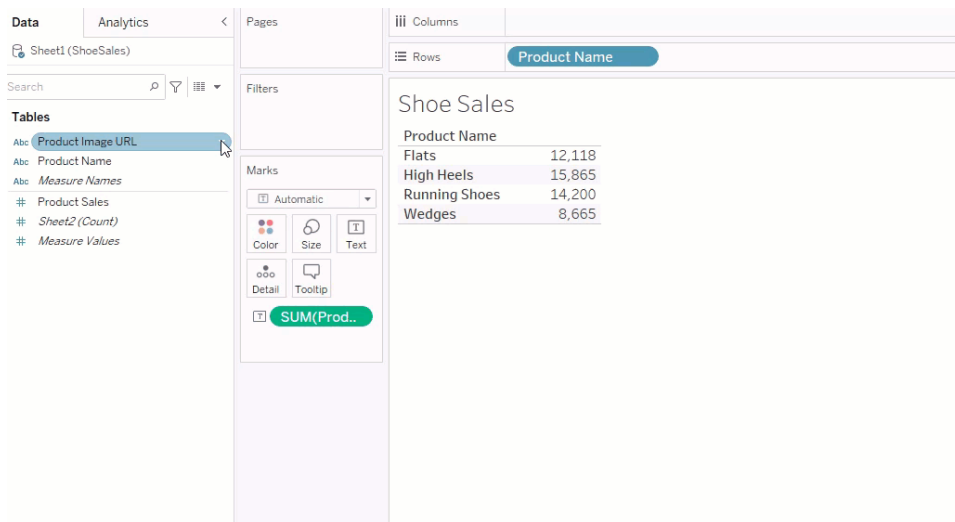

1. Open a new worksheet.
2. Locate a discrete dimension field that has image URLs.
3. Right-click (control click on Mac) the dimension field and select **Image Role > URL**.

The icon changes to an image icon, and your images are ready to use.

## Add images to your visualizations

From your worksheet, drag the Image Role field onto the Rows or Columns shelf. You can now see image searches along with their associated data on your viz.

## Share your visualizations

You can export your workbooks with images and share them. Be sure that the images used in your vizs are available to be viewed by everyone you share your vizs with. For example, if you're using images that are hosted on an internal server behind a firewall, be sure that everyone you share the viz with has sufficient permissions to access the images. In this example, users who view the viz while connected to the same server shouldn't have any issues seeing the

images. But users who export the viz to a pdf on a Tableau Cloud server may not be able to see the images.

If you export your workbook and your viewer attempts to open it in Tableau 2022.3 or earlier, your viewer won't be able to see the images.

**Note:** It's a best practice to always align an Image Role field with a text description to make the content accessible for screen readers and other accessibility software.

## Troubleshoot image connections

Sometimes images won't display if you exceed the number of images allowed per field, have large image files on a complex viz, or are viewing the viz on a mobile device. This section helps you troubleshoot those errors.

### None of the images are displaying in my viz

### There are too many images in the viz

Depending on the complexity of your viz, you can typically load 500 images per field. If you have a complex viz, it may default to server-side rendering. With server-side rendering, you can load 100 images per field.

If you get an error message that there are too many images in the viz, filter out images and try again.

### Tableau couldn't access the images

If you receive broken image icons instead of your images, first confirm that you have sufficient permissions to view the images (or if, for example, they're behind a firewall). Tableau must be able to access the images, and the images can't require a separate authentication to view them.

If you're sure that you have permission to view the images and they're within the size requirements, check that web images are enabled on your settings page.

In Tableau Desktop:

1. From your workbook, click **Help** in the toolbar.
2. Select **Settings and Performance > Set Dashboard Web View Security**.
3. Make sure that **Enable Web Page Objects and Web Images** is checked.

In Tableau Cloud:

1. From the home page, click **Settings**.
2. Under general, scroll down and locate **Web Page Objects and Web Images**.
3. Make sure that **Enable Web Page Objects and Web Images** is checked.

Some of the images aren't displaying in my viz

## The image file is too large

Each image file must be smaller than 200 kb to render. Check your image file size and try again.

## You're using an earlier version of Tableau

If you're using Tableau 23.1 or earlier, only .png, .jpeg, and .jpg image files are supported. Upgrade your version of Tableau or use a supported file type for the version of Tableau you're using.

## The image URL must begin with http or https

Each image URL must begin with either http or https. Tableau doesn't currently support FTP/SMTP calls. Verify your URL format and try again.

## The image file must be a URL

An Image Role can be assigned to only URLs that navigate to .png, .jpeg, or .jpg, .svg, .webp, .jiff, .ico, .bmp, or .gif image files. Verify your URL format and try again.

## The image file type isn't supported

An Image Role can be assigned to only URLs that navigate to .png, .jpeg, or .jpg, .svg, .webp, .jif, .ico, .bmp, or .gif image files. Verify your URL format and try again.

If you're using Tableau 23.1 or earlier, only .png, .jpeg, and .jpg image files are supported. Upgrade your version of Tableau or use a supported file type for the version of Tableau you're using.

In Tableau 23.2 and later, .gif files are supported, but .gif *animations* will only show on Tableau Cloud and Tableau Server with a client-side render. In Tableau Desktop and Tableau Server with a server-side render, the .gif file will show as a static image.

## The image file contains bad characters

An Image Role can't be assigned to URLs that have the following characters:

```
<> & \ ^ ' 
```

or the following character sequences:

```
.. \\. \r \n \t
```

Verify that your URL doesn't contain any of these characters or character sequences and try again.

## The images aren't displaying outside of my worksheet

### The images aren't displaying in Viz in Tooltip

Viz in Tooltip is processed with server-side rendering, which allows you to load up to 100 images per field. Verify that you have fewer than 100 images per field and try again.

For more about server and client-side rendering, see [Configure Client-Side Rendering](#).

For more about using Viz in Tooltip, see [Create Views in Tooltips \(Viz in Tooltip\)](#).

### The images aren't displaying in View in Thumbnail

View Thumbnail is processed with server-side rendering, which allows you to load up to 100 images per field. Verify that you have fewer than 100 images per field and try again.

For more about server and client-side rendering, see [Configure Client-Side Rendering](#).

## The images aren't displaying when I export my workbook

All exports and export-related features are processed with server-side rendering, which allows you to load up to 100 images per field. Verify that you have fewer than 100 images per field and try again.

## The images aren't displaying on a mobile device

Mobile devices have a lower complexity threshold than computers, so the processing is completed through server-side rendering, which allows you to load up to 100 images per field. Verify that you have fewer than 100 images per field and try again.

You can change the complexity settings on your mobile device. For more info on complexity thresholds, see [Configure the complexity threshold for computers and mobile devices](#).

# Organize and Customize Fields in the Data Pane

The Data pane has many features to help you organize and customize your fields.

Group and sort options are only available for relational data sources—not for cubes (multidimensional data sources).

## Organize the Data Pane

Single table data sources default to grouping by folder. Multi-table data sources default to grouping fields by the table they came from.

Grouping by folder lets you manually decide how to organize fields.

Grouping by table puts dimensions and measures together under their table. This structure is useful when fields with similar names appear in multiple tables.

Regardless of the default, you can switch between grouping by data source table and grouping by folder.

**Tip:** You can change between grouping by folder or grouping by table at any time. All folder information is preserved.

## Group by folder

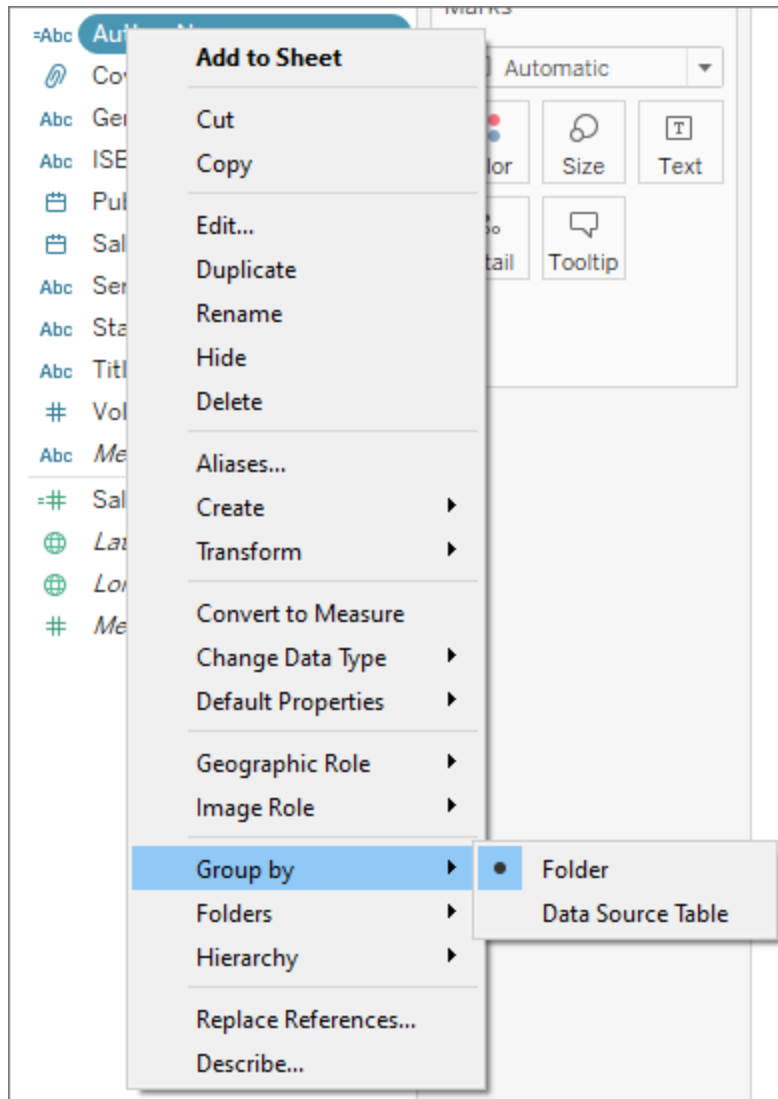

Items in the Data pane like fields, parameters, and sets can be manually grouped into folders.

- Open the Data Pane menu (under the data sources) and select **Group by Folder**.

- Or right-click on a field in the Data pane and select **Group by > Folder**.

**Note:** Many of the context menus in the Data pane change depending on how you access them. If the menu doesn't have what you're looking for, try opening the menu from another place. It's accessible from right-clicking on a field, right-clicking on white space in the Data pane, or using the drop-down menu by the search bar.

Some options only appear or are grayed out based on other settings (such as Create folder).

Before folders are set up, all fields are listed together with dimensions at the top and measures at the bottom.

## Create folders

After you set the Group by option to Folder, you must create your folders.

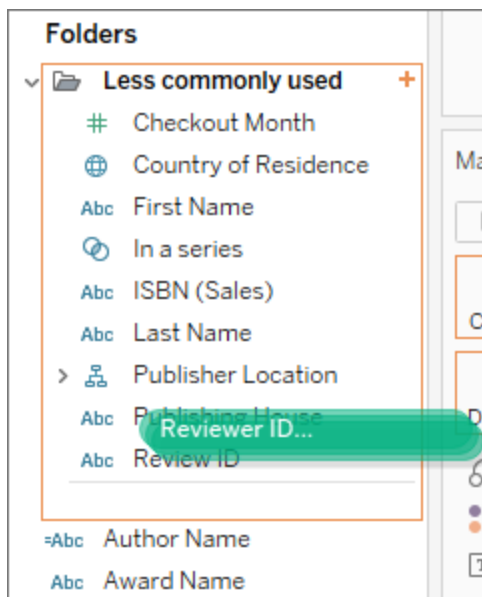

1. In the Data pane, select the fields you want to group together and right-click (or right-click an empty area in the Data pane).
2. Select **Folders > Create Folder**.
3. When prompted, name the new folder.

Folders are sorted alphabetically in the Data pane. You can start the folder name with a number to force them to appear in a specific order.

## Add fields to folders

After you create the folder structure, it's time to put fields in the folders.

- Drag a field on top of the folder name. If the folder is expanded, you can drag the field into the general area of the folder.

- Or you can right click on a field and select **Folder > Add to Folder >** then choose the

desired folder.

Fields can only appear in one folder, but you can duplicate (right-click > Duplicate) a field you want to have available in more than one folder.

## Sort fields in the Data pane

Whether they're grouped by table or by folder, you can configure how fields are sorted. These **Sort by** options are also in the Data pane menu.

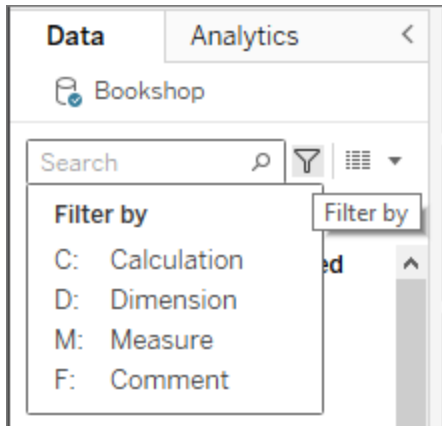

You can sort by one of the following options:

- **Sort by Name.** Lists the dimensions and measures in alphabetical order according to their field aliases.
- **Sort by Data Source Order.** Lists the dimensions and measures in the order they're listed in the underlying data source.

## Find fields

You can filter the Data pane to only show certain types of fields. Select the **Filter by** icon next to the search box to show the clickable list of options: dimensions, measures, calculations, or fields with comments. Clear the filter using the X in the search box.

## Search for a field

You can search the Data pane for items like fields, folders, or hierarchies.

1. Click into the search bar at the top of the Data pane under the data sources.
2. As you type in the search box, the contents of the Data pane are filtered to show items that contain the typed string.

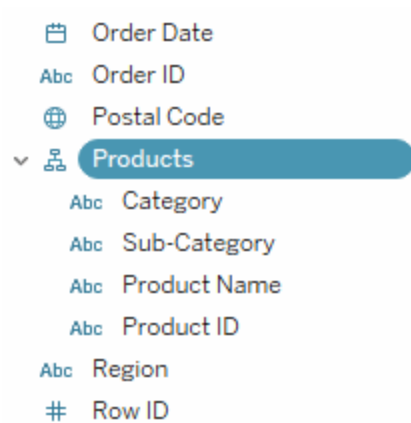

3. Use the **Filter by** prefixes to limit your search to specific types of fields, such as typing "D:" before searching "name" to return only dimensions that contain the string "name".
  - **C:** for calculations
  - **D:** for dimensions
  - **M:** for measures
  - **F:** for fields with comments

## Rename Fields

You can rename fields in the Data pane. For example, you could rename a field named **Customer Segment** in the data source to be **Business Segment** in Tableau. You can also rename user-created fields. Renaming a field doesn't change the name of the field in the underlying data source, rather it's given a special name that appears only in Tableau workbooks. The changed field name is saved with the workbook and when you export the data source. You can rename any type of field: dimensions, measures, sets, or parameters.

### Rename a field

1. Click field name in the Data pane and hold the mouse button down until the field name is shown in an edit box:

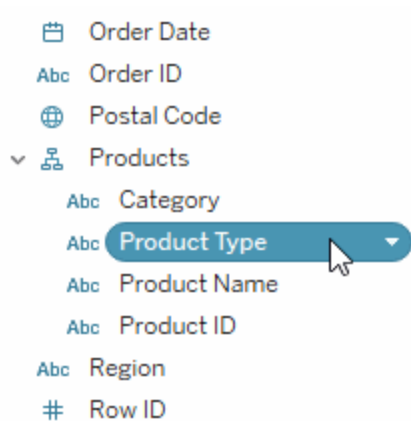

You can also press F2 or Ctrl + Enter to make the field name editable.

2. Type the new name for the field and press Enter.

The field displays with the new name in the Data pane.

## Revert to the Default Field Name

To revert a field's name, click the field name in the Data pane and hold the mouse button down until the name is shown in the box. At the right of the edit field is a small circular arrow that you can click to restore the original data source field name:

To revert the names of multiple fields that were in the original data source, select them all, right-click, and then choose **Reset Names**.

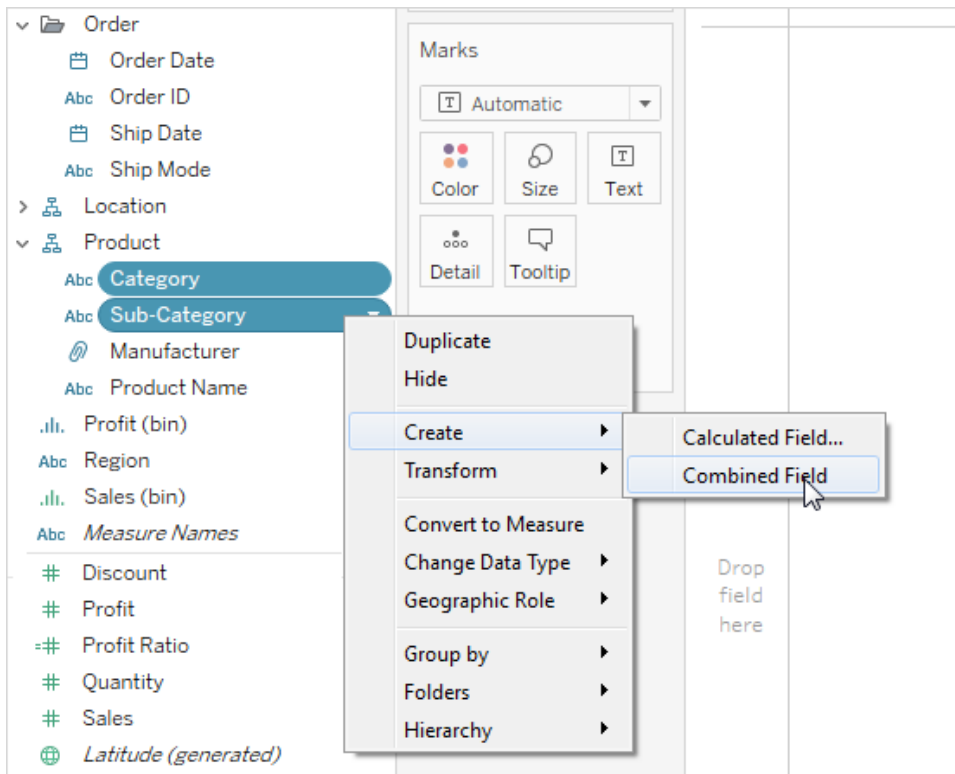

## Combine Fields

Combine fields to create a cross product of members from different dimensions. You can combine dimensions if you want to encode a data view using multiple dimensions.

To combine the fields, select multiple dimensions in the Data pane and then right-click (control-click on a Mac) the fields and select **Create > Combined Field**.

**Note:** For cube (multidimensional) data sources, you must select levels from different hierarchies. In Tableau, cube data sources are supported only in Windows.

For example, the selections in the example produce a new field that consists of the Category and Sub-Category dimensions.

The two dimensions are combined into a new dimension. The name of the field is automatically created from the names of the original fields. Right-click (control-click on a Mac) the new field and select **Rename** to change the name.

When you use the new field in a view, a header is created for each combination of the two original dimensions. For example, the following view shows the members of the combined Category and Sub-Category fields.

Sub-Category & Category ..	Region		
	Central	East	South
Accessories, Technology	\$33,956	\$45,033	\$27,277
Appliances, Office Supplies	\$23,582	\$34,188	\$19,525
Art, Office Supplies	\$5,765	\$7,486	\$4,656
Binders, Office Supplies	\$56,923	\$53,498	\$37,030
Bookcases, Furniture	\$24,157	\$43,819	\$10,899
Chairs, Furniture	\$85,231	\$96,261	\$45,176
Copiers, Technology	\$37,260	\$53,219	\$9,300
Envelopes, Office Supplies	\$4,637	\$4,376	\$3,346
Fasteners, Office Supplies	\$778	\$820	\$503
Furnishings, Furniture	\$15,254	\$29,071	\$17,307
Labels, Office Supplies	\$2,451	\$2,603	\$2,353

**Note:** For cube data sources, to choose to display the fully qualified name, right-click (control-click on a Mac) the combined field in the Data pane and select **Qualify Member Names**.

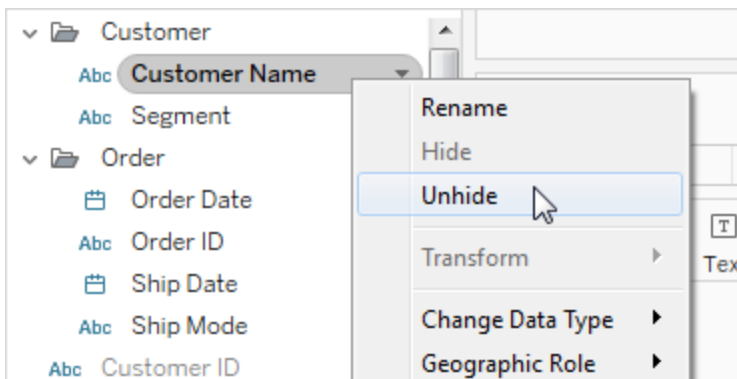

## Hide or Unhide Fields

You can selectively hide or show fields in the Data pane. To hide a field, right-click (control-click on a Mac) the field and select **Hide**.

When you want to change your fields from hidden to visible, select **Show Hidden Fields** on the Data pane menu.

The hidden fields are then shown in gray in the Data pane. You can then select one or more hidden fields, right-click (control-click on a Mac) and select **Unhide**.

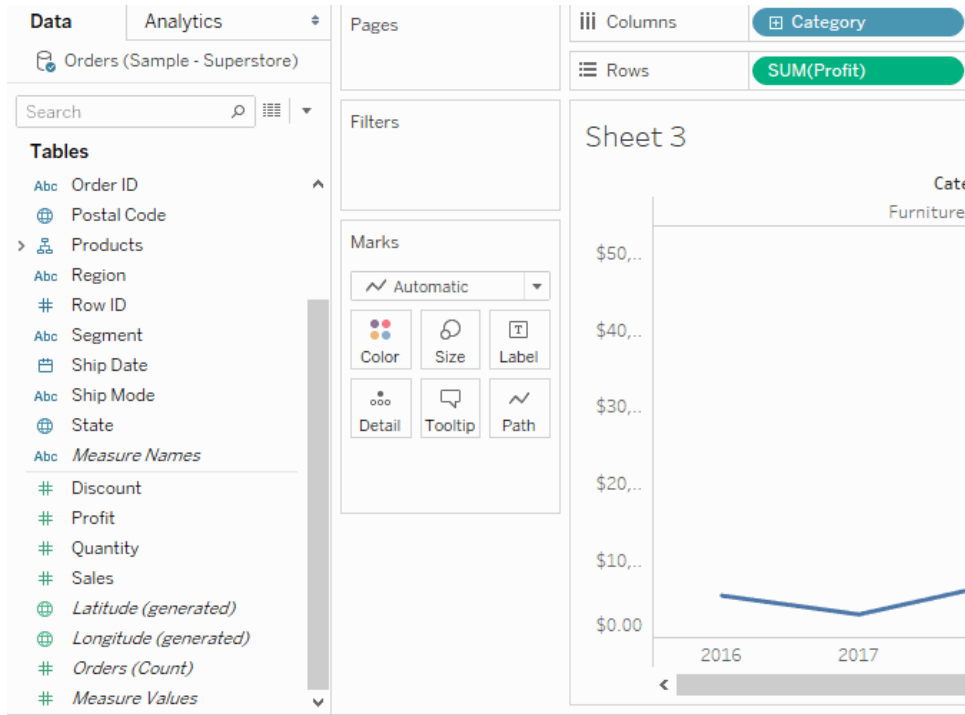

Select **Hide All Unused Fields** on the Data pane menu to quickly hide all the fields that aren't being used in the workbook.

**Note:** Hiding fields can be a good way to decrease the size of a data extract file because hidden fields are automatically excluded from the extract.

## Add Calculated Fields to the Data Pane

You can create calculated fields that appear in the Data pane. These new computed fields can be used like any other field. Select **Create Calculated Field** on the Data pane menu. Alternatively, select **Analysis > Create Calculated Field**.

## Edit Default Settings for Fields

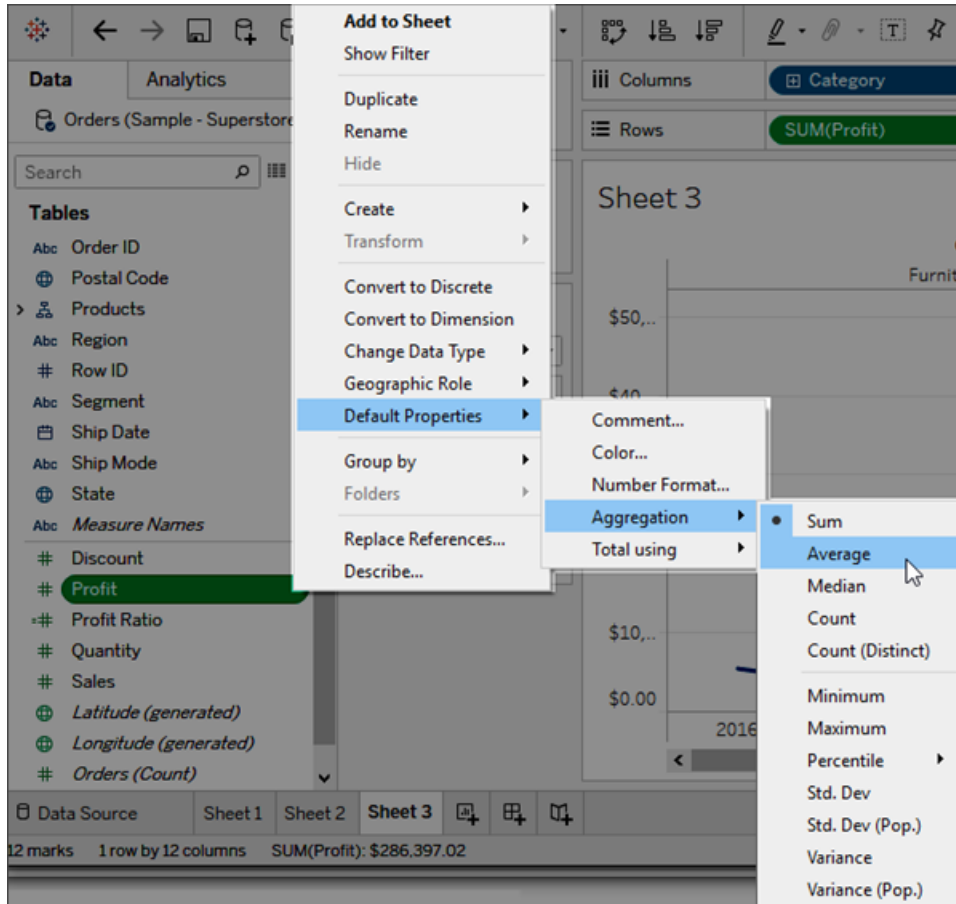

When you drag fields to shelves, the data is represented as marks in the view. The fields and their marks are displayed initially based on their default settings. You can control these default settings by clicking the drop-down arrow on a field.

The **Default Properties** menu includes default settings for aggregation, comments, number formatting, color, shape, and totals (based on the type of field).

## Set the default aggregation for a measure

You can specify a default aggregation for any measure. The default aggregation will be used automatically when the measure is first totaled in the view.

1. Right-click (control-click on a Mac) any measure in the Data pane and select **Default Properties > Aggregation**.
2. In the Aggregation list, select an aggregation.

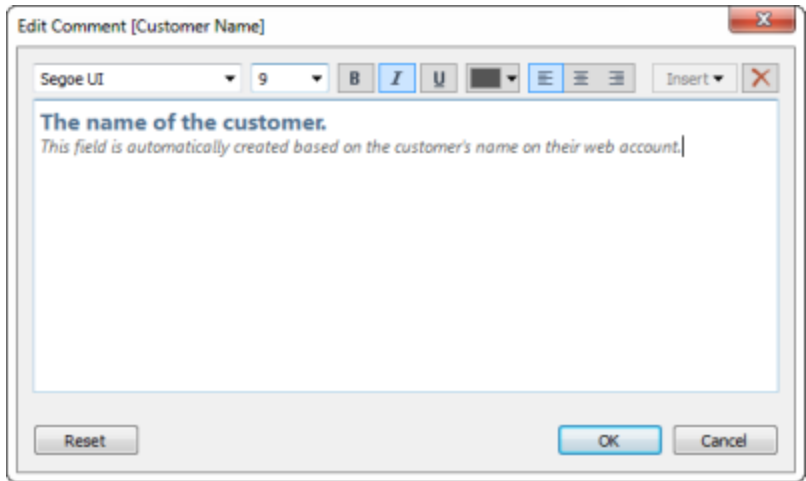

Whether you are specifying the aggregation for a field on a shelf or the default aggregation in the Data pane, you can select from several aggregations. See [Data Aggregation in Tableau on page 173](#) to learn about each type of aggregation.

## Add default comments for specific fields

Fields can have comments that describe them. The comments display in a tooltip in the Data pane and in the Calculated fields dialog box. Field comments are a good way to give more context to the data in your data source. Comments are especially useful when you are building a workbook for others to use.

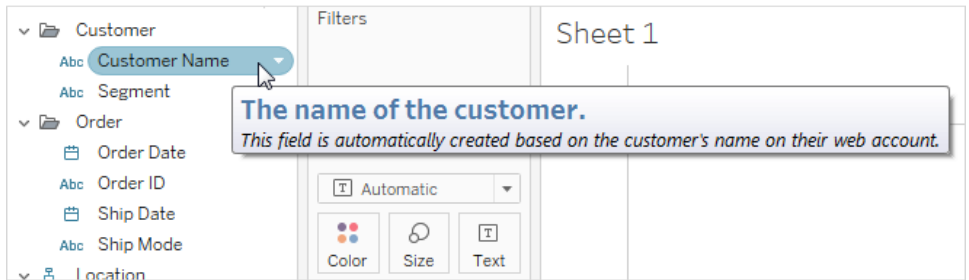

### To add a default comment for a field

1. Right-click (control-click on a Mac) a field in the Data pane and select **Default Properties > Comment**.
2. Write a comment in the subsequent dialog box. Comments support rich text formatting that will be represented in the tooltip.

3. When finished, click **OK**.

Now when you hover the cursor over the field in the Data pane, you see the comment.

### Set the default number format

You can set the default number format for date and number fields. For example, you may want to always show the Sales values as currency using the U.S. dollar sign and two decimal places. Or you may want to always show Discount as a percentage.

To set the default formats, right-click (control-click on Mac) a date or number field and select either **Date Format** or **Number Format** on the Default Properties menu. A dialog box opens where you can specify a default format.

## Set the default color

When you use a dimension to color encode the view, default colors are assigned to the field's values. Color encodings are shared across multiple worksheets that use the same data source to help you create consistent displays of your data. For example, if you define the Western region to be green, it will automatically be green in all other views in the workbook. To set the default color encodings for a field, right-click (control-click on Mac) the field in the Data pane and select **Default Properties > Color**.

For information about color properties, and how to configure and customize colors in Tableau, see [Color Palettes and Effects](#) on page 1237,

## Set the default shape

When you use a dimension to shape encode the view, default shapes are assigned to the field's values. Shape encodings are shared across multiple worksheets that use the same data source to help you create consistent displays of your data. For example, if you define that Furniture products are represented with a square mark, it will automatically be changed to a square mark in all other views in the workbook.

To set the default shape encodings for a field, right-click (control-click on Mac) the field in the Data pane and select **Default Properties > Shape**.

## Set the default sort order for the values within a categorical field

You can set a default sort order for the values within a categorical field so that every time you use the field in the view, the values will be sorted correctly. For example, let's say you have an Order Priority field that contains the values High, Medium, and Low. When you place these in the view, by default they will be listed as High, Low, Medium because they are shown in alphabetical order. You can set a default sort so that these values are always listed correctly.

To set the default sort order, right-click (control-click on a Mac) a dimension and select **Default Properties > Sort**. Then use the sort dialog box to specify a sort order.

**Note:** The default sort order also controls how the field values are listed in a filter in the view.

## Create Aliases to Rename Members in the View

You can create aliases (alternate names) for members in a dimension so that their labels appear differently in the view.

Aliases can be created for the members of discrete dimensions only. They can't be created for continuous dimensions, dates, or measures.

## Create an alias

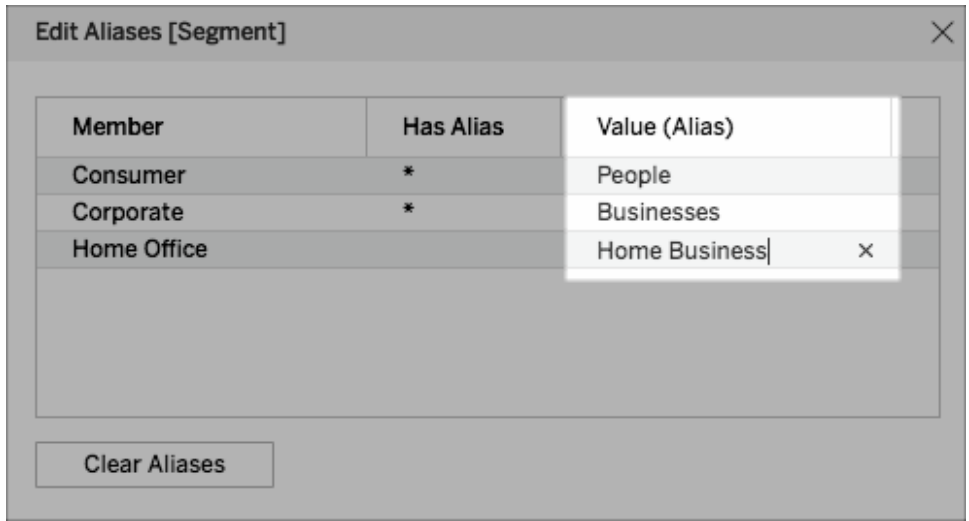

1. In the Data pane, right-click a dimension and select **Aliases**.

**Tip:** If the **Aliases** option doesn't appear in the dialog, verify that you aren't connected to a published data source and the field you're trying to alias is a discrete dimension.

2. In the Edit Aliases dialog box, under **Value (Alias)**, select a member and enter a new name.

**Tip:** To reset the member names back to their original names, click **Clear Aliases**.

3. To save your changes:
  - In Tableau Desktop, click **OK**.
  - On Tableau Server or Tableau Cloud, click the **X** icon in the top-right corner of the dialog box.

When you add the field to the view, the alias names appear as labels in the view. For example,

### When the Alias option isn't available

#### Measures can't be re-aliased

Tableau doesn't permit re-aliasing measures because it involves modifying data values themselves. If you have a field in your data that contains values such as *0* and *1* but actually encodes information such as *no* and *yes*, Tableau interprets this as a continuous measure. You

can convert it to a discrete dimension and then re-alias the values. For more information about discrete vs continuous and dimensions vs measures, see:

- [Dimensions and Measures, Blue and Green](#) on page 148
- [Convert a Measure to a Dimension](#) on the facing page
- [Convert Fields between Discrete and Continuous](#) below

## Published data sources

Alternatively, the Alias option can be missing for a discrete dimension because you're connected to a published data source. When using a published data source, you can't create or edit aliases. You can only change aliases on fields that you create in your workbook. You can edit aliases for the Measure Names field on the published datasource unless they have been set before publishing. If you didn't publish the data source, you can duplicate the field (right click > **Duplicate**) and edit aliases for the duplicate field without restriction.

## Convert Fields between Discrete and Continuous

You can convert measures from discrete to continuous or from continuous to discrete. And you can convert date dimensions and other numeric dimensions to be either discrete or continuous. For more information on continuous and discrete fields, see [Dimensions and Measures, Blue and Green](#) on page 148.

You can also [Convert a Measure to a Dimension](#) on the facing page.

### Convert measures

You can convert measures from discrete to continuous or from continuous to discrete. Click the field and choose **Discrete** or **Continuous**. The field is green when it is continuous, and blue when it is discrete.

For measures in the **Data** pane, right-click the field and choose **Convert to Discrete** or **Convert to Continuous**. The color of the field changes accordingly.

### Convert date fields

You can convert Date fields between discrete and continuous. Discrete dates act as labels and continuous dates will have an axis similar to a measure.

Click any Date field in the view and choose one of the options on the context menu to change it from discrete to continuous or from continuous to discrete.

To convert a Date field in the **Data** pane (and thus to determine the default result when you drag it into a view), right-click the field and choose **Convert to Discrete** or **Convert to Continuous**.

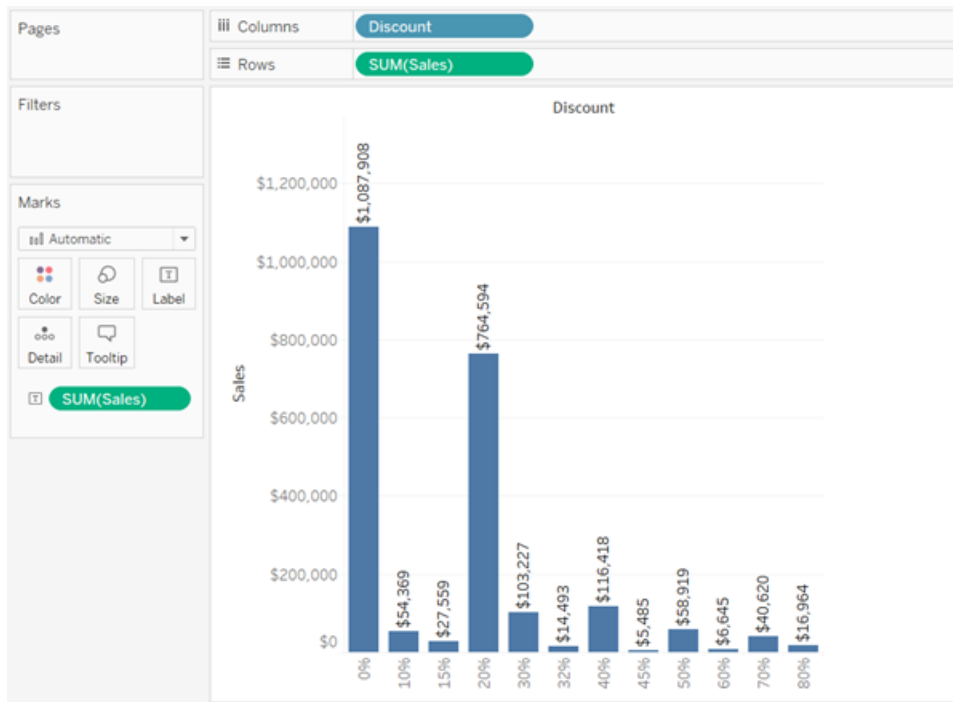

## Convert a Measure to a Dimension

You can convert a field from a measure to a dimension in the current view. Or, if you want the change to affect all future uses of the field in the workbook, you can convert a field in the **Data** pane from a measure to a dimension. For more information on dimensions and measures, see [Dimensions and Measures, Blue and Green](#) on page 148.

You can also [Convert Fields between Discrete and Continuous](#) on the previous page.

### Convert a measure in the view into a discrete dimension

You can drag a measure field from the **Data** pane but then use it as a dimension in the view. For example, suppose you want to know the aggregated sales totals for each possible discount rate. The view you are aiming for looks like this:

The **Discount** field contains numeric data, so when you connect to the data source, Tableau assigns it to the **Measures** area in the **Data** pane. In the **Sample - Superstore** data source, which is included with Tableau Desktop, the values for **Discount** range from 0% to 80%.

Here are the steps to create the view shown above:

1. Drag **Sales** to **Rows** and **Discount** to **Columns**. Tableau shows you a scatter plot—this is the default chart type when you put one measure on **Rows** and another on **Columns**.

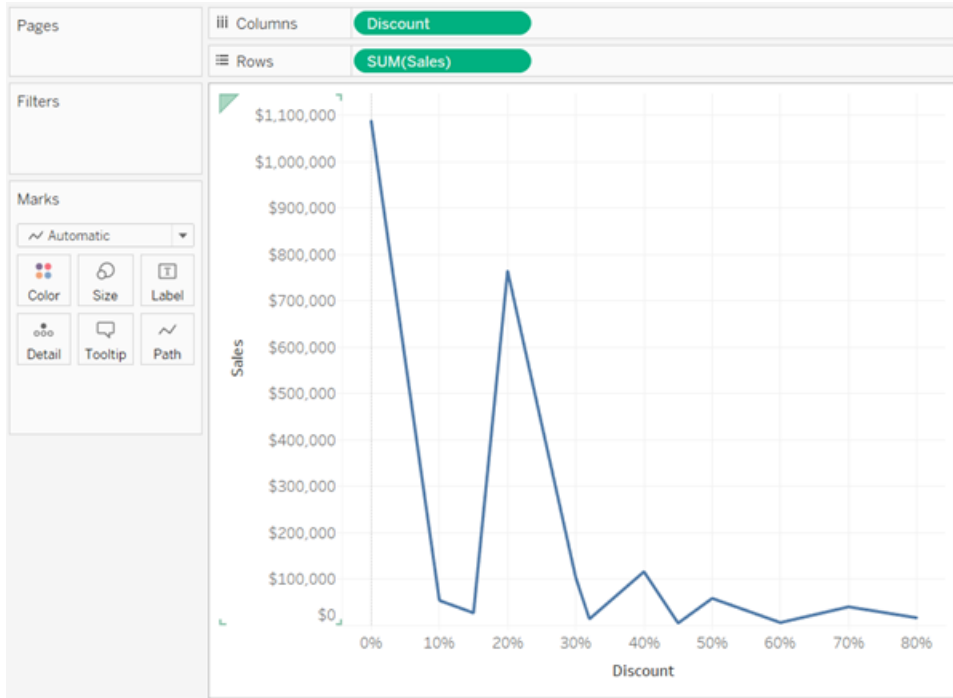

Tableau aggregates **Discount** as AVG, and **Sales** as SUM. The fields are both continuous, so along the bottom and left side of the view Tableau displays axes (and not column or row headers).

2. To treat **Discount** as a dimension, click the drop-down arrow on the field (on the **Columns** shelf) and select **Dimension** from the context menu. Tableau no longer aggregates the values for **Discount**, so what you see now is a line. But the values for **Discount** are still continuous, so Tableau still shows continuous axes for both fields:

- To complete the process, click the drop-down arrow on the **Discount** again and select **Discrete** from the context menu. The transformation of **Discount** is now complete. You now see the bar chart as in the initial image at the beginning of this topic. Across the bottom, you now see column headers (0%, 10%, 20%, etc.) instead of an axis.

Let's review how we got to this point:

Action	Result
Convert <b>Discount</b> from a measure to a dimension...	Sales values are no longer aggregated according to discount rate, resulting in a line chart instead of a scatter plot.
Convert <b>Discount</b> from continuous to discrete...	Tableau shows headers at the bottom of the view, instead of a continuous axis.

The only thing left to do is to drag **Sales** to Label and then format the labels for readability.

The resulting chart is somewhat useful because there are only 12 unique values for **Discount** in the data source. Had there been a unique value for each row, which would not have been unusual for a numeric field, the number of individual bars in the resulting view would have been equal to the number of rows in the data source, which would probably not result in a useful visualization.

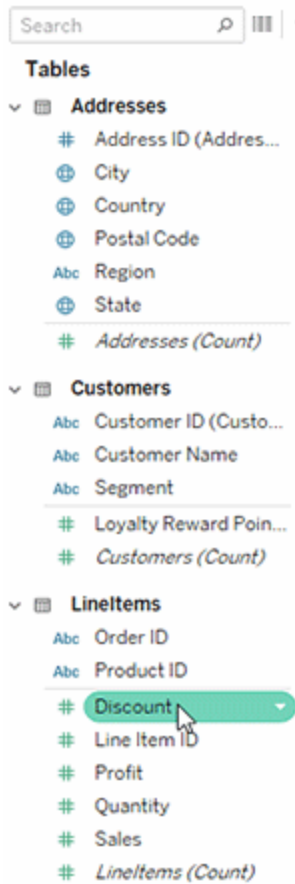

## Converting a measure in the Data pane into a dimension

When you first connect to a data source, Tableau assigns most fields that contain quantitative, numerical information (that is, fields where the values are numbers) as measure fields in the **Data** pane. The exception is for fields where the name suggests the data type, such as Year or Month (which Tableau would identify as Date dimensions) or fields containing words like “ID” and “Key,” which Tableau would categorize as dimensions, even when they are numeric.

However, you might decide that some of these fields that Tableau has categorized as measures should actually be dimensions. Postal codes are a classic example—they often consist entirely of numbers, but the information is categorical and not continuous—you would never want to aggregate postal codes by adding or averaging them. Similarly, a field containing individuals' ages may be categorized as a measure by default in Tableau because it contains numeric data. In some cases you may want to add or average ages, but you might also want to look at each individual age as a bin or category, in which case you want Tableau to create headers for this field rather than an axis. If this is how you want to use age in your view, you can convert the field to a dimension.

To convert a measure to a dimension in the **Data** pane, do either of the following.

- Click and drag the field from a measures area in the **Data** pane and drop it into a dimensions area (above the line).

- Right-click (control-click on a Mac) the measure in the **Data** pane and select **Convert to Dimension**.

If you place a field that you converted from a measure to a dimension on a shelf, it now produces headers instead of an axis.

Columns		Category		
Rows		Quantity		
Quantity	Furniture	Office Supplies	Technology	
1	\$18,491	\$17,224	\$17,536	
2	\$87,642	\$94,617	\$106,832	
3	\$137,952	\$142,844	\$141,265	
4	\$85,081	\$88,262	\$150,328	
5	\$127,640	\$136,841	\$151,180	
6	\$73,934	\$65,456	\$67,732	
7	\$69,862	\$74,779	\$95,267	
8	\$43,690	\$36,475	\$37,595	
9	\$55,255	\$32,040	\$41,211	
10	\$13,438	\$3,864	\$6,755	
11	\$7,035	\$3,695	\$5,042	
12	\$8,783	\$2,342	\$3,743	
13	\$8,300	\$15,895	\$8,143	
14	\$4,896	\$4,712	\$3,524	

## Create Hierarchies

When you connect to a data source, Tableau automatically separates date fields into hierarchies so you can easily break down the viz. You can also create your own custom hierarchies. For example, if you have a set of fields named Region, State, and County, you can create a hierarchy from these fields so that you can quickly drill down between levels in the viz.

### Create a hierarchy

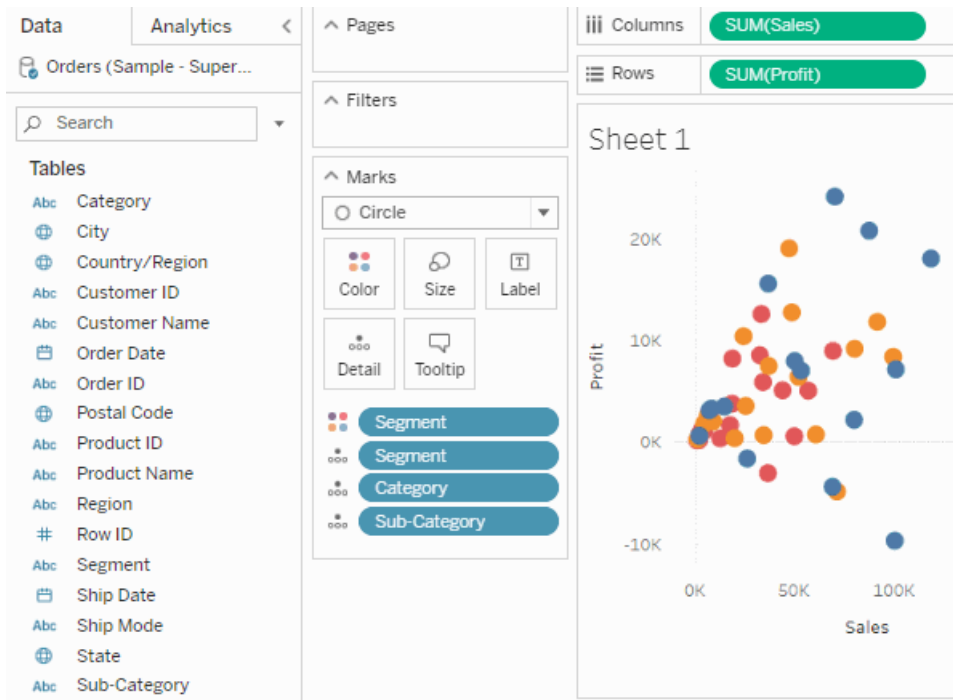

To create a hierarchy:

1. In the **Data** pane, drag a field and drop it directly on top of another field.

**Note:** When you want to create a hierarchy from a field inside a folder, right-click (control-click on a Mac) the field and then select **Create Hierarchy**.

2. When prompted, enter a name for the hierarchy and click **OK**.
3. Drag additional fields into the hierarchy as needed. You can also re-order fields in the hierarchy by dragging them to a new position.

## Drill up or down in a hierarchy

When you add a field from a hierarchy to the visualization, you can quickly drill up or down in the hierarchy to add or subtract more levels of detail.

To drill up or down in a hierarchy in Tableau Desktop or in web authoring:

- In the visualization, click the + or - icon on the hierarchy field.

When you are editing or viewing the visualization on the web, you have the option of clicking the + or - icon next to a field label.

Sales by Product Category

		Jan	Feb	Mar	Apr
<b>Furniture</b> 	2011	\$5,952	\$2,130	\$14,574	\$7,945
	2012	\$11,740	\$3,319	\$12,315	\$10,476
	2013	\$7,623	\$3,926	\$12,473	\$13,406

## Remove a hierarchy

To remove a hierarchy:

- In the **Data** pane, right-click (control-click on a Mac) the hierarchy and select **Remove Hierarchy**.

The fields in the hierarchy are removed from the hierarchy and the hierarchy disappears from the Data pane.

## Group Your Data

You can create a group to combine related members in a field. For example, if you are working with a view that shows average test scores by major, you might want to group certain majors together to create major categories. English and History might be combined into a group called Liberal Arts Majors, while Biology and Physics might be grouped as Science Majors.

Groups are useful for both correcting data errors (e.g., combining CA, Calif., and California into one data point) as well as answering "what if" type questions (e.g., "What if we combined the East and West regions?").

### Create a group

There are multiple ways to create a group. You can create a group from a field in the **Data** pane, or by selecting data in the view and then clicking the group icon.

#### Create a group by selecting data in the view

1. In the view, select one or more data points and then, on the tooltip that appears, click the

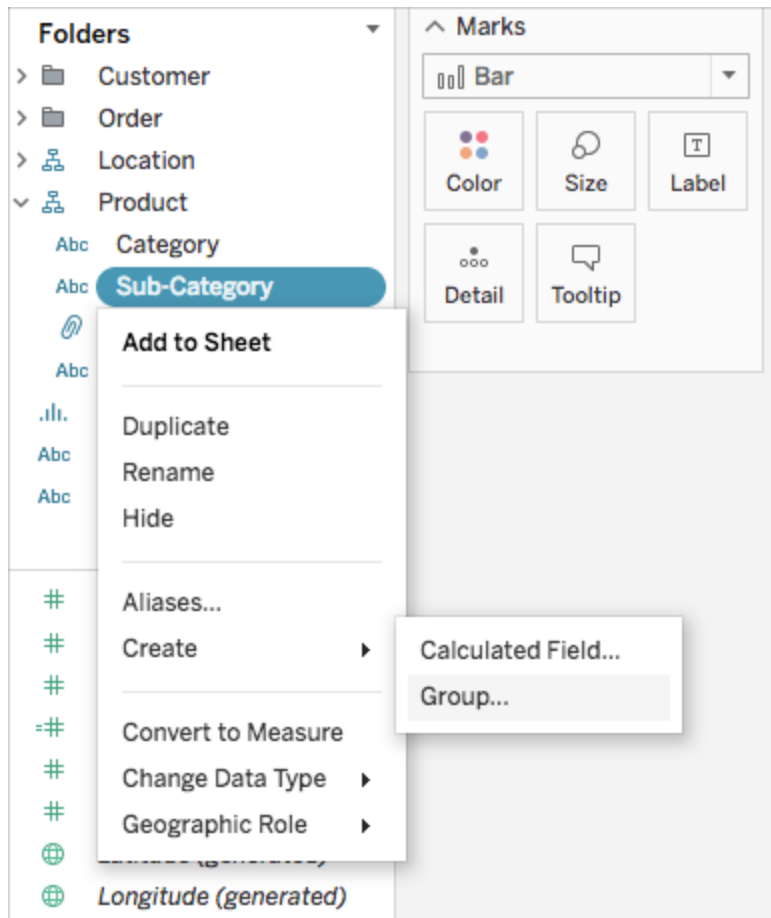

group icon  .

**Note:** You can also select the group icon on the toolbar at the top of the workspace.

If there are multiple levels of detail in the view, you must select a level to group the members. You can select to group all dimensions, or just one.

## Create a group from a field in the Data pane

1. In the **Data** pane, right-click a field and select **Create > Group**.

2. In the Create Group dialog box, select several members that you want to group, and then

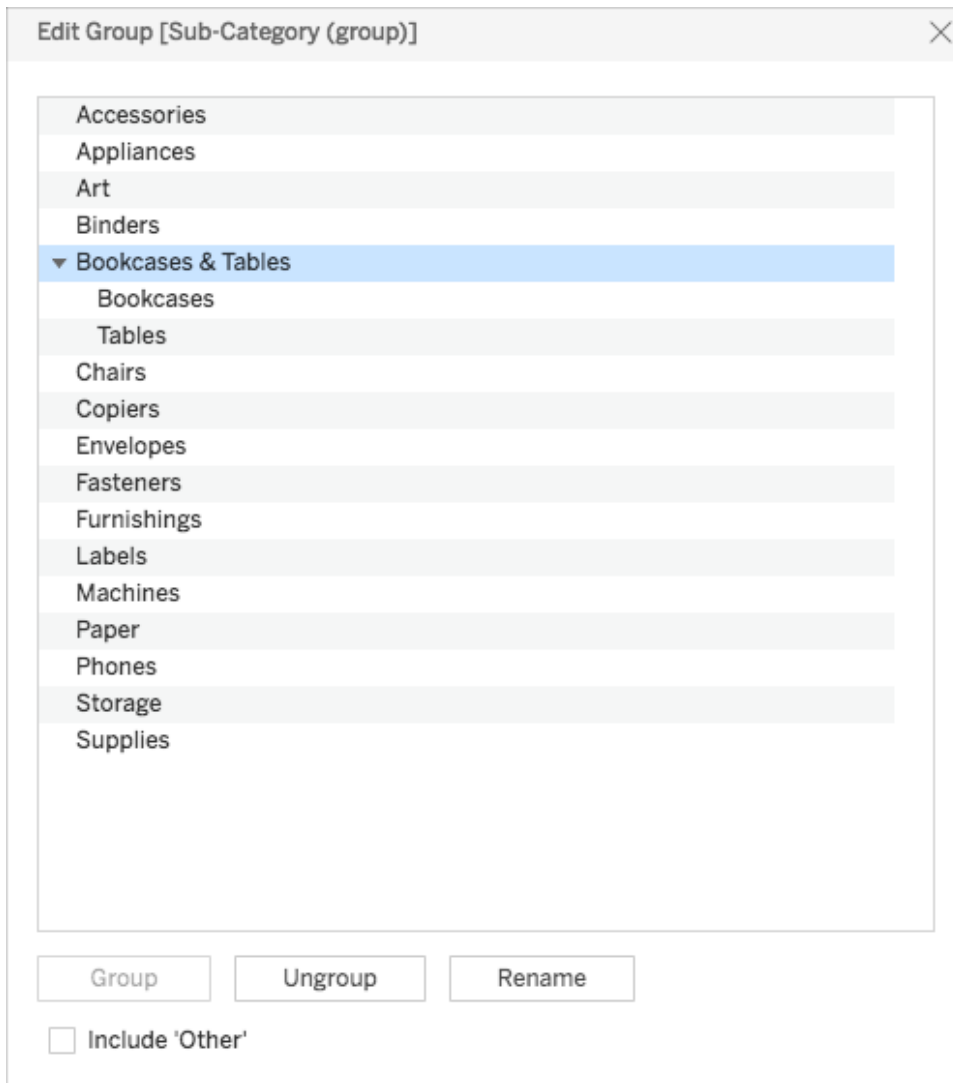

click **Group**.

The selected members are combined into a single group. A default name is created using the combined member names.

To rename the group, select it in the list and click **Rename**.

**Tip:** You can search for members using the **Find** option near the bottom-right of the dialog box. (Tableau Desktop only)

## Include an Other Group

When you create groups in Tableau, you have the option to group all remaining, or non-grouped members in an Other group.

The Include Other option is useful for highlighting certain groups or comparing specific groups against everything else. For example, if you have a view that shows sales versus profit product category, you might want to highlight the high and low performing categories in the view, and group all the other categories into an "Other" group.

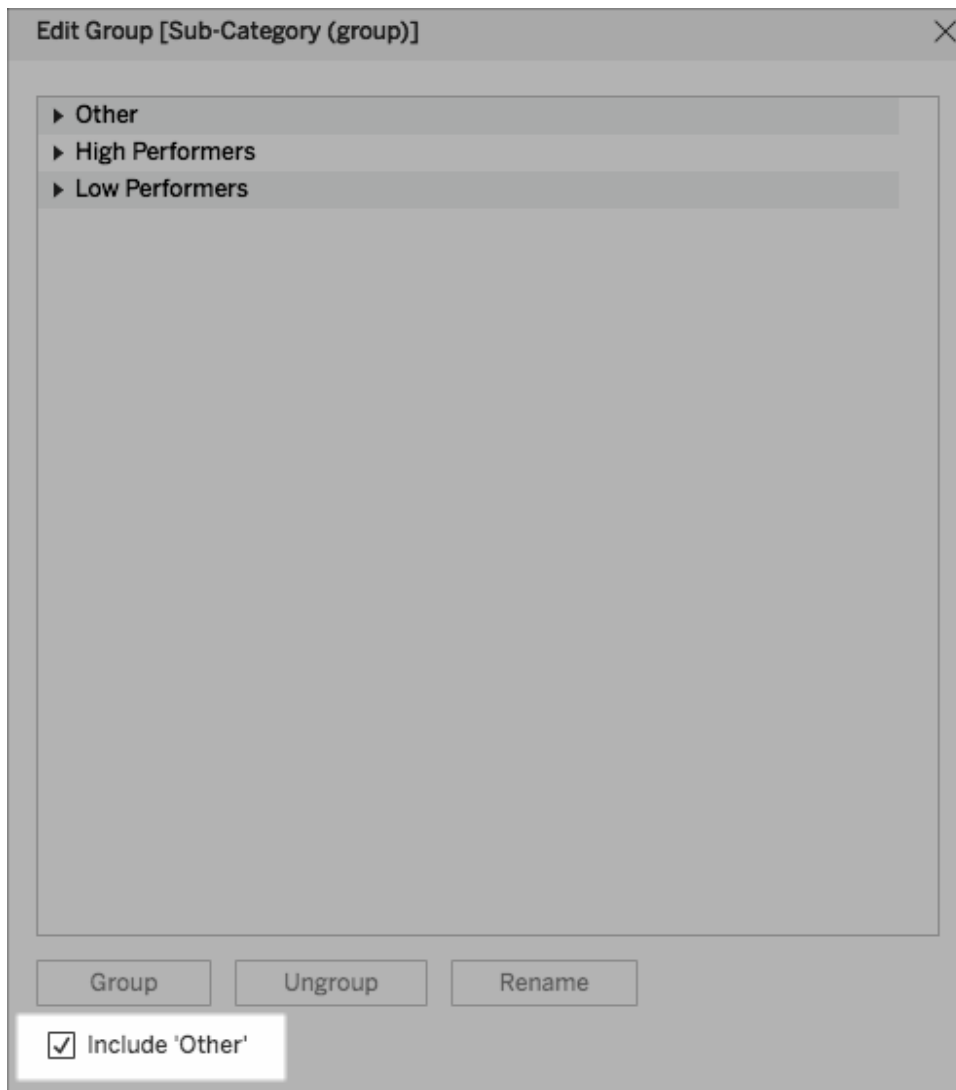

**Includes Other**

**Does not include Other**

To include an Other group:

1. In the **Data** pane, right-click the group field and select **Edit Group**.
2. In the Edit Group dialog box, select **Include 'Other'**.

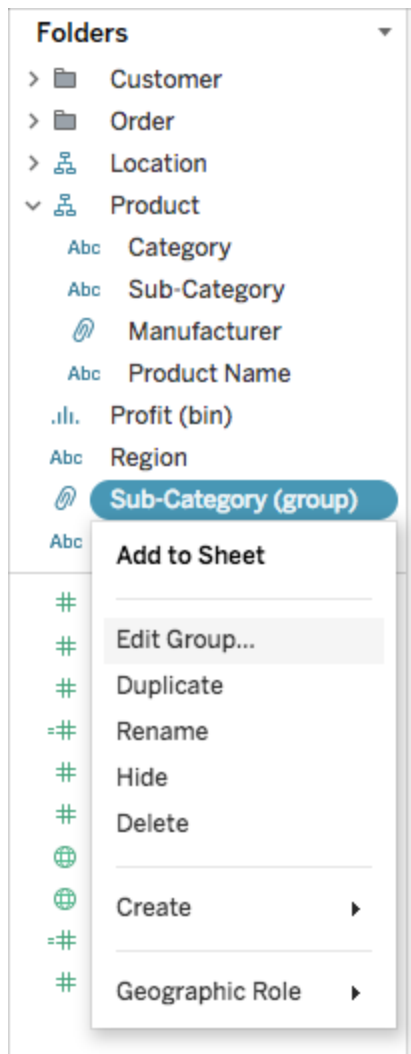

## Edit a Group

After you have created a grouped field, you can add and remove members from the groups, create new groups, change the default group names, and change the name of the grouped field. You can make some changes directly in the view, and others through the Edit Group dialog box.

**To add members to an existing group:**

- In the **Data** pane, right-click the group field, and then click **Edit Group**.

- In the Edit Group dialog box, select one or more members and drag them into the group you want.
- Click **OK**.

#### To remove members from an existing group:

- In the **Data** pane, right-click the group field, and then click **Edit Group**.
- In the Edit Group dialog box, select one or more members, and then click **Ungroup**.

The members are removed from the current group. If you have an Other group, the

members are added to it.

- Click **OK**.

#### To create a new group in a group field:

- In the **Data** pane, right-click the group field, and then click **Edit Group**.
- In the Edit Group dialog box, select one or more members, and then click **Group**.
- Click **OK**.

**Note:** To rename a group, select the group in the Edit Group dialog box, and then click **Rename**.

## See also

[Color a View Using Groups](#) below

[Correct Data Errors or Combine Dimension Members by Grouping Your Data](#) on page 1038

## Color a View Using Groups

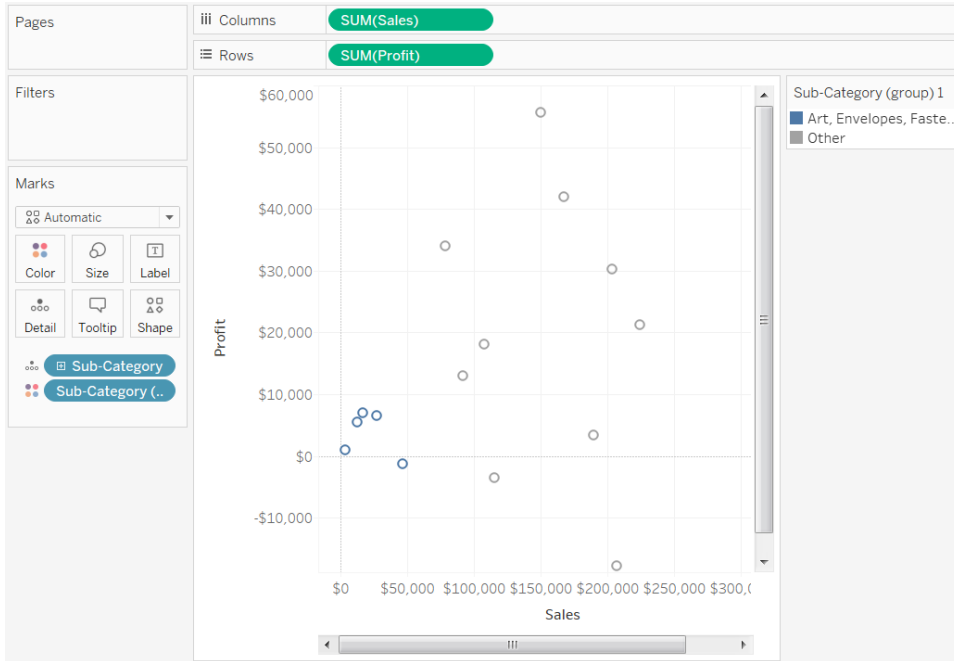

In addition to correcting data errors and combining dimensions, you can visually identify groups of related marks by selecting marks directly. This technique is especially useful when working with a scatter plot or a view that doesn't have headers that you can select when defining the group.

1. Press and hold the **CTRL** or **Shift** key on the keyboard to select one or more marks in the view. On a Mac, use the **Shift** key.
2. To create a group do one of the following:
  - For Tableau Desktop, click the **Group** button  on the toolbar or right-click and select **Group**.

- For Tableau Server or Tableau Cloud, click the **Group** icon on the tooltip.

The selected marks are grouped and all other members are combined into an "Other" category. The new group field is automatically added to Color. For more information about grouping fields using Other, see [Include an Other Group](#) on page 1030.

**Note:** If there were already fields on **Color**, they are moved to **Detail** and replaced with the group field.

When you create groups by selecting marks, it's possible that the marks will represent multiple dimensions. For example, you may have a scatter plot that shows the Sales vs. Profit by Region and Sub-Category. In this case, a selection of marks will represent members of both the Region and Sub-Category dimensions. When the selection represents multiple dimensions, the **Group** menu lets you choose to group on **All Dimensions** or on a particular dimension.

In the example above, the 5 selected marks represent a region and the following sub-category combinations .

- West, Copiers
- West, Binders
- West, Accessories
- East, Copiers
- Central, Copiers
- South, Art
- South, Envelopes
- South, Labels
- West, Envelopes
- West, Labels

The views below show the results of grouping these measures on All Dimensions, Sub-Category, and Region.

The 5 marks are combined and the rest of the marks are added to an "Other" category.

All marks associated with any of the three sub-categories are combined and everything

All marks associated with the four regions are combined and everything else is added

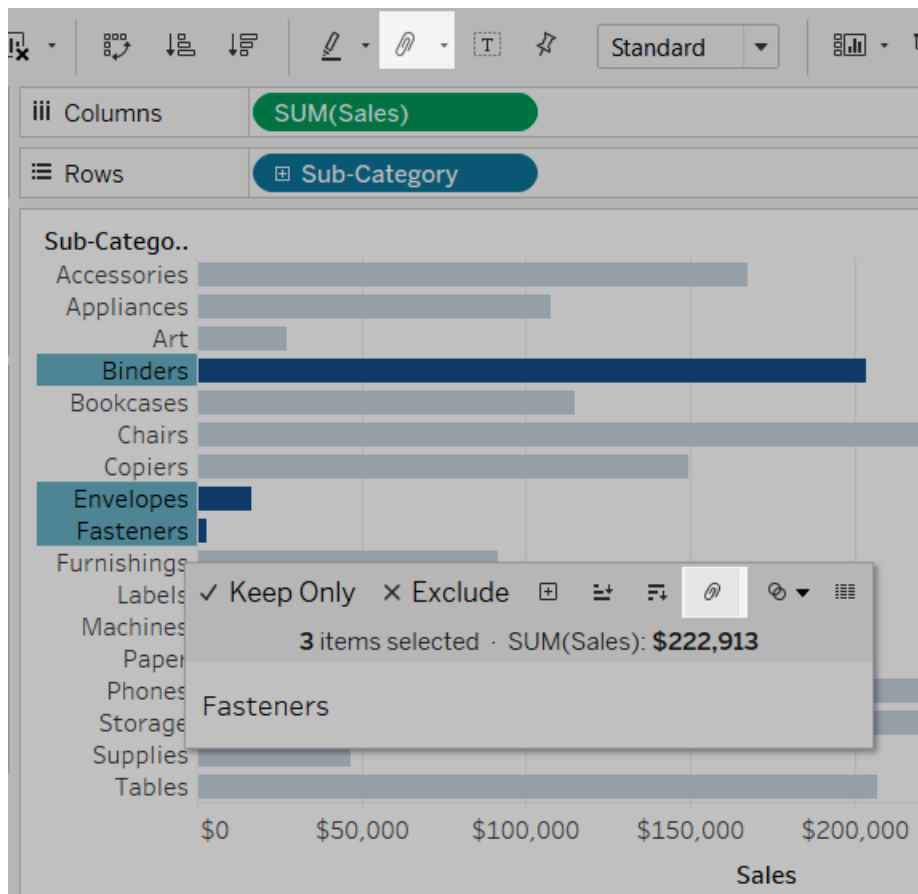

else is added to an "Other" category.

## Correct Data Errors or Combine Dimension Members by Grouping Your Data

If you are using groups to correct data errors (for example, to combine "CA" and "California") or to combine dimensions members (for example, to combine "East" and "West" regions), the easiest option is to select headers in the view.

1. Press and hold the **CTRL** or **Shift** key on the keyboard to multi-select headers in the view. On a Mac, press and hold the Command key.
2. To create a group, do one of the following:
  - On Tableau Desktop, click the **Group** button  on the toolbar, right-click and select **Group** or click the **Group** icon on the tooltip.

- On Tableau Server or Tableau Cloud, click the **Group** icon on the tooltip.

The selected members are combined into a single member. In this example, the view now shows the SUM(Sales) across all binders, envelopes and fasteners as a single mark. A default is automatically constructed using the combined member names. The dimension on the Rows or Columns shelf is replaced with the new grouped field.

## Create Sets

You can use sets to compare and ask questions about a subset of data. Sets are custom fields that define a subset of data based on some conditions.

You can make sets more dynamic and interactive by using them in [Set Actions on page 1379](#). Set actions let your audience interact directly with a viz or dashboard to control aspects of their analysis. When someone selects marks in the view, set actions can change the values in a set.

In addition to a Set Action, you can also allow users to change the membership of a set by using a filter-like interface known as a Set Control, which makes it easy for you to designate inputs into calculations that drive interactive analysis. For details, see [Show a set control in the view on page 1049](#).

### Create a dynamic set

There are two types of sets: dynamic sets and fixed sets. The members of a dynamic set change when the underlying data changes. Dynamic sets can only be based on a single dimension.

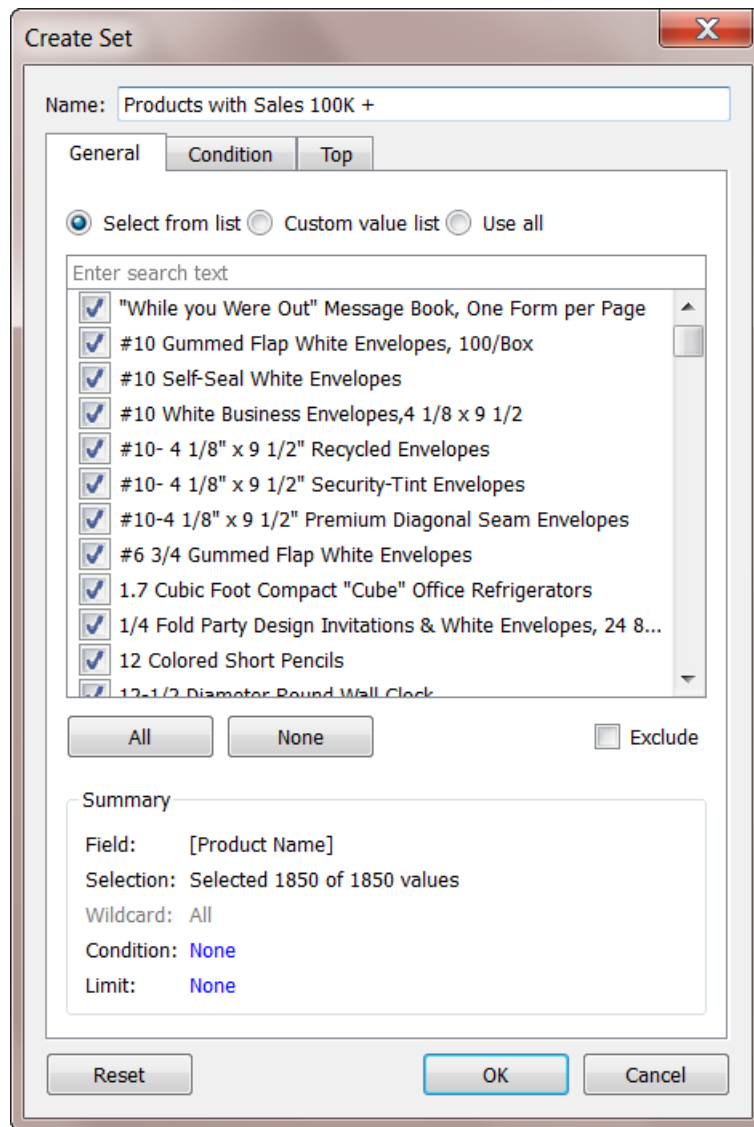

To create a dynamic set:

1. In the Data pane, right-click a dimension and select **Create > Set**.
2. In the Create Set dialog box, configure your set. You can configure your set using the following tabs:

- **General:** Use the General tab to select one or more values that will be considered when computing the set.

You can alternatively select the **Use all** option to always consider all members even when new members are added or removed.

- **Condition:** Use the Condition tab to define rules that determine which members to include in the set.

For example, you might specify a condition that is based on total sales that only includes products with sales over \$100,000.

**Create Set**

Name: Products with Sales 100K +

General Condition Top

None

By field:

Sales Sum

>= 100,000

Range of Values

Min: Load

Max:

By formula:

Reset OK Cancel

**Note:** Set conditions work the same as filter conditions. See [Filter Data from Your Views](#) on page 1252 to learn more.

- **Top:** Use the Top tab to define limits on what members to include in the set.

For example, you might specify a limit that is based on total sales that only includes the top 5 products based on their sales.

**Note:** Set limits work the same as Filter limits. See [Filter Data from Your Views on page 1252](#) to learn more.

3. When finished, click **OK**.

The new set is added to the bottom of the Data pane, under the Sets section. A set icon  indicates the field is a set.

## Create a fixed set

The members of a fixed set do not change, even if the underlying data changes. A fixed set can be based on a single dimension or multiple dimensions.

To create a fixed set:

1. In the visualization, select one or more marks (or headers) in the view.
2. Right-click the mark(s) and select **Create Set**.

3. In the Create Set dialog box, type a name for the set.
4. Optionally complete any of the following:
  - By default, the set includes the members listed in the dialog box. You can select the option to **Exclude** these members instead. When you exclude, the set will

include all of the members you didn't select.

- Remove any dimensions that you don't want to be considered by clicking the red "x"

icon that appears when you hover over a column heading

- Remove any specific rows that you don't want to include in the set by clicking the red "x" icon that appears when you hover over the row .
- If the marks you selected represent multiple dimensions, each member of the set will be a combination of those dimensions. You can specify the character that separates the dimension values. To do so, for **Separate members by**, enter a character of your choice.
- Select **Add to Filters shelf** to automatically move the set to the Filters shelf once it is created.

5. When finished, click **OK**.

The new set is added to the bottom of the Data pane, under the Sets section. A set icon  indicates the field is a set.

---

## Sets

-  State - High Sales & Profit
  -  Top Customers by Profit
- 

## Add or remove data points from sets

If you created a set using specific data points, you can add more data to or subtract data from the set.

### To add or remove data points from a set:

1. In the visualization, select the data points you want to add or remove.
2. In the tooltip that appears, click the Sets drop-down menu icon, and then select **Add to [set name]** or **Remove from [set name]** to add or remove data from a particular set.

## Use sets in the visualization

After you create a set, it displays at the bottom of the Data pane in the Sets section. You can drag it into the viz like any other field.

When you drag a set to the viz in Tableau Desktop, you can choose to show the members of the set or aggregate the members into In/Out categories.

In Tableau Server or Tableau Cloud you can only aggregate the members of the set into In/Out categories.

### Show In/Out members in a set

In most cases, when you drag a set to the viz, Tableau displays the set using the In/Out mode. This mode separates the set into two categories:

- In - The members in the set.
- Out - The members that aren't part of the set.

For example, in a set defined for the top 25 customers, the top customers would be part of the In category and all other customers would be part of the Out category.

Using the In/Out mode makes it easy to compare the members in the set to everything else.

**To show In/Out members in the visualization:**

- In Tableau Desktop, right-click the set in the visualization workspace and select **Show In/Out of Set**.

When a set is in In/Out mode, the field on the shelf is prefaced by the text, "IN/OUT", followed by the set name.

**Note:** In/Out mode is not available in workbooks created before version 8.2 that use Microsoft Excel or text file data sources, workbooks that use the legacy connection, or workbooks that use Microsoft Access data sources.

## Show members in a set

As an alternative to showing the set using In/Out mode, you can list the members in the set. Showing the members in the set automatically adds a filter to the view that includes only the members of the set.

### To switch a set to list the individual members:

- In the visualization workspace, right-click the set and select **Show Members in Set**.

**Note:** To display the fully qualified member names for cubes, right-click the set in the Data pane and select **Qualify Member Names**.

## Let users change set values

### Add a set action

You can use set actions to give your audience more control over their analysis of your visualization.

Set actions take an existing set and update the values contained in that set based on a user's action in the viz. As the author, you can use a set or sets that you have already created to define the scope of the set action.

For details on how to create and use set actions, see [Set Actions on page 1379](#).

### Show a set control in the view

To give your audience the ability to quickly modify members of a set, you can also display a Set Control. A set control is a worksheet card that is very similar to a parameter control or filter card. You can add set controls to worksheets and dashboards and they are included when you publish to Tableau Server or Tableau Cloud, or save to the web on Tableau Public.

To display the set control, right-click (Control-click) the set in the Data pane and select **Show Set**.

Like other cards, set controls have a menu that you can open using the drop-down arrow in the upper right corner of the card. Use this menu to customize the display of the control, which supports both single-value and multiple-value selection modes. For example, you can show radio buttons for individual selection, or a drop-down list that supports multiple selections.

**Note:** You can only display a set control for dynamic sets—not fixed sets. This is by design, as fixed sets aren't meant to change in membership. In addition, if the dynamic set is not in play in the view (that is, if it's not referenced in a calculation or instantiated on the sheet), the context menu item will be disabled, reminding you to add the set to the view.

## Combine sets

You can combine two sets to compare the members. When you combine sets you create a new set containing either the combination of all members, just the members that exist in both, or members that exist in one set but not the other.

Combining sets allows you to answer complex questions and compare cohorts of your data. For example, to determine the percentage of customers who purchased both last year and this year, you can combine two sets containing the customers from each year and return only the customers that exist in both sets.

To combine two sets, they must be based on the same dimensions. That is, you can combine a set containing the top customers with another set containing the customers that purchased last year. However, you cannot combine the top customers set with a top products set.

### To combine sets:

1. In the Data pane, under Sets, select the two sets you want to combine.
2. Right-click the sets and select **Create Combined Set**.
3. In the Create Set dialog box, do the following
  - Type a name for the new combined set.
  - Verify that the two sets you want to combine are selected in the two drop-down menus.
  - Select one of the following options for how to combine the sets:
    - **All Members in Both Sets** - the combined set will contain all of the members from both sets.
    - **Shared Members in Both Sets** - the combined set will only contain members that exist in both sets.
    - **Except Shared Members** - the combined set will contain all members from the specified set that don't exist in the second set. These options are equivalent to subtracting one set from another. For example, if the first set contains Apples, Oranges, and Pears and the second set contains Pears and Nuts; combining the first set except the shared members would contain just Apples and Oranges. Pears is removed because it exists in the second set.
  - Optionally specify a character that will separate the members if the sets represent multiple dimensions.
4. When finished, click **OK**.

**Note:** This functionality is not available in workbooks created before version 8.2 that use Microsoft Excel or text file data sources, workbooks that use the legacy connection, or workbooks that use Microsoft Access data sources.

## Examples of sets

There are many ways you can use sets to answer complex questions and compare cohorts of data. Below are some examples of ways you can use sets to define and compare subsets of data.

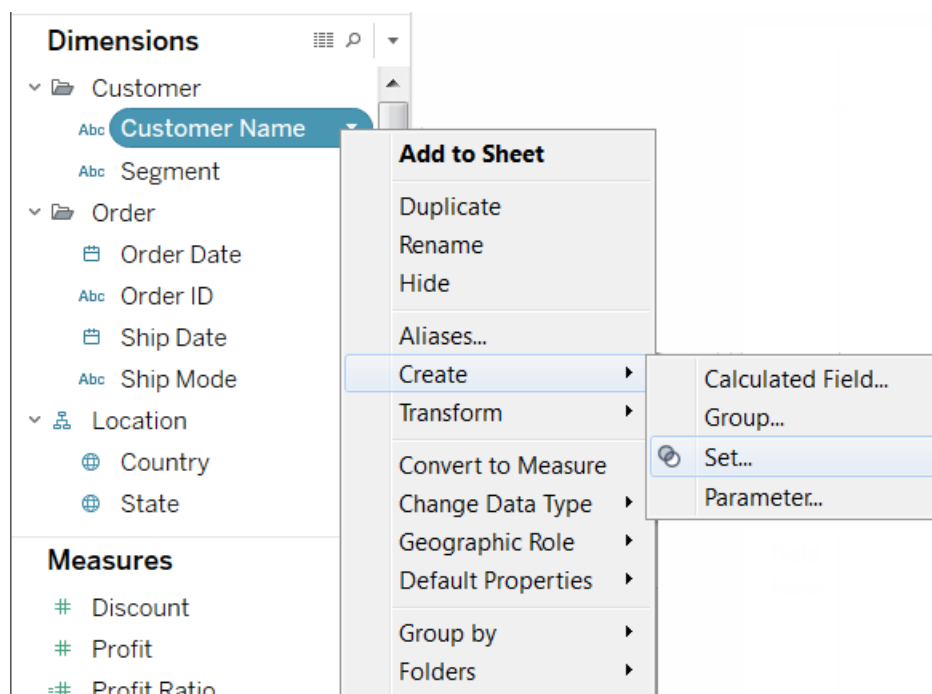

## How do members of a set contribute to the total?

You may have all kinds of questions surrounding how the members in a set contribute to the overall total. For example, what percent of total sales come from repeat customers? You can answer these types of questions using the IN/OUT mode for a set.

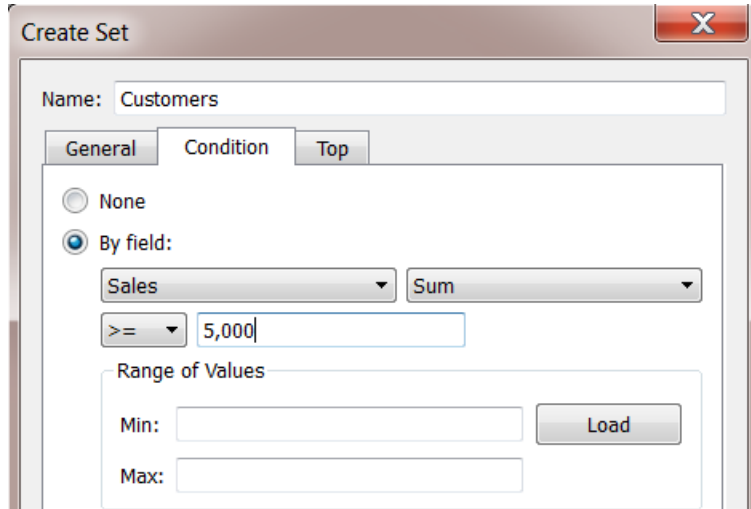

The example below uses sales data to create a set for customers who have purchased 5,000 USD or more in products.

### Create the set

1. Right-click (control-click on Mac) the **Customer Name** dimension in the Data pane and select **Create > Set**.

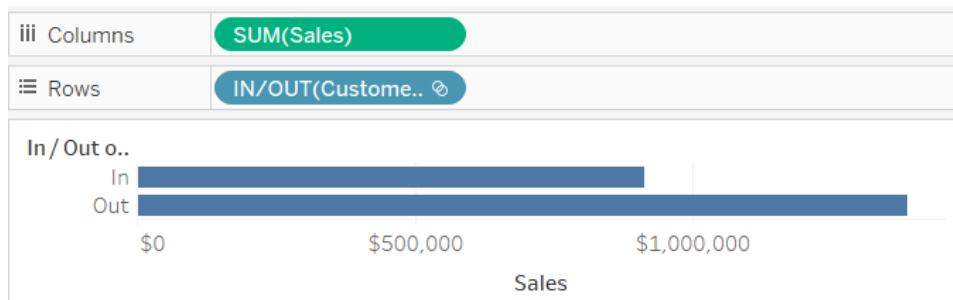

2. In the Create Set dialog box, type a name for the set. In this example, we'll call the set, "Customers"
3. Select the **Use all** option so the condition always applies to all values even when new customers are added.
4. On the Condition tab, click **By field**, and then define a condition that only includes customers when **Sum** of **Sales** is greater than or equal to **5,000**.

5. Click **OK**.

### Create the visualization

1. Drag the new set from the **Sets** area at the bottom of the **Data** pane to the **Rows** shelf.
2. Drag **Sales** to the **Columns** shelf. The view now shows the total sales for customers who have purchased more than 5,000 USD of product and the total sales for all other customers.

3. Finally, click on the drop-down arrow on the **Sum (Sales)** field on the Column shelf and select **Quick Table Calculation > Percent of Total** on the context menu.

The view now shows that customers with sales greater than or equal to 5,000 make up about 39% of the overall sales.

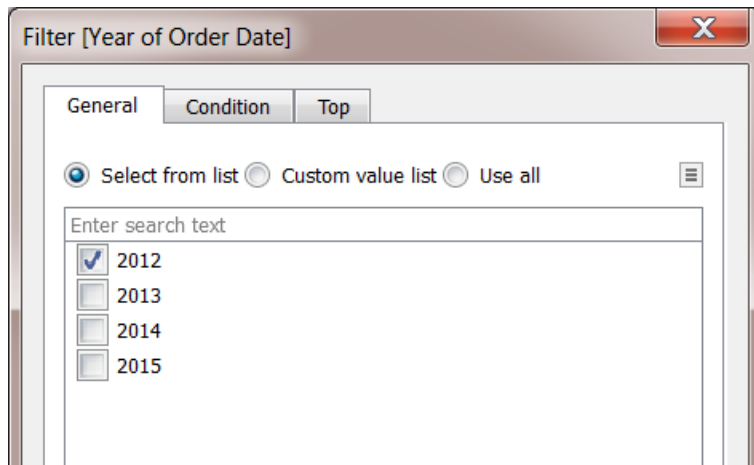

## How many members of a set exist in another set?

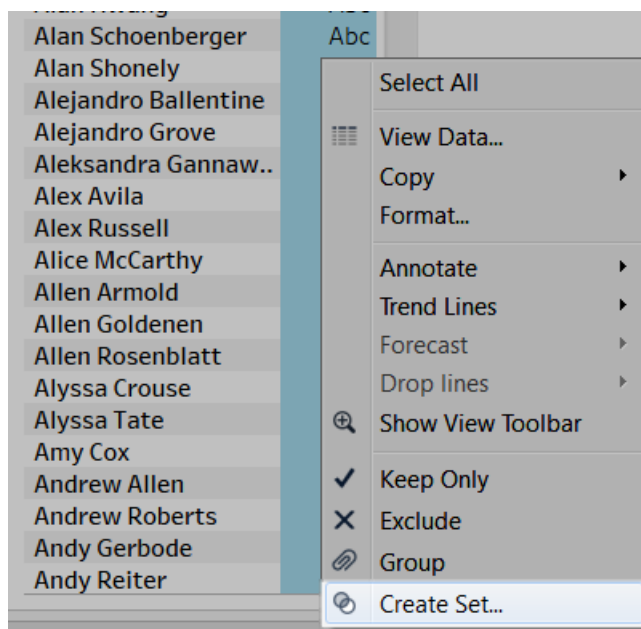

Another common use of sets is to compare subsets of data or cohorts. For example, you may wonder how many customers that purchased last year also purchased this year. Or if a customer purchased a specific product, what other products did they buy? You can answer these types of questions by creating multiple sets and combining them. The example below uses sales data to determine how many customers who purchased in 2012 also purchased in 2013.

### Create a combined set

1. Drag the **Customer Name** field to the Rows shelf.
2. Drag the **Order Date** field to the Filters shelf.
3. In the Filter Field dialog box, select **Years** and click **Next**.
4. In the Filter dialog box, select **2012** and click **OK**.

5. Back in the view, press CTRL + A (Command-A on a Mac) on your keyboard to select all of the customers.
6. Right-click (control-click on Mac) the selection and select **Create Set**.

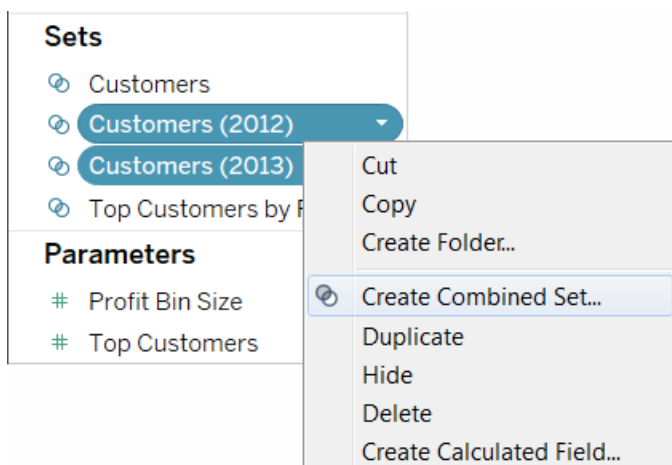

7. In the Create Set dialog box that opens, type a name for the set. In this example, we'll call the set "Customers (2012)".
8. Click **OK**.
9. On the **Filters** shelf, right-click (control-click on Mac) **Order Date** and select **Edit Filter**.

- In the Filter dialog box, change the filter to only include **2013** instead of **2012**, and then click **OK**.

- Again, press CTRL + A (Command-A on a Mac) on your keyboard to select all of the customers.
- In the view, right-click (control-click on Mac) the selection and select **Create Set**.
- In the Create set dialog box that opens, type a name for the set. This set will be called "Customers (2013)".
- Click **OK**.
- In the **Data** pane, select both the **Customers 2012** and **Customers 2013** by holding the Ctrl key (Command key on a Mac) on your keyboard as you select.
- Right-click (control-click on Mac) the selection and select **Create Combined Set**.

17. In the Create Set dialog box, type a name for the new set. In this example, we'll call the set "Customers (2012 & 2013)".
18. Make sure the correct two sets are selected in the drop-down menus.
19. Select the option to include **Shared Members in Both Sets**.

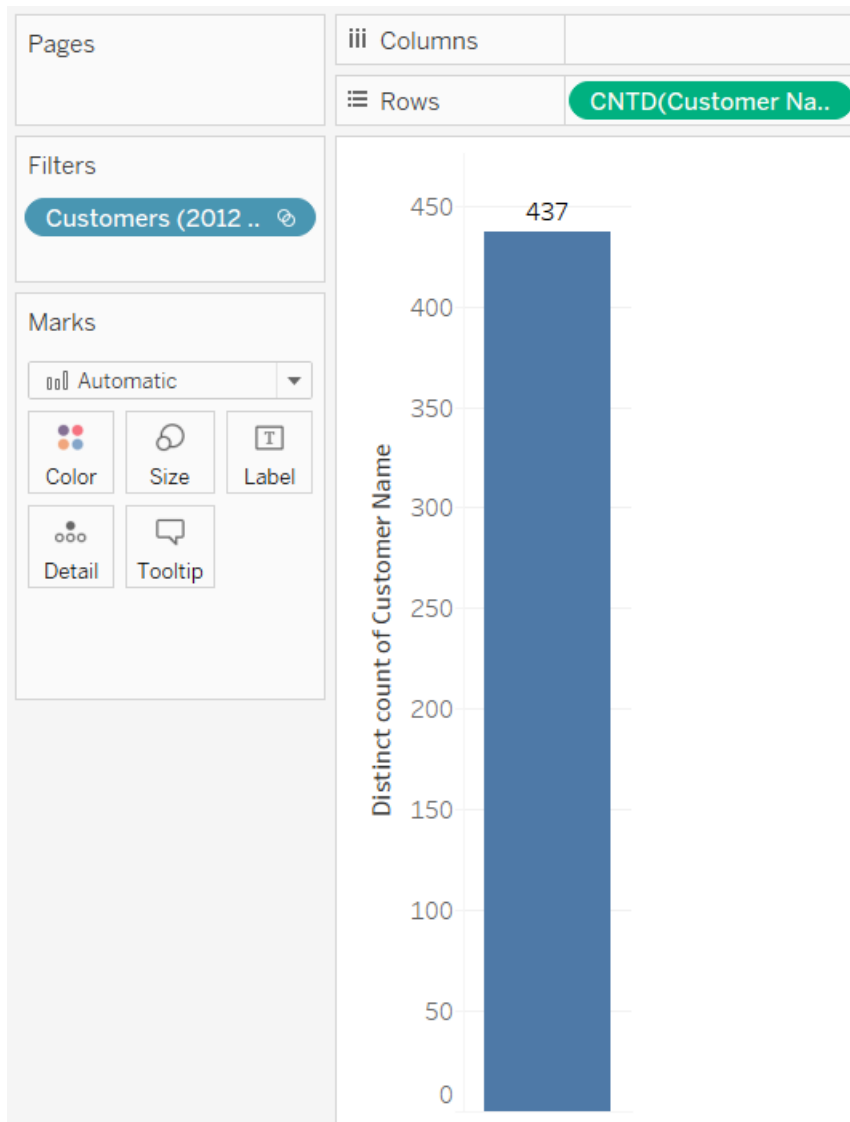

20. Click **OK**.

## Create the visualization

1. At the bottom of the workbook, click the New Worksheet  icon.
2. In the new worksheet, drag the **Customer Name** dimension to the **Rows** shelf.
3. Click the drop-down arrow on the Customer Name field on the Rows shelf and select **Measure > Count (Distinct)** from the context menu.
4. Finally, from the **Sets** area of the **Data** pane, drag the **Customers (2012 & 2013)** field to the **Filters** shelf. You can see that 437 customers purchased products in both 2012 and

2013.

## Hierarchical sets and descendants

A hierarchical set filters data to the selected members and all of their descendants. They are unique to multidimensional (cube) data sources and are defined within the data source prior to connecting to Tableau Desktop.

When you create sets in Tableau from a cube data source, descendants and any hierarchical structures are automatically included with the selected members.

For example, a set named **Dairy** is created from the **Product** hierarchy. As shown below, it includes only the Dairy product department.

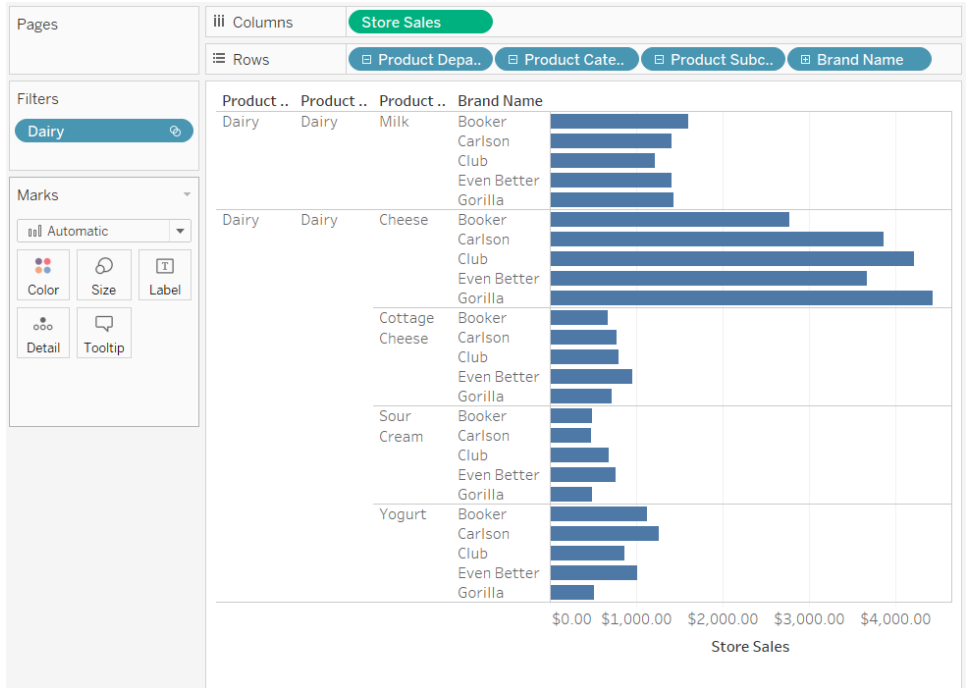

Consider the following view. The **Product Department** dimension is placed on the **Rows** shelf and the **Store Sales** measure is placed on the **Columns** shelf.

If you place the **Dairy** set on the **Filters** shelf, you can see that the view is filtered to include only the Dairy product categories.

As shown below, you can drill down into **Product Department** to reveal the **Product Category**, **Product Subcategory**, and **Brand Name** levels. As these descendants are revealed, row headers are added to the view. This is because a set filter allows you to view the levels of detail contained within the filtered members.

## Sets for Top N and Others

If you collect large sets of data that you want to visualize, you might find that limiting the amount of information displayed to an important subset of records helps you work with and answer questions about the data more effectively.

This article describes how to create an interactive view that separates your customers into two dynamic groups:

- The top N customers
- All other customers

The view includes a control that your users can adjust to change the number of customers included in the top customers group. When they change the number, the view updates accordingly.

## Sets and supported data sources

The method described in this article for creating a view of the top customers uses the In/Out functionality of sets.

Sets were introduced with Tableau Desktop version 8.0.

For live connections, the In/Out functionality requires a relational or multidimensional data source.

If you use a file-based data source, such as a Microsoft Excel workbook or text file, you can take an extract with which you can create sets.

### Step 1: Create the parameter

1. In Tableau Desktop, open a new workbook and connect to the **Sample-Superstore** data source.
2. Open a new worksheet.
3. In the Data pane, click the drop-down arrow in the upper right corner and select **Create Parameter**.
4. In the Create Parameter dialog box, do the following:
  - In the **Name** text box, type **Top Customers 2**.
  - For **Data type**, select **Integer**.
  - For **Current value**, type **5**.
  - For **Allowable values**, click **Range**.
  - Under Range of values, do the following:
    - Click **Minimum** and type **5**.
    - Click **Maximum** and type **20**.
    - Click **Step size** and type **5**.

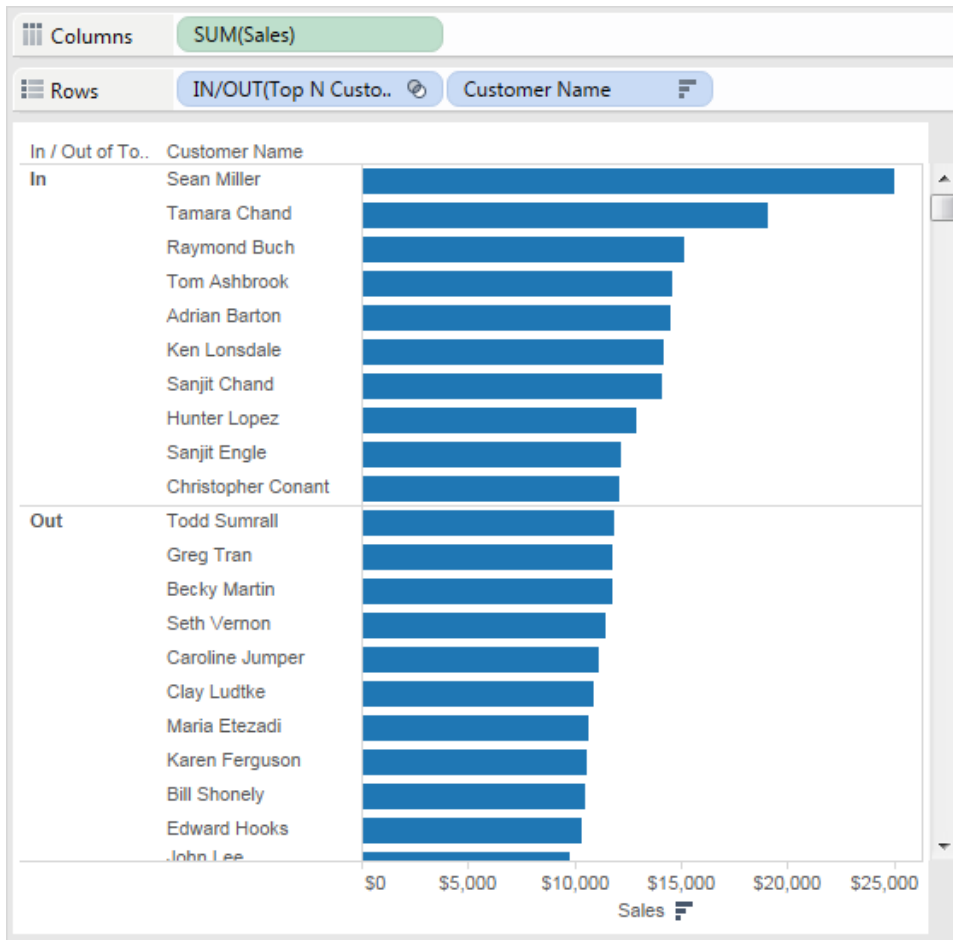

This parameter will be used, in combination with the top N set you will create in the next step, to quickly adjust the top N value in the view.

### Step 2: Create the top N customers set

1. In the Data pane, right-click the **Customer Name** dimension and select **Create > Set**.
2. In the Create Set dialog box that opens, do the following:
  - In the **Name** text box, type **Top N Customers by Sales**.
  - Click the **Top** tab.
  - Select **By Field**.
  - From the field drop-down list (Category), select **Sales**.
  - From the aggregation drop-down list, select **Sum**.
  - When finished, click **OK**.

### Step 3: Set up the view

1. From the Data pane, under **Sets**, drag **Top N Customers by Sales** to the **Rows** shelf.
2. Drag the **Customer Name** dimension to the **Rows** shelf, positioning it to the right of the set.
3. Drag the **Sales** measure to the **Columns** shelf.
4. On the toolbar, click the Sort Descending button  to make sure that the set is working.

5. In the Data pane, right-click the **Top N Customers by Sales** set, and then click **Create Calculated Field**.
6. In the Calculated Field dialog box that opens, complete the following steps:

- In the **Name** text box, type **Subset Labels**.
- In the **Formula** text box, type the following formula to create dynamic labels for the customers in the set:

```
IF [Top N Customers by Sales]
  THEN "Top " + str([Top Customers 2]) + " Customers"
  ELSE "Others"
  END
```

- When finished, click **OK**.
7. From the Data pane, drag **Subset Labels** to the **Rows** shelf, placing it between the Top N set and the **Customer Name** dimension.
  8. On the **Rows** shelf, right-click the **IN/OUT(Top N Customers by Sales)** set, and then clear **Show Header**.

This hides the In/Out labels while retaining the sort order so that your top N subset always appears at the top of the view.

9. From the Data pane, drag the **Top N Customers by Sales** set to **Color** on the **Marks** card.

#### Step 4: Combine the Top N set with a dynamic parameter

1. In the Data pane, right-click **Top N Customers by Sales**, and then select **Edit Set**.
2. In the Edit Set dialog box, do the following:
  - Select the **Top** tab.
  - Click the value drop-down menu, and select the **Top Customers 2** parameter.
  - Click **OK**.

This links the **Top N Customers by Sales** set to the **Top Customers 2** dynamic parameter, instead of to a static list of 10.

This parameter will be used in combination with the Top N Customers by Sales set, to adjust the top N value in the view.

3. In the Data pane, under Parameters, right-click the **Top Customers 2** parameter, and select **Show Parameter**.

You can control the top N value by using the **Top Customers 2** parameter control that appears in the view.

### Additional tips for improving the view's functionality

Here are some additional steps you can take to give your viewers more flexibility in displaying the customer subsets.

1. From the Data pane drop-down menu, select **Create Parameter**.
2. In the Create Parameter dialog box that opens, do the following:
  - For **Name**, type **Expand or Collapse**.
  - For **Data type**, select **String**.
  - For **Allowable values**, select **List**.
  - In the **List of values**, type the values **Expand** and **Collapse**.

**Create Parameter**

Name:

**Properties**

Data type:

Current value:

Value when workbook opens:

Display format:

Allowable values:  All  List  Range

**List of values**

Value	Display As
Expand	Expand
Collapse	Collapse
Add	

Fixed

When workbook opens

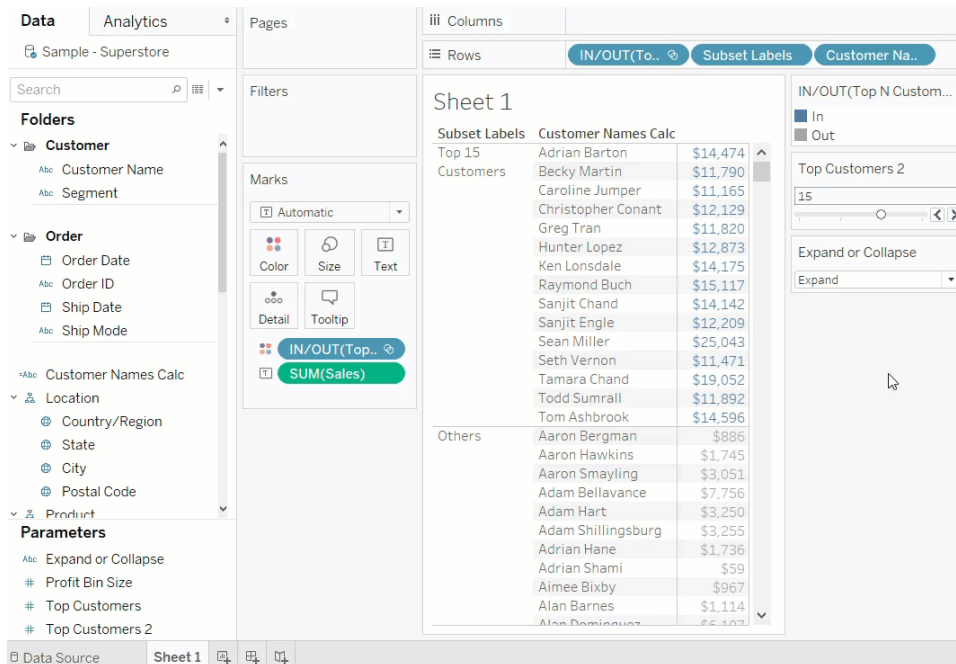

- When finished, click **OK**.
3. Select **Analysis > Create Calculated Field**.
  4. In the Create Calculated Field dialog box that opens, do the following to create a calculation that uses the parameter you just created. This calculation enables viewers to specify how to view customers in the Others subset:
    - For **Name**, enter **Customer Names Calc**.
    - In the formula box, type the following formula, and then click **OK**:
 

```
IF [Expand or Collapse]="Collapse" THEN
  IF [Top N Customers by Sales]
  THEN [Customer Name]
  ELSE "Others" END
ELSE [Customer Name] END
```
  5. In the Data pane, under Parameters, right-click the **Expand or Collapse** parameter, and select **Show Parameter**.
  6. From the **Columns** shelf, drag the **SUM(Sales)** measure to **Label** on the **Marks** card.

- From the Data pane, drag **Customer Names Calc** directly on top of the **Customer Name** field on the **Rows** shelf, so that it replaces it.

Now you can use the **Expand or Collapse** parameter control to see the list of names in the top N customers and the remaining customers rolled up into a single **Others** entry.

## Create Parameters

A parameter is a workbook variable such as a number, date, or string that can replace a constant value in a calculation, filter, or reference line.

For example, you may create a calculated field that returns True if Sales is greater than \$500,000 and otherwise returns False. You can replace the constant value of “500000” in the formula with a parameter. Then, using the parameter control, you can dynamically change the threshold in your calculation.

To use a parameter, you must:

1. Set up the initial parameter.
2. Use the parameter in an element such as a calculation, filter, or reference line.
3. Adjust the parameter value by:
  - Showing the parameter control
  - Using a parameter action
  - Setting a dynamic parameter to update automatically

## Create a parameter

To create a parameter from the Data pane:

1. In the Data pane, click the drop-down arrow in the upper right corner and select **Create Parameter**.

2. In the Create Parameter dialog box, give the field a **Name**.

Create Parameter

Name  
My Parameter

Properties

Data type	Display format
Float	1

Current value: 1

Value when workbook opens: Current value

Allowable values

All  List  Range

Cancel OK

3. Specify the data type for the values it accepts:

Properties

Data type

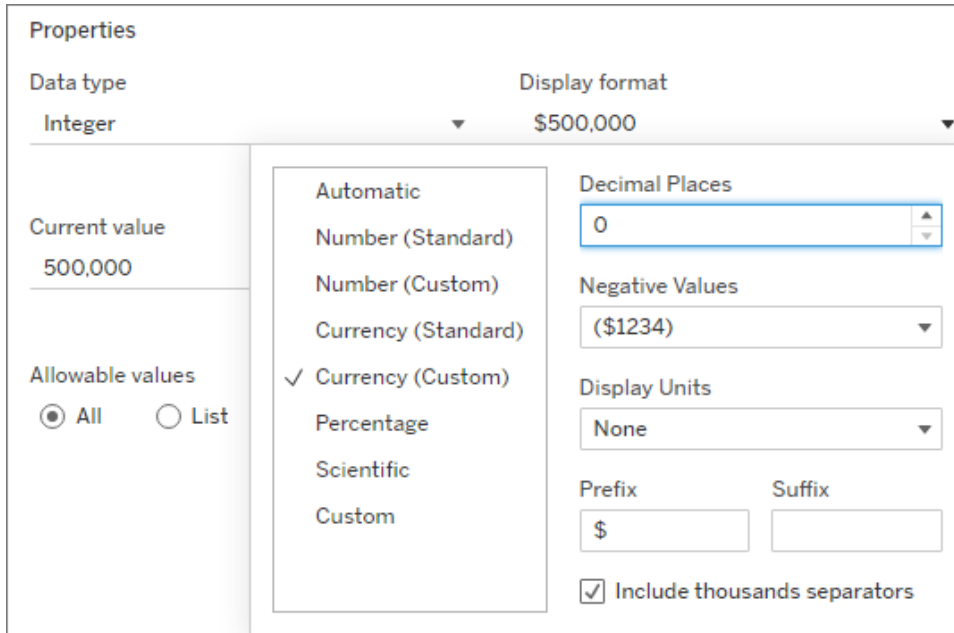

Integer

- Float
- ✓ Integer
- String
- Boolean
- Date
- DateTime

4. *Optional:* Specify a current value. This is the default value for the parameter.

5. *Optional*: Specify a value when the workbook opens.
6. Specify the display format to use in the parameter control (Tableau Desktop only).

7. Specify how the parameter accepts values. You can select from the following options:
  - **All**: The parameter control is a simple text field.
  - **List**: The parameter control provides a list of possible values for you to select from.
    - If you select List, you must specify the list of values. Click in the left column to type your list of values, or you can add members of a field or paste from the clipboard by selecting **Add values from**.

- **Range**: The parameter control lets you select values within a specified range.
  - If you select Range, you must specify a minimum, maximum, and step size. The step size controls the jumps between values, such as letting you choose each number (5, 6, 7...) or going from 5 to 10 to 15.

The availability of these options is determined by the data type. For example, a string parameter doesn't support Range.

To refresh the parameter's list of values (or domain) whenever the workbook opens, select **List** or **Range**, and then select **When the workbook opens**. Notice that some options are grayed out because the workbook is dynamically pulling values from the data source.

- When finished, click **OK**.

The parameter is now listed in the Parameters section at the bottom of the Data pane.

## Edit a parameter

You can edit parameters from the Data pane or the parameter control. Editing is for things like changing the allowable range or the data type. To simply change the value or a parameter, use the parameter control. See [Show a parameter control in the viz on page 1076](#).

To edit a parameter:

- Do one of the following:
  - Right-click the parameter in the Data pane and select **Edit**.
  - Select **Edit Parameter** on the parameter control menu.
- In the Edit Parameter dialog box, make your changes.
- Click **OK**. The parameter is updated along with any elements that use it.

## Delete a parameter

To delete a parameter, right-click it in the Data pane and select **Delete**. Any calculated fields that use the deleted parameter become invalid.

## Use a parameter

A parameter won't do anything until it's tied to an element in the viz. Parameters can be referenced in calculations, filters, and reference lines. Parameters are global across the workbook and can be used in any worksheet.

After the element references the parameter, be sure to **Show a parameter control in the viz on the next page** (or set up a parameter action, or a dynamic parameter). If there's no way to change the value of the parameter, it doesn't do any good to have it set up in the first place.

### Use a parameter in a calculation

Parameters give you a way to dynamically modify values in a calculation. Rather than manually editing the calculation (and all dependent calculations), you can use a parameter. Then when you want to change the value, you open the parameter control, change the value, and all calculations that use that parameter are updated.

To use a parameter in a calculation, type the name of the parameter and it appears in the suggested options, just like typing a field name. You can also drag the parameter from the Data pane and drop it in the calculation editor.

### Use a parameter in a filter

Parameters give you a way to dynamically modify values in a Top N filter. Rather than manually setting the number of values you want to show in the filter, you can use a parameter. A list of parameters is available in the drop-down lists on the **Top** tab of the Filter dialog box. Select the parameter you want to use in the filter.

## Use a parameter in a reference line

Parameters give you a way to dynamically modify a reference line, band, or box. For example, instead of showing a reference line at a fixed location on the axis, you can reference a parameter. Then you can use the parameter control to move the reference line.

A list of parameters is available in the **Value** drop-down list in the Add Reference Line, Band, or Box dialog box. Select the parameter you want to use. The reference line is drawn at the Current Value specified by the parameter.

## Show a parameter control in the viz

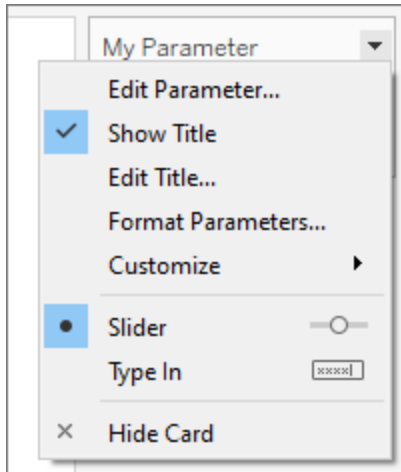

The parameter control is a worksheet card that lets you modify the parameter value. Parameter controls are similar to filter cards in that they contain controls that modify the view. You can open parameter controls on worksheets and dashboards and they're included when you save to the web or publish to Tableau Server.

To open the parameter control, right-click (Control-click) the parameter in the Data pane and select **Show Parameter**.

Like other cards, parameter controls have a menu that you can open using the drop-down arrow in the upper right corner of the card. Use this menu to customize the display of the control. For example, you can show a list of values as radio buttons, a compact list, a slider, or a type in field.

The options available on this menu depend on the data type of the parameter and whether it accepts all, a list, or a range of values.

## Make a dynamic parameter

### Parameter actions

You can make your parameters more dynamic and interactive by using them in [Parameter Actions on page 1355](#). Parameter actions let your audience change a parameter value through direct interaction with a viz, such as clicking or selecting a mark.

### Dynamic current value

You can create a parameter that can refresh its current value to the result of a calculation, a list of values (based on a field), or a range of values. This refresh happens each time the workbook is opened or whenever you select **Refresh** from the data source's context menu.

#### **Use a calculation as the current value of a parameter**

If the current value is the result of a calculation, it must be a single-value, view-independent calculation. If the calculation's result could be more than one value, the workbook can't choose a default value. The calculation must also be view-independent so that the value won't change as the viz changes.

To do this, you can use a FIXED level of detail (LOD) expression that isn't dependent on the structure of the viz. All parts of the calculation must be inside the FIXED LOD expression. If you

use a FIXED LOD expression as the default value and are using context filters, the dynamic parameter won't reflect any context filters.

For more information on LOD expressions, see [Create Level of Detail Expressions in Tableau](#) on page 2525.

**Note:** We don't recommend using a dynamic parameter in a data extract filter because it impacts performance. If you use a dynamic parameter for a data extract filter, Tableau needs to first process all the data to determine the value of the parameter, and thus which data to filter. For example, if you use a dynamic parameter filter to return the last 30 days of data, Tableau evaluates the entire data source to find the last 30 days of data and then filters it. This results in reduced performance and a longer time to load.

## Troubleshoot parameters

Here are a few scenarios when a default parameter value or a refreshable list of parameter values (domain) won't update as expected:

- The default field returns a value whose data is incompatible with the parameter's data type.
- The default field for the parameter's current value doesn't return a single value.
- The default field returns null.
- The default field is in a data source that isn't connected.
- The default field was deleted.
- The user cancels the query to the data source while Tableau is attempting to connect.

In Tableau Desktop, these queries are initially evaluated when the workbook is opened and Tableau connects to the fields' data sources for the first time. You can also evaluate the queries by refreshing the data source. To do this, press F5, or open the data source's context menu and select **Refresh**. On Tableau Server and Tableau Cloud, you can refresh the data source by clicking the Data Source Refresh button in the toolbar. In this case, however, remember that the value returned depends on the server's cache policies.

If the default fields fail to return values, the parameter behaves as follows:

- The current value keeps the latest valid value.
- The list of values are empty because Tableau doesn't serialize the values returned from the query in the workbook.

The current value must be in the list of values for it to be assigned to the parameter. If the list of values is empty, the parameter will get assigned a fallback value according to the data type (1 for integer, 1.0 for float, "" for string, and the current date for date and datetime).

## Use Parameters to Make Views More Interactive

Parameters are useful when you want to add interactivity and flexibility to a report, or to experiment with what-if scenarios. Suppose you are unsure which fields to include in your view or which layout would work best for your viewers. You can incorporate parameters into your view to let viewers choose how they want to look at the data.

When you use parameters, you need to tie them to the view in some way:

- You can use parameters in calculations and calculated fields that are used in the view.
- You can display the parameter control in the view for users to select parameters.
- You can reference parameters in [parameter actions](#).

Before you begin, decide which fields you want to make interactive. For example, you could allow users to view the categories within a dimension by color, or to view sales data over a period of time that they choose, and so on. The example described here sets up a table for which users can select the dimensions to display in the columns and rows.

**Watch a video:** For an in-depth presentation, watch [Parameters | Oh, the places you'll go!](#) (45 minutes).

**Learn more:** See [Use Parameters to Add Multiple Views to Your Viz](#) on the Tableau [blog](#) and multiple practical topics on how to use parameters on the [Data School](#) website.

### Create the parameters

These steps use the Superstore sample to create new parameters.

1. In the Data pane, click the drop-down arrow in the upper right corner and select **Create Parameter**.
2. In the Create Parameter dialog box, complete the following steps:
  - a. Name the parameter so that viewers can tell what changing it will do. This example uses **Select Column 1 Heading**.
  - b. For **Data type**, select **String**.
  - c. For **Allowable Values**, select **List**, type **None** as the first value in the list, and then press **Enter**.

- d. Complete the list by typing the names of the additional dimension fields that you want to expose through the parameter.

**Note:** This example uses the customer name, customer segment, region, department, and category fields. These are all dimensions of the same data type (string). If you wanted to include a measure such as profit in this list, one option would be to convert the measure to a string value. You would do this when you build the calculated field, using the `STR()` function. This article covers only the single data type scenario.

The **Display As** aliases default to the field name, and for this exercise you can leave them as they are.

**Create Parameter**

Name:

**Properties**

Data type:

Current value:

Value when workbook opens:

Display format:

Allowable values:  All  List  Range

**List of values**

Value	Display As
None	None
Customer Name	Customer Name
Customer Segment	Customer Segment
Region	Region
Department	Department
Category	Category
Add	

Fixed  When workbook opens

- e. Click **OK** to return to the Calculated Field dialog box.

3. Repeat the previous step to create the following additional parameters:

- Select Column 2 Heading
- Select Row 1 Heading
- Select Row 2 Heading

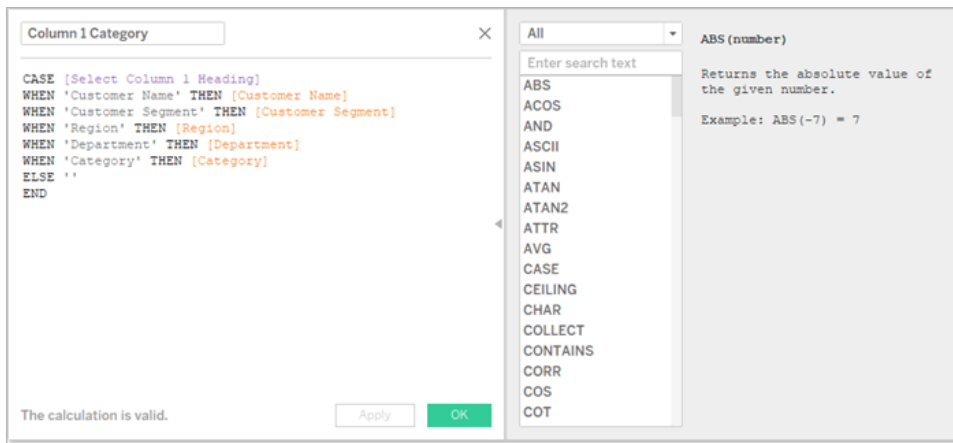

**Tip:** Instead of typing each value in the list, click **Add values from > Parameters** to add them from **Select Column 1 Heading**.

### Create the calculated fields

These steps use the Superstore sample to build the calculated fields that will take advantage of your parameters.

1. In the Data pane, click the drop-down arrow in the upper right corner and select **Create Calculated Field**.
2. In the Calculated Field dialog box, for **Name**, type **Column 1 Category**.
3. In the Calculated Field dialog box, for **Formula**, build the following calculation:

```
CASE [Select Column 1 Heading]
WHEN 'Customer Name' THEN [Customer Name]
WHEN 'Customer Segment' THEN [Customer Segment]
WHEN 'Region' THEN [Region]
WHEN 'Department' THEN [Department]
WHEN 'Category' THEN [Category]
ELSE ''
END
```

Confirm that the status message indicates that the formula is valid, and then click **OK**.

**Note:** ELSE accounts for the **None** value that you included in the parameter, and it returns an empty string.

4. Create three more calculated fields, one for each of the additional parameters you created:

Parameter name	Calculated field name
Select Column 2 Heading	Column 2 Category
Select Row 1 Heading	Row 1 Category
Select Row 2 Heading	Row 2 Category

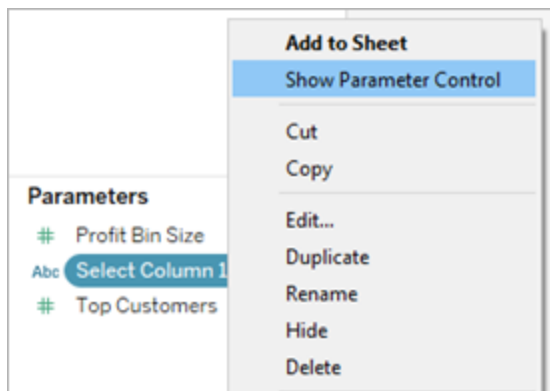

The basic formula for each calculated field is the same as in the previous step, except that you reference a different parameter in each `CASE` statement.

### Give viewers a way to interact with views

Next, expose the parameter control so users can select the categories they want to display.

1. For each parameter you created, do the following:

Under Parameters, right-click the parameter and select **Show Parameter Control**.

2. From the Data pane, drag the calculated fields you created to the Columns and Rows shelves.

- From the Data pane, drag a measure to the view. In this example, **Sales** is placed on **Label** on the Marks card.
- Test your parameters by selecting fields in the parameter controls.

**Tips:**

- Sort the dynamic dimension fields alphabetically.
- Hide field labels for rows and columns.

The screenshot shows the Tableau Desktop interface with a pivot table. The Columns shelf contains 'Column 2 Category' and 'Column 1 Category'. The Rows shelf contains 'Row 2 Category' and 'Row 1 Category'. The Marks card has 'SUM(Sales)' on the Label property. The view displays a table with columns for Region (Central, East, South, West), Category (Consumer, Corporate, Home Office, Small Business), and various product sub-categories (Bookcases, Chairs & Chairmats, Office Furnishings, Tables, Appliances, Binders and Binder Accessories, Envelopes). The data is summarized by region and category.

Region	Category	Bookcases	Chairs & Chairmats	Office Furnishings	Tables	Appliances	Binders and Binder Accessories	Envelopes
Consumer	Central	\$13,744	\$77,482	\$21,336	\$63,355	\$15,283	\$33,412	\$1,929
	East	\$26,188	\$76,484	\$20,717	\$63,102	\$9,221	\$36,127	\$1,908
	South	\$11,664	\$29,831	\$12,669	\$35,076	\$24,097	\$27,154	\$1,481
	West	\$41,028	\$121,585	\$14,808	\$67,400	\$15,207	\$6,937	\$32,326
Corporate	Central	\$38,255	\$139,235	\$41,303	\$123,086	\$58,497	\$56,719	\$16,556
	East	\$32,631	\$110,812	\$30,666	\$95,268	\$49,228	\$89,138	\$17,314
	South	\$48,177	\$57,515	\$16,653	\$55,407	\$24,714	\$31,254	\$3,318
	West	\$142,822	\$100,158	\$26,880	\$90,218	\$35,501	\$48,044	\$7,275
Home Office	Central	\$37,953	\$71,701	\$53,555	\$52,917	\$57,314	\$57,364	\$3,197
	East	\$7,688	\$58,804	\$26,850	\$100,094	\$30,957	\$41,971	\$11,344
	South	\$13,013	\$39,512	\$47,167	\$86,505	\$22,067	\$32,739	\$3,667
	West	\$20,750	\$42,817	\$70,414	\$47,993	\$14,417	\$16,396	\$4,373
Small Business	Central	\$27,631	\$39,492	\$18,362	\$38,810	\$38,752	\$41,496	\$7,324
	East	\$17,596	\$134,088	\$17,551	\$46,125	\$45,180	\$84,031	\$22,507
	South	\$10,448	\$34,641	\$10,890	\$37,095	\$3,900	\$16,810	\$6,551
	West	\$17,707	\$30,428	\$14,604	\$59,471	\$12,389	\$18,990	\$6,852

- Reset all parameters to **None** and publish the workbook to Tableau Server.

Viewers can set up their own reports, save their parameter settings, and share views with others.

**Additional information**

For information about building views dynamically, see [Swap Measures Using Parameters](#).

For information about the different areas in the Tableau interface in which you can create and incorporate parameters, see [Create Parameters on page 1070](#) and its related topics in the Tableau Help.

**Disclaimer:** This topic includes information about parameters from a third-party blog, [The Information Lab: Data School](#). Please note that while we make every effort to keep references to third-party content accurate, the information we provide here might change without notice as content on their website changes.

## Example: Add a Parameter to a Map View

This example uses the World Indicators sample data source to demonstrate the following:

- How to build a map view that shows the birth rate for each country in the world.
- How to create a calculated field that distinguishes countries/regions with a low birth rate from those with a high birth rate.
- How to create and display a parameter so that users can set the threshold for low vs. high birth rate.

### Build a map view

1. In the **Data** pane, double-click **Latitude** and then **Longitude**.  
Tableau puts **Longitude** on **Columns**, **Latitude** on **Rows**, and displays a map of the world.
2. Drag the **Year** dimension to **Filters**.
3. In the Filter Field [Year] dialog box, choose **Years** and then click **Next**:

4. In the Filter [Year of Year] dialog box, select **2012** and then click **OK**:

5. Drag the **Country** dimension to **Detail**.
6. Set the Marks type to Map:

You can zoom the map or hover to see a tooltip for any country.

## Create a calculated field to set a threshold

Next, you'll distinguish a low birth rate from a high birth rate.

1. From the top menu, select **Analysis > Create Calculated Field** .
2. Name the field `High Birth Rate` and type or paste this calculation in the formula field:

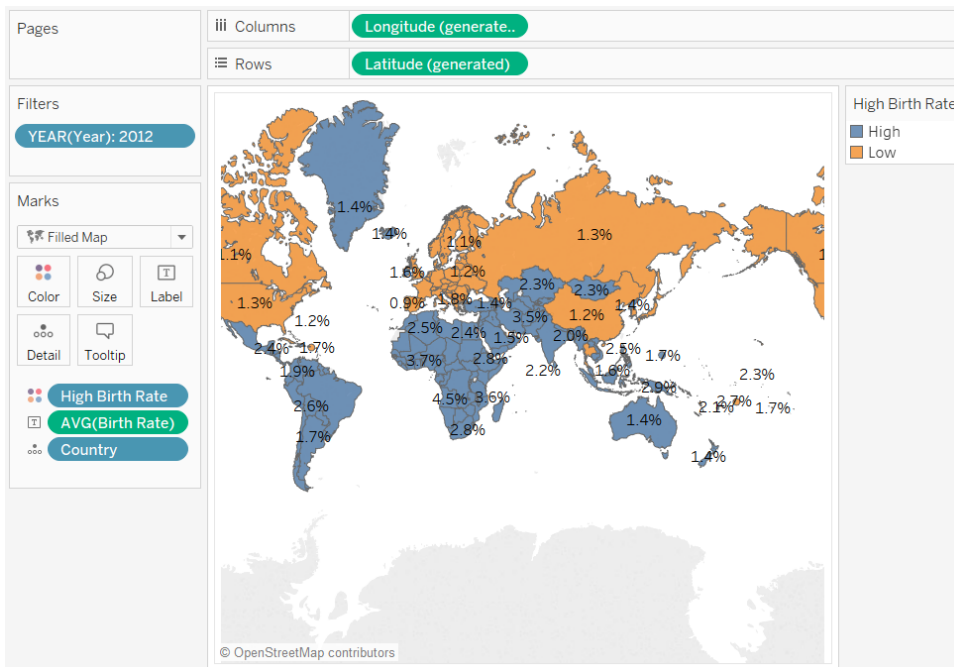

```
IF ([Birth Rate]) >= 0.014 THEN "High" ELSE "Low" END
```

The value 0.014 is equivalent to 1.4%. The range of actual values that we can see on the map range from below 1% up to nearly 5%.

When you click **OK** to apply and save this calculation, Tableau categorizes it as a dimension.

3. Drag **High Birth Rate** to **Color**.

The map now shows low birth rate countries/regions in one color and high birth rate countries/regions in another:

But the definition of high birth rate as anything equal to or greater than 1.4% is arbitrary—that value was chosen because it divided the world's countries/regions about evenly.

Instead, you can let users define that threshold, or give them a control that they can use to see how changing the threshold changes the map. To do this, you create a parameter.

### Create a parameter

1. Right-click (control-click on a Mac) in the **Data** pane and select **Create > Parameter**.

**Note:** If you clicked on a field on the Data pane, some fields might be filled. You can just change the fields as needed.

2. In the Create Parameter dialog box, name the new parameter `Set Birth Rate` and configure it as shown:

For information on the fields in the Create Parameter dialog box, see [Create Parameters on page 1070](#).

Because the **Data Type** is **Float**, the parameter control, when you display it in the next procedure, will be in the form of a slider. This is because floating point values are continuous—there are an infinite number of possible values.

The **Current value** sets the default for the parameter: 0.019 is 1.9%. The **Range of values** section sets the minimum and the maximum values and the step size—that is, the least amount by which the value can change.

3. Click **OK**.

## Create and display the parameter control

Now you must connect the parameter to the **High Birth Rate** field.

1. Right-click **High Birth Rate** in the **Data** pane and select **Edit**.
2. Replace the hard-coded 0.014 value in the field definition with the parameter name:

```
IF ([Birth Rate]) >= [Set Birth Rate] THEN "High" ELSE "Low" END
```

Then click OK.

3. Right-click the **Set Birth Rate** parameter in the **Data** pane and select **Show Parameter Control**.

By default, the parameter control is shown on the right. Now you and users of your view can raise or lower this value incrementally to see how changing the definition of "high birth rate" affects the map.

## Example: Swap Measures Using Parameters

You may want to create a view that shows how the values of two measures compare against each other. But what if you also wanted to be able to choose which measures were being compared—or better yet, add a control to the view that would let any user select the measures to be compared. You can create such a view using parameters and calculated fields. The calculated fields replace the measures in the view and can be set interactively by the user with parameter controls or parameter actions. Using swap measures also allows you to use [Dynamic Axis Titles](#).

### General steps

1. Create the parameters.
2. Create calculated fields to change the measures in the view.
3. Set up the view.

This article includes an additional section that you can use as an alternative to step 2:

- Create calculated fields to change measures and specify aggregations

The following sections break these procedures down into specific instructions.

The scenario uses the **Sample - Superstore** data source provided with Tableau Desktop.

### Create the parameters

Follow these steps.

1. In the Data pane, click the drop-down arrow in the upper right corner and select **Create Parameter**.
2. In the Create Parameter dialog box, do the following:
  - a. Name the parameter **Placeholder 1 Selector**.
  - b. Set the **Data type** to **String**.
  - c. Skip down to the **Allowable values** field, and choose **List**.
  - d. Type individual measure names in the **List of values** area: **Discount**, **Profit**, **Quantity**, and **Sales**.

The Create Parameter dialog box should now look like this:

**Create Parameter**

Name  
Placeholder 1 Selector

Properties

Data type: String  
Display format: Discount

Current value: Discount  
Value when workbook opens: Current value

Allowable values

All  List  Range

Value	Display As
Discount	Discount
Profit	Profit
Quantity	Quantity
Sales	Sales
Click to add	

Fixed  
 When workbook opens

Add values from ▼

Remove Selected

Cancel OK

e. Click **OK** to close the Edit Parameter dialog box.

3. Create a second parameter, **Placeholder 2 Selector**, with the exact same configuration.

There are different ways you can do this. The easiest way is to click **Placeholder 1 Selector** in the **Data** pane, choose **Duplicate**, and then change the name of the duplicated parameter to **Placeholder 2 Selector**.

Create calculated fields to change the measures in the view

Follow these steps.

1. Choose **Analysis > Create Calculated Field** to open the calculation editor. Name the calculation **Placeholder 1** and type or paste the following in the formula area:

```
CASE [Placeholder 1 Selector]
WHEN "Discount" THEN [Discount]
WHEN "Profit" THEN [Profit]
WHEN "Quantity" THEN [Quantity]
WHEN "Sales" THEN [Sales]
END
```

**Note:** The calculated field must reference the **Value** entry for a given row, and not the **Display As** value.

2. Click **OK** to exit the calculation editor.
3. Create a second calculated field, **Placeholder 2**, with the same definition. Again, the easiest way to do this is to click **Placeholder 1** in the **Data** pane, choose **Duplicate**, and then change the name of the duplicated field to **Placeholder 2**. Then replace **Placeholder 1** selector with **Placeholder 2**.

## Set up the view

Follow these steps.

1. Drag **Placeholder 2** to **Columns** and **Placeholder 1** to **Rows**.  
Because you dragged measures to both shelves, the default view is a scatter plot. For more on why Tableau does this, see [Example: Scatter Plots, Aggregation, and Granularity on page 183](#).
2. Drag **Customer Name** to **Detail** and **Region** to **Color**.
3. In the Parameters area of the Data pane, click each **Placeholder 1 Selector** and choose **Show Parameter Control**. Then do the same for **Placeholder 2 Selector**.
4. Tableau displays the parameter controls beyond the right side of the view by default. Drag them over to the left side to make them easier for your users to see.

Your view is now complete. The parameter controls let users select the measures to be used on the X and Y axes. For example, the view below on the left shows **Quantity** vs. **Discount**, while in the view the right the parameter controls have been used to show **Profit** vs. **Sales**.

## Create calculated fields to change measures and specify aggregations

As an alternative to the **Create calculated fields to change the measures in the view** section, above, consider creating calculated fields that specify aggregations for individual measures. As written above, the calculated fields do not specify aggregations. Notice in the image above that Tableau automatically assigns an aggregation (SUM) to the **Placeholder 1** and **Placeholder 2** fields. But you know your data, and you may want to dictate which aggregation Tableau uses for your measures. So instead of the calculated field definition above, consider a definition like the following:

```
CASE [Placeholder 1 Selector]
WHEN "Discount" THEN SUM([Discount])
WHEN "Profit" THEN AVG([Profit])
WHEN "Quantity" THEN SUM([Quantity])
WHEN "Sales" THEN AVG([Sales])
END
```

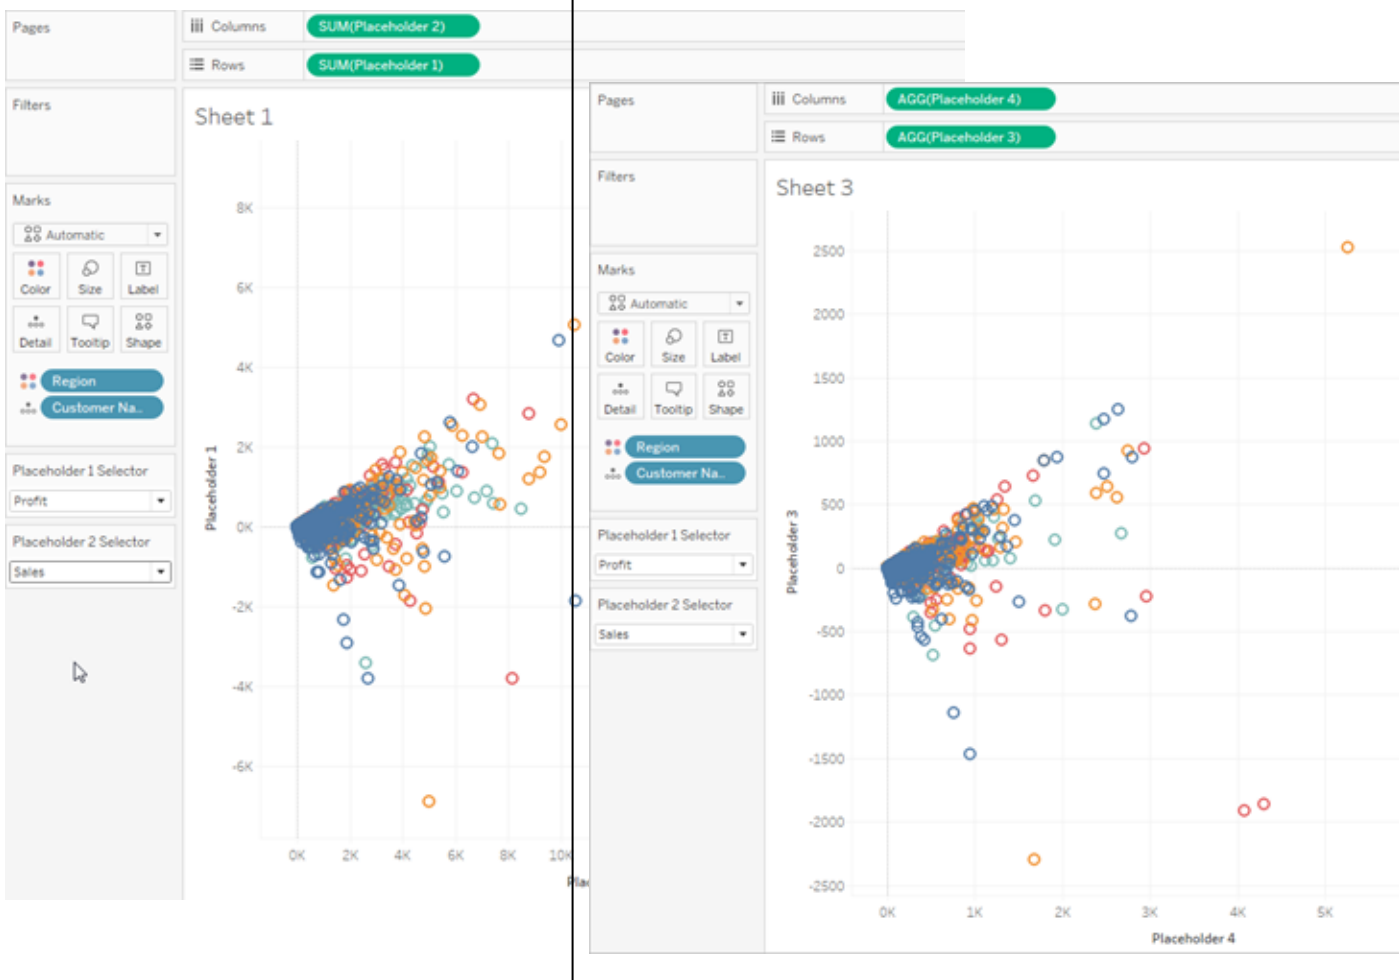

It's up to you to decide whether to explicitly aggregate measures in your field definitions. The only thing you cannot do is mix-and-match: that is, you cannot define aggregations for some measures, but not for others.

Here's how the **Profit vs. Sales** scatter plot changes when you specify AVG as the aggregation for these fields, as opposed to not specifying an aggregation and letting Tableau default to SUM:

**Profit vs. Sales** with default aggregation

**Profit vs. Sales** with explicit aggregation

# Tableau Desktop and Web Authoring Help

Similar, but different.

## Dates and Times

How you work with dates in Tableau depends on whether you are using a relational or cube (multidimensional) data source. This section discusses the differences.

### Dates in Cube (Multidimensional) Data Sources

In Tableau Desktop, cube (multidimensional) data sources are supported only in Windows.

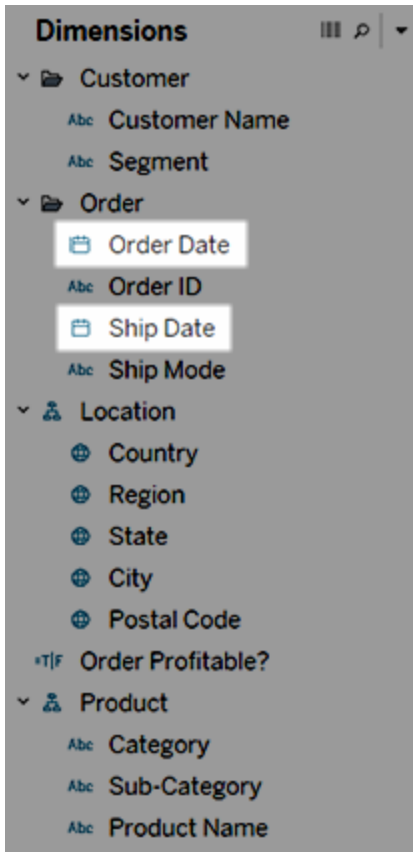

For cube data sources, dates dimensions are usually organized into hierarchies that contain levels such as year, quarter, and month. In addition, some multidimensional data sources have time intelligence enabled, which makes it possible to look at data levels different ways, such as Months by Year, Months by Quarter, Weekends, etc. These levels are represented as attributes of the hierarchy. Hierarchies and attributes are defined when the cube is created and you cannot modify them in Tableau. For example, the **Year** dimension from an Oracle Essbase data source is shown below.

When you place a multidimensional date on a shelf, the field is treated like any other dimension. For example, you can drill down, drill up, and so on.

### Dates in Relational Data Sources

For relational data sources, dates and times are automatically placed in the Dimensions area of the **Data** pane and are identified by the date  or date-time  icon. For example, the Order Date and Ship Date dimensions from an Excel data source are shown below.

When you place a relational date on a shelf, the field name is automatically modified to reflect the default date level. Tableau defines the default date level to be the level at which there are multiple instances. For example, if the date field includes multiple years, the default level is year. However, if the date field contains data for just one year but includes multiple months, then the default level is month.

If you don't want Tableau to automatically select a date level and would rather have a date dimension be a continuous field, you can right-click (control-click on Mac) the field in the **Data** pane and select **Convert to Continuous**. The dimension then turns green in the **Data** pane; now when you use that dimension in a view, it will be continuous. You can easily revert back by selecting **Convert to Discrete** from the field's context menu in the **Data** pane. You can also convert a field in the view to continuous while it is on a shelf by selecting **Continuous** on its context menu (which you can see when you right-click (control-click on Mac) the field). The field on the shelf turns green but the field in the **Data** pane is still discrete.

## Date Properties for a Data Source

You can set date properties for a data source. To do so, right-click (control-click on Mac) a data source in the **Data** pane and choose Date Properties. The

### Date Property Options

#### Default calendar

Specifies which calendar system to use, **Standard Gregorian** or **ISO-8601 Week-Based**. Setting the default calendar determines how dates are used in the view by default. See [Date Functions on page 2200](#)

#### Week start

Specifies which day is considered the first day of the week. You can override the data source level **Week start** for certain date functions by including a `start_of_week` parameter. See [Date Functions on page 2200](#).

The initial value for this setting is sometimes determined by your data source. If the data source doesn't initialize the start-of-week day, then Tableau consults the system's locale settings. The day that is considered the first day of the week varies from region to region. For example, Sunday is the first day of the week in the US, while Monday is the first day in the EU.

This setting is unavailable for multidimensional data sources because this information is defined when the cube designer creates the datetime dimension.

After a data source is created, the **Week start** value doesn't automatically update to stay in sync with the host operating system (for example, if the published data source is used in a different country). Calendar controls reflect the workbook locale rather than the data source's **Week start** setting.

**Note:** An exception is a week truncation that shows the week number. This function uses the data source's **Week start** setting to provide a consistent week number value in the calendar.

## Fiscal year start

Specifies which month is considered the first month of the fiscal year. This setting is applied to the data source overall.

## Specific date fields

To specify whether a particular field uses the standard calendar (Jan. 1 - Dec. 31) or the fiscal calendar:

1. Right-click the field in the Data pane
2. Select **Default Properties > Fiscal Year Start**

For any date field in the view, you can then specify whether to use the standard calendar or the fiscal calendar. For details, see [Fiscal Dates on page 1110](#).

## Date format

Specifies the default format for date fields in locations such as the tooltip or labels. To override the default date format, right-click the field in the Data pane and select **Default Properties > Date Format**, then set a format.

## Day of the week sorting

If Tableau sorts the names of days of the week alphabetically, check your workbook locale. The local setting tells Tableau how to sort the days of the week in the correct chronological order. For information on setting the locale, see [Language and Locale on page 109](#).

If none of the supported locales is appropriate, you can sort the days of the week manually. See [Sort Data in a Visualization on page 1289](#).

## Supported date formats

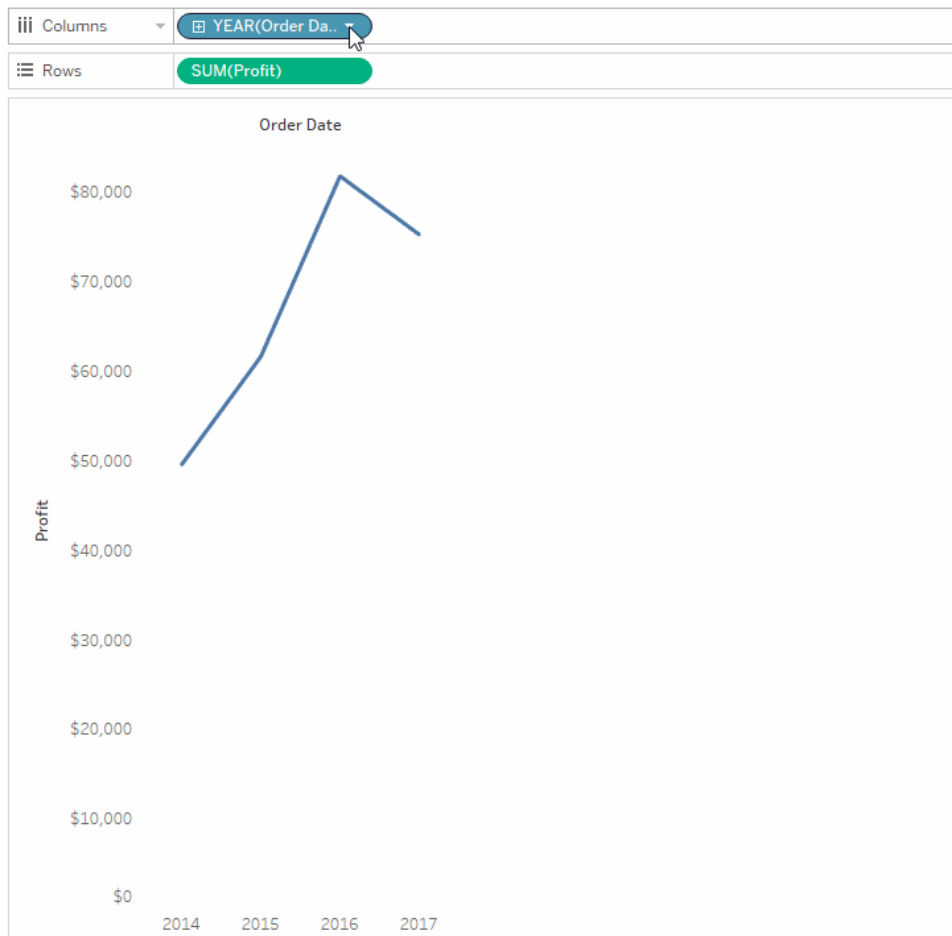

When working with dates, Tableau retrieves date formats automatically from the data source.

For a list of supported date formats, see the table of supported date format symbols in [Custom Date Formats on page 1113](#).

## Change Date Levels

To change the date level of a field, drag it to Rows or Columns (or another shelf), click its context menu, and then select a level.

Each level has a preview to indicate the effect of the setting.

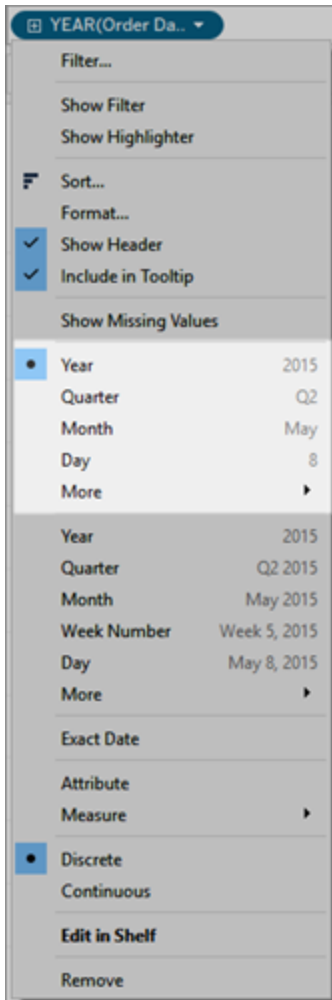

**Learn more:** For related concepts about dates, see [Dates in Tableau make me want to tear my hair out!](#) in the [VizPainter](#) blog by Tableau Visionary, Josh Milligan. For an in-depth demonstration of how date parts and date values work, see the free video presentation [Greatest of All Time Analytics: Conquering Date Calculations](#) (58 minutes).

In Tableau Desktop, cube (multidimensional) data sources are supported only in Windows. For cube (multidimensional) dates, the levels available in the context menu are given by the levels defined in the date hierarchy.

## Date level settings

The date level settings are organized by sections for date parts and date values.

Date parts give you data aggregated to the level of a specific part of a date. For example, the month of May for any year or the eighth day of any month.

### *Date Parts*

Date values give you the actual date, truncated to a specific level, such as May 2015 or May 8, 2015.

Date Values (also known as truncated dates or Date Truncs)

To get the most granular level of detail, which is also known as row-level or record-level data, you can select **Exact Date**.

### Exact Date

When you select a particular level, Tableau performs a computation on the date field. Suppose a particular row in your data source has a date entry of 01/23/16. The year is 2016, the quarter is 1 because January falls in the first quarter, and the week number is 4 because January 23rd falls in the fourth week.

How the date level is computed depends on how Date Properties are configured for the data source. For more information, see [Date Properties for a Data Source](#) on page 1099.

**Note:** Not all date levels are always relevant. For example, if the date format doesn't include time information such as hour, minute, or second, then these options don't add any data to your view.

### Use multiple date levels in the same viz

You can work with dates at varying levels of detail simultaneously. To do so, click the  control on a date field in the view. This is known as drilling into a date. For example, if you drill into a discrete date **YEAR(Order Date)**, Tableau adds a second field to the right of the initial date, **QUARTER(Order Date)**. You can continue drilling down until you reach the finest available granularity for the date field.

You can also drag date fields to the **Rows** or **Columns** shelf multiple times to nest them and to drill down into them at varying levels of detail.

For example, this view drills down from the year level to display the quarter level as well.

By removing one of the date fields, and then selecting **Month** from the remaining date field's context menu, you can look at each month across all years.

To display even finer granularity, select Month from the lower, continuous section of the field's context menu.

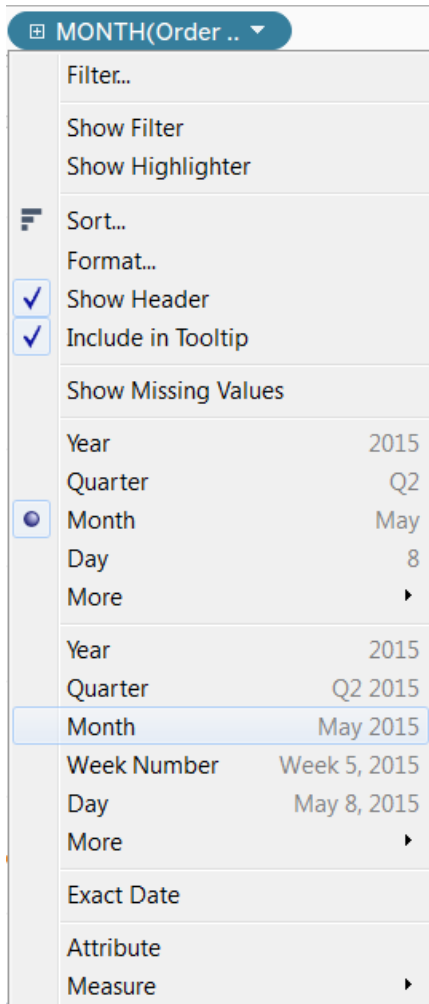

Tableau then displays the dates across the range of available years, at a month-by-month level of granularity.

## Custom Dates

Custom dates are useful if you always use a date at a specific level, or if you want to create calc that rely on a binned or truncated date.

You can create a custom date in the **Data** pane or writing a calc with the `DATEPART` or `DATETRUNC` functions.

1. Right-click (control-click on Mac) a date field in the **Data** pane and select **Create > Create Custom Date**.
2. From the **Detail** list, select the level you want.
3. Specify whether you want the custom date to be discrete (**Date Parts**) or continuous (**Date Value**).

- 4. Optional: Enter your own name for the field.
- 5. When you're finished, click **OK**.

Custom dates created this way appear as new fields in the **Data** pane.

### Example - format column headers as Month, Day, Year

This example uses the Sample - Superstore data source.

- 1. Drag [**Order Date**] to **Columns**.
- 2. Drag **Sales** to **Rows**.
- 3. Right-click [**Order Date**] on the **Columns** shelf and choose **More > Custom**.
- 4. In the Custom Date dialog box, choose **Month / Day /Year** from the **Detail** drop-down list.

The view now has the column headers in the correct format:

## Fiscal Dates

In some situations, a date field needs to be expressed in terms of an organization's fiscal year. Calendar years run from January 1st until December 31st, but an organization's fiscal year might start in a different month. For example, a company's fiscal year might run from June 1st through May 31st. In such cases, it's appropriate to display some date values in a view using fiscal equivalents (Fiscal Year, Fiscal Quarter, and Fiscal Week Number) rather than their calendar equivalents.

To set the fiscal year start month for a data source, follow these steps:

1. Right-click (Control-click on Mac) the data source in the **Data** pane to open the Date Properties dialog box.
2. Set the **Fiscal year start** field to the appropriate month.

For each date dimension, you set the fiscal year start-month separately. In the **Data** pane, right-click a date dimension (Ctrl-click on Mac), and select **Default Properties > Fiscal Year Start**.

Whether a given level of a date dimension is affected by the use of the Fiscal Calendar depends on the specific case.

<b>Date Level</b>	<b>When Converted to Fiscal</b>
Year	Reflects the fiscal year. For example, if <b>Fiscal year start</b> is set to April, the year for the date June 1, 2004 would be shown as FY 2005.
Quarter	The Quarter reflects the fiscal quarter. For example, if <b>Fiscal year start</b> is set to April, the quarter for the date June 1, 2004 would be Q1.
Month	No change in behavior. The calendar month is the same as the fiscal month.
Day	No change in behavior. The calendar day is the same as the fiscal day.
Hour	No change in behavior. The calendar hour is the same as the fiscal hour.
Minute	No change in behavior. The calendar minute is the same as the fiscal minute.
Second	No change in behavior. The calendar second is the same as the fiscal second.
Week Number	The Week Number reflects the fiscal week number. For example, if <b>Fiscal year start</b> is set to April, the week number for the date April 1, 2004 would be 1.
Weekday	No change in behavior. The calendar weekday is the same as the fiscal week-

Date Level	When Converted to Fiscal
	day.
MM/YYYY	No change in behavior. This date format always displays calendar dates, even when a fiscal year has been assigned.
M/D/Y	This date format always displays Calendar dates, even when a fiscal year has been assigned.

The only date levels that explicitly indicate that the fiscal calendar is in use are the Year and Quarter level. Specifically, fiscal years and quarters are shown with the FY prefix. This is not true for fiscal months or week numbers, however, which are not shown with any special fiscal markings.

Fiscal year designations for any given date dimension are applied to all instances of the field in the Tableau workbook. Fiscal dates can only be applied to dimensions in a relational data source.

Fiscal year formatting is applied to all date formats that include a year, or a year and a quarter. In particular, if you apply a custom date format, and only use the “y” and “q” placeholders, then `FY` will be prepended to each year.

## Date Levels

When a date dimension is using a fiscal calendar, only the following date parts and truncations present in the view will reflect the fiscal calendar:

### Date part or truncation - When using a fiscal calendar

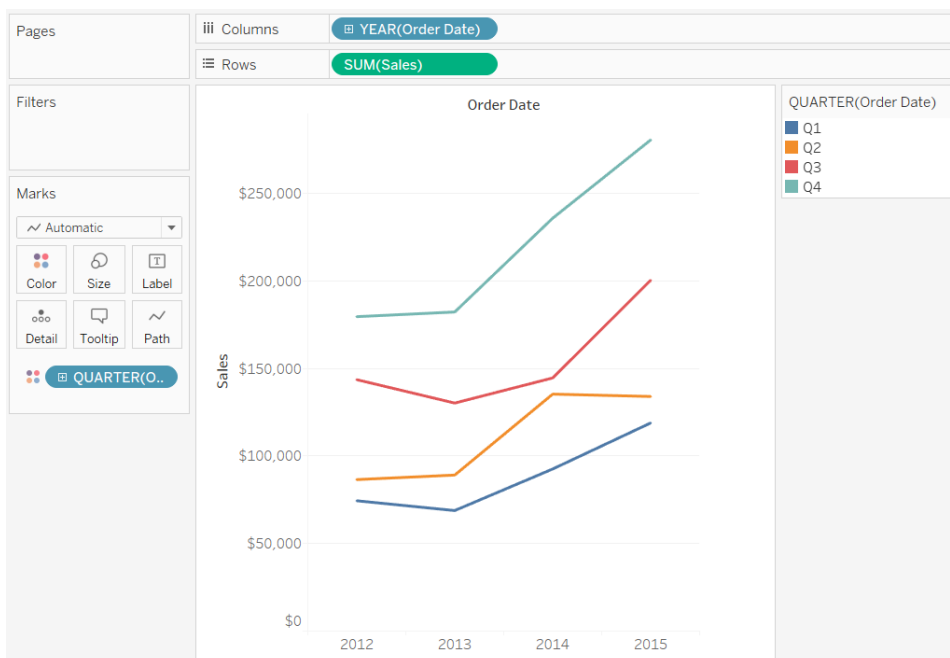

Year date part	<b>Fiscal year start</b> is set to April, the year for the date June 1, 2004 would be shown as FY 2005.
Quarter date part	<b>Fiscal year start</b> is set to April, the quarter for the date June 1, 2004 would be Q1.
Week Number date part	<b>Fiscal year start</b> is set to April, the week number for the date April 1, 2004 would be 1.
Year date truncation	<b>Fiscal year start</b> is set to May, the date June 1, 2004 would become May 1, 2004.
Quarter date truncation	<b>Fiscal year start</b> is set to July, the date June 1, 2004 would become April

cation 1, 2004.

## Perfect Pivoting with Dates

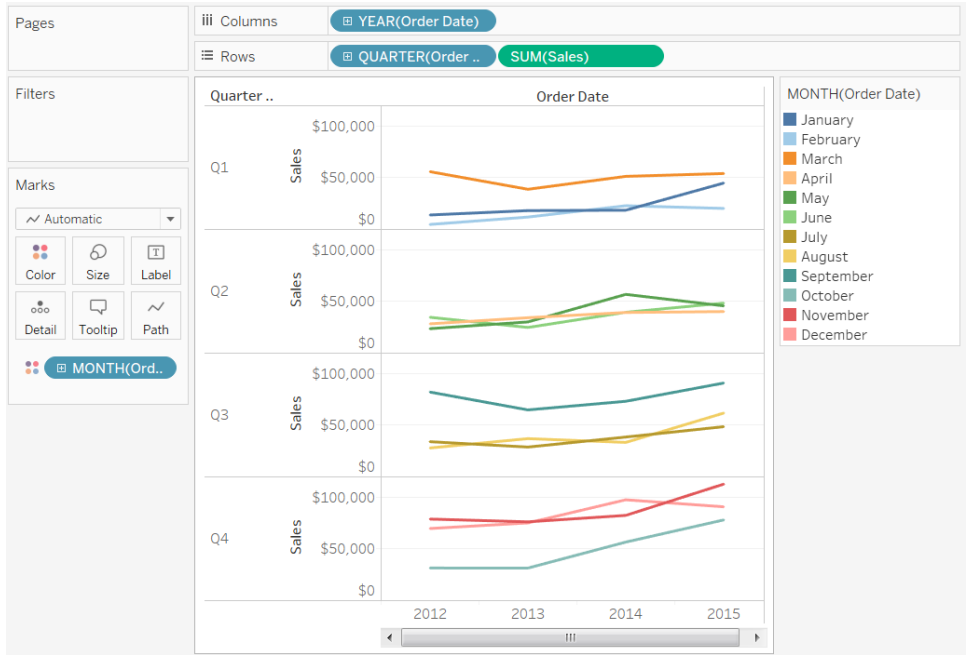

You can perfect pivot dates by placing different date levels on different worksheet shelves simultaneously. Place the date field on a variety of shelves and then select the desired date level from the fields' context menus.

For example, the following line chart displays years as column headers and then color-encodes the marks by quarter.

You can separate the marks by month and by quarter as shown below.

## Custom Date Formats

This article discusses using the custom date format field to format dates in a view. For an overview of how Tableau works with dates, see [Dates and Times](#), or [Changing Date Levels](#). For setting date properties for a **data source**, see [Date Properties for a Data Source](#).

### How to find the custom date format field

#### Format a date field in a view (Tableau Desktop)

To format a date field in the view in Tableau Desktop, right-click (Control-click on a Mac) the field and choose **Format**.

This opens the **Format** panel to the left of your view. Select the **Dates** field.

When you format dates, Tableau presents a list of available formats. Usually, the last item in the list is **Custom**. You can specify a custom date using format symbols listed in the Supported date format symbols table, either alone or in combination.

## Format a date field in a view (Tableau Cloud and Tableau Server)

To format a date field in the view in Tableau Cloud and Tableau Server, right-click (Control-click on a Mac) the field and choose **Format Date**.

## Format a date field in the Data pane (Tableau Desktop only)

To format a date field in the **Data** pane, right-click the field and choose **Default Properties > Date Format**.

The date formats in the table are supported when your workbook is connected to a Tableau extract or has a live connection to a data source that also supports the date format. (Refer to your data source's documentation to verify that the date format you want is supported.)

Tableau retrieves date formats from the data source. Tableau Server can also retrieve date formats from the Run As user account on the server that's running Tableau Server.

**Note:** The following date formats might not be the same as those used with the [Type Conversion](#) function. See [Convert Strings to Date Fields](#) for more information.

### Supported date format symbols

Use the following symbols to construct a custom date format.

Symbol	Description
(:)	Time separator. In some locales, a different character is used to represent the time separator. The time separator separates hours, minutes, and seconds when time values are formatted. The actual character used as the time separator in formatted output is determined by your system settings.
(/)	Date separator. In some locales, a different character is used to

	represent the date separator. The date separator separates the day, month, and year when date values are formatted. The actual character used as the date separator in formatted output is determined by your system settings.
c	Display the date as dddd and display the time as tttt, in that order. Display only date information if there's no fractional part to the date serial number; display only time information if there's no integer portion.
d	Display the day as a number without a leading zero (1-31).
dd	Display the day as a number with a leading zero (01-31).
ddd	Display the day as an abbreviation (Sun, Sat).
dddd	Display the day as a full name (Sunday, Saturday).
dddd	Display the date as a complete date (including day, month, and year), formatted according to your system's short date format setting. The default short date format is m/d/yy.
dddddd	Display a date serial number as a complete date (including day, month, and year) formatted according to the long date setting recognized by your system. The default long date format is mmm dd, yyyy.
aaaa	The same as dddd, only it's the localized version of the string.
w	Display the day of the week as a number (1 for Sunday through 7 for Saturday).
ww	Display the week of the year as a number (1-54).
M	Display the month as a number without a leading zero (1-12). If m immediately follows h or hh, the minute rather than the month is displayed.
MM	Display the month as a number with a leading zero (01-12). If m immediately follows h or hh, the minute rather than the month is displayed.

MMM	Display the month as an abbreviation (Jan-Dec).
MMMM	Display the month as a full month name (January-December).
MMMMM	Display the month as a single letter abbreviation (J-D)
oooo	The same as MMMM, but localized.
q	Display the quarter of the year as a number (1- 4).
y	Display the day of the year as a number (1-366).
yy	Display the year as a 2-digit number (00-99).
yyyy	Display the year as a 4-digit number (100-9999).
h	Display the hour as a number without leading zeros (0-23).
Hh	Display the hour as a number with leading zeros (00-23).
N	Display the minute as a number without leading zeros (0 59).
Nn	Display the minute as a number with leading zeros (00 59).
S	Display the second as a number without leading zeros (0 59).
Ss	Display the second as a number with leading zeros (00 59).
000	Display milliseconds. Use a period character as a separator before specifying milliseconds.
t t t t	Display a time as a complete time (including hour, minute, and second), formatted using the time separator defined by the time format recognized by your system. A leading zero is displayed if the leading zero option is selected and the time is before 10:00 A.M. or P.M. The default time format is <code>h : mm : s s</code> .
AM/PM	Use the 12-hour clock and display an uppercase AM with any hour before noon; display an uppercase PM with any hour between noon and 11:59 P.M.
am/pm	Use the 12-hour clock and display a lowercase AM with any hour before noon; display a lowercase PM with any hour between noon and 11:59 P.M.

A/P	Use the 12-hour clock and display an uppercase A with any hour before noon; display an uppercase P with any hour between noon and 11:59 P.M.
a/p	Use the 12-hour clock and display a lowercase A with any hour before noon; display a lowercase P with any hour between noon and 11:59 P.M.
AMPM	Use the 12-hour clock and display the AM string literal as defined by your system with any hour before noon; display the PM string literal as defined by your system with any hour between noon and 11:59 P.M. AMPM can be either uppercase or lowercase, but the case of the string displayed matches the string as defined by your system settings. The default format is AM/PM.

### Custom date format examples

Any of the date format symbols in the table above can be used alone or in combination.

Specifying a custom format yyyy-MM-dd HH:mm:ss.000 would produce dates in the format 2015-05-10 11:22:16.543. Such a format might be appropriate for scientific data.

Specifying a custom format DDDD DD would produce dates that show the Weekday and the Day, as shown below.

Specifying a custom format `yy-mm-dd (dddd)` would produce dates in the format **18-01-04 (Thursday)**.

Specifying a custom format `"Q"1 YYYY` would produce dates that show **Q1 2018**.

### Support for Japanese era-based date formats

Tableau supports Japanese emperor-era-based date (Wareki) formats. Here's how to apply an era-based date format to a field in your view:

1. Set your workbook locale to Japanese.
2. Right-click the field in the view for which you want to set a date format.
3. Choose **Format**.
4. In the **Format** pane, from the **Dates** drop-down list, select a format.

If the format that you want isn't listed, you can construct your own date format. To do this, choose **Custom format** in the **Dates** box, then type your format using the Tableau date placeholders. The following era-based year placeholders are available:

Symbol	Description
g	Short era name (such as H for the Heisei era).

gg	Era name (such as 平成).
ggg	Long era name (for Japanese, this is the same as the regular era name).
e	Era-based year, such as 1 for the first year of an era.
ee	Era-based year, such as 01 for the first year of an era. If there's only one digit, then the era-based year will have a zero added to the front.

If your workbook locale isn't Japanese, you can create a custom date format, then insert the language code !ja\_JP! in front of your format, so that it looks like this:

```
!ja_JP! gg ee"年"mm"月"dd"日"
```

The language code forces the date to be treated as if it's a Japanese date.

Era-based dates aren't fully supported by the Tableau Server browser view. In particular, if you publish a workbook that contains an interactive filter, the e and g placeholders won't be filled in:

**Order Date** gg ee年 01月 01日  gg ee年 12月 31日

To avoid this issue, don't show era-based dates in interactive filters if your workbook will be viewed in a browser.

### Using literal text in a date format

You may want your date format to include some words or phrases, such as **Fiscal Quarter q of yyyy**. However, if you type that text directly into the Tableau format box, it may treat the letters like date parts:

**Quarter of Order Date**

---

Fi01/1/2010a1 1quarter 1 of 2010

Fi04/1/2010a1 2quarter 2 of 2010

Fi07/1/2010a1 3quarter 3 of 2010

Fi10/1/2010a1 4quarter 4 of 2010

To prevent Tableau from doing this, put double quotes around the letters and words that shouldn't be treated as date parts: "Fiscal Quarter" q "of" yyyy.

If you want a literal quote inside of a quoted section, insert this code: "\ ". For example, the format "Fiscal \" Quarter" would be formatted as **Fiscal " Quarter**.

## Format syntax in DATEPARSE function for extract data sources

If you're using the DATEPARSE function in an extract, use the syntax defined by the Unicode Consortium.

The following table lists the field types that can be represented in the format parameter of the DATEPARSE function. Click the field type to get information about the symbols, field patterns, examples, and descriptions from the Unicode Consortium website.

Unit of time	Notes
<a href="#">Era</a>	n/a
<a href="#">Year</a>	<p>All symbols are supported in .hyper extracts except for "U".</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• Negative values denote a year before Christ (BC). For example, <code>DATEPARSE('y', '-10')</code> returns the first January of 11BC and <code>DATEPARSE('y', '-0')</code> returns the first January of 1BC.</li> <li>• When working with the calendar year "y", the pattern "yy" requests the two low-order digits of the year. For numbers &lt; 70, the DATEPARSE function returns the year 2000+x. For numbers &gt;=70, the DATEPARSE function returns the year 1900+x.</li> <li>• When working with "Y" in "ISO week date" based calendars, the year transition occurs on a week boundary and may differ from the calendar year transition. The "Y" designation is used in conjunction with pattern character "w" in ISO year-week calendar. The ISO week date system is effectively a leap week calendar system that is part of the ISO 8601 date and time standard. Similar to "y", negative values for "Y" denote a year before Christ (BC).</li> </ul>
<a href="#">Month</a>	<p>All symbols are supported in .hyper extracts except for "l".</p> <p><b>Notes:</b></p>

Unit of time	Notes
	<ul style="list-style-type: none"> <li>The month designations are used in conjunction with "d" for the day number.</li> <li>In contrast to ICU, .hyper extracts allow values 1–12. Other values cause an error.</li> </ul>
Week	<p>All symbols are supported in .hyper extracts except for "W".</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>When working with "w", in contrast to ICU, .hyper extracts allow only valid weeks. A year has 52 or 53 weeks (ISO 8601). The DATEPARSE function validates the input. For example, an error occurs for the 53rd week of 2016 because the 53rd week doesn't exist for 2016.</li> <li>When working with "W", ICU doesn't support this designation, but it's useful for dates like 1st Monday of September.</li> </ul>
Day	<p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>When working with "d", in contrast to ICU, .hyper extracts only allow valid day numbers. For example, an error occurs for the 31st of February.</li> <li>When working with "D", in contrast to ICU, .hyper extracts only allow valid day numbers. For example, an error occurs for the 366th day of 2017.</li> </ul>
Hour	<p>Only "h" and "H" symbols are supported in .hyper extracts.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>When working with "h", .hyper extract don't allow negative values for this field. Negative values cause an error.</li> <li>When working with "H", .hyper extracts don't allow</li> </ul>

Unit of time	Notes
	negative values for this field. Negative values cause an error.
Minute	<b>Note:</b> In contrast to ICU, .hyper extracts don't allow negative values for this field. Negative values will cause an error.
Second	<b>Notes:</b> <ul style="list-style-type: none"> <li>In contrast to ICU, .hyper extracts don't allow negative values for this field. Negative values will cause an error.</li> <li>When working with "S", <code>DATEPARSE('ss.SSSS', '12.3456')</code> returns 1990-01-01 00:00:12:3456 AD.</li> </ul>
Quarter	<b>Note:</b> In contrast to ICU, .hyper extracts only allow values 1–4. All other values cause an error.
Weekday	<b>Notes:</b> <ul style="list-style-type: none"> <li>When working with "e" and "ee", in contrast to ICU, .hyper extracts only allow values 1–7. All other values cause an error.</li> <li>When working with "c.cc", in contrast to ICU, .hyper extracts only allow values 1–7. All other values cause an error.</li> </ul>
Period	n/a

## ISO-8601 Week-Based Calendar

The ISO-8601 Week-Based Calendar is an international standard for date-related data. The purpose of the ISO-8601 calendar is to provide a consistent and clear method to represent and calculate dates. ISO-8601 calendars divide dates into years, quarters, weeks, and weekdays. Unlike the Gregorian calendar, ISO-8601 calendars have a consistent number of weeks in each quarter and a consistent number of days each week. This makes the ISO-8601 calendar popular when calculating retail and financial dates.

## Set ISO-8601 as the default calendar

To set the ISO 8601 calendar for a data source, follow these steps:

1. Right-click (control-click on Mac) the data source in the **Data** pane to open the Date Properties dialog box.
2. Set the **Default calendar** field to ISO-8601 Week-based.

For each date field on the shelf, you can set the calendar type separately. In the shelf, right-click a date dimension (Ctrl-click on Mac), and select **ISO-8601 Week-Based**.

## Differences between ISO-8601 and Standard Gregorian calendars

Not all date levels are relevant in a fiscal calendar.

Gregorian	ISO-8601	Differences between calendars
Year	ISOYEAR	ISO-8601 years always start on the first Monday closest to January 1. This means the year may start anywhere between December 29 and January 4. Gregorian calendars always start the year on January 1. This can cause some discrepancy in years between the two calendar systems around those dates. Each ISO-8601 year is either a <i>long</i> or a <i>short</i> year, with 52 or 53 weeks, depending on when the ISO-8601 year begins.
Quarter	ISOQUARTER	The first three quarters in the ISO-8601 always have 13 weeks. The last quarter has either 13 weeks (in a short year) or 14 weeks (in a long year).

Gregorian	ISO-8601	Differences between calendars
Month		The ISO-8601 week-based calendar doesn't use months. Many retail and financial systems divide ISO-8601 quarters into three segments of 4-4-5 weeks, though other "month" patterns also exist. These can be defined using calculations. See <a href="#">Create a 4-4-5 calendar on the facing page</a> .
Week Number	ISOWEEK	All weeks in the ISO-8601 week-based calendar have exactly 7 days and start on a Monday. Each week belongs to single year, unlike the Gregorian calendar which permits weeks to extend across years. Long years have 53 weeks, short years have 52 weeks.
Day		The ISO-8601 week-based calendar doesn't use numerical days (such as the 14th or 23rd).
Weekday	ISOWEEKDAY	ISO-8601 weekdays always start on Monday and are represented as single digits. Monday is 1, Tuesday is 2, through to 7 for Sunday.

## Date Functions that support ISO-8601

The following date functions are compatible with the ISO-8601 week-based calendar.

### DATEADD and DATEDIFF

The result truncates an ISO-8601 date to the nearest ISO level if non-ISO-8601 date parts (`day` or `month`) are used. For example, adding one month to an ISO-8601 date results in the `iso-week` changing.

### DATENAME

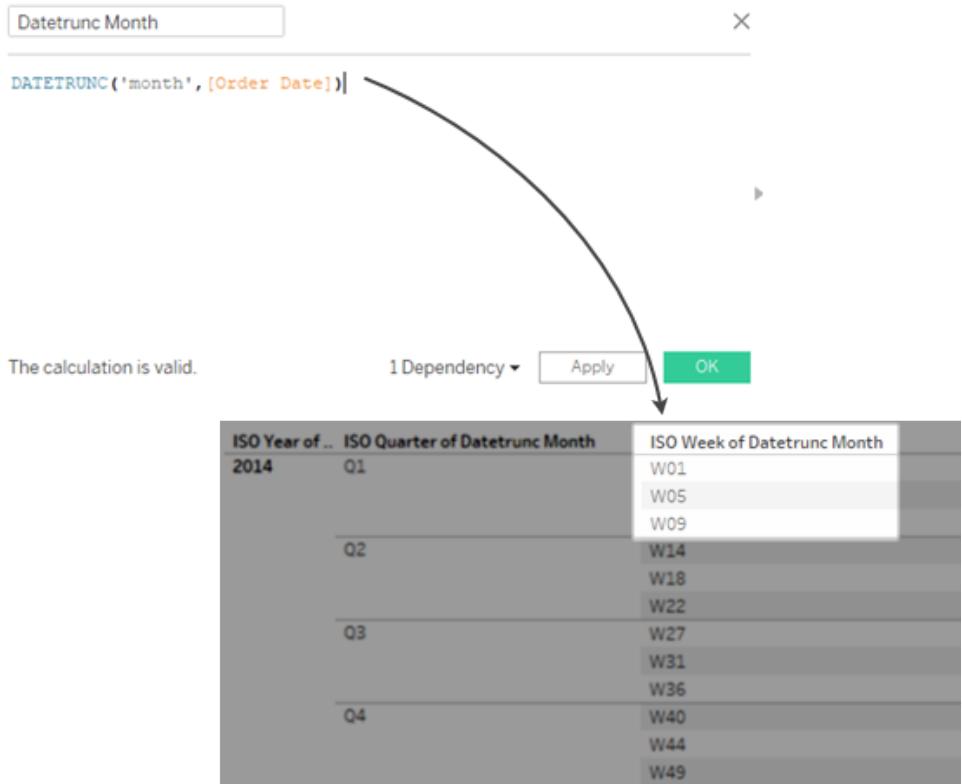

The result is a Gregorian date unless you use the `iso-year`, `iso-quarter`, `iso-week`, or `iso-weekday` date parts.

### DATEPART

The result is a Gregorian date unless you use the `iso-year`, `iso-quarter`, `iso-week`, or `iso-weekday` date parts.

## DATETRUNC

Truncates an ISO-8601 date to the nearest ISO level. For example, even though the ISO-8601 doesn't use months, truncating the ISO date at 'month' displays the first *iso-week* of the Gregorian month.

### Create a 4-4-5 calendar

The ISO-8601 week-based calendar doesn't use months. Many retail and financial systems divide ISO-8601 quarters into three segments of 4-4-5 weeks, though other segment systems also exist.

Follow along with these steps to learn how to implement a 4-4-5 calendar in Tableau Desktop.

## Step 1: Set up the visualization

1. Open Tableau Desktop and connect to the **Sample-Superstore** saved data source.
2. Right-click the data source in the Data pane to open the Date Properties dialog box. Change the default calendar to ISO-8601 Week-based.

3. From the **Data** pane, drag **Order Date** to the **Rows** shelf.
4. On the Rows shelf, click the '+' icon on ISOYEAR(Order Date) to expand out ISOQUARTER(Order Date).
5. From the **Data** pane, drag **Sales** to the **Columns** shelf.

## Step 2: Find the number of weeks in each quarter

In a 4-4-5 segment calendar, each quarter is divided into 3 segments (analogous to months) with 4 or 5 weeks in them. We must find how many weeks are in each quarter to divide them into segments.

1. Select Analysis > Create Calculated Field.
2. Name the calculated field **Week of Quarter**
3. Enter the following calculation in the calculation dialog

```
DATEPART('iso-week', [Order Date]) - (DATEPART('iso-quarter', [Order Date]) - 1) * 13
```

### Step 3: Create the 4-4-5 calendar calculation

1. Select Analysis > Create Calculated Field.
2. Name the calculated field **4-4-5 Segment**.
3. Enter the following calculation in the calculation dialog

```
IF([Week of Quarter] <= 4) THEN "1" ELSEIF ([Week of Quarter] <= 8) THEN "2" ELSE "3" END
```

*The values 1, 2, 3 are labels for the three segments and can be replaced with any value you choose.*

4. From the data pane, drag the **4-4-5 Segment** calculated field to the Rows shelf.

The resulting viz now has each quarter broken down into three segments.

## Modify the pattern

In the **4-4-5 Segment** calculation, the cutoffs  $\leq 4$  and  $\leq 8$  come from the 4-4-5 pattern.

The first segment's cutoff is  $\leq 4$  for the first four weeks (1-4). The second segment's cutoff is  $\leq 8$  (encompassing weeks 5-8), and the remaining weeks (9-13) are captured in the ELSE portion. (IF statements are calculated until a condition is true, so the second segment only needs to specify the upper limit.)

These cutoffs can be modified for other patterns. Specifically:

- 4-5-4 cutoffs: 4 (for the first four weeks, 1-4) and 9 (for the next five weeks, 5-9)
- 5-4-4 cutoffs: 5 and 9

The week and year numbering in an ISO-8601 calendar is different from a standard Gregorian calendar. Here's how January 2nd, 2011 would be represented:

Calendar System	Week Number	Year Number
Standard Gregorian	1	2011
ISO-8601	52	2010

When formatting dates, it's important to ensure that your month, week and year numbers all come from the same calendar system. Otherwise, the date might not make sense. There are two ways to do this:

- Let Tableau guess which calendar system you want to use for each placeholder. For example, if you type `mm_yyyy` (a month followed by a year), Tableau uses the standard Gregorian year. In this case, it makes sense to use that year with a month number.
- In your format string, place an annotation after each week (`ww`) or year (`yyyy`) placeholder, to indicate what kind of placeholder it should be:

Annotation	Calendar to Use	Example Format String
[Y]	ISO-8601	ww[Y] yyyy[Y]
[y]	Standard Gregorian	ww[y] yyyy[y]

**Important:** To get correct ISO-8601 week numbering, your computer's location must be set to one of the [above](#) locales, and you must set your data source start of week to Monday. (For information on how to do this, see [Date Properties for a Data Source on page 1099](#).)

Otherwise, Tableau will number weeks using your data source start of week setting, which may result in partial weeks at the beginning and end of years being created.

**Note:** ISO week numbering will not occur if you are using a fiscal year that doesn't start in January, regardless of the locale you choose.

### Sample format strings for the date December 31, 2013

Here are sample format strings for the date December 31, 2013, where m stands for a month or day-of-month placeholder. Time placeholders, such as hours, minutes, and seconds, don't influence whether or not a year is week-based or year-based.

Format string	Formatted output
yyyy	2013
yyyy[Y]	2014
yyyy ww	2014 1
yyyy mm	2013 12
ww yyyy	1 2014
mm yyyy	12 2013
ww yyyy[y]	1 2013
mm yyyy[Y]	12 2014
yyyy mm ww	2013 12 1
mm yyyy ww	12 2013 1
ww mm yyyy	1 12 2013
ww mm yyyy[Y]	1 12 2014
ww yyyy mm	1 2014 12 (format is ambiguous)
ww yyyy[y] mm	1 2013 12
ww yyyy mm yyyy	1 2014 12 2013
ww yyyy yyyy mm	1 2014 2013 12
yyyy mm ww yyyy	2013 12 1 2014

## Continuous Dates

By default, dates come into the view as a discrete field. Date parts (such as year or month) can be used like any other discrete field and create labels in the view.

However, you can change dates to continuous if you choose. Select one of the Continuous date options on the field's context menu to use date truncations (such as March 2020 or 25/03/2022) instead of date parts. Continuous dates create an axis in the view.

Discrete date part

Continuous date truncation

### Change the default

To make a given date field continuous by default, right-click (control-click on Mac) the field in the **Data** pane and select **Convert to Continuous**. The field turns green and defaults to a

continuous date when used in the view. To revert to discrete again, right-click (control-click on Mac) the field in the **Data** pane and select **Convert to Discrete**.

See also

For more information on the impact of using a continuous or discrete field, refer to [Dimensions and Measures, Blue and Green](#) on page 148.

## Build Data Views from Scratch

This section describes the various features at your disposal and tasks related to building visualizations in Tableau.

Every view that you build in Tableau should start with a question. What do you want to know? Every time you drag a field into the view or onto a shelf, you are asking a question about the data. The question will vary depending on where you drag various fields, the types of fields, and the order in which you drag fields into the view.

For every question you ask about your data, the marks in your viz update to represent the answer visually—with shapes, text, size, color, headers, axes, hierarchies, or table structures.

For information on building and viewing visualizations on the web, see [Use Tableau on the Web](#) on page 3106.

Looking for a data set to work with? Check out our tips to [find good data sets](#).

## Start Building a Visualization by Dragging Fields to the View

The basic structure for every view is made of dimension and measure fields placed on the Rows and Columns shelves, and on different properties in the Marks card.

You build visualizations by adding fields from the Data pane to the view. As you build a visualization, you can add as many fields as necessary to different areas of the view, and then move those fields around as you explore your data.

### Different ways to start building a view

When you build a view, you add fields from the **Data** pane. You can do this in different ways. For example:

- Drag fields from the **Data** pane and drop them onto the cards and shelves that are part of every Tableau worksheet.
- Double-click one or more fields in the **Data** pane.
- Select one or more fields in the **Data** pane and then choose a chart type from **Show Me**, which identifies the chart types that are appropriate for the fields you selected. For details, see [Use Show Me to Start a View](#) on page 1173.
- Drop a field on the **Drop field here** grid, to start creating a view from a tabular perspective.

As you start exploring data in Tableau, you will find there are many ways to build a view. Tableau is extremely flexible, and also very forgiving. As you build a view, if you ever take a path that isn't answering your question, you can always undo to a previous point in your exploration.

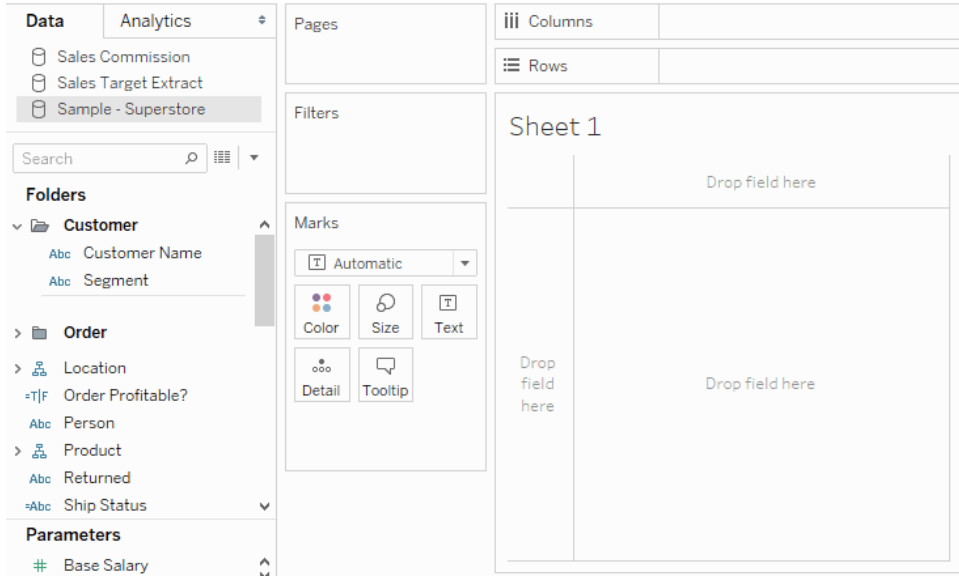

- To undo or redo, click undo ← or redo → on the toolbar.

You can undo all the way back to the last time you opened the workbook. You can undo or redo an unlimited number of times.

## Dragging basics

When you begin creating a new data view on a blank worksheet, you can drag a field from the **Data** pane and drop it directly into the view, rather than to a shelf.

In Tableau Desktop, while dragging fields, you can hover over the different areas in the view to see how the field will be incorporated into the structure of the view. For example, dimensions typically add a row and column headers to the view, while measures add continuous axes. Below are some examples of how fields can be added to the view.

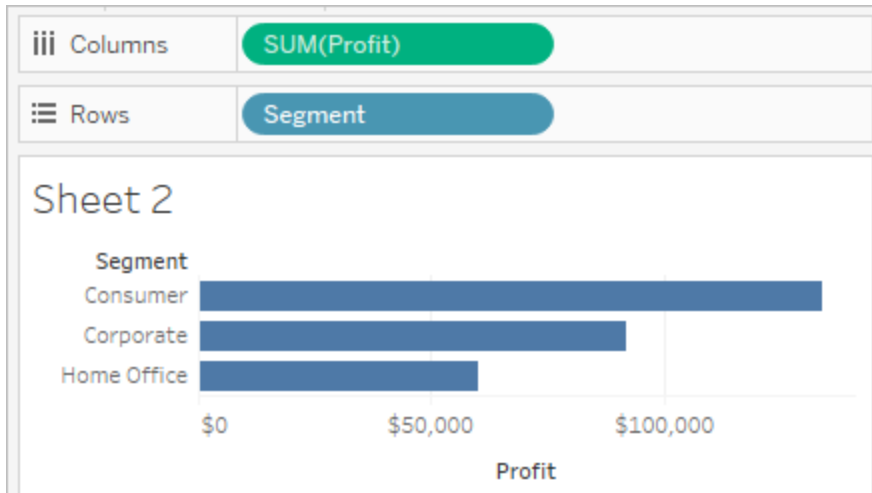

**Dimensions add headers**

**Measures add axes**  
**Show Me automatically adds the field according to best practices**

For a more advanced discussion of dimensions and measures, see [Dimensions and Measures, Blue and Green](#) on page 148.

When you drop a field on one of the active areas in the view, the field is added to the view and also to one of the shelves or cards. For example, in the view below the **Segment** dimension was added to the **Rows** shelf and the **Profit** measure was added to the **Columns** shelf—and automatically aggregated so that the values in the data are summed.

You can, of course, also drag fields directly to the shelves instead of to the active areas in the view. You can also drag fields from one shelf to another shelf. To remove a field from a shelf, drag it off the worksheet or select **Remove** from the field's menu (available when you right-click (control-click on Mac) a field in the view). In Tableau Desktop, you can also quickly remove multiple fields from a shelf by right-clicking (control-click on Mac) the shelf and selecting **Clear Shelf**.

## Add headers

You can add headers to a view by dragging a discrete (blue) dimension and dropping it to either side of an existing header, or to the left of an axis. For example, in the view below you can add the **Region** dimension by dragging it and dropping it to the right of the Sub-Category names.

## Tableau Desktop and Web Authoring Help

The screenshot shows the Tableau Desktop interface. On the left is the Data pane with a search bar and a list of folders: Location (Region, Country/Region, State, City, Postal Code), Product (Category, Sub-Category), and Parameters (Base Salary). The main view is a table titled 'Sheet 1' with columns for Sub-Category and Segment (Consumer, Corporate, Home Office). The table contains 20 rows of data, each with 'Abc' values. A dotted black line is visible at the top of the table, indicating an active area for adding headers. The Marks card in the center shows 'Automatic' as the mark type, with options for Color, Size, Text, Detail, and Tooltip.

Sub-Category	Segment		
	Consumer	Corporate	Home Office
Accessories	Abc	Abc	Abc
Appliances	Abc	Abc	Abc
Art	Abc	Abc	Abc
Binders	Abc	Abc	Abc
Bookcases	Abc	Abc	Abc
Chairs	Abc	Abc	Abc
Copiers	Abc	Abc	Abc
Envelopes	Abc	Abc	Abc
Fasteners	Abc	Abc	Abc
Furnishings	Abc	Abc	Abc
Labels	Abc	Abc	Abc
Machines	Abc	Abc	Abc
Paper	Abc	Abc	Abc
Phones	Abc	Abc	Abc

As you hover over the view, a dotted black line indicates active areas where you can add headers.

If you drop **Region** there, it adds a column for Region along the top of the table, and slices the data so that you see results for each region within each sub-category.

Columns		Segment		
Rows		Sub-Category	Region	
Sheet 2				
Sub-Category	Region	Segment		
		Consumer	Corporate	Home Of..
Accessories	Central	Abc	Abc	Abc
	East	Abc	Abc	Abc
	South	Abc	Abc	Abc
	West	Abc	Abc	Abc
Appliances	Central	Abc	Abc	Abc
	East	Abc	Abc	Abc
	South	Abc	Abc	Abc
	West	Abc	Abc	Abc
Art	Central	Abc	Abc	Abc
	East	Abc	Abc	Abc
	South	Abc	Abc	Abc
	West	Abc	Abc	Abc
Binders	Central	Abc	Abc	Abc
	East	Abc	Abc	Abc

## Add axes

You can add axes by dragging a continuous (green) measure and dropping it on an active area in the view. If an axis already exists in the view you can replace the existing axis, blend the new measure with the existing axis, or add a secondary axis.

### Replace the Existing Axis

Drag the new measure to the top left portion of the axis in the view. A small square drop zone appears and a single axis icon displays to indicate that a single axis will be left when you drop the measure. In this case you are replacing one measure (**Sales**) with another (**Profit**).

### Blend the Measures on Single Axis

You can show multiple measures on a single axis by dragging the new measure directly on top of the existing axis. Blending measures uses the Measure Names and Measure Values fields. For more information, see [Measure Values and Measure Names](#) on page 1160.

In the image below you are adding a second measure (**Profit**) to the existing measure (**Sales**) on the axis.

The result is a view with both measures plotted along a single axis. In this case, Sales is shown in orange and Profit is shown in blue.

## Add a Dual Axis

Drag the field to the right side of the view to add the measure as a dual axis. Dual Axes are useful when you want to compare two fields that have different scales. In this case, blending the two axes would distort the view. Instead you can add a dual axis.

The result is a dual axis view where the Profit axis corresponds to the blue line and the Sales axis corresponds to the orange line.

You can add up to four axes to the view: two on the Columns shelf and two on the Rows shelf. To turn a measure into a dual axis, right-click (control-click on Mac) a field on the **Rows** or **Columns** shelf and select **Dual Axis**.

## Rearrange rows and columns

You can rearrange the rows and columns in the view by changing the order of the fields in the Rows and Columns shelves, or by dragging the selection border for headers or an axis.

### Automatically add fields to the view with double-click

Tableau supports an additional method for automatically generating views of data called Automatic Double-Click. To use this method, double-click fields in the Data pane you are interested in. Tableau automatically adds each field to the view. That is, each double-click results in an additional field added to a shelf in an intelligent way. Like **Show Me**, this function leverages Tableau’s ability to make an intelligent “best guess” of how the data should be displayed. Double-clicking sometimes creates a view that you can use without further modification. More often, it can provide a starting point, which you can then modify to get the ideal result.

1. Double-clicking the **Profit** measure in the **Data** pane automatically adds that field to the view in an intelligent way.

2. Double-clicking the **Category** dimension in the **Data** pane automatically adds that field to the view based on the fact that Profit is already on the Rows shelf.

3. Double-clicking the **Order Date** dimension in the **Data** pane automatically adds that field to the **Columns** shelf based on the placement of other fields in the view. As you double-click fields they are successively added to the view. The order in which you click fields determines the type of view created.

The following table describes some of the rules used in creating automatic views by double-clicking fields in the **Data** pane.

Text Table	Adding a dimension first produces a text table (or cross-tab). All subsequent clicks on fields result in refinement of the text table.
Bars	Adding a measure first and then a dimension produces a bar view. All subsequent clicks result in refinement of the bar view, unless a date dimension is added, at which time the view is changed to a line.
Line	Adding a measure and then a date dimension produces a line view. All subsequent clicks result in refinement of the line view.
Continuous Line	Adding a continuous dimension and then a measure produces a continuous line view. Subsequent dimensions result in refinement of the continuous line view. Subsequent measures add quantitative axes to the view.
Scatter	Adding a measure and then another measure produces a scatter view. Subsequent dimensions result in refinement to the scatter view. Subsequent measures will create a scatter matrix.

## Maps

Adding a geographic field produces a map view with latitude and longitude as axes and the geographic field on the Level of Detail shelf. Subsequent dimensions add rows to the view while subsequent measures further refine the map by adding size and color encoding.

## Other resources

[Build a Basic View to Explore Your Data](#) on page 3

[Build Common Chart Types in Data Views](#) on page 1417

## Add Axes for Multiple Measures in Views

There are several different ways to compare multiple measures in a single view. You can:

- Create individual axes for each measure.
- Blend two measures to share an axis.
- Add dual axes where there are two independent axes layered in the same pane.

In any of these cases you can customize the marks for each axis to use multiple mark types and add different levels of detail. Views that have customized marks are called combination or combo charts.

**Note:** For details on how to edit axes, see [Edit Axes on page 2886](#).

### Add individual axes for measures

To add individual axes for each measure, drag measures to the **Rows** and **Columns** shelves.

- Adding a continuous field on the Rows shelf adds an additional axis to the rows of the table.
- Adding a continuous field on the Columns shelf adds an additional axis to the columns of the table.

The example below shows quarterly sales and profit. The Sales and Profit axes are individual rows in the table and have independent scales.

The Order Date field on the Columns shelf is a discrete date dimension. Because it is discrete, it creates headers rather than an axis. For details on how to edit axes, see [Edit Axes on page 2886](#).

### Blend axes for multiple measures into a single axis

Measures can share a single axis so that all the marks are shown in a single pane.

To blend multiple measures, drag one measure or axis and drop it onto an existing axis.

Instead of adding rows and columns to the view, when you blend measures there is a single row or column and all of the values for each measure is shown along one continuous axis. For example, the view below shows quarterly sales and profit on a shared axis.

**Note:** If you drag a measure on to the canvas and only see a single ruler indicator instead of the double ruler indicator shown below, Tableau creates dual axes instead of a blended axis. For more information about how to create dual axes, see [Compare two measures using dual axes on the next page](#).

Blending measures uses the **Measure Names** and **Measure Values** fields, which are generated fields that contain all of the measure names in your data source and all of the measure values. The shared axis is created using the **Measure Values** field. The **Measure Names** field is added to **Color** on the Marks card so that a line is drawn for each measure. Finally, the **Measure Names** field is filtered to only include the measures you want to blend.

**Note:** Blending axes is most appropriate when comparing measures that have a similar scale and units. If the scales of the two measures are drastically different, the trends may be distorted.

## Compare two measures using dual axes

You can compare multiple measures using dual axes, which are two independent axes that are layered on top of each other. Dual axes are useful for analyzing two measures with different scales.

To add a measure as a dual axis, drag the field to the right side of the view and drop it when you see a black dashed line appear.

You can also right-click (control-click on Mac) the measure on the Columns or Rows shelf and select **Dual Axis**.

The result is a dual axis view where the Profit axis corresponds to the blue line and the Sales axis corresponds to the orange line.

You can add up to four layered axes: two on the Columns shelf and two on the Rows shelf.

## Synchronize axes to use the same scale

To align the two axes in a dual axes chart to use the same scale, right-click (control-click on Mac) the secondary axis, and select **Synchronize Axis**. This aligns the scale of the secondary axis to the scale of the primary axis.

In this example, the Sales axis is the secondary axis and the Profit axis is the primary axis.

**Note:** To synchronize axes, the data types for both measures must be the same. If the data types for your measures are different, see the section below.

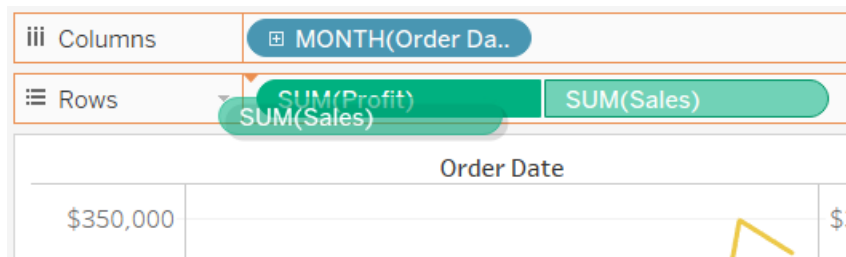

You can synchronize dual axes for numeric data types that don't match. For example, you

can synchronize an axis that uses an integer data type and an axis that uses decimal data type.

If you would like to change which axis is the primary, and which axis is the secondary, select the field on the Columns or Rows shelf that is the secondary, and drag it in front of the primary field on the shelf until you see an orange triangle appear.

In this example, you can select the **SUM(Sales)** field on the **Rows** shelf, and drag it in front of the **SUM(Profit)** field. The Sales axis is now the primary and the Profit axis is the secondary.

### Synchronize axes with measures of different data types

The **Synchronize Axis** option ensures that you make a scaled and correct comparison in a dual axes chart. However, sometimes this option may not be available (grayed out). This is because the data type of one of the axes is different from the other.

**Note:** In a chart with dual axes, starting with version 2018.1, you can synchronize dual axes for numeric data types that don't match. For example, you can synchronize an axis that uses an integer data type and an axis that uses decimal data type.

To resolve this issue, you must change the data type of one of the axes. Follow the example below to change the data type for an axis.

1. Click the new Worksheet  icon to open a new worksheet.
2. Drag **Order Date** to Columns, then click the drop-down arrow on the field on the shelf and select **Month** from the context menu.
3. Drag **Sales** to Rows, then drag **Quantity** to the right side of the view and drop it when you see a black dashed line appear to create a dual axis.

If you right-click on the **Quantity** Axis, you can see that the **Synchronize Axis** option is grayed out

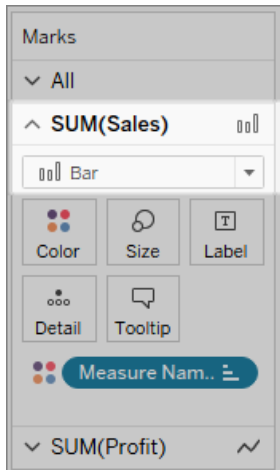

4. In the Data pane, click on the drop-down arrow on the **Quantity** field, and select **Change Data Type > Number (decimal)** in the context menu. This changes the data type for this field.

5. Replace the **Quantity** measure on the view.
6. Right-click the secondary axis, and then select **Synchronize Axis**.

### Customize the marks for a measure

1. Select the Marks card for the measure that you want to customize. There is a Marks card for each measure on the Rows and Columns shelves.

2. Select a new mark type for the measure.

Any changes to the mark type, shape, size, color, detail and other mark properties will be applied to the selected measure.

For example, in the view below the **Sales** Marks card is active. The Mark Type has been changed to **Bar** and when **Product Type** is placed on **Color** on the **Sales** Marks card, the encoding and level of detail is only applied to the Sales marks. The Budget Sales mark is not broken down by Product Type.

## Tips

- Select a field in the Marks card to modify only its properties.
- Select the **All** Marks card to modify properties for all measures at once.
- To change the order of a field's marks in the view, right-click its axis, and then select **Move marks to front**.

## Create a combo chart (assign different mark types to measures)

When working with multiple measures in a view, you can customize the mark type for each distinct measure. Because each measure can have customized marks, you can customize the level of detail, size, shape, and color encoding for each measure too.

For example, you could create a view that uses two measures in dual axes. One measure shows Profit with a line mark, and the other measure shows Sales with bar marks. You could also choose to display the measures as individual axes or blended axes.

**To create a combo chart like this example**

1. Connect to the Sample - Superstore data source.
2. Drag the Order Date measure to the Columns shelf, and then click Order Date change Year to Month.

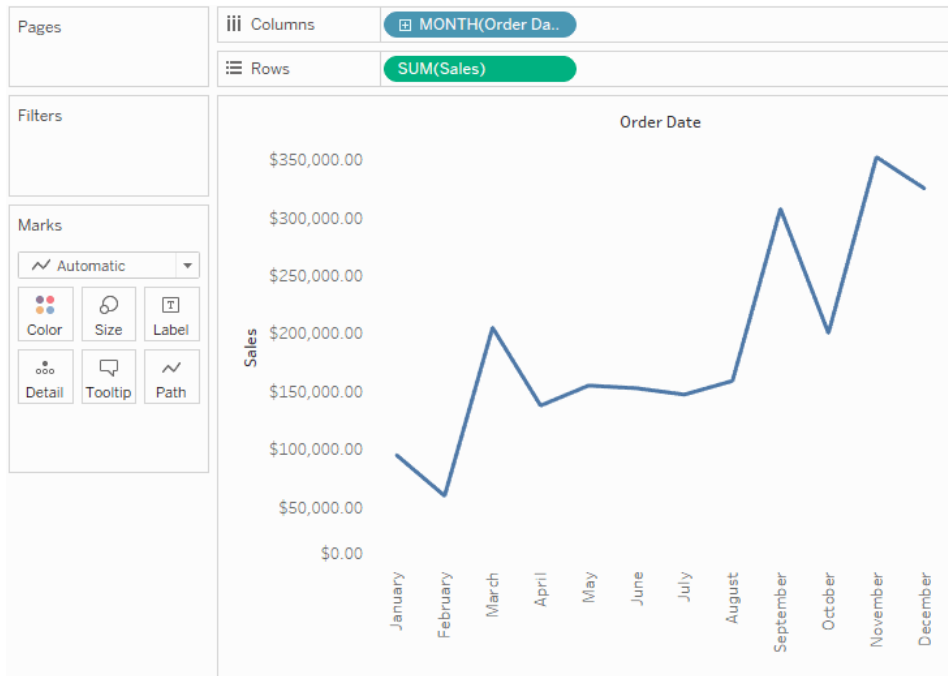

3. Drag the Sales measure to the Rows shelf.

4. Drag the Profit measure to the right side of the view and drop it when you see a black dashed line appear.

## Tableau Desktop and Web Authoring Help

5. Click the Sales card. Change the Sales mark type to **Bar**.

**Optional:** To adjust the colors used for the Sales and Profit marks:

1. Click the **All** card, click **Color**, and then click **Edit Colors**.
2. Click the Profit data item, and then click a different color in the palette. Click the Sales data item, and then click a different color in the palette.
3. Click **Apply**, and then click **OK**.

## Measure Values and Measure Names

The Data pane always contains a number of fields that do not come from your original data, two of which are **Measure Values** and **Measure Names**. Tableau automatically creates these fields so that you can build certain types of views that involve multiple measures.

- The **Measure Values** field contains all the measures in your data, collected into a single field with continuous values. Drag individual measure fields out of the Measure Values card to remove them from the view.
- The **Measure Names** field contains the names of all measures in your data, collected into a single field with discrete values.

### How you can use Measure Names and Measure Values

Tableau automatically creates these fields so that you can build certain types of views that involve multiple measures.

**Measure Values** and **Measure Names** are in most respects like other fields in Tableau:

- You can display a filter for **Measure Names**.
- You can format **Measure Values**—the formatting is then inherited as the default formatting for all measures.
- You can drop **Measure Values** and **Measure Names** on shelves.
- You can assign aliases to the values for **Measure Names**.
- You can change the manual sort order for the values for **Measure Names**.

### The Measure Values card

When **Measure Values** is in the view, Tableau creates a **Measure Values** card, outlined in red, below, that lists the measures in the data source with their default aggregations.

You can remove individual measures from the view by dragging them out of the **Measure Values** card.

### About Measure Names

When you want to show multiple measures in a view, you can use the **Measure Values** and the **Measure Names** fields. When you add **Measure Names** to a view, all of the measure names appear as row or column headers in the view. The headers include each measure name. This feature becomes useful when you are working with a text table that shows multiple measures. For example, suppose you have a text table containing the aggregated profit of each product category by region.

Pages

Columns: Category

Rows: Region

Filters

Sheet 2

Region	Category		
	Furniture	Office Supplies	Technology
Central	-\$2,871	\$8,880	\$33,697
East	\$3,046	\$41,015	\$47,462
South	\$6,771	\$19,986	\$19,992
West	\$11,505	\$52,610	\$44,304

Marks

Automatic

Color Size Text

Detail Tooltip

SUM(Profit)

Now suppose you want to show both the **Profit** and the **Sales** for each category and region. When you add **Sales** to the text table (by dragging it and dropping it in the view), the measures are combined and the **Measure Values** field is added to Text. The **Measure Names** field is automatically added to the **Rows** shelf.

Pages

Measure Values

Measure Values

SUM(Profit)

SUM(Sales)

Notice how the header names removed the aggregation label by default. You may want to include the aggregations or call it "Total Profit" and "Total Sales." To change the measure names, right-click (control-click on Mac) the Measure Names field on the Rows shelf and select **Edit Aliases**. Make the changes and click **OK**.

Region		Category		
		Furniture	Office Supplies	Technology
Central	Total Profit	-\$2,871	\$8,880	\$33,697
	Total Sales	\$163,797	\$167,026	\$170,416
East	Total Profit	\$3,046	\$41,015	\$47,462
	Total Sales	\$208,291	\$205,516	\$264,974
South	Total Profit	\$6,771	\$19,986	\$19,992
	Total Sales	\$117,299	\$125,651	\$148,772
West	Total Profit	\$11,505	\$52,610	\$44,304
	Total Sales	\$252,613	\$220,853	\$251,992

### Create a visualization using Measures Names and Measure Values

You can use **Measure Values** and **Measure Names** to display the values for all measures in your data source, using their default aggregations, simultaneously. The view below was created with the Sample - Superstore data source. It shows the values of all measures in the Data pane, using their default aggregations.

#### To create this view

Create a new worksheet using the Superstore example workbook.

Drag **Measure Values** to Rows

Click Text Table in Show Me.

Text Table from Show Me.

Sheet 3	
Discount	16%
Number of Records	9,994
Profit	\$286,397
Profit Ratio	12%
Quantity	37,873
Sales	\$2,297,201

Of course, this view is not well suited for any more than a quick survey of your data because you can't generate a great deal of insight by comparing numbers that aren't measuring the same thing—**Profit** and **Sales** are both in dollars, but **Discount** and **Profit Ratio** are percentages.

When **Measure Names** and **Measure Values** automatically get added to the view

Tableau will automatically add **Measure Names** and **Measure Values** fields to the view in response to certain actions on your part.

### Blending Axes

You can show multiple measures on the same continuous axis by blending axes. For details, see [Blend axes for multiple measures into a single axis](#) on page 1150. When you use this

technique, Tableau automatically adds Measure Names and Measure Values to the view, allowing you add additional measures to the blended axis.

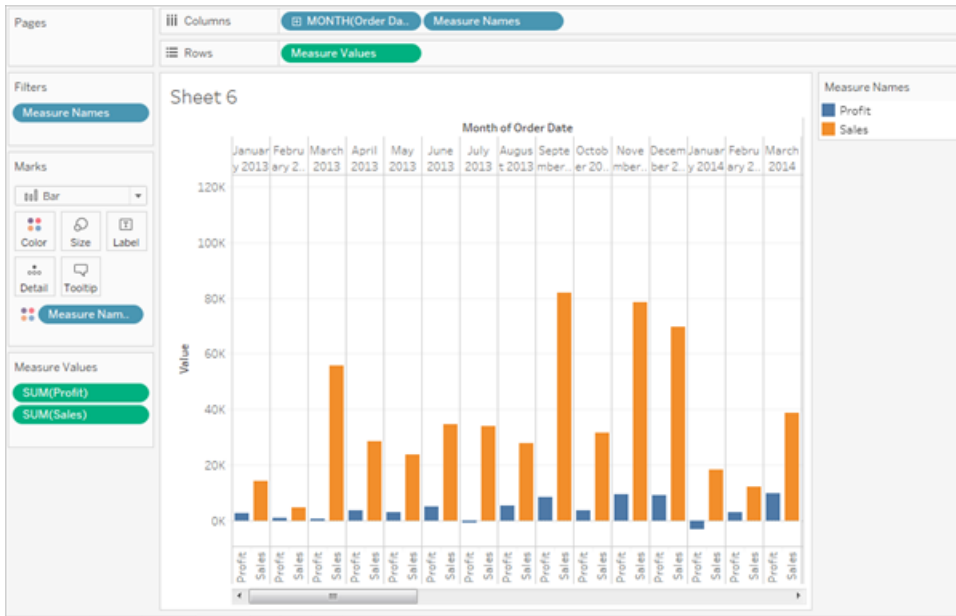

### Using Show Me When Multiple Measures Are in the View

When there are multiple measures in the view, Tableau will automatically add **Measure Names** and **Measure Values**—or just **Measure Names**—when you choose certain visualization types from Show Me.

- When you choose side-by-side bars when there are multiple measures in the view, Tableau adds both **Measure Values** and **Measure Names**. For example, your original view might use lines to show **Sales** and **Profit** over time:

- If you choose side-by-side lines from Show Me, the view updates to include **Measure Names** and **Measure Values**:

- When you choose side-by-side circles from Show Me when there are multiple measures in the view, Tableau adds **Measure Values** and **Measure Names**:

- When you choose dual lines from Show Me when there are multiple measures in the view, Tableau adds **Measure Names** but not **Measure Values**:

This is similar to blending axes, except that Tableau uses separate value ranges (one on the left of the view and one on the right) to make the lines align as closely as possible. With blended axes, Tableau uses a single value range and the lines may or may not align well.

## How Measure Values and Measure Names work with Legends Per Measure

When **Measure Values** and **Measure Names** are in the view, you can color code data for each individual measure. For details, see [Measure values and color legends](#) on page 91.

## Handling Null and Other Special Values

Some data requires special handling in Tableau. Specifically:

- null values
- unrecognized or ambiguous geographic locations
- negative or zero values when working with a logarithmic scale
- negative or zero values when working with treemaps

### Special values indicator

When your data contains any of these special values, Tableau cannot plot them in the view. Instead, it displays an indicator in the lower right corner of the view. Click the indicator to see options for how to handle these values.

If you don't know how to handle the values, you can choose to leave the special values indicator. Generally, you should continue to show the indicator so that you know there is data that is not being shown in the view. However, to hide the indicator, right-click (control-click on a Mac) it and select **Hide Indicator**.

### Null numbers and dates, and negative values on log axes

A null value is a field that is blank, and signifies missing or unknown values.

When you drag a measure or continuous date to the view, the values are shown along a continuous axis. If the field contains null values, or if there are zeroes or negative values on a logarithmic axis, Tableau cannot plot them. When these values exist, Tableau displays an indicator in the lower right corner of the view that says unknown values exist. Click the indicator and choose from the following options:

- **Filter Data** - exclude the null values from the view using a filter. When you filter data, the null values are also excluded from any calculations used in the view.
- **Show Data at Default Position** - show the data at a default location on the axis. The null values will still be included in calculations. The default position depends on the data type. The table below defines the defaults.

Type of Data	Default Position
Numbers	0

Type of Data	Default Position
Dates	12/31/1899
Negative Values on a Log Axis	1
Unknown Geographic Location	(0,0)

## Hiding null values

- To filter null dimensions or discrete measures, drag the pill to the Filter shelf and deselect **Null**. The null value will appear in the list with discrete values, where you can then remove it.
- When a measure contains null values, they are usually plotted in a view as zero. To see other options, including how to suppress these null values altogether, see [Format null values on page 2942](#).

**Note:** See [Logical Functions on page 2223](#) for functions, such as ISNULL() and IFNULL(), which you can use to handle null values with a calculated field.

## Unknown geographic locations

When working with maps and geographic fields, unknown or ambiguous locations are identified by the indicator in the lower right corner of the view. Click the indicator and choose from the following options:

- **Edit Locations** - correct the locations by mapping your data to known locations.
- **Filter Data** - exclude the unknown locations from the view using a filter. The locations will not be included in calculations.
- **Show Data at Default Position** - show the values at the default position of (0, 0) on the map.

## Zero and negative values in treemaps

When working with treemaps, any null or zero values display in the indicator in the lower right corner of the view. Click the indicator and choose from the following options:

- **Filter Data** - exclude the unknown locations from the view using a filter. The locations will not be included in calculations.

- **Use Absolute Values** - use the absolute value to determine the size of the corresponding area in the view. For example, both values of 5 and -5 are shown as the same size.

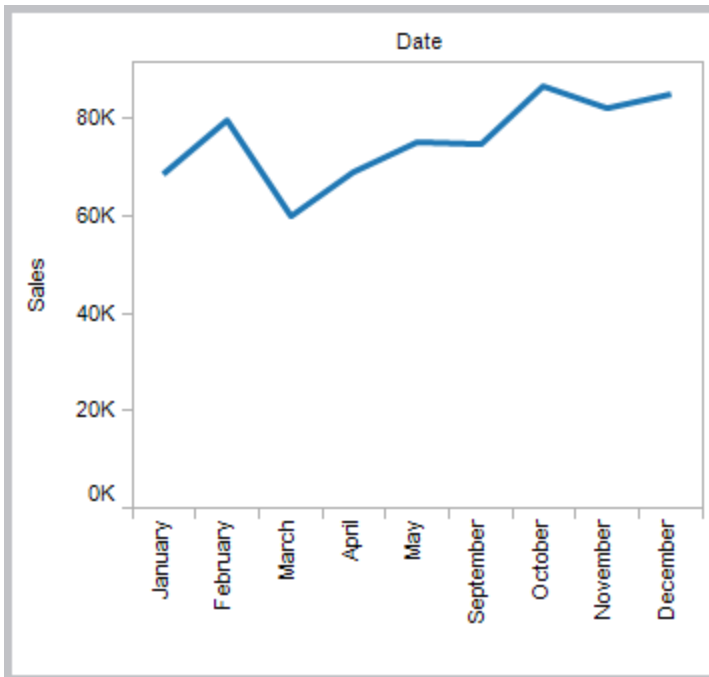

## Show or Hide Missing Values or Empty Rows and Columns

When you're working with dates or numeric bins, Tableau only shows the values that are represented in your data. If your data does not contain the complete range of values, the missing values will not be shown. For example, your data may contain data for January through May and September through December. However, there was no data recorded for June, July, and August. If you create a line chart in Tableau, the missing months will not be shown. You can optionally show the missing months to make it clear that there was no data recorded during that time.

**Note:** You can replace missing values with a calculated field using the ZN() function. See [Number Functions](#) on page 2171 for details.

### Missing Values Hidden (Default)

By default, missing values in a date range or numeric bins are not shown.

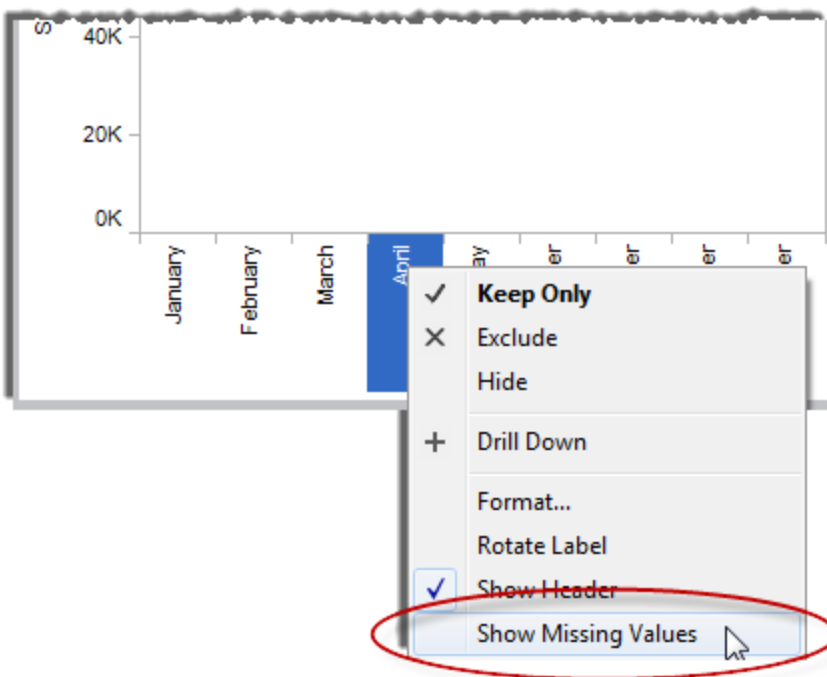

### Missing Values Shown

You can show the missing values to indicate incomplete data.

To show missing values in a range, right-click (control-click on Mac) the date or bin headers and select **Show Missing Values**.

**Note:** You can also perform calculations on missing values that are shown in the view. To do this, open the **Analysis** menu at the top, and then select **Infer Properties from Missing Values**. For an example of this, see [Predictive Modeling with Generated Marks on page 2055](#).

### Show and Hide Empty Rows and Columns

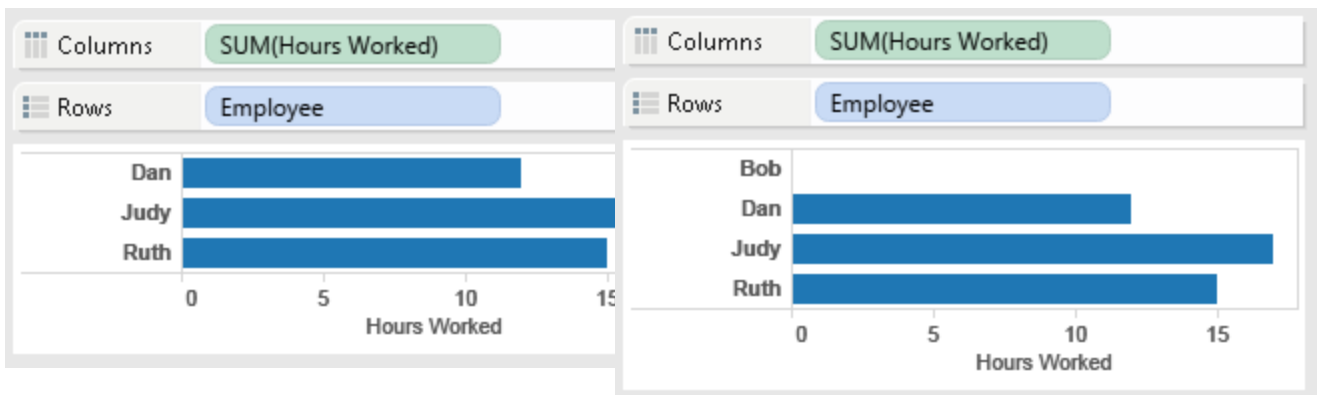

When you are working with fields that are not dates or numeric bins, Tableau hides missing values by default. For example, you may be showing workers and the number of hours worked in a particular month. If a worker didn't work at all that month, there may not be a row in the database for that worker. When you drag the Worker field to the Rows shelf, the workers that didn't work are hidden by default. You can show the empty rows by selecting **Analysis > Table Layout > Show Empty Rows**. Similarly, show the empty columns by selecting **Analysis > Table Layout > Show Empty Columns**.

#### Empty Rows Hidden (default)

Bob did not work in January so there are no records in the database for him. By default he is not listed.

#### Empty Rows Shown

Even though Bob did not work in January, he is listed but no marks are drawn.

### Use Show Me to Start a View

Show Me creates a view based on the fields already used in the view and any fields you've selected in the Data pane. Open Show Me by clicking **Show Me** on the toolbar  **Show Me**.

## Start a view based on fields that you select

To use Show Me, select the fields you want to analyze in the Data pane, and then select the type of view you want to create in the Show Me pane. Tableau automatically evaluates the selected fields and gives you the option of several types of views that would be appropriate for those fields. Show Me also highlights the visualization type that best matches the data.

1. In the **Data** pane, select the fields that you want to analyze. Hold the Ctrl key (Command key on a Mac) to make multiple selections.

2. Click **Show Me** on the toolbar and then select the type of view you want to create.

Any view type that is not gray will generate a view of your data. As you hover over each view type, the description at the bottom shows the minimum requirements. In this example, Stacked Bars is selected.

3. View the Result. Tableau automatically creates a view of the data.

## Create a Line Chart with Show Me

In this example, you use **Show Me** to create a line chart that displays profit as a function of time.

1. In the **Data** pane, select **[Order Date]** and **Profit**. Hold down the Ctrl key (or the command key on a Mac) as you select the fields.

2. Click **Show Me** on the toolbar to display the **Show Me** card, if it isn't already displayed.

3. In the **Show Me** pane, see what type of view Tableau suggests.

Because a date dimension and a measure are selected, Tableau suggests you build a line view. A line is often the optimal way to look at how measure values change over time.

The view below shows the resulting chart. Each point on the line represents the sum of profit for the corresponding year.

# Tableau Desktop and Web Authoring Help

You can more easily see the points by clicking the **Show Mark Labels** button on the toolbar.

## Create a Scatter Plot with Show Me

In this example you use **Show Me** to build a scatter plot to show sales versus profit for each product and customer.

1. In the **Data** pane, select the **Customer Name** and **Product Name** dimension fields, and the **Profit** and **Sales** measure fields. To select multiple fields, hold down the Ctrl key (or the command key on a Mac) as you click fields.

2. Click **Show Me** on the toolbar.

3. Select the scatter plot chart type from **Show Me**.

Tableau creates a scatter plot using the fields you selected. You can drag fields to further refine the view.

## Add Detail

The Marks card is a key element for doing visual analysis in Tableau. When you drag measures and dimensions to the Marks card, you encode your data with color, size, shape, text, and other properties that add context, detail, and meaning to the marks in the view.

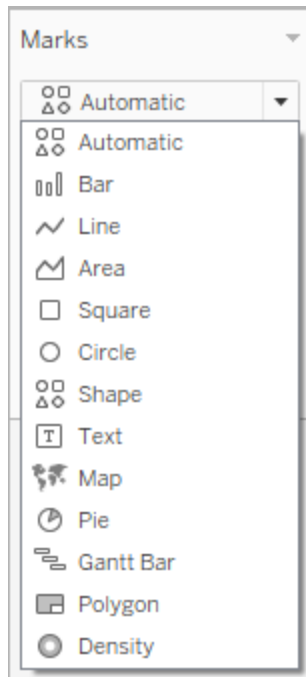

## Change the Type of Mark in the View

You can change the type of marks displayed in the view to fit your analysis. For example, you can change the marks from bars to lines. This article describes how to change the type of marks used in the view, and explains the different types of marks available. For related information on marks, see [Control the Appearance of Marks in the View](#) on page 1205 and [Marks card](#) on page 62.

### Change the mark type

To change the mark type:

- On the **Marks card** on page 62, click the Mark Type drop-down and select an option from the list.

For descriptions of each mark type, see the following sections:

- [Automatic mark](#)
- [Bar mark](#)
- [Line mark](#)
- [Area mark](#)
- [Square mark](#)
- [Circle mark](#)
- [Shape mark](#)
- [Text mark](#)
- [Map mark](#)
- [Pie mark](#)
- [Gantt Bar mark](#)
- [Polygon mark](#)
- [Density mark](#)

## Automatic mark

When the Marks card drop-down menu is set to **Automatic**, Tableau automatically selects the best mark type for your data view. The mark type that is automatically selected is determined by the inner fields on the **Rows** and **Columns** shelves. The icon in the Marks card drop-down menu indicates which type of mark was automatically selected. The mark types below are automatically selected for the following scenarios.

### Text

The Text mark type is automatically selected when there are dimensions as inner fields on both the **Rows** and **Columns** shelves.

The screenshot shows the Tableau interface with the following configuration:

- Columns shelf:** YEAR(Order Date)
- Rows shelf:** Region
- Marks card:** Set to Automatic, with the Text icon highlighted.
- Table View:** A table with 'Region' on the vertical axis and 'Order Date' on the horizontal axis. The data is as follows:

Region	2012	2013	2014	2015
Central	Abc	Abc	Abc	Abc
East	Abc	Abc	Abc	Abc
South	Abc	Abc	Abc	Abc
West	Abc	Abc	Abc	Abc

### Shape

The Shape mark type is selected when there are measures as inner fields on both the **Rows** and **Columns** shelves.

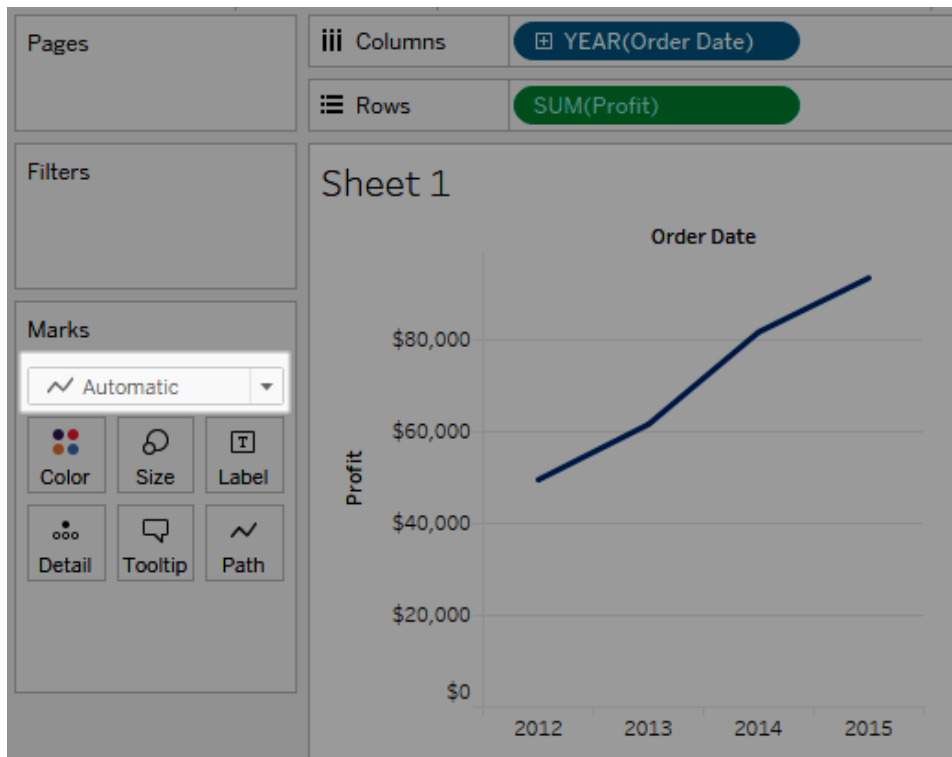

## Bar

The Bar mark type is selected when there is a dimension and a measure as inner fields on **Rows** and **Columns** shelves.

## Line

The Line mark type is selected when there is a date field and a measure as the inner fields on the **Rows** and **Columns** shelves.

**Note:** You can override the default selection and use any mark type that provides insight into your data. However, you should exercise some caution when manually selecting a mark type because the resulting view might hide important information about your data.

## Bar mark

The Bar mark type is useful when you want to compare measures across categories, or when you want to break data down into stacked bars. Tableau displays your data using bars when:

- The Marks card drop-down menu is set to **Automatic**, and you place a dimension and a measure as the inner fields on the **Rows** and **Columns** shelves. If the dimension is a date dimension, the Line mark is used instead.
- You select **Bar** from the Marks card drop-down menu.

Marks are automatically stacked.

**Note:** For views where the mark type is Bar and there are continuous (green) fields on both **Rows** and **Columns**, Tableau supports additional options and defaults for sizing the bar

marks on the axis where the bars are anchored. See the Continuous axis mark sizing section in [Change the size of marks](#) on page 1207 for details.

The data view shown below displays a dimension as the columns of the table, and a measure as the rows of the table. It is also color-encoded by a dimension (**Category**). Because the Marks card drop-down menu is set to **Automatic**, data is displayed using bars.

To try some hands-on exercises for building bar charts, see [Build a Bar Chart](#) on page 1419.

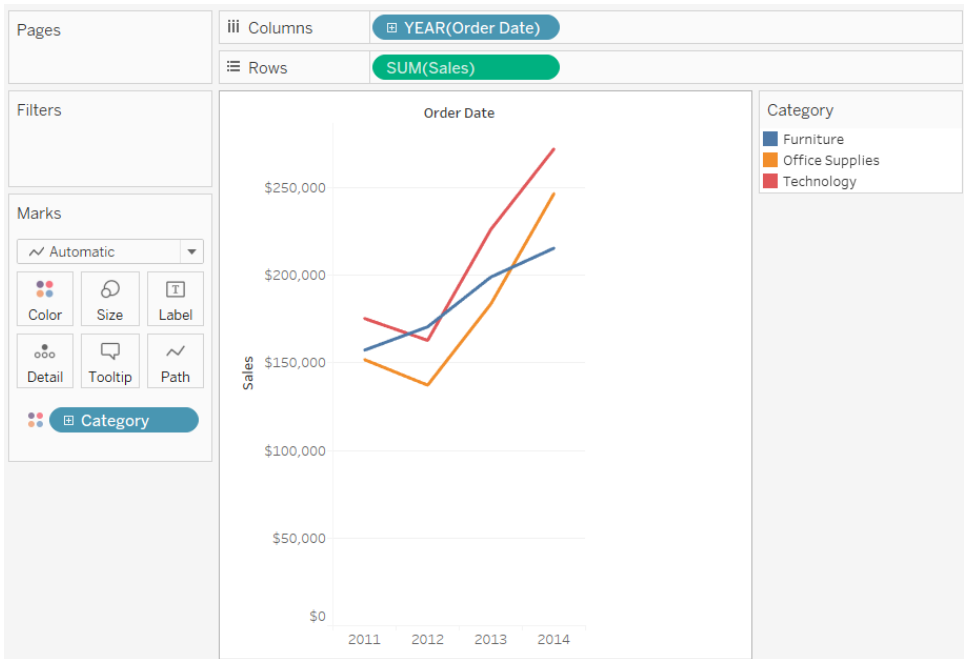

## Line mark

The line mark type is useful when you want to see trends in data over time, your data are ordered, or interpolation makes sense. Tableau displays data using lines when:

- The Marks card drop-down menu is set to **Automatic**, and you place one or more measures on either the **Columns** shelf or the **Rows** shelf, and then plot the measures against a date dimension or a continuous dimension.
- You select **Line** from the Marks card drop-down menu.

**Note:** In views that use the line mark type, you can use the **Path** property in the Marks card to change the type of line mark (linear, step, or jump), or to encode data by connecting marks using a particular drawing order. For details, see [Path properties](#) in the [Control the Appearance of Marks in the View](#) on page 1205

The data view shown below displays a date dimension as the columns of the table and a measure as the rows of the table.

As the density of data increases, trends are often easier to see when using lines. This view shows 93 data points.

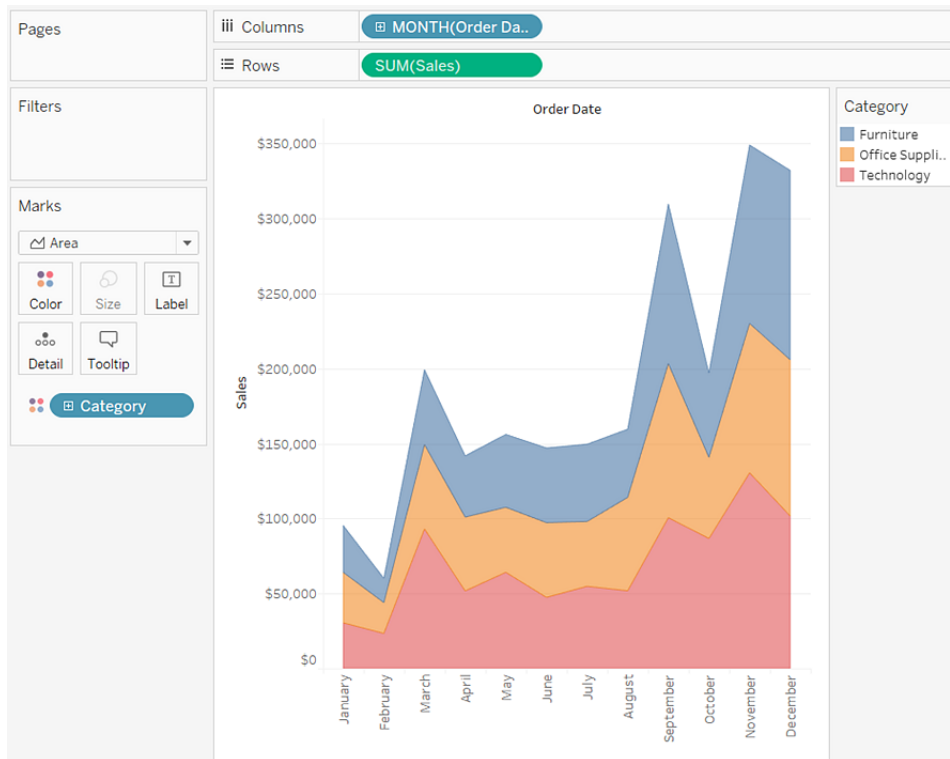

To try some hands-on exercises for building line charts, see [Building Line Charts on page 1470](#).

## Area mark

The Area mark type is useful when you have a view where the marks are stacked and do not overlap. For more information about stacked marks, see [Stack Marks on page 1235](#). In an area chart, the space between each line and the next line is filled with a color. This type of chart is not the best way to show specific values along the line but it can clearly show the total values so you can get an idea of how a dimension is contributing to an overall trend. Tableau displays your data using areas when:

- The Marks card drop-down menu is set to **Automatic** and one or more measures is plotted against a date dimension or continuous dimension. The **Analysis > Stack Marks** option must also be selected.

The view below shows a date dimension on the **Columns** shelf and a measure on the **Rows** shelf. Each line represents the sales for a product category. The lines have been stacked so that they do not overlap.

**Note:** You can add labels, edit the color legend, and highlight areas. In addition, you can turn on color effects, such as mark borders. For more information, see [Control the Appearance of Marks in the View](#) on page 1205.

## Square mark

The square mark type is useful when you want to clearly see individual data points. When you select **Square** from the **Marks** card drop-down menu, Tableau displays your data using squares.

The view shown below displays several dimensions on both the rows and columns shelves. By default, the data is displayed using text. However, when you place a measure on **Color**, Tableau converts the marks to squares and creates a heat map. To try some hands-on exercises for building highlight tables, see [Build a Highlight Table or Heat Map](#) on page 1455.

When you add additional levels of detail by placing a dimension on **Detail**, **Color**, **Shape**, **Size**, or **Label** on the **Marks** card, the squares are displayed side-by-side and wrap to fill the cell. If the window is too small to show all of the squares, an ellipsis indicates that there are more values than you can see.

You can also use the square mark to create treemaps. A treemap displays hierarchical data as a set of nested rectangles. To try a hands-on exercise for building a treemap, see [Build a Treemap on page 1501](#).

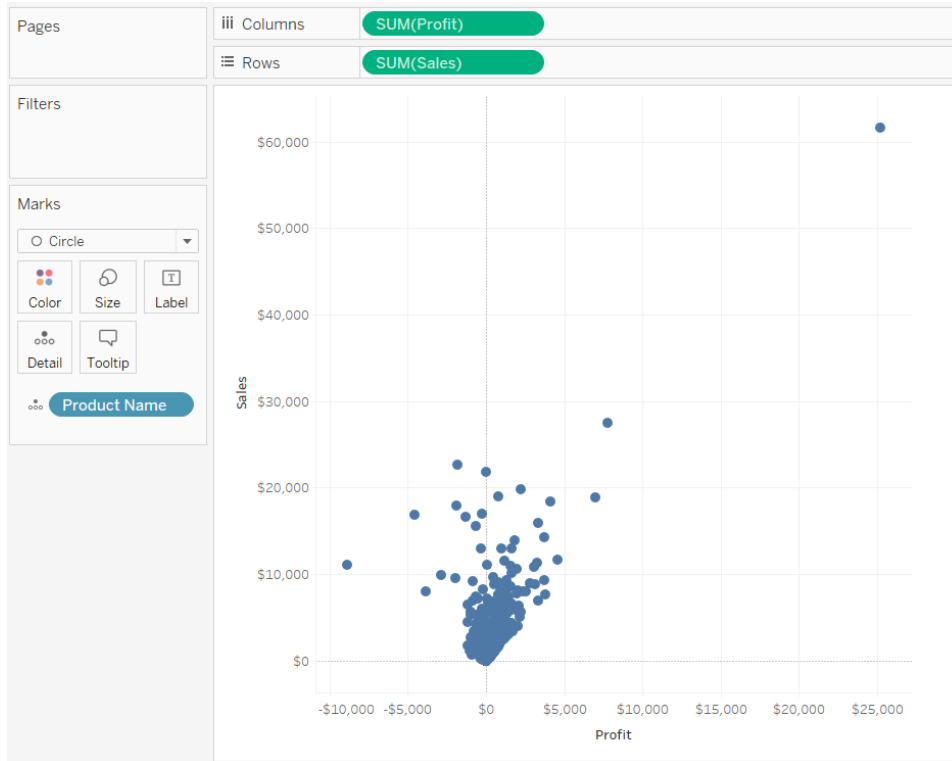

## Circle mark

When you select **Circle** from the Marks card drop-down menu, Tableau displays your data using filled circles.

If the mark type was set to **Automatic**, Tableau would display the data using a shape (that is, an open circle).

## Shape mark

The shape mark type is useful when you want to clearly see individual data points while also viewing categories associated with those points. Tableau displays your data using a shape when:

- The Marks card drop-down menu is set to **Automatic**, and you place one or more measures on both the **Rows** and the **Columns** shelves.
- You select **Shape** from the Marks card drop-down menu.

The view shown below displays the data from two measures. Because the Marks card drop-down menu is set to **Automatic**, the data are displayed using a shape.

By default, the shape used is an open circle. To select a different shape, click **Shape** on the Marks card. Twenty unique shapes are available:

To add more data to the view, you can place a field on **Shape** on the Marks card. Tableau separates the marks according to the values in the field. If the field is a dimension, each member is assigned a unique shape. If the field is a measure, the measure is automatically binned into

distinct buckets and each bucket is assigned a unique shape. The shape legend displays how shapes are distributed.

As shown below, the **Ship Mode** dimension is placed on **Shape** on the Marks card to encode each mark with information about how the order was shipped.

For details on how to build a scatterplot, see [Build a Scatter Plot](#) on page 1488.

### Text mark

The Text mark type is useful when you want to display the numbers associated with one or more dimension members. This type of view is often called a text table, a cross-tab, or a pivot table.

Tableau displays your data using text when:

- The Marks card drop-down menu is set to **Automatic**, and you place one or more dimensions as the inner fields on both the **Rows** and the **Columns** shelves.
- You select **Text** from the Marks card drop-down menu.

Initially, the data is displayed as **Abc**.

The screenshot shows the Tableau Desktop interface. On the left, the 'Columns' shelf contains 'YEAR(Order Date)' and the 'Rows' shelf contains 'Sub-Category'. The 'Marks' card is set to 'Automatic'. The main view, titled 'Sheet 1', displays a pivot table with the following data:

Sub-Catego..	Order Date			
	2012	2013	2014	2015
Accessories	Abc	Abc	Abc	Abc
Appliances	Abc	Abc	Abc	Abc
Art	Abc	Abc	Abc	Abc
Binders	Abc	Abc	Abc	Abc
Bookcases	Abc	Abc	Abc	Abc
Chairs	Abc	Abc	Abc	Abc
Copiers	Abc	Abc	Abc	Abc
Envelopes	Abc	Abc	Abc	Abc
Fasteners	Abc	Abc	Abc	Abc
Furnishings	Abc	Abc	Abc	Abc
Labels	Abc	Abc	Abc	Abc
Machines	Abc	Abc	Abc	Abc
Paper	Abc	Abc	Abc	Abc

To complete the view, you must place a field (typically a measure) on **Text** on the Marks card. In the view below, the **Sales** measure, which is aggregated as a sum, is used to complete the table.

Sub-Catego..	2011	2012	2013	2014
Accessories	\$25,014	\$40,524	\$41,896	\$59,946
Appliances	\$15,314	\$23,241	\$26,050	\$42,927
Art	\$6,058	\$6,237	\$5,910	\$8,914
Binders	\$43,488	\$37,453	\$49,485	\$72,986
Bookcases	\$20,037	\$38,544	\$26,275	\$30,024
Chairs	\$77,242	\$71,735	\$83,919	\$95,554
Copiers	\$10,850	\$26,179	\$49,599	\$62,899
Envelopes	\$3,856	\$4,512	\$4,730	\$3,379
Fasteners	\$661	\$545	\$960	\$858
Furnishings	\$13,826	\$21,090	\$27,874	\$28,915
Labels	\$2,841	\$2,956	\$2,827	\$3,861
Machines	\$62,023	\$27,764	\$55,907	\$43,545
Paper	\$14,835	\$15,288	\$20,638	\$27,718
Phones	\$77,391	\$68,314	\$78,660	\$105,643
Storage	\$50,329	\$45,048	\$58,632	\$69,834
Supplies	\$14,394	\$1,952	\$14,278	\$16,049
Tables	\$46,088	\$39,150	\$60,833	\$60,894

**Note:** To create a cross-tab of any data view, select **Worksheet > Duplicate as Crosstab**.

When you add additional levels of detail by placing a dimension on **Detail, Color, Shape, Size,** or **Text** on the Marks card, the values are shown side-by-side and wrap to fill the cell. Allowing the text to stack up makes it possible to create word cloud visualizations like the one shown below.

If the application window is too small for all of the text values, some of the displayed text values will be truncated.

Sub-Catego..	2012	2013	2014	2015
Accessories	\$552 ...	\$438 ...	\$32 ...	\$522 ...
Appliances	\$715 ...	\$294 ...	\$114 ...	\$156 ...
Art	\$178 ...	\$98 ...	\$42 ...	\$153 ...
Binders	\$6 \$13 ...	\$17 \$6 ...	\$11 ...	\$9 \$64 ...
Bookcases	\$2,095 ...	\$7,406 ...	\$5,161 ...	\$3,954 ...
Chairs	\$461 ...	...	\$1,084 ...	\$230 ...
Copiers	\$1,200 ...	\$2,700 ...	\$480 ...	\$480 ...
Envelopes	\$69 ...	\$51 ...	\$45 ...	\$9 \$64 ...
Fasteners	\$26 ...	\$22 ...	\$78 ...	\$68 ...

If the application window is too small for all of the text values, the cell displays an ellipses to indicate that there are more values than can be displayed. Number values that can't be displayed are indicated with pound signs (#).

For details on how to build a text table, see [Build a Text Table](#) on page 1493.

## Map mark

The Map mark type uses geocoding to fill a polygon or line with a color based on data. The primary use of the map mark type is for creating polygon or line maps. The area to be filled is defined by the geographic fields used in the view. Tableau displays data using a filled map when:

- A geographic dimension is on **Detail** on the Marks card, along with **Latitude** and **Longitude** on the **Rows** and **Columns** shelves. A measure or continuous dimension is added to **Color** on the Marks card.
- You select **Map** from the Marks card drop-down menu.

The data view below shows a map with the **State** geographic dimension on **Detail** on the Marks card. The **Profit** measure is on **Color** on the Marks card.

The polygon for each state is filled with a color based on the profit for that state. The profit in Texas is low (in fact, negative) while the profit in California is high.

You can also use the Map mark type when you are plotting two measures against each other. By default, placing measures on both the **Rows** and **Columns** shelves creates a scatter plot. However, adding a geographic dimension allows you to change the mark type to Map. Each mark becomes the area defined by the geographic field. For example, the view below shows **Sales** versus **Profit** for a selection of states. Rather than showing a round mark with a label for each state, the view uses the Map mark type to draw the outline of each state. While this works well for recognizable areas, it is not the best choice for areas that are similar in shape or difficult to recognize.

For more details on building maps, see [Get Started Mapping with Tableau](#) on page 1593 and [Maps and Geographic Data Analysis in Tableau](#) on page 1593.

## Pie mark

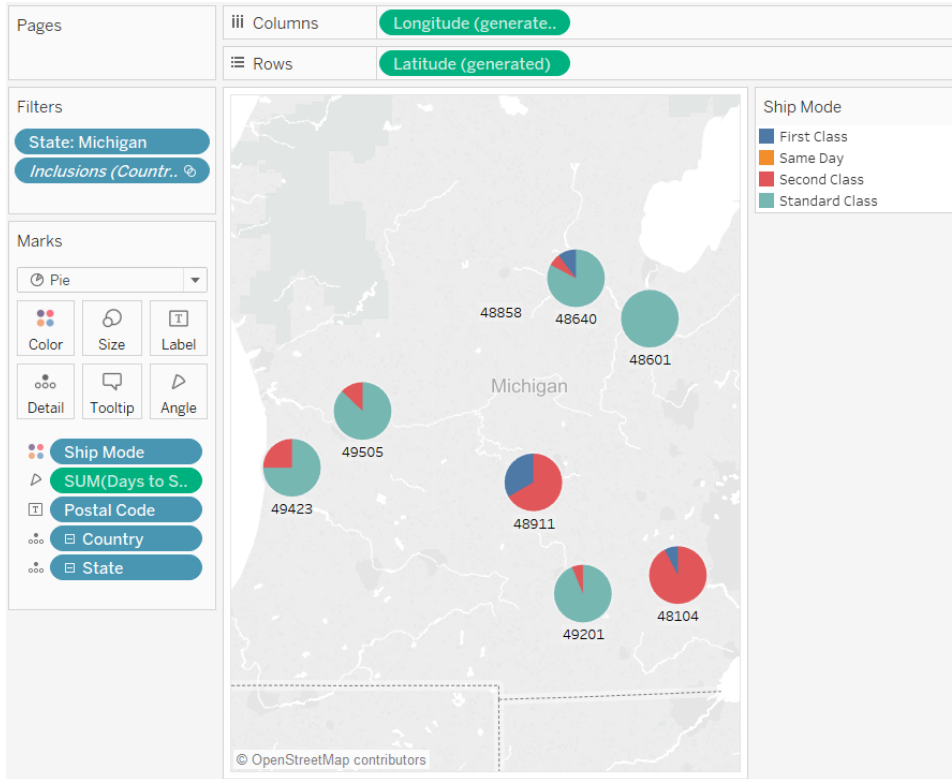

You can use the Pie mark to show proportions. Although generally this type of information can be better shown using stacked bar charts, there are cases where pie marks can be very effective—for example, when trying to convey the percentage allocation of marketing expenses by state where the spending of geographically close states are very relevant.

Tableau will never use the Pie mark as an automatic mark type, but you can select **Pie** from the Marks card drop-down menu.

When you select the Pie mark type, an additional target named Angle is displayed on the Marks card. The Angle target determines the angular measure of the pie wedges. For example, if you place a measure such as **Sales** on **Angle** on the Marks card, the 360 degrees of the pie corresponds to the total sum of sales, and each wedge is divided by the values of the field on **Color** on the Marks card.

The view below shows the time it took to ship products by various ship modes. The data overlays a map and shows data by state. We can see that standard class shipping takes the longest in most areas.

For details on how to build and use pie charts, see [Build a Pie Chart](#) on page 1484 and [Get Started Mapping with Tableau](#) on page 1593.

### Gantt Bar mark

- The Marks card drop-down menu is set to **Automatic** and you place one or more dimensions on either the **Columns** shelf or the **Rows** shelf, and then plot the dimensions against a continuous quantity.
- You select **Gantt Bar** from the Marks card drop-down menu.

The distinguishing characteristic of Gantt Bars is that the length of every mark is proportional to the measure placed on **Size** on the Marks card.

The view below displays a dimension as a function of a continuous date. If the Marks card drop-down menu is set to **Automatic**, the data would be displayed using bars. Selecting **Gantt Bar** and adding additional fields will display a view like the following.

In particular, placing the **Days to Ship** measure on **Size** on the Marks card causes every bar in the view to be drawn with a length that indicates the delivery time of an order. Additionally, placing the **Ship Mode** dimension on **Color** on the Marks card causes each bar to be colored according to the ship mode.

For details on how to build Gantt Bar chart, see [Build a Gantt Chart](#) on page 1448.

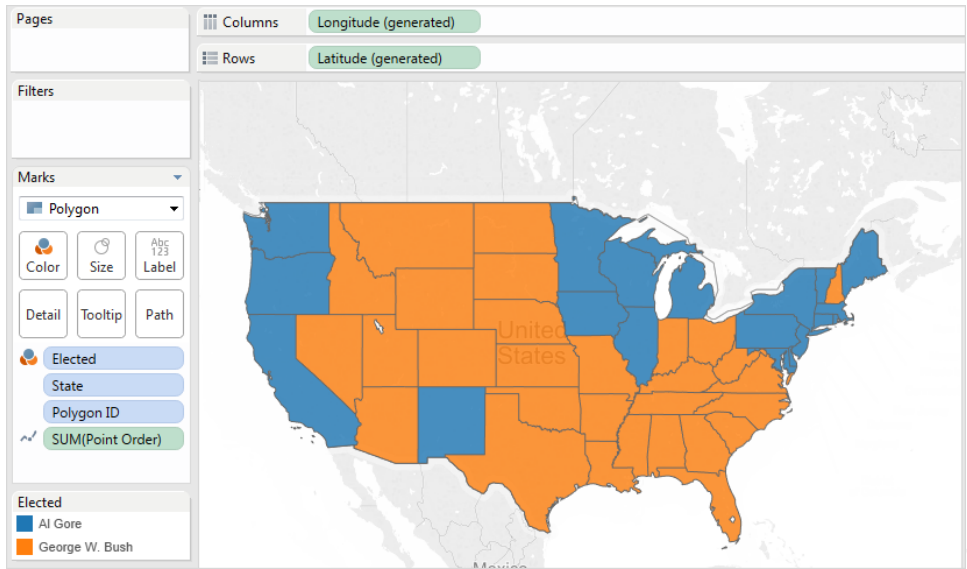

## Polygon mark

Polygons are points connected by lines enclosing an area. The polygon mark type is useful when you want to connect points to create data areas. Tableau displays data using polygons when you select Polygon from the **Marks** menu.

The polygon mark is not commonly used and often requires a specially constructed data source.

The view shown below comes from a specially constructed data source that holds geographic and election data. It displays the 48 contiguous US states as a function of latitude and longitude and color-encodes each state by the 2000 presidential election results.

If **Marks** is set to Automatic, the data will be displayed using a shape. Manually selecting Polygon and adding additional fields to the view causes a different view to be created.

Every state is considered to be a polygon in the data source. The **PolygonID** field on the **Detail** target is distinct for each US state. You can remove states from the view by filtering this field.

Additionally, you can specify the drawing order of the lines that constitute each polygon by placing a field on the **Path** target. In this example, the **PointOrder** measure is used to draw each state.

### Density mark (Heatmap)

You can use the density mark to visualize patterns or trends in dense data with many overlapping marks. Although generally this type of information can be shown using a circle mark, there are cases where density marks can be very effective—for example, when there are many data points in an area, and you need to understand where those marks are most concentrated. The density mark can be used effectively with maps or charts that use point-based marks (scatterplots, unit histograms, box plots over individual marks, or point maps).

Tableau does this by grouping overlaying marks, and color-coding them based on the number of marks in the group.

Density marks work by using color to show the relative intensity of data in a given area of the chart. You can adjust the colors of the density mark by selecting **Color** from the Marks card. Choose from ten density color palettes, or any of the existing color palettes.

In the Color menu, use the Intensity slider to increase or decrease the vividness of the density marks. For example, increasing intensity, or vividness, lowers the "max heat" spots in your data, so that more appear.

Low Intensity (50%)

High Intensity (80%)

The view shown below comes from a data source that contains many geographic points for one month of taxi pickups in Manhattan. It displays the location and frequency of taxi pickups, with lighter colors being most frequent.

You can select **Density** from the Marks card drop-down menu.

For details on how to build a density map or a density chart, see [Create Heatmaps that Show Trends or Density in Tableau](#) on page 1742 and [Build with Density Marks \(Heatmap\)](#) on page 1439.

## Control the Appearance of Marks in the View

Control color, size, shape, detail, text, and tooltips for marks in the view using the Marks card. Drag fields to buttons on the Marks card to encode the mark data. Click the buttons on the Marks card to open Mark properties. For related information on marks, see [Change the Type of Mark in the View](#) on page 1182 and [Marks card](#) on page 62.

**Note:** The order of dimension fields on the Marks card is hierarchical from top to bottom, and affects sorting in the view. Tableau first considers the topmost dimension field when ordering marks in the view, and then considers the dimensions beneath it on the Marks card.

## Assign colors to marks

To assign a color to marks in the view, do one of the following:

- On the Marks card, click **Color**, and then select a color from the menu.

This updates all marks in the view to the color you choose. All marks have a default color, even when there are no fields on **Color** on the **Marks** card. For most marks, blue is the default color; for text, black is the default color.

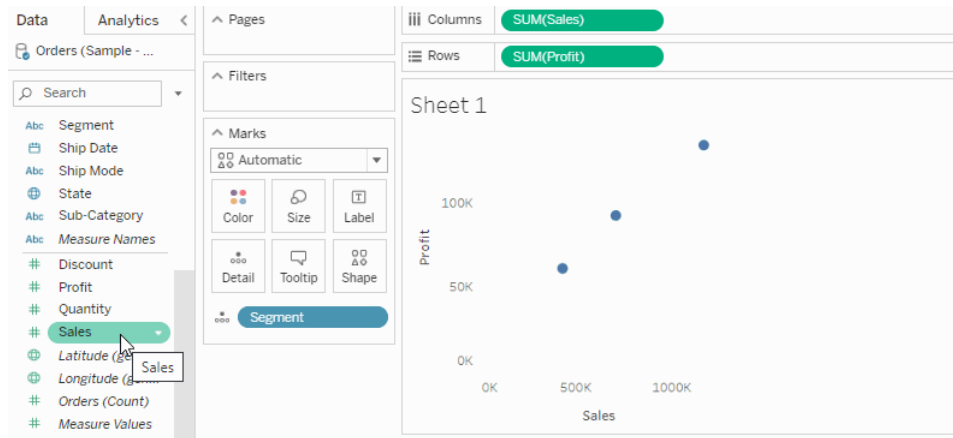

- From the **Data** pane, drag a field to **Color** on the Marks card.

Tableau applies different colors to marks based on the field's values and members. For example, if you drop a discrete field (a blue field), such as Category, on Color, the marks in the view are broken out by category, and each category is assigned a color.

If you drop a continuous field, such as SUM(sales), on Color, each mark in the view is

colored based on its sales value.

## Edit colors

To change the color palette or customize how color is applied to your marks:

- On the Marks card, click **Color** > **Edit Colors**.

For more information, see [Color Palettes and Effects on page 1237](#).

## Change the size of marks

To change the size of marks in the view, do one of the following:

- On the Marks card, click **Size**, and then move the slider to the left or right.

The Size slider affects different marks in different ways, as described in the following table.

Mark Type	Description
Circle, Square, Shape, Text	Makes the mark bigger or smaller.

Mark Type	Description
Bar, Gantt Bar	Makes bars wider or narrower.
Line	Makes lines thicker or thinner.
Polygon	You cannot change the size of a polygon.
Pie	Makes the overall size of the pie bigger and smaller.

The size of your data view is not modified when you change marks using the **Size** slider. However, if you change the view size, the mark size might change to accommodate the new formatting. For example, if you make the table bigger, the marks might become bigger as well.

- From the **Data** pane, drag a field to **Size** on the Marks card.

When you place a discrete field on **Size** on the **Marks** card, Tableau separates the marks according to the members in the dimension, and assigns a unique size to each member. Because size has an inherent order (small to big), categorical sizes work best for ordered data like years or quarters.

Size-encoding data with a discrete field separates the marks in the same way as the **Detail** property does, and then provides additional information (a size) for each mark. When you add categorical size encoding to a view, Tableau displays a legend showing the sizes assigned to each member in the field on the **Size** target. You can modify how these sizes are distributed using the Edit Sizes dialog box.

When you place a continuous field on **Size** on the **Marks** card, Tableau draws each mark with a different size using a continuous range. The smallest value is assigned the smallest sized mark and the largest value is represented by the largest mark.

When you add quantitative size encoding to the view, Tableau displays a legend showing the range of values over which sizes are assigned. You can modify how these sizes are distributed using the Edit Sizes dialog box.

### Edit marks sizes

To edit the size of marks, or change how size is being applied to marks in the view:

1. On the Size legend card (which appears when you add a field to Size on the Marks card), click the drop-down arrow in the right-hand corner and select **Edit Sizes**.

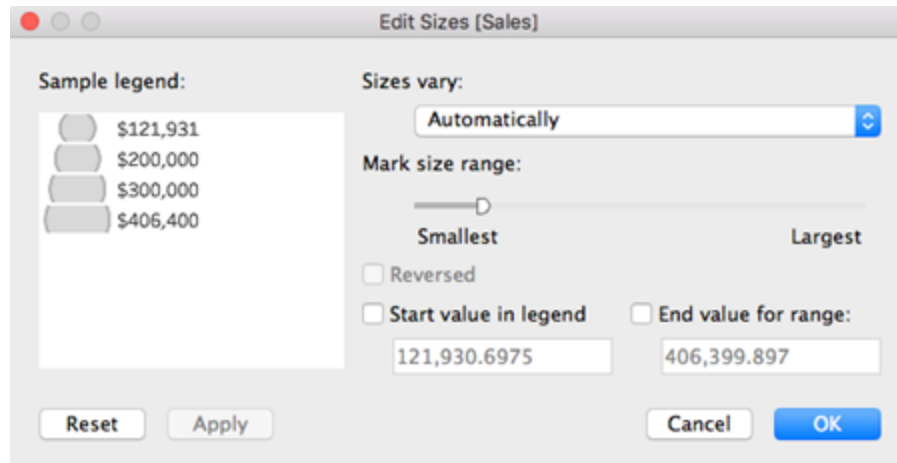

2. In the Edit Sizes dialog box that appears, make your changes and then click **OK**.

The options available depend on whether the field being applied to Size is a continuous or discrete field.

#### For continuous fields, you can do the following:

- For **Sizes vary**, click the drop-down box and select one of the following:
  - **Automatically** - Selects the mapping that best fits your data. If the data is numeric and does not cross zero (all positive or all negative), the From zero mapping is used. Otherwise, the By range mapping is used.
  - **By range** - Uses the minimum and maximum values in the data to determine the distribution of sizes. For example, if a field has values from 14 to 25, the sizes are distributed across this range.

- **From zero** - Sizes are interpolated from zero, assigning the maximum mark size to the absolute value of the data value that is farthest from zero.
- Use the range slider to adjust the distribution of sizes. When the From zero mapping is selected from the Sizes vary drop-down menu, the lower slider is disabled because it is always set to zero.
- Select **Reversed** to assign the largest mark to the smallest value and the smallest mark to the largest value. This option is not available if you are mapping sizes from zero because the smallest mark is always assigned to zero.
- To modify the distribution of sizes, select the **Start value in legend** and **End value for range** check boxes and type beginning and end values for the range.

**For discrete fields, you can do the following:**

- Use the range slider to adjust the distribution of sizes.
- Select **Reversed** to assign the largest mark to the smallest value and the

smallest mark to the largest value.

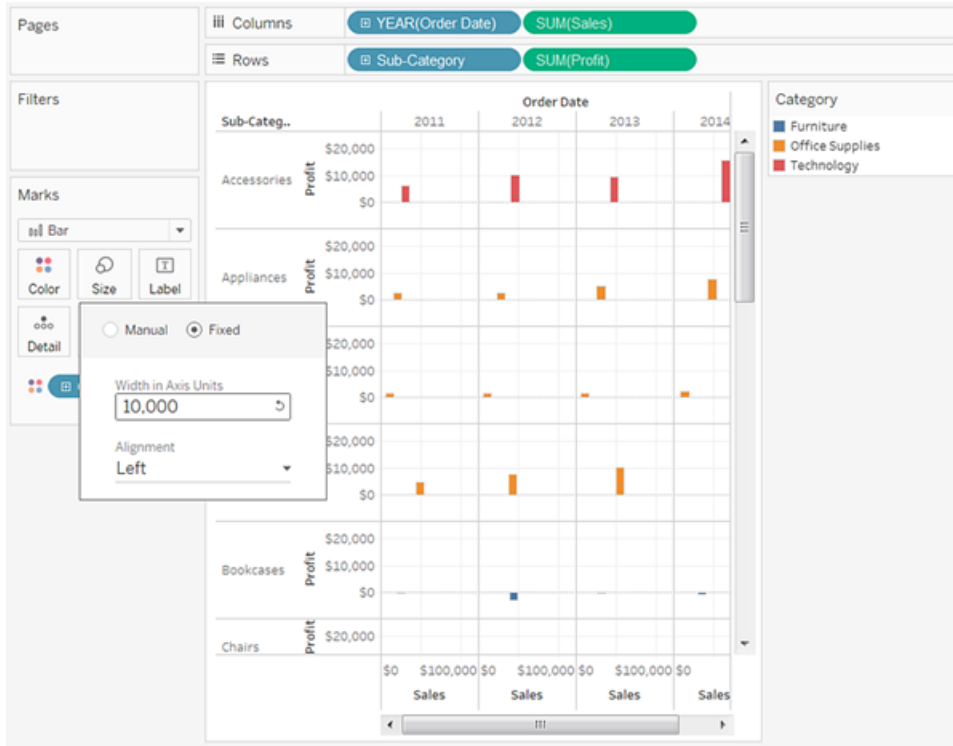

### Continuous axis mark sizing

For views where the mark type is **Bar** and there are continuous (green) fields on both **Rows** and **Columns**, Tableau supports additional options and defaults for sizing the bar marks on the axis where the bars are anchored.

- The bar marks in histograms are continuous by default (with no spaces between the marks), and are sized to match the size of the bins. See [Build a Histogram on page 1462](#) for an example.
- When there is a field on **Size**, you can determine the width of the bar marks on the axis where the bars are anchored by using the field on **Size**. To do this, click the **Size** card and select **Fixed**.

- When there is no field on **Size**, you can specify the width of the bar marks on the axis where the bars are anchored in axis units. To do this, click the **Size** card, choose **Fixed**, and then type a number in the **Width in axis units** field.

- When there is a continuous date field on the axis where the bars are anchored, the width of the marks is set to match the level of the date field. For example, if the level of the continuous date field is MONTH, the bars are exactly one month wide—that is, slightly wider for 31-day months than for 30-day months. You can configure the width of the bars by clicking the **Size** card, choosing **Fixed**, and then typing a number in the **Width in days** field, but the resulting bar widths don't take into account the varying lengths of time units such as months and years.

### Add labels or text for marks

To add mark labels or text to the visualization:

- From the **Data** pane, drag a field to **Label** or **Text** on the Marks card.

When working with a text table, the Label shelf is replaced with Text, which allows you to view the numbers associated with a data view. The effect of text-encoding your data view depends on whether you use a dimension or a measure.

- **Dimension** – When you place a dimension on **Label** or **Text** on the Marks card, Tableau separates the marks according to the members in the dimension. The text labels are driven by the dimension member names.

- Measure – When you place a measure on **Label** or **Text** on the Marks card, the text labels are driven by the measure values. The measure can be either aggregated or disaggregated. However, dis-aggregating the measure is generally not useful because it often results in overlapping text.

Text is the default mark type for a text table, which is also referred to as a cross-tab or a PivotTable.

	Segment		
Sub-Categ..	Consumer	Corporate	Home Office
Accessories	\$87,105	\$48,191	\$32,085
Appliances	\$52,820	\$36,589	\$18,124

Supplies	\$25,741	\$19,435	\$1,497
Tables	\$99,934	\$70,872	\$36,160

Separate marks in the view by dimension members

To separate marks in the view (or add more granularity):

- From the **Data** pane, drag a dimension to **Detail** on the Marks card.

When you drop a dimension on **Detail** on the Marks card, the marks in a data view are separated according to the members of that dimension. Unlike dropping a dimension on the **Rows** or **Columns** shelf, dropping it on **Detail** on the Marks card is a way to show more data without changing the table structure.

### Add tooltips to marks

Tooltips are details that appear when you hover over one or more marks in the view. Tooltips are also convenient for quickly filtering or removing a selection, or viewing underlying data. You can edit a tooltip to include both static and dynamic text. You can also modify which fields are included in a tooltip and whether you want to be able to use those fields to select marks in the view.

For details on showing a visualization from a worksheet in a tooltip (Viz in Tooltip), [Create Views in Tooltips \(Viz in Tooltip\)](#) on page 1315.

### Add a tooltip

1. Drag a field to **Tooltip** on the **Marks** card.
2. Click **Tooltip** on the **Marks** card to open the Edit Tooltip dialog box, where you can add text, rearrange the tooltip contents, and insert more fields.

**Note:** Dimensions are added to the tooltip using the ATTR aggregation, which means the tooltip may sometimes display as an asterisk. The asterisk indicates that there are multiple dimension members that apply to the mark you are pointing at. For example, a mark may represent the aggregated sales for all regions. Adding the Region field to the tooltip results in an asterisk because the mark represents more than one region. To avoid showing an asterisk, add the dimension to Detail on the Marks card or use it elsewhere in the view to ensure the marks are at the same level of detail.

## Tooltip options

After you open the Edit Tooltip dialog box, there are several options that you can choose from to format the tooltips in your view and configure their behavior. You can choose from the options below.

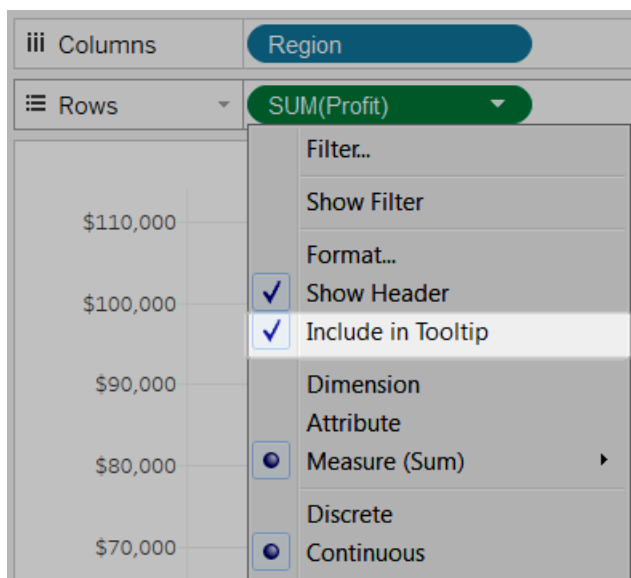

- **Format tooltips:** Tooltips are specified on a per-sheet basis and can be formatted using the tools on the top of the Edit Tooltip dialog box.
- **Adding dynamic text:** Use the **Insert** menu at the top of the dialog box to add dynamic text such as field values, sheet properties, and more. The **All Fields** command on the **Insert** menu adds all field names and values that are used in the view to the tooltip for any mark in the view.
- **Show tooltips:** Tooltips are shown by default. If you prefer to hide automatic tooltips, clear the **Show Tooltips** check box.
- **Configure tooltip behavior:** Configure how tooltips behave by selecting one of the following options in the drop-down list next to the **Show Tooltips** check box:
  - **Responsive - Show tooltips instantly:** Select this option to show tooltips instantly as you move the cursor over the marks in the view. This is the default for all views. With this option, tooltips appear without command buttons. You must first click a mark in the view to see the command buttons.
  - **On Hover - Show tooltips on hover:** Select this option to show tooltips only after you rest the cursor on a mark. However, with this option, command buttons appear on the tooltip without any further action from you (unless you specify otherwise in the Edit Tooltips dialog box).
- **Show commands:** Select the **Include command buttons** check box to add **Keep Only**, **Exclude**, **Group Members**, **Create Set** and **View Data** buttons at the top of the tooltip.

These buttons show both in Tableau Desktop and when the view is published to the web or viewed on a mobile device.

For more information about grouping members, see [Correct Data Errors or Combine Dimension Members by Grouping Your Data](#) on page 1038. For more information about creating sets, see [Create Sets](#) on page 1040.

- **Select marks in a view from the tooltip.** Select the **Allow selection by category** check box to be able to select marks in a view that have the same value by clicking on a discrete field in a tooltip. If this check box is selected, you can use this feature to select marks in a view in Tableau Desktop, when the view is published to the web or viewed on a mobile device.
- **Add or remove fields:** To add and remove fields when using the automatic tooltip, right-click (control-click on Mac) the field on one of the shelves in the view and select **Include in Tooltip**.

**Note:** The **Include in Tooltip** option is only available if you have not customized the tooltip. If you have customized the tooltip, you can return to the automatic tooltip by clicking **Tooltip** on the Marks card and then clicking **Reset** in the Edit Tooltip dialog box.

## Change the shape of marks

To change the shapes of marks:

- From the **Data** pane, drag a field to **Shape** on the Marks card.

When you place a dimension on **Shape** on the **Marks** card, Tableau separates the marks according to the members in the dimension, and assigns a unique shape to each member. Tableau also displays a shape legend, which shows each member name and its associated shape. When you place a measure on **Shape** on the **Marks** card, the measure is converted to a discrete measure.

Shape-encoding data separates the marks in the same way as the Detail property does, and then provides additional information (a shape) for each mark. Shape is the default mark type when measures are the inner most fields for both the **Rows** shelf and the **Columns** shelf.

In the view below, the marks are separated into different shapes according to the members of the **Customer Segment** dimension. Each shape reflects the customer segment’s contribution to profit and sales.

## Edit shapes

By default, ten unique shapes are used to encode dimensions. If you have more than 10 members, the shapes repeat. In addition to the default palette, you can choose from a variety of shape palettes, including filled shapes, arrows, and even weather symbols.

1. Click **Shape** on the **Marks** card, or select **Edit Shape** on the legend's card menu.
2. In the Edit Shape dialog box, select a member on the left and then select the new shape in the palette on the right. You can also click **Assign Palette** to quickly assign the shapes to the members of the field.

Select a different shape palette using the drop-down menu in the upper right.

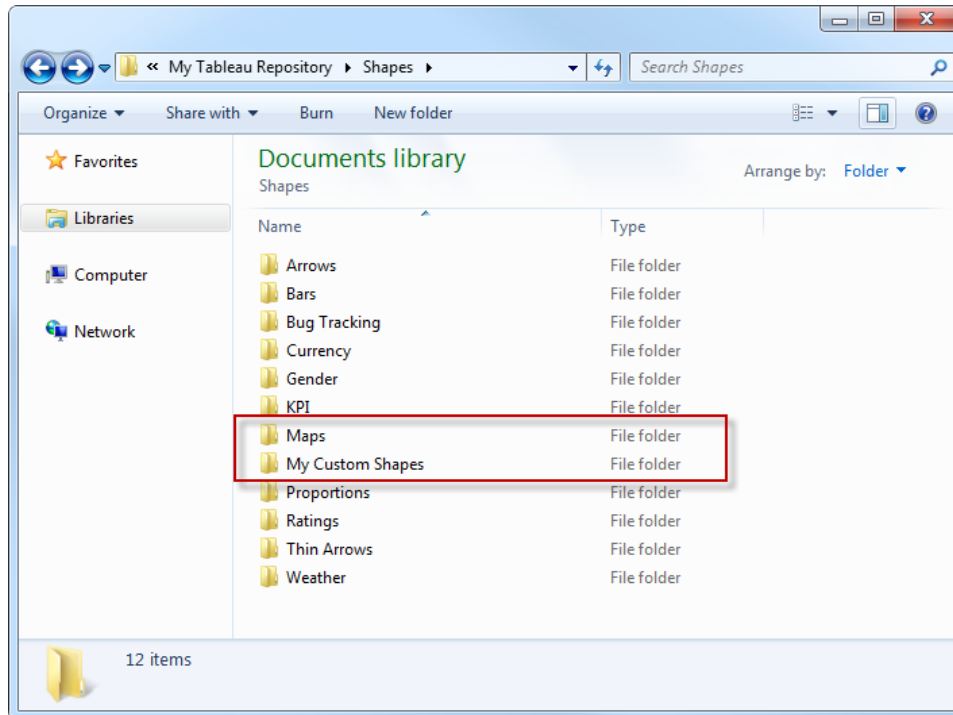

**Note:** Shape encodings are shared across multiple worksheets that use the same data source. For example, if you define Furniture products to be represented by a square, they will automatically be squares in all other views in the workbook. To set the default shape encodings for a field, right-click (control-click on Mac) the field in the **Data** pane and select **Default Properties > Shape**.

### Use Custom shapes

You can add custom shapes to a workbook by copying shape image files to the Shapes folder in your Tableau Repository, which is located in your Documents folder. When you use custom shapes, they are saved with the workbook. That way the workbook can be shared with others.

## Tableau Desktop and Web Authoring Help

1. Create your shape image files. Each shape should be saved as its own file and can be in any of several image formats including bitmap (.bmp), portable network graphic (.png), .jpg, and graphics interchange format (.gif).
2. Copy the shape files to a new folder in the My Tableau Repository\Shapes folder in your Documents folder. The name of the folder will be used as the name of the palette in Tableau. In the example below, two new palettes are created: Maps and My Custom Shapes.

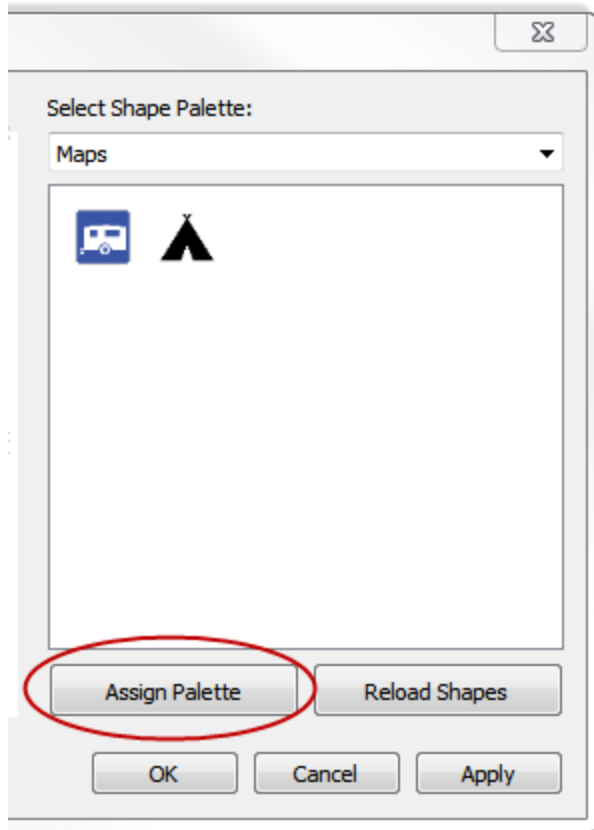

3. In Tableau, click the drop-down arrow on the shape legend, and select **Edit Shape**.

4. Select the new custom palette in the drop-down list. If you modified the shapes while Tableau was running, you may need to click **Reload Shapes**.

5. You can either assign members shapes one at a time, or click **Assign Palette** to automatically assign the shapes to the members.

**Note:** You can return to the default palette by clicking the **Reset** button. If you open a workbook that uses custom shapes that you don't have, the workbook will show the custom shapes because the shapes are saved as part of the workbook. However, you can click **Reload Shapes** in the Edit Shapes dialog box to use the ones in your repository instead.

Below are some examples of views that use both the default and custom shape palettes.

## Tips for creating custom shapes

When you create custom shapes there are a few things that you can do to improve how your shapes look and function in the view. If you are creating your own shapes, we recommend following general guidelines for making icons or clip art.

- **Suggested size** - Unless you plan on using Size to make the shapes really large, you should try to make your original shape size close to 32 pixels by 32 pixels. However, the original size depends on the range of sizes you want available in Tableau. You can resize the shapes in Tableau by clicking Size on the **Marks** card, or by using the cell size options on the **Format** menu.
- **Adding color encoding** - If you plan to also use Color to encode shapes, you should use a transparent background. Otherwise, the entire square of the image will be colored rather than just the symbol. GIF and PNG file formats both support transparency. GIF files support transparency for a single color that is 100% transparent, while PNG files support alpha channels with a range of transparency levels available on every pixel in the image. When Tableau color encodes a symbol, the amount of transparency for each pixel won't be modified, so you can maintain smooth edges

**Note:** Avoid including too much transparency around an image. Make the size of the custom shape as close to the size of the image as possible. Extra transparent pixels around the edges of the image can negatively effect the hover or click behavior near the image, especially when custom shapes overlap each other. When the actual shape area is bigger than what is visible, it can make hovering and clicking the shape more difficult and less predictable for users.

- **File formats** - Tableau doesn't support symbols that are in the Enhanced Meta File format (.emf). The shape image files can be in one of the following formats: .png, .gif, .jpg, .bmp, and .tiff.

### Draw paths between marks

The Path property is available when the **Line** or **Polygon** mark type is selected in the **Marks** card drop-down menu. For more information about how to change the type of mark displayed in your viz, see [Change the Type of Mark in the View on page 1182](#).

You can use the Path property in the Marks card to change the **type of line mark (linear, step, or jump)**, or to encode data by connecting marks **using a particular drawing order**. You can path-encode your data using either a dimension or a measure.

- **Dimension** – When you place a dimension on **Path** on the Marks card, Tableau connects the marks according to the members in the dimension. If the dimension is a date, the drawing order is driven by the date order. If the dimension includes words such as customer names or product types, the drawing order is driven by the order of the members in the data source. You can change the order that data points are connected by changing the sort order of the members. For more information, see [Sort Data in a Visualization on page 1289](#).
- **Measure** – When you place a measure on **Path** on the **Marks** card, Tableau connects the marks according to the values of the measure. The measure can be aggregated or disaggregated.

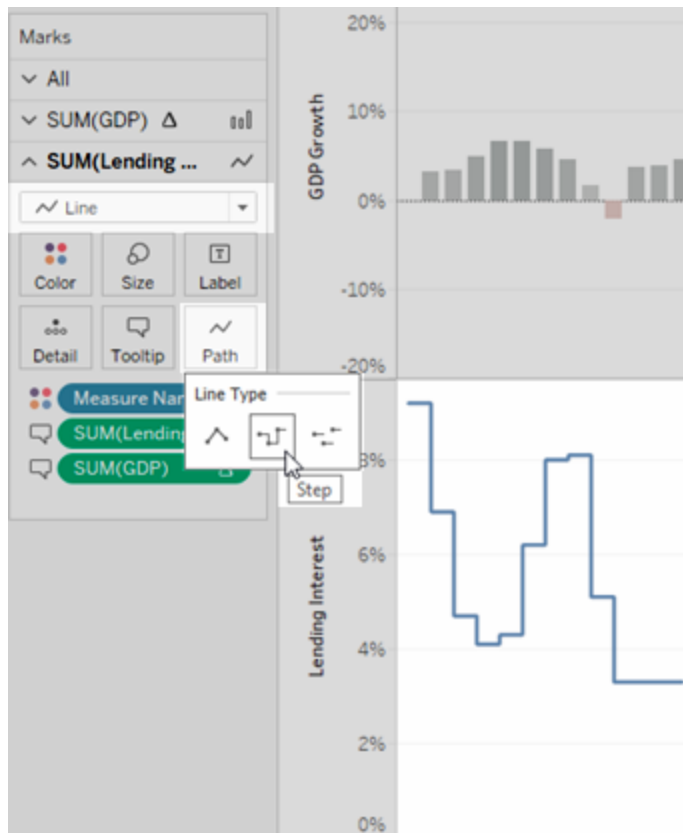

### Change the line type (linear, step, jump)

When the mark type is set to be a line (Automatic or Line), you can click the **Path** property in the Marks card to change the line type.

Use these line types for numeric data that remains constant for periods of time, with noticeable changes or deltas – such as account balances, inventory levels, or interest rates. Step lines work

well for emphasizing the magnitude of change. Jump lines help to emphasize the duration of change between data points.

1. Click **Path** in the Marks card.
2. Select **Linear**, **Step**, or **Jump** to change the line type.

### Change the line pattern (solid, dashed, dotted)

Starting in Tableau 23.2, when the mark type is set to be a line (Automatic or Line), you can click the **Path** property in the Marks card to change the line pattern.

Use different line patterns to help differentiate secondary measures. For example, when you want to highlight actual values vs baseline metrics. Line Patterns are helpful when indicating that specific lines are thresholds (such as goals and limits) and other measures are less certain (such as a forecast or modeled data). Line patterns soften the visual weight of a line and can help certain trends from being the primary focus when comparing multiple trends against one another.

1. Click **Path** in the Marks card.
2. Select **Solid line**, **Dashed line**, or **Dotted line** to change the line pattern.

**Note:** Dashed and dotted line patterns aren't compatible with continuous size encoding. If you have a mark set to change size or thickness based on a quantitative value, you must use a solid line pattern.

### Create a path-encoded view

To create a useful path-encoded view, your data table should contain at least one measure. You can't create a path that connects only categorical data (dimensions).

The view below was created using storm data from the Atlantic basin in 2010. The view uses line marks with the path determined by the date of the storm. This lets you see the path of the storm. By placing the continuous date on **Path** on the **Marks** card, this tells Tableau to draw the lines in chronological order. For more information, see [Create Maps that Show a Path Over Time in Tableau](#) on page 1734 and [Create Maps that Show Paths Between Origins and Destinations in Tableau](#) on page 1748.

## Show, Hide, and Format Mark Labels

You can add labels to the marks in your viz. Labels can display the data already represented in that mark, or additional fields can be added to the Label shelf on the Marks card.

Labels aren't quite the same thing as annotations (which are more like comments than labels). For more information on annotations, see [Add Annotations](#) on page 1306.

## Turn labels on or off

To show mark labels in a viz, do one of the following:

- Select the Mark Label button in the tool bar 
- On the Marks card, select **Label**, and then select **Show mark labels**.
- Drag a field to the Label shelf on the Marks card.

**Note:** If the Mark type is Text (including Automatic text), the label shelf may say **Text** instead of **Label**.

To turn off labels, select the Mark Label button again or clear the Show mark labels option.

## Use a specific field as a label

If you didn't specify what field to use as the label, Tableau will use a default field. To set a specific field as the label, drag the desired field to the **Label** shelf on the Marks card.

### Change what labels appear

By default, all marks are labeled unless the labels would overlap. Overlap can often be illegible if there are too many marks nearby, but you can turn it on if you choose.

On the Marks card, click **Label**. Check the option **Allow labels to overlap other marks**.

## Configure Marks to Label

The **Marks to Label** section offers more nuanced settings for what labels appear.

Not all options are available at all times. Some, like Line Ends, only appear when the structure of the viz supports it. The appearance of the dialog differs depending on if you're using Tableau Desktop or web editing in the browser.

Label options in Tableau Desktop: All

Label option in Web Editing: Min/Max

On the Marks card, click **Label**. Select an option:

- **All**. Label all marks in the viz. (This is the default)
- **Min/Max**. Label only the minimum and maximum values for a field in the viz. Additional options appear with this setting:
  - **Scope**: you can label the min/max for the entire table, per pane, per cell, or per line/pie.
  - **Field**: set which field's min/max is used.
  - **Options**: you can choose to label only the min or max or both.
- **Line Ends**. Label the ends of all lines. use the Additional options if you want to label only the start or end.
- **Selected**. Labels appear when you select one or more marks in the viz.
- **Highlighted**. Label only the highlighted marks in the view. Highlighting can occur in several ways:
  - Selecting a member in a legend
  - Selecting a mark or marks in the viz (this is the same behavior as the Selected option)

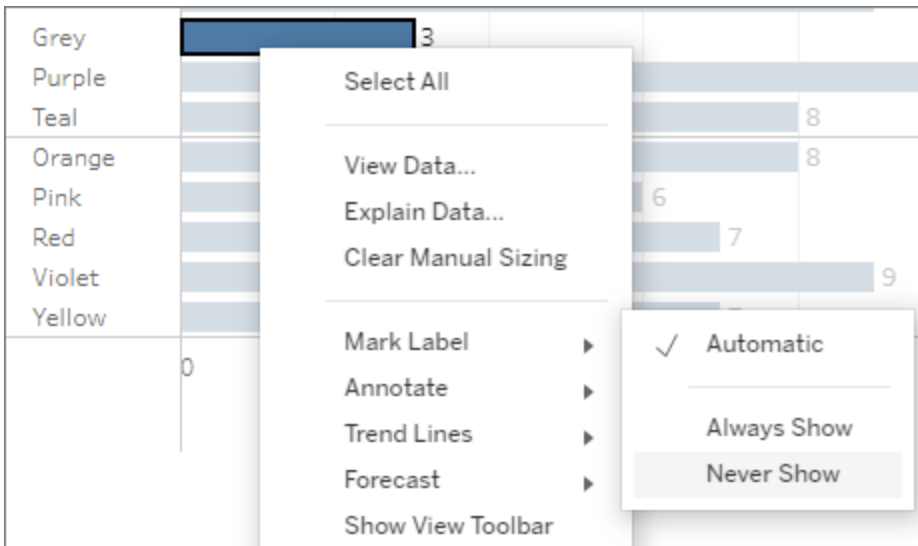

- Using the Highlighter. For more information about how to use the Highlighter, see [Highlight Data Points in Context on page 1340](#).
- **Most Recent.** Label the most recent marks in the view. When there's a date field in the view, you can label all marks that correspond to the most recent date or time in the view. Like Min/Max, this setting has a scope option.

## Show and hide individual mark labels

You might want to show labels for only individual marks, or hide specific overlapping mark labels.

In the viz, right click the mark you want to show or hide a mark label for, select **Mark Label**, and then select one of the following options:

- **Automatic:** select this option to turn the label on and off depending on the view and the settings in the Label drop-down menu.
- **Always Show:** select this option to show the mark label.
- **Never Show:** select this option to hide the mark label.

## Format mark labels

There are several formatting options to help you adjust the appearance of the labels. You can customize the text, adjust the font properties, and set an alignment. These options only available in Tableau Desktop.

## Edit the label text

**Note:** A field must be on the Label shelf before you can edit the label text.

1. On the Marks card, click **Label**.
2. In the dialog box that opens, under **Label Appearance**, click the more options button [ ... ] next to **Text**.
3. Edit the text.
  - You can edit aspects of the font and alignment in this text editor, but for more complete options, use the Label dialog itself(see the next sections).
  - You can use the Insert button in the editor to add more fields to the label, but only fields that were added to the Label shelf are available in that drop down.
4. Select **OK**.

## Edit the label font

1. On the Marks card, click **Label**.
2. In the dialog box that opens, under **Label Appearance**, click the **Font** drop-down. Here you can:
  - Select a font type, size, and emphasis.
  - Select a color for the labels:
    - To select a specific color, click a color from the options.
    - To match labels to the color of their marks, click **Match Mark Color**.
  - Adjust the opacity of the labels by moving the slider at the bottom of the menu.

## Edit the label alignment

1. On the Marks card, click **Label**.
2. In the dialog box that opens, under **Label Appearance**, click the **Alignment** drop-down. Here you can:
  - Align the label horizontally (left, center, right).
  - Change the direction of the text.
  - Align the label vertically (bottom, middle, top).
  - Set the Wrap to automatic, on, or off.

## Move mark labels manually

Once a label is present, you can drag it to a new position. For example, in a stacked bar chart, the mark labels are automatically placed in the center of each bar. However, you may want to stagger the labels so that the longer ones don't overlap.

Select the mark label and, without releasing the mouse button, drag the label to its desired location.

## Move Marks

In a dual-axis view that contains many marks, some marks can become hidden behind others, making it difficult to see details in your view. Tableau provides a **Move Marks** option to move selected marks forward or backward, depending on the axis that you select.

To move marks forward or backward, right-click on one of your axes and select one of the following options:

- **Move Marks to Front**
- **Move marks to Back**

## Example - Move marks forward

In this example, suppose you have a view that uses the **Circle** mark type on a dual axis and shows department **Sales** and **Profit** for each **Category**.

The shape of each mark represents **Sales** and **Profit**, while **Category** is encoded as **Color**. The right axis represents the **Sales** mark, while the left represents the **Profit** mark.

Because the profit marks are in front, it is difficult to see the **Sales** marks in the **Office Supplies** category.

To move the **Sales** marks in front of the **Profit** marks, do the following:

1. Right-click on the **Sales** axis.
2. Select **Move marks to front** from the context menu.

By moving the **Sales** mark to the front, you can now see that rubber bands are below \$100,000 in sales, whereas they were nearly invisible before.

### Stack Marks

Stacking marks is relevant when your data view includes numeric axes. That is, at least one measure has been placed on the **Rows** or **Columns** shelves. When marks are stacked, they are drawn cumulatively along an axis. When marks are not stacked, they are drawn independently along an axis. That is, they are overlapping.

Stacking marks is particularly useful for bar charts which is why Tableau automatically stacks bars. You might find that stacking marks is useful for other marks such as lines as well.

You can control whether marks are stacked or overlapping in any given view by selecting the **Analysis > Stack Marks** menu item.

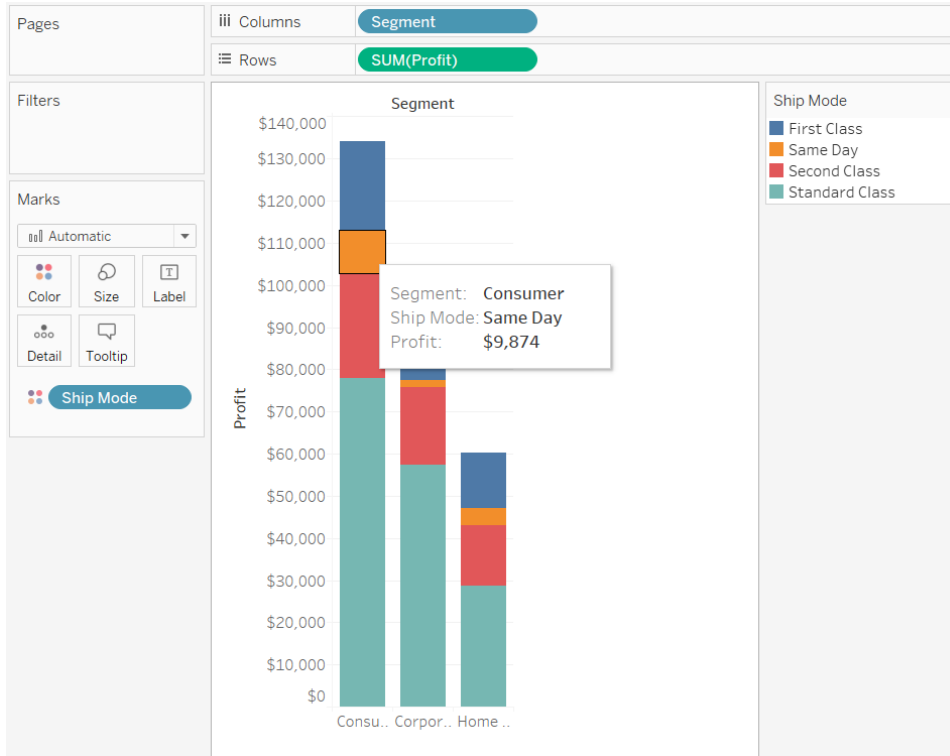

You can either allow Tableau to automatically select whether the marks are stacked or you can specify **On** or **Off**. The default setting is **Automatic**. When you are in automatic mode, the Stack Marks menu shows whether stacked marks is on or off.

Selecting **On** or **Off** on the **Stack Marks** menu, switches into manual mode. Your selection remains throughout any changes you make to the view.

The following examples illustrate stacking marks.

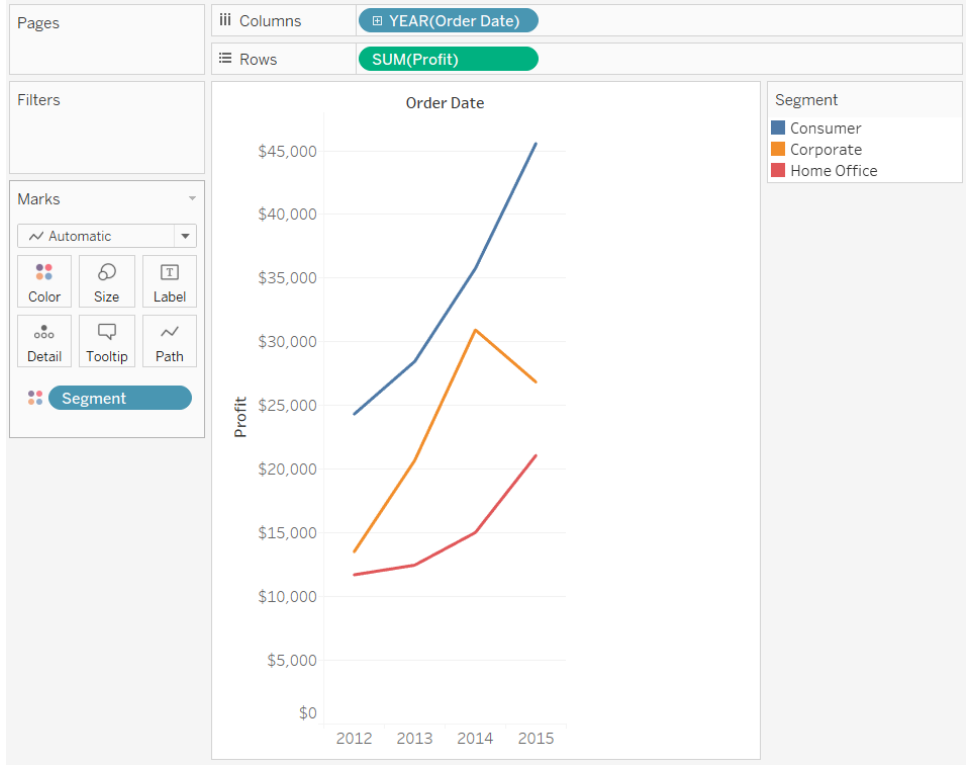

#### Example: Stacking Bars

Consider the stacked bars view shown below. It was created by placing a dimension on the **Columns** shelf, placing a measure on the **Rows** shelf, and color-encoding the data by a dimension (that is, dropping a dimension on **Color** on the Marks card).

### Example: Stacking Lines

Consider the data view shown below. It was created by placing a date dimension on the **Columns** shelf, placing a measure on the **Rows** shelf, and color-encoding the data by a dimension (that is, dropping a dimension on **Color** on the Marks card). Because the mark type is Line, the marks are not automatically stacked. Instead, they are drawn independently from the horizontal axis.

### Color Palettes and Effects

All marks have a default color, even when there are no fields on **Color** on the **Marks** card. For most marks, blue is the default color; for text, black is the default color. Also see [Assign colors to marks](#) on page 1206 and [Example – Multiple Fields on Color](#) on page 1247.

### Categorical Palettes

When you drop a field with discrete values (typically a dimension) on **Color** on the **Marks** card, Tableau uses a categorical palette and assigns a color to each value of the field. Categorical palettes contain distinct colors that are appropriate for fields with values that have no inherent order, such as departments or shipping methods.

To change colors for values of a field, click in the upper-right corner of the color legend. In Tableau Desktop, select **Edit Colors** from the context menu. In Tableau Server or Tableau Cloud, the Edit Colors dialog opens automatically.

#### Tableau Desktop version

#### Web version

## Change the color for a value

1. Click on an item on the left, under **Select Data Item**.
2. Click a new color in the palette on the right. In Tableau Desktop you can hover over a swatch to identify the color.
3. Repeat for as many values that you want to change.
4. In Tableau Desktop, click **OK** to exit the Edit Colors dialog box. In Tableau Server or Tableau Cloud, simply close the dialog box.

## Select a different palette

The **Select Color Palette** drop-down list in the Edit Colors dialog box provides color palettes that you can use for discrete fields. The list contains both categorical and ordinal palettes.

At the top of the list are categorical palettes, such as *Tableau 10*. As noted above, categorical palettes are appropriate for discrete fields with no inherent order.

At the bottom of the list are ordinal palettes such as *Orange*. Ordinal palettes contain a range of related colors and are appropriate for fields that have an associated order, such as dates or numbers.

After you select a palette, click **Assign Palette** to automatically assign the new palette colors to the members in the field.

To return to the Automatic palette and the default color assignments, click **Reset** in the Edit Colors dialog box.

### Quantitative Palettes

When you drop a field with continuous values on the **Marks** card (typically a measure), Tableau displays a quantitative legend with a continuous range of colors.

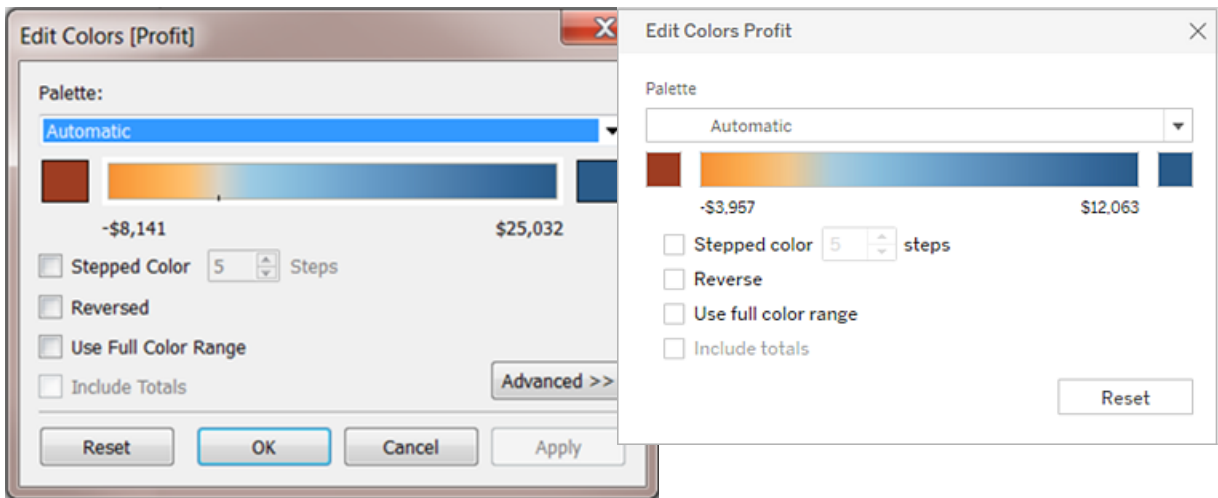

You can change the colors used in the range, the distribution of color, and other properties. To edit colors, click in the upper right of the color legend. In Tableau Desktop, select **Edit Colors** from the context menu. In Tableau Server or Tableau Cloud, the Edit Colors dialog opens automatically.

When there are both negative and positive values for the field, the default range of values will use two color ranges and the Edit Colors dialog box for the field has a square color box on either end of the range. This is known as a diverging palette.

#### Tableau Desktop version

#### Web version

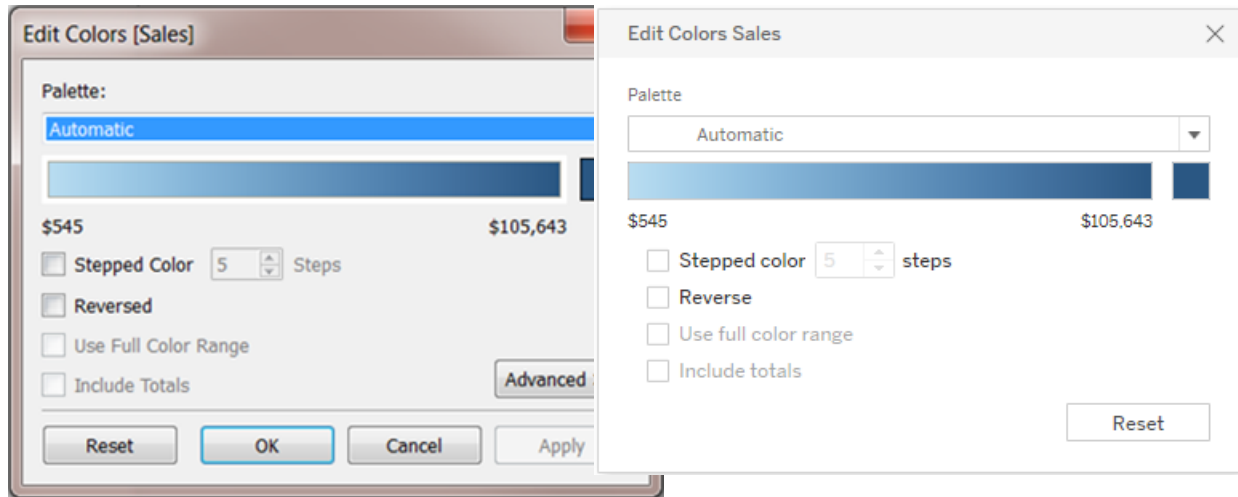

#### *Edit Colors dialog box for a diverging palette*

When all values are either positive or negative, the default range of values will use a single color range and the Edit Colors dialog box for the field has a square color box only at the right end of the range. This is known as a sequential palette.

## Tableau Desktop version

## Web version

*Edit Colors dialog box for a sequential palette*

You can specify whether Tableau uses a diverging or a sequential palette for a continuous field on **Color**, and also configure the range of colors for the field's values.

The **Palette** drop-down list provides a range of color palettes from which you can choose. There are two types of quantitative palettes available for continuous fields:

- All palettes with *Diverging* in the name are diverging quantitative palettes—for example, *Orange-Blue Diverging*. You can choose a diverging palette for any continuous field—it isn't necessary for the range of values to contain both positive and negative numbers.

To change the colors for a diverging palette, click one of the square color boxes at either end of the palette spectrum. Depending on whether you are authoring in Tableau Desktop or on the web, do one of the following:

- In Tableau Desktop, in the color configuration dialog box (which is part of your computer's operating system), select a color from the color picker or enter custom values.
- In Tableau Server or Tableau Cloud, enter a custom Hex value in the **Custom Color** field. If the value isn't valid, no changes are made.
- All other palettes are sequential quantitative palettes. To change the colors for a sequential palette, click the square color box at the right end of the palette spectrum to either open the color configuration dialog box (Tableau Desktop), or enter a custom Hex value in the **Custom Color** field (Tableau Server or Tableau Cloud).

## Options for quantitative palettes

The following options are available in the Edit Colors dialog box for a continuous field.

**Note:** Options differ where noted for Tableau Server and Tableau Cloud.

### Stepped Color

Select **Stepped Color** to group values into uniform bins, where each bin is associated with a color. Use the spin control to specify how many steps (bins) to create. For example, for a range of values from 0 to 100 you could specify five steps to sort values into five bins (0-20, 20-40, etc.).

#### Tableau Desktop version

#### Web version

If a diverging color palette is selected, the point where the palette transitions between colors is shown on the color ramp with a small black tick mark. When the number of steps is odd, the mark is placed in the middle of the transitional step. When the number of steps is even, the mark is placed at the boundary between the steps where the color changes.

### Reversed

Select **Reversed** to invert the order of colors in the range. For example, if you want lower values to have a darker intensity in a sequential palette, reverse the palette. For a diverging palette, reversing the color palette means swapping the two colors in the palette, in addition to inverting the shades within each color range.

## Use Full Color Range

With a diverging (two-color) palette, you can select to **Use Full Color Range**. Tableau assigns both the starting number and the ending number a full intensity for both color ranges. So if the range is from -10 to 100, the color representing negative numbers will be adjusted to change in shade much more quickly than the color representing positive numbers. If you don't select **Use Full Color Range**, Tableau assigns the color intensity as if the range of values was from -100 to 100, so that the change in shade is the same on both sides of zero. This means there will be much less change on the negative side, where actual values only range from -10 to 0, than on the positive side, where values range from 0 to 100.

The image on the left below shows a red-green diverging color palette for values from -858 to 72,986. Without using the full color range, -858 (associated with the small box at the lower right of the chart) shows as gray, because -858 is only about 1% as far to the negative side as 72,986 is to the positive side. When the full color range is used, as in the image on the right, -858 shows as a dark red, equal in intensity to the maximum positive value.

## Include totals

Select **Include Totals** to include totals, sub-totals and grand totals in the color encoding. This option only applies when total values are included in the view.

## Limit the color range

In Tableau Desktop, when you click **Advanced** in the Edit Colors dialog box, you can choose to specify the start, end, and center values for the range by selecting the check box and typing a new value into the field and the color ramp is adjusted accordingly.

The **Start** value is the lower limit in the range, the **End** value is the upper limit, and the **Center** value is where the neutral color is located on a diverging color palette.

**Note:** This option is not currently available in Tableau Server or Tableau Cloud.

## Reset the color range

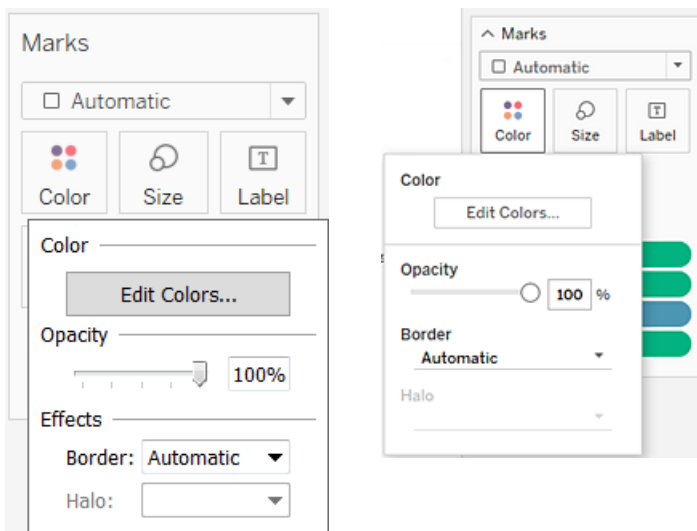

To return to the Automatic palette and the default color assignments, click **Reset** in the Edit Colors dialog box.

**Note:** If you are in web authoring mode and click **Reset**, the color palette will return to the default settings. Any options that were set in the **Advanced** option will also be reset. To undo this action, you can click **Undo** in the top menu. If your changes have already been saved, you must change the Advanced options in Tableau Desktop and republish the view.

## Configure Color Effects

Click the **Color** drop down on the **Marks** card to configure additional **Color** settings not related to the actual colors shown.

### Tableau Desktop version    Web version

## Opacity

Modify the opacity of marks by moving the slider.

Adjusting opacity is especially useful in dense scatter plots or when you are looking at data overlaying a map or background image. As you slide the slider toward the left, marks become more transparent.

## Mark borders

By default, Tableau displays all marks without a border. You can turn on mark borders for all mark types except text, line, and shape. On the **Color** drop-down control, select a mark border color.

### Tableau Desktop version

### Web version

Borders can be useful for visually separating closely spaced marks. For example, the views below show a scatterplot with mark borders turned on (left) and turned off (right). When borders are turned on, marks are easier to distinguish in areas where they are tightly clustered.

# Tableau Desktop and Web Authoring Help

**Note:** You can also use the opacity setting to show the density of marks.

When you are viewing a large number of color-encoded small marks, it is usually better to leave mark borders off. Otherwise borders can dominate the view, making it difficult to see the color encoding.

For example, the views below show bars that are segmented by a large number of color-encoded dimension members. With mark borders turned on (right), some of the narrower marks are difficult to identify by color. With borders turned off (left), the marks are easy to distinguish.

## Mark halos

To make marks more visible against a background image or map, surround each mark with a solid contrasting color called a halo. Mark halos are available when you have a background image or a background map. On the **Color** drop-down control, select a mark halo color.

## Markers

In Tableau Desktop, when you are using the Line mark type, you can add a marker effect to show or hide points along the line. You can show selected points, all points, or no points. On the **Color** drop-down control, select a marker in the **Effects** section.

**Note:** This option is not currently available in Tableau Server or Tableau Cloud.

### Example - Multiple Fields on Color

If you drop one field on Color and then drop a different field on Color, the second field replaces the first field. However, depending on the chart type, for example treemaps and bullet graphs, you can put multiple fields on color. You can use one field to set the hue, and the other to show gradations within that hue.

Follow these steps, using the Sample - Superstore data source, to build a treemap with two fields on Color.

1. Drag **Category** and **Sub-Category** to **Columns**.
2. Drag **Sales** to **Size** on the **Marks** card.
3. Click **Show Me** in the toolbar, then select the Treemap chart type.

Tableau moves all fields to the **Marks** card, putting **SUM(Sales)** on both **Size** and **Color**, and **Category** and **Sub-Category** on **Label**:

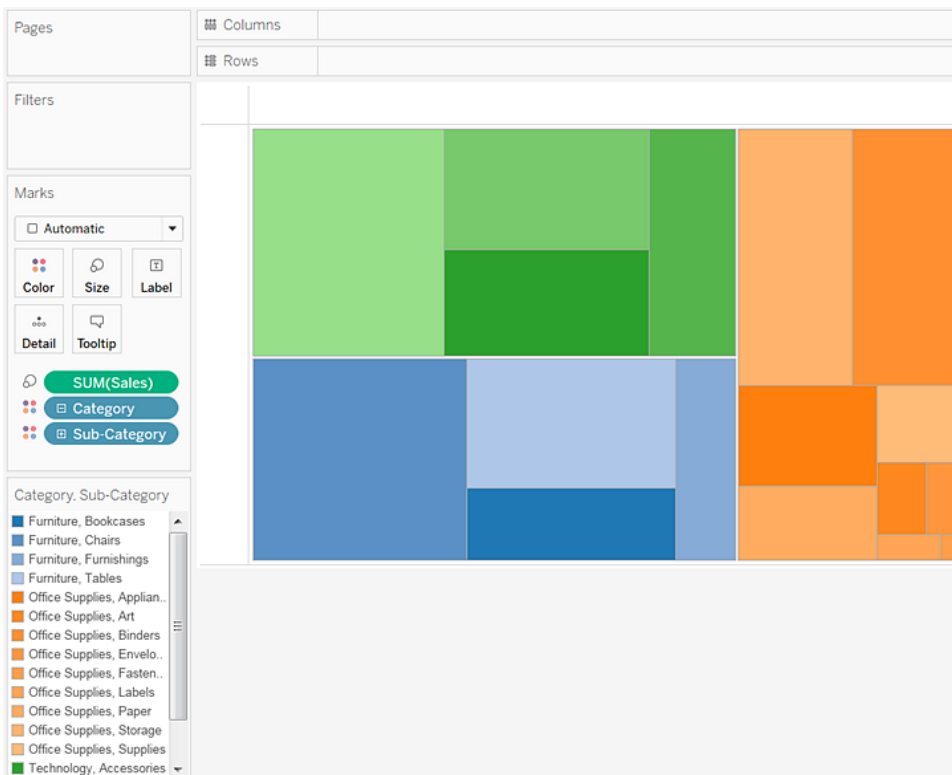

4. Click the label icon to the left of **Category** on the **Marks** card and select **Color**:

**Category** replaces **SUM(Sales)** on **Color**. The marks are still sized by the sum of **Sales**, but now they are colored by **Category**:

5. Click the label icon to the left of **Sub-Category** on the Marks card and select **Color**.  
Tableau uses distinct, categorical colors for the first field, **Category**, and a range of sequential shades to distinguish values for the second field, **Sub-Category**:

The size of the individual rectangles is still determined by **Sales**, per **Category** and **Sub-Category**.

The two fields on **Color** (**Category** and **Sub-Category**) are related within a hierarchy, so if you swap their positions on the **Marks** card, moving **Sub-Category** to be above **Category**, the effect is the same as if you had removed **Category** from the view altogether. The treemap changes to show a uniquely colored rectangle for each **Sub-Category**:

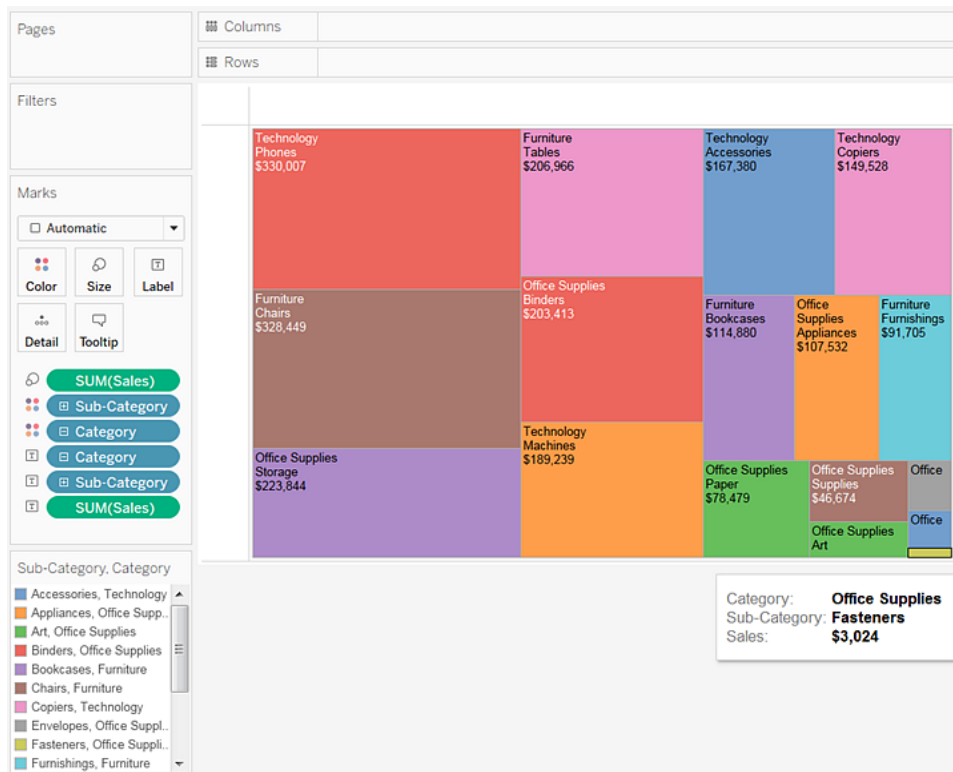

When the two fields on Color are not related within a hierarchy, you can switch the order of the fields on the Marks card so that the field that was used for categorical colors was used for sequential shades, and vice versa.

If you aren't satisfied with the colors that Tableau used, you can change them. To open the Edit Colors dialog, do one of the following:

- In Tableau Desktop, double-click the color legend.
- In Tableau Server or Tableau Cloud, click the drop-down arrow in the top right-hand corner of the legend.

6. Make the view more readable by adding **Category**, **Sub-Category**, and **Sales** to **Label**. Users can hover to see tooltips for any rectangle that is too small to show text by default.

## Filter and Sort Data in the View

This section describes the various ways you can filter and sort data in Tableau visualizations. Read the following articles for information on how to filter data from your visualizations and across multiple worksheets and data sources, sort data in the visualization, create nested sorts, and more.

### Filter Data from Your Views

Filtering is an essential part of analyzing data. This article describes the many ways you can filter data from your view. It also describes how you can display interactive filters in the view, and format filters in the view.

## Filtering Order of Operations

Before you begin filtering data in Tableau, it's important to understand the order in which Tableau executes filters in your workbook.

Tableau performs actions on your view in a very specific order; this is called the Order of Operations. Filters are executed in the following order:

1. Extract filters
2. Data source filters
3. Context filters
4. Filters on dimensions (whether on the Filters shelf or in filter cards in the view)
5. Filters on measures (whether on the Filters shelf or in filter cards in the view)

To learn more, see [Tableau's Order of Operations](#) on page 162.

**Note:** When you drag a discrete dimension to the Filters shelf, the **Filter** dialog box offers four tabs for filtering: General, Wildcard, Condition, and Top. The settings on each of these tabs are additive starting with the General tab; what you set on each tab will affect the filter results on each tab to the right. For details on the Filter dialog box, see [Drag dimensions, measures, and date fields to the Filters shelf](#) on page 1255 and [Filter categorical data \(dimensions\)](#) on page 1256.

## Select to keep or exclude data points in your view

You can filter individual data points (marks), or a selection of data points from your view. For example, if you have a scatter plot with outliers, you can exclude them from the view so you can better focus on the rest of the data.

To filter marks from the view, select a single mark (data point) or click and drag in the view to select several marks. On the tooltip that appears, you can:

- Select **Keep Only** to keep only the selected marks in the view.

- Select **Exclude** to remove the selected marks from the view.

**Note:** These filtering options are not available if a Wildcard Match filter is already specified for the same field. See [Drag dimensions, measures, and date fields to the Filters shelf on the facing page](#) to learn more about Wildcard Match filters.

### Select headers to filter data

You can also select headers to filter them from your view.

To filter entire rows or columns of data from your view, select the header in the view. On the tooltip that appears, select to **Exclude** or **Keep Only** the selected data.

When you select a table header that is part of a hierarchy, all of the next level headers are also selected. For example, the view shown below consists of two unrelated dimensions placed on the **Columns** shelf, and two levels of the same hierarchy placed on the **Rows** shelf.

The selected row headers include the Furniture member of the **Category** dimension, and the Binders and Labels members of the **Sub-category** dimension. When Furniture is selected, all members from the next (inner) level in the hierarchy are automatically selected. In this case, that means the Bookcases, Chairs, Furnishings, and Tables members.

Columns		Region / State									
Rows		Region / State									
Sheet 21		Region / State									
Category	Sub-Catego..	Illinois	Indiana	Iowa	Kansas	Michigan	Minnes..	Missouri	Nebras..	North Dakota	Oklaho..
Furniture	Bookcases	\$4,283				\$810		\$213			\$342
	Chairs	\$14,563	\$6,463	\$1,408		\$13,878	\$6,079	\$61	\$564		\$3,963
	Furnishings	\$2,878	\$1,514	\$49	\$111	\$1,916	\$232	\$941	\$1,381		\$1,445
	Tables	\$6,551	\$3,519	\$1,185		\$5,717	\$1,300	\$1,722			\$2,534
Office Supplies	Appliances	\$975	\$4,160		\$82	\$4,324	\$2,844	\$3,670	\$501		\$1,491
	Art	\$930	\$389	\$147	\$163	\$1,005	\$103	\$240	\$19	\$182	\$59
	Binders	\$4,539	\$4,012	\$248	\$612	\$22,822	\$12,470	\$1,876	\$128	\$26	\$445
	Envelopes	\$384	\$890	\$13		\$310	\$31	\$71			\$407
	Fasteners	\$141	\$8	\$46	\$24	\$110	\$43		\$58	\$7	
	Labels	\$225	\$276		\$19	\$881	\$161	\$15	\$14		\$64
	Paper	\$3,456	\$1,880	\$316	\$303	\$2,011	\$320	\$302	\$333		\$197
	Storage	\$9,080	\$4,120	\$13	\$394	\$6,187	\$3,398	\$1,792	\$1,165	\$705	\$2,345
Supplies	\$178			\$358	\$74	\$37	\$4,217	\$17		\$22	
Technology	Accessories	\$5,536	\$2,279		\$92	\$4,933	\$1,520	\$1,022	\$240		\$1,817
	Copiers	\$5,920	\$18,500			\$1,150	\$550	\$5,500			
	Machines	\$3,756	\$84			\$3,411					
	Phones	\$16,772	\$5,460	\$1,154	\$757	\$6,731	\$775	\$565	\$3,046		\$4,551

Drag dimensions, measures, and date fields to the Filters shelf

Another way to create a filter is to drag a field directly from the Data pane to the Filters shelf.

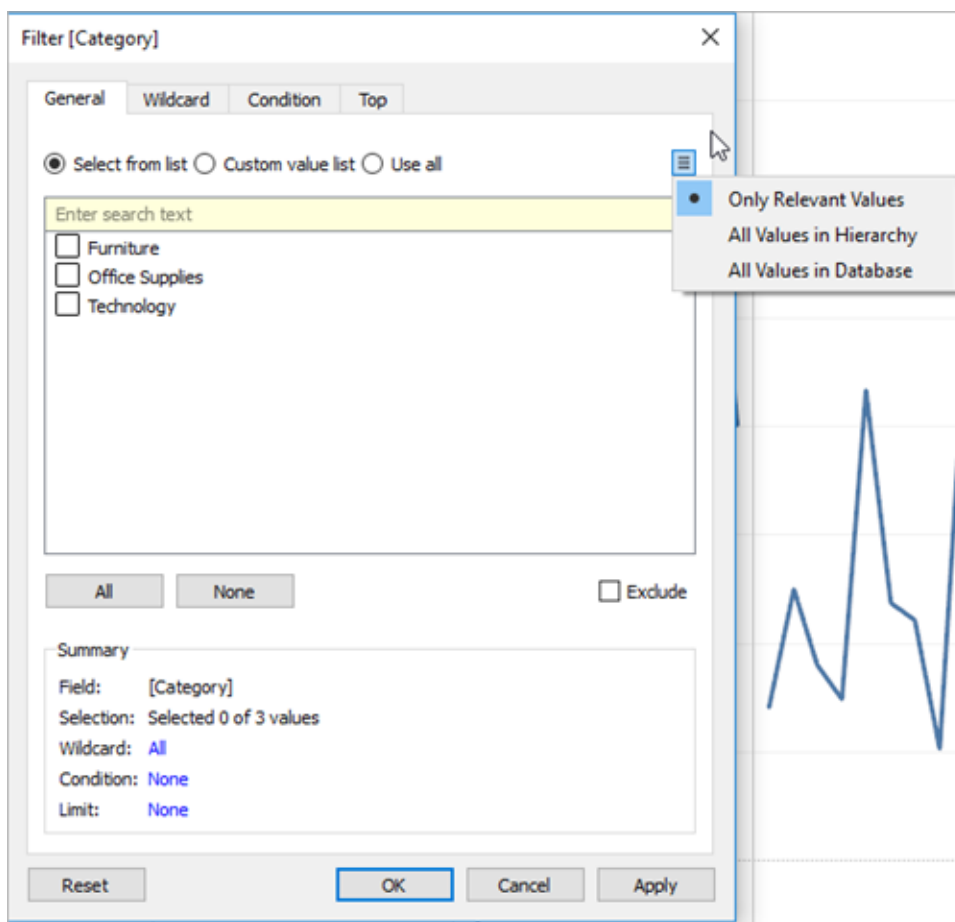

When you add a field to the Filters shelf, the Filter dialog box opens so you can define the filter. The Filter dialog box differs depending on whether you are filtering categorical data (dimensions), quantitative data (measures), or date fields.

### Filter categorical data (dimensions)

Dimensions contain discrete categorical data, so filtering this type of field generally involves selecting the values to include or exclude.

When you drag a dimension from the Data pane to the Filters shelf in Tableau Desktop, the following Filter dialog box appears:

- **General:** Use the General tab to select the values you want to include or exclude.
- **Wildcard** (Tableau Desktop only): Use the Wildcard tab to define a pattern to filter on. For example, when filtering on email addresses you might want to only include emails from a specific domain. You can define a wildcard filter that ends with "@gmail.com" to only include Google email addresses.
- **Condition:** Use the Condition tab in the Filter dialog box to define rules to filter by. For example, in a view showing the average Unit Price for a collection of products, you may want to only show the Products that have an average unit price that is greater than or equal to \$25. You can use the built-in controls to write a condition or you can write a custom formula.
- **Top:** Use the Top tab in the Filter dialog box to define a formula that computes the data that will be included in the view. For example, in a view that shows the average Time to Ship for a collection of products, you can decide to only show the top 15 (or bottom) products by Sales. Rather than having to define a specific range for Sales (e.g., greater

than \$100,000), you can define a limit (top 15) that is relative to the other members in the field (products).

**Important Note:** Each tab adds additional definitions to your filter. For example, you can select to exclude values under the General tab, and also add limits under the Top tab. Selections and configurations from both tabs are applied to your filter.

At any time, you can see the definitions of your filter under Summary on the General tab.

### Filter quantitative data (measures)

Measures contain quantitative data, so filtering this type of field generally involves selecting a range of values that you want to include.

When you drag a measure from the Data pane to the Filters shelf in Tableau Desktop, the following dialog box appears:

Select how you want to aggregate the field, and then click **Next**.

In the subsequent dialog box, you're given the option to create four types of quantitative filters:

**Range of Values:** Select the Range of Values option to specify the minimum and maximum values of the range to include in the view. The values you specify are included in the range.

**At Least:** Select the At Least option to include all values that are greater than or equal to a specified minimum value. This type of filter is useful when the data changes often so specifying an upper limit may not be possible.

**At Most:** Select the At Most option to include all values that are less than or equal to a specified maximum value. This type of filter is useful when the data changes often so specifying a lower limit may not be possible.

**Special:** Select the Special option to filter on Null values. Include only Null values, Non-null values, or All Values.

**Note:** If you have a large data source, filtering measures can lead to a significant degradation in performance. It is sometimes much more efficient to filter by creating a set containing the measure and then apply a filter to the set. For more information about creating sets, see [Create Sets on page 1040](#).

## Filter dates

When you drag a date field from the Data pane to the Filters shelf in Tableau Desktop, the following Filter Field dialog box appears:

You can select whether you want to filter on a relative date; filter between a range of dates; or select discrete dates or individual dates to filter from the view.

- **Filter relative dates:** Click Relative dates to define a range of dates that updates based on the date and time you open the view. For example, you may want to see Year to Date sales, all records from the past 30 days, or bugs closed last week. Relative date filters can also be relative to a specific anchor date rather than today.
- **Filter a range of dates:** Select Range of dates to define a fixed range of dates to filter. For example, you may want to see all orders placed between March 1, 2009 and June 12, 2009.
- **Filter discrete dates:** Select a discrete date value in the dialog box if you want to include entire date levels. For example, if you select Quarters, you can choose to filter specific quarters (e.g. Q1, Q2, Q3, Q4) from your view, regardless of the year.

**Latest date preset:** If you want to ensure that only the most recent date in a data source is selected in the filter when the workbook is shared or opened, select a discrete date such as Month/Day/Year or Individual Dates and then, on the General tab, select **Filter to latest date value when workbook is opened**.

**Notes:** When you filter to the latest date value, this setting applies only to data source filters in a workbook.

In the order of operations, the latest date filter is global to the workbook, while context filters apply per worksheet. The latest date is determined just after the workbook opens for first use, after data source filters, but before context filters. At that point the date is set, and the latest date preset is used as a dimension filter.

If you are using additional filters in views (including relative date filters and context filters), the latest date value setting may result in an empty view with no data when those additional filters do not select data from the latest date in the database.

On Tableau Server and Tableau Cloud, presets are applied when the view first loads in the browser, but not when the browser or data is refreshed.

- **Filter individual dates:** Select Individual dates to filter specific dates from your view.
- **Additional date filter options:** When you select Relative dates or Range of dates, the Filter dialog box opens. In that dialog box, you can define a Starting date or Ending date. You can also select Special to include null dates, non-null dates, or all dates.

## Filter table calculations

To create a table calculation filter, create a calculated field, and then place that field on the Filters shelf.

Filters based on table calculations do not filter out underlying data in the data set, because table calculation filters are applied last in the order of operations. This means Tableau evaluates any table calculations in the view first, and then applies table calculation filters on the results in the current view.

## Apply table calculation filter to totals

When you show totals in a view and you want a table calculation filter to apply to the totals, you can select **Apply to totals** in the drop-down menu for that filter (on the Filters shelf). This option lets you decide when a table calculation filter should be applied to totals.

This options is available when you show totals in the view, and you add a table calculation filter to the view. Select **Apply to totals** to apply the table calculation filter to all of the results in the table, including the totals.

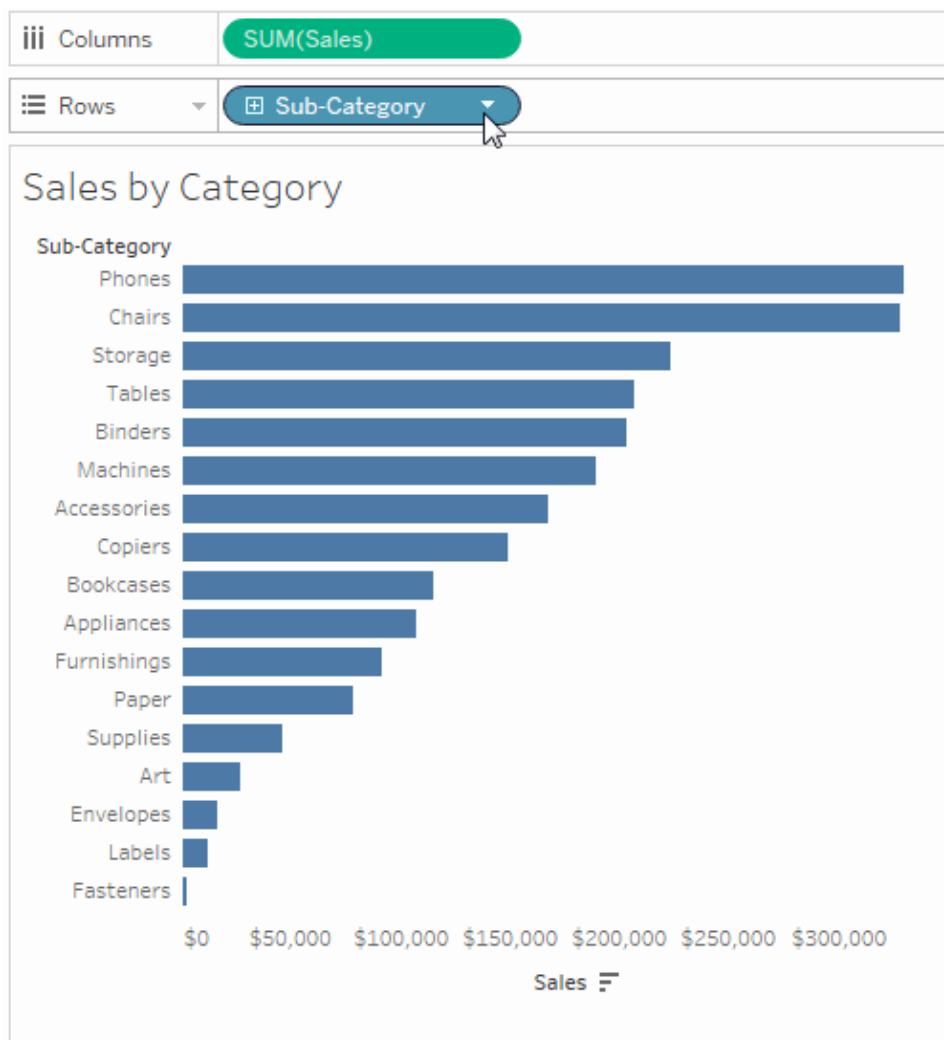

### Display interactive filters in the view

When an interactive filter is shown, you can quickly include or exclude data in the view.

**Note:** In web authoring, interactive filters are automatically added to the view when you drag a field to the Filters shelf.

**To show a filter in the view:**

1. In the view, click the field drop-down menu and select **Show Filter**.

The field is automatically added to the Filters shelf (if it is not already being filtered), and a filter card appears in the view. Interact with the card to filter your data.

**Note:** In Tableau Desktop, you can add an interactive filter to the view for a field that is not currently used in the view. To do so, In the Data pane, click the field drop-down menu, and then select **Show Filter**.

## Set options for filter card interaction and appearance

After you show a filter, there are many different options that let you control how the filter works and appears. You can access these options by clicking the drop-down menu in the upper right corner of the filter card in the view.

Some options are available for all types of filters, and others depend on whether you're filtering a categorical field (dimension) or a quantitative field (measure).

You can customize how filters appear in the view, in dashboards, or when published to Tableau Server or Tableau Cloud.

### Here are some of the general filter card options:

- **Edit Filter** - This option opens the main Filter dialog box so you can further refine the filter by adding conditions and limits.
- **Remove Filter** - Removes the filter from the Filters shelf and removes the filter card from the view.
- **Apply to worksheets** - Allows you to specify whether the filter should apply to only the current worksheet or be shared across multiple worksheets. For more information, see [Apply Filters to Multiple Worksheets](#) on page 1286.
- **Format Filters** (Tableau Desktop only) - Customize the font and colors of all your filter cards in the view.
- **Only relevant values** - Specifies which values to show in the filter. When you select this option other filters are considered and only values that pass these filters are shown. For example, a filter on State will only show the Eastern states when a filter on Region is set.

You can use the toggle at the top of the filter card to switch between this option and the All Values in Database option.

- **All values in hierarchy** - Specifies which values to show in the filter. When you create a filter from a hierarchical field, this option is selected by default. Filter values are displayed based on relevance of the parent/child relationships in the hierarchy.
- **All values in database** - Specifies which values to show in the filter. When you select this option all values in the database are shown regardless of the other filters on the view.
- **All values in context** (Tableau Desktop only) - When one of the filters in the view is a context filter, select this option on a different filter to only display values that pass through the context filter. For more information, see [Use Context Filters on page 1281](#).
- **Include values** - When this option is selected, the selections in the filter card are included in the view.
- **Exclude values** - When this option is selected, the selections in the filter card are excluded from the view.
- **Hide Card** (Tableau Desktop only) - Hides the filter card but does not remove the filter from the Filters shelf.

## Filter card modes

You can control the appearance and interaction of your filter card in the view by selecting a filter card mode.

To select a filter card mode, in the view, click the drop-down menu on the filter card and then select a mode from the list.

The types of filter card modes you see in the list of options depend on whether your filter is on a dimension or a measure. Below you can find brief descriptions of the types of filter card modes available for dimensions and measures.

For dimensions, you can choose from the following filter modes:

- **Single Value (List):** Displays the values of the filter as a list of radio buttons where only a single value can be selected at a time.
- **Single Value (Dropdown):** Displays the values of the filter in a drop-down list where only a single value can be selected at a time.
- **Single Value (Slider):** Displays the values of the filter along the range of a slider. Only a single value can be selected at a time. This option is useful for dimensions that have an

implicit order such as dates.

- **Multiple Values (List):** Displays the values in the filter as a list of check boxes where multiple values can be selected.
- **Multiple Values (Dropdown):** Displays the values of the filter in a drop-down list where multiple values can be selected.
- **Multiple Values (Custom List):** Displays a text box where you can type a few characters and search for the value. Alternatively, you can type or paste a list of values into the text box to create a custom list of values to include.
- **Wildcard Match:** Displays a text box where you can type a few characters. All values that match those characters are automatically selected. You can use the asterisk character as a wildcard character. For example, you can type “tab\*” to select all values that begin with the letters “tab”. Pattern Match is not case sensitive. If you are using a multidimensional data source, this option is only available when filtering single level hierarchies and attributes.

For measures, you can choose from the following filter modes:

- **Range of Values/Dates:** shows the filtered values as a pair of sliders that you can adjust to include or exclude more values. Click on the upper and lower limit readouts to enter the values manually.

The darker area inside the slider range is called the data bar. It indicates the range in which data points actually lie in the view. Use this indicator to determine a filter that makes sense for the data in your data source. For example, you may filter the Sales field to only include values between \$200,000 and \$500,000 but your view only contains values between \$250,000 and \$320,000. The range of data you can see in the view is indicated by the data bar while the sliders show you the range of the filter.

- **Note:** Data bars only show in filters where the filtered field is also used in the view (e.g., on Columns, Rows, or on the Marks card, and so on) and are at the same aggregation level as the field on the Filters shelf. For example, a filter on SUM (Sales) will only display data bars if the SUM(Sales) field is used in the view. It won't show if AVG(Sales) is used in the view. Even though in both scenarios, the filtered field, Sales is used in the view; in the latter case the aggregation is different

than the aggregation of the filter.

- **At Least/Starting Date:** shows a single slider with a fixed minimum value. Use this option to create a filter using an open ended range.
- **At Most/Ending Date:** shows a slider with a fixed maximum value. Use this option to create a filter using an open ended range.
- **Relative to Now:** this option shows a control where you can define a dynamic date range that updates based on when you open the view. The option is only available for filters on continuous date fields.
- **Browse periods:** shows common date ranges such as past day, week, month, three months, one year, and five years. This option is only available for filters on continuous date fields.

**Note:** When you expose a filter for Measure Values or Measure Names as a single value list, selecting All will automatically convert the filter to a multiple values list. For information on Measure Values and Measure Names, see [Measure Values and Measure Names on page 1160](#).

## Customize filter cards

In addition to the general filter options and the filter modes, you control how your filter appears in the worksheet, on dashboards, or when published to the web even further in Tableau Desktop.

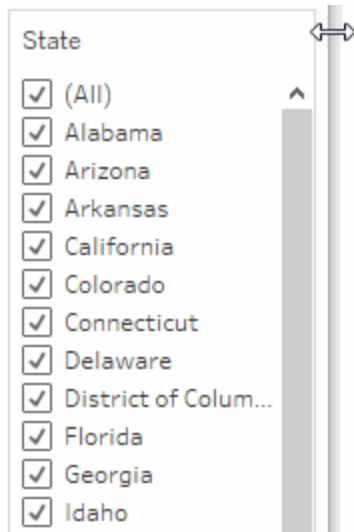

To customize filters, click the filter card drop-down menu and select **Customize**.

You can select from the following options:

- **Show “All” Value** - toggles whether to show the “All” option that displays by default in multiple values and single value lists.
- **Show Search Button** - toggles whether to show the search button at the top of the filter.
- **Show Include/Exclude** - toggles whether to show the Include Values and Exclude Values commands on the filter card menu. When shown, users can switch the filter between include and exclude modes.
- **Show Control Types** - toggles whether to let users change the type of quick filter shown. For example, when shown, a user can change a multiple values list to a compact list.
- **Show More/Fewer button** - toggles whether to show the More/Fewer button  at the top of the filter.
- **Show All Values button** - toggles whether to display the Show All Values button  on the filter card.

Whenever data is excluded in the filter, the small red "x" appears on the Show All Values button. When all values are showing, the red "x" disappears.

- **Show Apply Button** - toggles whether to show the Apply button at the bottom of the filter. When shown, changes to the filter are only applied after you click the button. Pending changes are indicated with a green color. This option is only available in multiple values lists and dropdowns. This options is available in web authoring.
- **Show Readouts** - controls whether the minimum and maximum values are displayed as text above a range of values. The readouts can be used to manually type a new value instead of using the sliders.
- **Show Slider** - controls whether the slider displays. When this option is cleared, the filter only displays the readouts.
- **Show Null Controls** - shows a drop-down list that lets you control how the filter handles null values. You can select from values in a range; values in a range and null values; null values only, non-null values, or all values.

**Note:** Not all of the above options are available for views published to Tableau Server or Tableau Cloud.

## Filter Data Across Multiple Data Sources

While working with multiple data sources in a workbook, you might want to compare the data between them using a field they have in common. To do so, you can apply a filter across multiple primary data sources.

For example, the following dashboard shows the order quantity, average sales, and average profit for customers. It has three views. Each of the views uses a different data source as its primary data source, and those data sources all have a field in common: Customer Name. There is also a filter card in the view for Customer Name.

This is an interesting dashboard with a lot of great information, but you might want to update all of the views in the dashboard at the same time by the customer you're analyzing. For example, maybe you want to see the average sales, profit, and number of orders you've received from one of your customers, Aaron Riggs.

To do so, you can filter all three data sources on the Customer Name field.

Follow the steps below to learn how to filter data across multiple data sources.

## Before you start, you might want to know the following:

Starting with version 10.0, you can filter data across multiple primary data sources. You cannot filter data across secondary data sources. Filtering data across a worksheet's secondary data source is not currently supported in Tableau Desktop.

If you want to filter data across secondary data sources, consider the following alternatives:

- Join tables that are in the same data source, instead of blending them. For more information, see [Join Your Data on page 738](#).
- Create a cross-database join if your tables are in different data sources. For more information, see [Join Your Data on page 738](#).
- Make the primary data source the secondary data source, and the secondary data source the primary. **Note:** This might not always be feasible given the level of detail you want in the final view.

**Note:** To ensure the data strings with mixed capitalization are treated as case-insensitive in the filter, create a calculated field using the UPPER() string function, and then create the filter relationship using that calculated field.

For more FAQs about cross data-source filters, see the [Cross data-source filtering FAQs](#) forum post in the Tableau Community.

## Step 1 Define relationships between your data sources

Before you can create relationships between data sources, you must ensure that there is a common field between the data sources you're mapping. The fields do not need to be named the same in each data source, but they should have some data in common.
