About Tableau Help	ccxxvi
Addressing Implicit Bias in Technical Language	ccxxvi
What's New and Changed in Tableau Server	1
New in version 2021.4	1
Server authorization-to-run (ATR) service	1
Increased ziplogs granularity, by time	2
New services in version 2021.4	2
Register an EAS to enable SSO for embedded content	2
Add-ons	3
Tableau Resource Monitoring Tool- part of the Server Management Add-on	3
Updated Performance Chart for Slow View Load Requests	3
Run As User account for Agent	3
New command to update service setup - rmtadmin-service-setup	4
Slow View incident updates	4
Tableau External Repository - part of the Server Management Add-on	4
Google Cloud Platform support	4
Enable or disable encryption between Tableau Server and External Repository ..	4
Tableau Content Migration Tool - part of the Advanced Management	5
Import user mappings from a CSV file	5
Support for Amazon Athena, Amazon EMR, and Salesforce data connection types	5

Virtual connections and data policies - part of the Data Management Add-on	5
With virtual connections you get Quick Help	5
Tableau Catalog - part of the Data Management Add-on	6
Increase in memory recommendations for production installations of Tableau Server	7
Search using attributes, operators, and special characters is no longer supported	8
IdP-initiated SLO support for server-wide and site-specific SAML	8
Offline activation process is simpler	8
Features Introduced in Previous Versions of Tableau Server	8
Added or changed in previous versions	9
Version 2021.3	9
Server or site administrator	9
New configuration key for sharing embedded view links	9
Set new permission capability for metrics	9
Control access to Explain Data with new site setting and Run Explain Data permission capability	10
Limit the number of tags per item	10
Integrate a Tableau Server site with a Slack workspace	11
Manage data freshness	11
New configuration key for changing gateway logging levels	11
Set up server-wide and site-level OAuth for Dremio and Salesforce CDP	11
Add-ons	12

- Tableau Catalog - part of the Data Management Add-on 12
- Resource Monitoring Tool - part of the Advanced Management 12
 - Agent Registration Security Improvements 12
 - Session Time Limit 12
 - Inclusive Language Update 13
- Content Migration Tool - part of the Advanced Management 13
 - Copy project permissions and ownership settings 13
 - Apply saved credentials for data connections 13
 - Improved user and group mappings 13
- Python package is installed with Tableau Server 14
- Backup behavior changed 14
- Tableau Server no longer supports Windows Server 12 or Windows Server 12 R2 14
- Tableau Server no longer supports Internet Explorer 11 14
- SP-initiated SLO support for site-specific SAML 15
- Version 2021.2 15
 - Server or site administrator 15
 - Multiple analytics extensions in a site 15
 - New Server service - Collections 16
 - Configure settings for extracts in web authoring 16
 - Streamlined site settings for Ask Data 16
 - Bring Einstein Discovery predictions into your Prep flows on the web 16

Share explanations from Explain Data in published dashboards	17
Daily removal of embedded external assets without downstream connections ..	17
New Subscription jobs configuration key	18
Configure custom OAuth	18
Add-ons	18
Tableau Catalog - part of the Data Management Add-on	18
Resource Monitoring Tool - part of the Server Management Add-on	19
Automated Process Discovery	19
CLI support for Environment setup	19
New CLI commands	20
Node Selector	20
Agent Compatibility	21
External Repository - part of the Server Management Add-on	21
Content Migration Tool - part of the Server Management Add-on	21
Encrypted communication channel with Active Directory is required	21
Secure SAML configuration is enforced	22
Site SAML secure configuration verification	22
Tableau Server on Windows installer logging changes	23
Tableau Prep Flow Service has been renamed to Tableau Prep Minerva Ser- vice	23
New configuration key for setting maximum time for single subscription job	24
Version 2021.1	24

- Server or site administrator 24
- Integration of Einstein Discovery Predictions 24
- Server authorization-to-run (ATR) service 25
- Zero downtime licensing 25
- Specify ports that should not be used during dynamic port allocation 25
- Block ingestion of complex content 25
- Use personal access tokens for admin impersonation 26
- Backup performance improvements 26
- New Server Process - Content Exploration Service 26
- Redesigned notifications center now includes notifications for sharing and comments 26
- Add-ons 27
- Azure Key Vault - part of the Server Management Add-on 27
- External File Store and External Repository- part of the Server Management Add-on 27
- Resource Monitoring Tool - part of the Server Management Add-on 27
- Tableau Catalog- part of the Data Management Add-on 28
- Change in default behavior for snapshot backups 28
- SHA-256 hash algorithm enforced for SAML assertions with IdP 28
- New SAML configuration keys 29
- Client and CA certificates used for mutual SSL must meet minimum security requirements 30

Improvements to JVM maximum heap size scaling for Tableau Catalog ingestion and elastic server	30
Old notifications do not appear in new notifications center	30
Version 2020.4	31
Server or site administrator	31
Enable and configure Catalog or Metadata API indexing limits for content	31
Activate and register multiple product keys	31
Configure Tableau Server for offline maps	32
Turn off Web Page objects	32
Improved control of extract query workloads	32
Automatic configuration of query cache size	32
Custom sign in note appears for server sign in errors	33
New processes related to Tableau Prep flows	33
Ask Data Usage and Adoption admin view	33
New tsm schedules commands	33
Checkpoint upgrades	34
Additional dynamically configurable keys for logging	34
Create extracts on the web	34
Create and interact with flows on the web	34
Add-ons	35
Tableau Resource Monitoring Tool updates- part of the Server Management Add-on	35

- Tableau Server External Repository- part of the Server Management Add-on ...36
- Tableau Catalog updates - part of the Data Management Add-on36
- Tableau Prep Conductor updates - part of the Data Management Add-on37
- SHA1 certificates disabled for SSL mutual authentication37
- wgserver.domain.whitelist config key has been deprecated38
- CPU requirement update38
- Checkpoint Upgrade for Tableau Server38
- PostgreSQL upgrade39
- Visual improvements to user, group, and site dialogs39
- Changes to default JVM heap size for Tableau Catalog ingestion39
- Version 2020.340
- Server "Pre-flight Check"40
- New command to list dynamically configurable keys41
- Set the Site Time Zone for Extracts41
- Automatically Suspend Extract Refreshes for Inactive Workbooks42
- Manage Licenses for User Groups with Grant Role on Sign In42
- Tableau Catalog updates - part of the Data Management Add-on42
- Use admin tools to get indexing status for Catalog and Metadata API43
- Tableau Content Migration Tool updates - part of the Advanced Management ...43
- Tag Stale Content for Archiving44
- Data Acceleration for Workbooks that use the Object Model Framework45
- Version 2020.245

Combined What's New and What's Changed in Tableau Server	46
Applies to label for Data Management and Server Management Add-ons	46
Use Relationships to Combine Data for Multi-table Analysis	46
Create Metrics to Track Data	47
New Admin Views	48
Changes to Create and Modify Schedule	48
Data Acceleration	49
Extract Query Load Balancing	49
Dynamic Configuration	49
Tableau Catalog updates - part of the Data Management Add-on	50
Analytics extensions (external service) connections must be reconfigured	51
Oracle data source connections require updated driver	51
WDC behavior change if Run As service account has admin group privileges ..	52
Tableau Resource Monitoring Tool Updates	52
The Startup Values of some TSM services have changed	52
Version 2020.1	53
Run Now Server and Site Setting	54
New configuration options for Hyper	54
Support for Login-based License Management	54
Support for Kerberos delegation with Vertica data source	55
Support for managing site role limits	55
Updates for Permission Dialog	55

- Lock nested projects 55
- Tableau Server External File Store (Server Management Add-on) 55
- Tableau Catalog updates - part of the Data Management Add-on 56
- Tableau Server no longer supports Windows 7 or Windows 2008 57
- tableau-server-obliterate script now preserves backup and log files 57
- Improvements to the tsm topology deploy-coordination-service command 58
- Large statistical file extracts consume system resources 58
- Version 2019.4 59
- Request access 59
- Configure recommendations for views 60
- Enable or disable Ask Data for a site 60
- Personal access tokens 60
- Secure SMTP 60
- Test Email Configuration 61
- Create Extracts on the Web 61
- New Installers for Tableau Server and tabcmd 61
- Custom welcome banner 61
- Limit visibility of user information 61
- Manage Sandboxed Extensions 62
- Tableau Server installer has been rewritten 62
- New tabcmd installer for Windows 63
- Updates to Tableau Server Job management 63

Updates to tsm maintenance cleanup command	64
Changed behavior for Copy Link when sharing a view	64
Version 2019.3	64
Add PDF Attachments to Subscription Emails	65
Tableau Catalog features—part of the Data Management	65
Tableau Catalog on the server—part of the Data Management	65
Tableau Metadata API	66
Job Management	66
Support for Embedded Credentials in Bootstrap Files	66
Advanced Management	67
Extract Encryption at Rest	68
Date-range Support for Ziplogs	68
Tableau Server Usage Data	68
Add a Note to Tableau Server Sign In Page	68
Support added for Italian	69
Default cipher suite no longer includes default support for old ciphers	70
Usage data is sent to Tableau	71
Upgrade without needing to provide a password	72
Some tsm command options are no longer configurable	72
Version 2019.2	73
Direct access with TSM CLI	74
Local authentication password policy improvements	74

- Select from ten different languages for Tableau 75
- Set a site-level start page 76
- Windows Server 2019 76
- Elastic Server on multiple nodes 77
- SSL connection to TabPy external service 77
- Configuring the threshold for suspending data-driven alerts 77
- Configuring logging levels for TSM processes 77
- Minimum hardware requirements have changed 78
- Upgrade requires at least 15% free disk space on each node 78
- "Referrer-Policy" HTTP header added 78
- Map-related internet addresses have changed 78
- Version 2019.1 79
- Web authoring auto recovery 80
- Microservice Container Processes 80
- TSM client authentication 80
- Ask Data and Elastic Server Processes 80
- Tableau Prep Conductor Server Process 81
- Tableau Data Management Add-On 81
- Node roles for Backgrounder Process 81
- SSL connection to Rserve external service 82
- High-resolution thumbnails 82
- Project card images 83

Version 2018.3	83
Materialize calculations in extracts already published to Tableau Server	84
Secure extract data at the row level	84
Improved content browsing (in-release beta)	84
Support for Content Security Policy	85
Improved support for LDAP	85
Connections to external services support SSL	85
SAML now supports PKCS#8 key files	85
Improved key and secrets refresh process	86
Backup without compression (added in version 2018.3.2)	86
Connecting to secondary trusted Active Directory domains may result in error ..	86
Floating worksheet captions become transparent	87
Changes to some Data Engine tsm configuration set options	87
SSL Off-loading and SAML	87
Version 2018.2	88
Include colleagues on data conversations with @mentions	88
Tableau Services Manager	89
Dynamic topology support	89
Lightweight Directory Access Protocol (LDAP) support	89
Support for using SAML SSO with Kerberos database delegation	90
Manage Dashboard Extensions in Tableau Server	90
Tableau Services Manager	91

Moving the repository in a two-node cluster not supported	91
Updates to Tableau Server Apache Logs	91
The Read Only site role is now deprecated	92
The tabcmd initialuser command prompts for password	92
Plan Your Deployment	95
Comparing Functionality of tabadmin and TSM	95
Features only available from the TSM command line	96
Preferred active repository	96
Data cache configuration	96
Initial install-only settings	97
Initial SQL	97
Site SAML	97
SAP HANA SSO	97
Rebuilding the Search Index	97
Differences in functionality	98
Host name configuration	98
Archive logs requires local administrator privilege	98
Windows Firewall configuration	98
Backup and restore process	98
Asset keys	99
Configuration import and export	99
Kerberos configuration	99

File storage	99
Ziplogs collects two days of log files	100
TSM is a batch file	100
You need to authenticate to use TSM	100
Cleanup and clear cache	100
Web Data Connectors	100
Uninstall and remove Tableau Server	101
Tableau Server \bin directory	101
Tableau Server installation directory	102
Fixed file locations	102
Log file snapshots	102
Changes in high availability and distributed deployments	103
Upgrade process changes	104
Functionality that is not implemented in TSM	108
Server Administrator Overview	108

 - Minimum hardware requirements for installation 226
 - Minimum production hardware recommendations 227
 - Determining Computer Hardware 230
 - Manually determining the number of cores on your computer 231
- Install TSM 232
 - What version are you installing or upgrading to? 232
 - Prerequisites 232
 - Use the TSM web interface 233
 - Running Setup 233
 - Use the TSM CLI 237
 - Install Tableau Server 237
 - Configure Tableau Server for a forward proxy 238
 - Next step 238
- Activate and Register Tableau Server 238
 - Prerequisite 239
 - Use the TSM web interface 239
 - Use the TSM CLI 243
 - Configure for forward proxy 243
 - Activate Tableau Server 243
 - Register Tableau Server 243

Next step	245
Activate Tableau Server Using the Authorization-To-Run (ATR) Service	245
Select the Server ATR option	246
Set or change the Server ATR duration	246
Move a Server ATR license to another Tableau Server	247
How do ATR leases work?	247
Activate the same license on another Tableau Server	248
Remove product keys that were activated using Server ATR	248
Stop using Server ATR for activation	248
Offline Activation When Installing Tableau Server	249
Offline activation overview and prerequisites	250
In this article	250
Log in to Tableau Services Manager	252
Step 1 - Generate an offline activation request file	253
Step 2 - Upload the offline activation request to Tableau	253
Step 3 - Initialize or activate your license	253
Deactivate Tableau Server Offline	254
Configure Product Key Operations with Forward Proxy	255
Before you begin	256
Step 1: Verify proxy configuration	256
Step 2: Temporarily change log on account for Tableau Server Administrative Controller service	257

- Step 3: Activate, refresh, or deactivate Tableau product keys 258
- Step 4: Revert the log on account back to Network Service 258
- Configure Initial Node Settings 259
 - Prerequisite 259
 - Use the TSM web interface 259
 - Identity store settings 261
 - Run As service account 262
 - Gateway port 263
 - Product usage data 263
 - Sample workbook installation 264
 - Initializing install 264
 - Use the TSM CLI 265
 - Configure identity store settings 265
 - Configure gateway settings (optional) 266
 - Configure product usage data (optional) 266
 - Configure sample workbook installation (optional) 266
 - Apply pending configuration changes 267
 - Verify LDAP configuration (Optional) 267
 - Initialize and start Tableau Server 268
- Next Step 268
- Configuration File Example 268
 - Entities vs keys 269

Server Usage Data	270
Disable Usage Data Sharing	271
Disabling the sharing of usage data at install	271
Disabling the sharing of usage data after install	271
Use the TSM web interface	271
Use the TSM CLI	272
Basic Product Data	272
Disabling sharing of Basic Product Data on individual computers	273
Disabling the sharing of Basic Product Data at the enterprise level	274
Add an Administrator Account	274
Prerequisites	275
Use web UI	275
Use tabcmd CLI	276
Next steps	276
Initial Node Installation Defaults	277
Jump-start Installation	278
Before you begin	278
Step 1: Install Tableau Server and start Tableau Services Manager	279
Step 2: Activate and register Tableau Server	281
Step 3: Configure local identity store	285
Step 4: Add administrator account	287
Step 5: Validate your installation	288

- Install Tableau Server in a Disconnected (Air-Gapped) Environment312
 - Prerequisites313
 - Installing Tableau Server on an Air-Gapped Computer Running Windows313
 - Activating Tableau Server in an Air-Gapped Environment314
 - Step 1. Log in to Tableau Services Manager314

Step 2. Transcribe data from your air-gapped system into an activation request template.	314
Step 3. Initialize or activate your license	316
Displaying Maps in an Air-Gapped Environment	316
Configuring Tableau Server to use offline maps (version 2020.4.0 and later): .	317
Workarounds to display maps in Tableau Server in an offline environment (versions earlier than 2020.4.0):	317
Install Tableau Server in the Cloud	318
Post Installation Tasks	319
Security Hardening Checklist	319
Installing security updates	319
1. Update to the current version	319
2. Configure SSL/TLS with a valid, trusted certificate	320
3. Disable older versions of TLS	320
4. Configure SSL encryption for internal traffic	321
5. Enable firewall protection	321
6. Restrict access to the server computer and to important directories	322
7. Update the Tableau Server Run As User account	322
8. Generate fresh secrets and tokens	322
9. Disable services that you're not using	323
JMX Service	323
10. Verify session lifetime configuration	323

- 11. Configure a server allowlist for file-based data sources 324
- 12. Enable HTTP Strict Transport Security for web browser clients 325
- 13. Disable Guest access 326
- 14. Set referrer-policy HTTP header to 'same-origin' 327
- 15. Configure TLS for SMTP connection 327
- 16. Configure SSL for LDAP 328
- 17. Scope permissions for non-default installation locations 329
- Change List 330
- Configure SMTP Setup 330
 - Secure SMTP 331
 - Use the TSM web interface 331
 - Use the TSM CLI 332
 - SMTP CLI configuration reference 334
 - TLS ciphers 338
- Configure Server Event Notification 340
 - Use the TSM web interface 341
 - Use the TSM CLI 344
 - Set notification values individually 344
 - Set all notification values with a single json file 346
- Configure Data Cache 347
- Database Drivers 348
 - Install drivers in a cluster 348

Tableau Server Pre-Flight Check	348
tsm pre-flight check commands	349
Server Crash Reporter	349
Configure Server Crash Reporter	350
Use the TSM web interface	350
Use the TSM CLI	351

Server administrator tasks	357
Site administrator tasks	358
Move Tableau Server to Another Drive	359
Before you start	359
Tableau Server product key activation	361
Distributed and High Availability Tableau Server Installations	362
Prerequisite	363
Licensing	364
Creating a distributed Tableau Server installation	364

- Creating a highly available (HA) Tableau Server installation 364
- If an initial node fails 366
- Recover from an initial node failure 366
- Configure Coordination Service ensemble on additional nodes 367
- Add Client File Service (CFS) to additional nodes 367
- Tableau Server service license check 367
- Distributed Requirements 368
- Hardware 368
- Hardware Guidelines for High Availability 368
- Software 369
- Installation location 369
- Networking and Ports 369
- Best Practices 370
- SSL 371
- Distributed Installation Recommendations 372
- Recommendations for all installations 372
- Install and Configure Additional Nodes 374
- Installation location 374
- Use the TSM web interface 374
- Generate the node bootstrap file 374
- Install and initialize an additional node 375
- Configure the additional node with Cluster Controller 379

Use the TSM CLI	381
Generate the node bootstrap file	382
Install and initialize an additional node	382
Configure the additional node	383
Install drivers	385
Drivers and administrative views	385
Install Tableau Resource Monitoring Tool Agent	385
Database Drivers	385
Install drivers in a cluster	385
Example: Install and Configure a Three-Node HA Cluster	386
A Single Server System	386
A Three-Node System	388
Configuration steps	390
Before you begin	390
Use the TSM web interface	390
Step 1: Install the initial node	390
Step 2: Generate a bootstrap file for the additional nodes	390
Step 3: Install and initialize an additional node	391
Step 4: Install and initialize a second additional node	394
Step 5: Configure the new node with a minimum topology	397
Step 6: Deploy a Coordination Service ensemble	398
Step 7: Configure Client File Services (CFS) on additional nodes	401

- Step 7: Configure processes for the second node 402
- Step 8: Configure processes for third node 403
- Use the TSM CLI 404
- Step 1: Install the initial node 404
- Step 2: Generate a bootstrap file for the additional nodes 404
- Step 3: Install an additional node 405
- Step 4: Install a second additional node 406
- Step 5: Add a process to the additional nodes 406
- Step 6: Deploy a Coordination Service ensemble 407
- Step 7: Configure Client File Services (CFS) on additional nodes 409
- Step 7: Configure processes for the second node 410
- Step 8: Configure processes for third node 411
- Step 9: Configure firewall rules (optional) 412
- Add a Load Balancer 413
- Add a Load Balancer 413
- Configure Tableau Server to work with a load balancer 414
 - Load balancer configuration key-value pairs 414
 - Configuration template example 416

Server Upgrade - Minimum Hardware Recommendations	491
Determining Computer Hardware	494
Manually determining the number of cores on your computer	494
Server Upgrade - Review What's Changed	496
Increase in memory recommendations for production installations of Tableau Server	497
Search using attributes, operators, and special characters is no longer supported	497
IdP-initiated SLO support for server-wide and site-specific SAML	497
Offline activation process is simpler	497
Python package is installed with Tableau Server	498
Backup behavior changed	498
Tableau Server no longer supports Windows Server 12 or Windows Server 12 R2	498
Tableau Server no longer supports Internet Explorer 11	499
SP-initiated SLO support for site-specific SAML	499

- Encrypted communication channel with Active Directory is required **499**
- Secure SAML configuration is enforced **500**
- Site SAML secure configuration verification **501**
- Tableau Server on Windows installer logging changes **501**
- Tableau Prep Flow Service has been renamed to Tableau Prep Minerva Service **501**
- New configuration key for setting maximum time for single subscription job **502**
- Change in default behavior for snapshot backups **502**
- SHA-256 hash algorithm enforced for SAML assertions with IdP **502**
- New SAML configuration keys **503**
- Client and CA certificates used for mutual SSL must meet minimum security requirements **504**
- Improvements to JVM maximum heap size scaling for Tableau Catalog ingestion and elastic server **504**
- Old notifications do not appear in new notifications center **504**
- SHA1 certificates disabled for SSL mutual authentication **505**
- wgserver.domain.whitelist config key has been deprecated **506**
- CPU requirement update **506**
- Checkpoint Upgrade for Tableau Server **506**
- PostgreSQL upgrade **507**
- Visual improvements to user, group, and site dialogs **507**
- Changes to default JVM heap size for Tableau Catalog ingestion **507**
- Data Acceleration for Workbooks that use the Object Model Framework ... **507**

Analytics extensions (external service) connections must be reconfigured	508
Oracle data source connections require updated driver	508
WDC behavior change if Run As service account has admin group privileges	509
Tableau Resource Monitoring Tool Updates	509
The Startup Values of some TSM services have changed	509
Tableau Server no longer supports Windows 7 or Windows 2008	510
tableau-server-obliterate script now preserves backup and log files	510
Improvements to the tsm topology deploy-coordination-service command	511
Large statistical file extracts consume system resources	511
Tableau Server installer has been rewritten	512
New tabcmd installer for Windows	512
Updates to Tableau Server Job management	512
Updates to tsm maintenance cleanup command	513
Changed behavior for Copy Link when sharing a view	513
Default cipher suite no longer includes default support for old ciphers	514
Usage data is sent to Tableau	515
Upgrade without needing to provide a password	515
Some tsm command options are no longer configurable	516
Minimum hardware requirements have changed	516
Upgrade requires at least 15% free disk space on each node	516
"Referrer-Policy" HTTP header added	517

- Map-related internet addresses have changed 517
- High-resolution thumbnails 517
- Project card images 518
- Connecting to secondary trusted Active Directory domains may result in error 519
- Floating worksheet captions become transparent 519
- Changes to some Data Engine tsm configuration set options 519
- SSL Off-loading and SAML 520
- Server Upgrade - Gather Configuration Details 520

 - General Troubleshooting Steps **614**
 - Common Tableau Server Install Issues **615**
 - Installation logs location **615**
 - Install program does not prompt for location to install to **615**
 - Install program does not restart Windows **616**
 - TSM Install fails with "initialization failed" error **616**
 - TSM Initialize screen does not display **616**
 - Unable to log into TSM or Tableau Server (sign in screen redisplay after entering credentials) **616**

Multiple install attempts fail	617
Obliterate script generates error: "refresh-environment-variables.cmd" is not recognized as an internal or external command	618
Install fails due to hardware requirements	618
Install or upgrade fails due to CPU requirements	618
Common Tableau Server Upgrade Issues	619
Error: Failed to establish a connection with Active Directory	619
Maps do not display or display incompletely after upgrading	619
Upgrade script error: "Tableau Server Version change validation failed."	620
Upgrade logs location	620
Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error	620
Upgrade stops or fails at 12%, 78%, or 92%	621
Upgrading fails due to lack of disk space	621
Upgrade fails on RebuildSearchIndex job	622
Upgrade fails on 2020.4.0 or later	622
Common Settings Import Issues	624
Import of settings file causes "not present on any node" validation error due to missing services	624
Import of settings file causes "configuration value you specified does not match" error	625
"You cannot directly modify instances of the Coordination Service" error	626
If you see this error after importing a settings file:	626

- If you see the error when setting the process count for Coordination Service manually: **628**

SSL	1449
Configure SSL for External HTTP Traffic to and from Tableau Server	1450
SSL certificate requirements	1450
Configuring SSL for a Cluster	1452
SSL with multiple gateways	1452
Additional configuration information for Tableau Server cluster environments ..	1452
Prepare the environment	1453
Configure SSL on Tableau Server	1453
Use the TSM web interface	1453
Use the TSM CLI	1454
Port redirection and logging	1455
Change or update SSL certificate	1456
Example: SSL Certificate - Generate a Key and CSR	1456
Steps to generate a key and CSR	1457
Configure a certificate for multiple domain names	1457
Set the OpenSSL configuration environment variable (optional)	1457
Generate a key	1458
Create a certificate signing request to send to a certificate authority	1458
Send the CSR to a certificate authority to obtain an SSL certificate	1460

- Use the key and certificate to configure Tableau Server 1460
 - For SAN certificates: modify the OpenSSL configuration file 1460
 - Additional information 1462
- Configure SSL for Internal Postgres Communication 1462
 - Use the TSM web interface 1462
 - Use the TSM CLI 1464
- What the command does 1464
- Option for repository-ssl enable 1465
- Cluster environments 1465
 - Configure Postgres SSL to Allow Direct Connections from Clients 1465
 - Configure Mutual SSL Authentication 1467
 - User authentication session time limits 1467
 - Certificate usage 1468
- Client certificate requirements 1469
 - Use the TSM web interface 1469
 - Use the TSM CLI 1471
- Step 1: Require SSL for external server communication 1471
- Step 2: Configure and enable mutual SSL 1472
- Additional options for mutual SSL 1473
 - Fallback authentication 1473
 - User name mapping 1473
 - Certificate Revocation List (CRL) 1474

Mapping a Client Certificate to a User During Mutual Authentication	1474
User-name mapping options	1474
Change the certificate mapping	1475
Address user-name mapping ambiguity in multi-domain organizations ..	1476
Configure Encrypted Channel to LDAP External Identity Store	1477
Certificate requirements	1478
Import certificate into the Tableau keystore	1478
LDAPS encryption method	1479
Configure encrypted channel for simple bind	1479
When to configure	1479
For new installations of Tableau Server	1479
Security Hardening Checklist	1480
Installing security updates	1480
1. Update to the current version	1480
2. Configure SSL/TLS with a valid, trusted certificate	1481
3. Disable older versions of TLS	1481
4. Configure SSL encryption for internal traffic	1482
5. Enable firewall protection	1482
6. Restrict access to the server computer and to important directories	1483
7. Update the Tableau Server Run As User account	1483
8. Generate fresh secrets and tokens	1483
9. Disable services that you're not using	1484

JMX Service	1484
10. Verify session lifetime configuration	1484
11. Configure a server allowlist for file-based data sources	1485
12. Enable HTTP Strict Transport Security for web browser clients	1486
13. Disable Guest access	1486
14. Set referrer-policy HTTP header to 'same-origin'	1487
15. Configure TLS for SMTP connection	1488
16. Configure SSL for LDAP	1489
17. Scope permissions for non-default installation locations	1489
Change List	1490

Troubleshoot Tableau Server Install and Upgrade	2268
General Troubleshooting Steps	2268
Common Tableau Server Install Issues	2269
Installation logs location	2269
Install program does not prompt for location to install to	2269
Install program does not restart Windows	2269
TSM Install fails with "initialization failed" error	2270
TSM Initialize screen does not display	2270
Unable to log into TSM or Tableau Server (sign in screen redisplay after entering credentials)	2270
Multiple install attempts fail	2271
Obliterate script generates error: "refresh-environment-variables.cmd" is	2271

- not recognized as an internal or external command 2272
- Install fails due to hardware requirements 2272
- Install or upgrade fails due to CPU requirements 2272
- Common Tableau Server Upgrade Issues 2272
 - Error: Failed to establish a connection with Active Directory 2272
 - Maps do not display or display incompletely after upgrading 2273
 - Upgrade script error: "Tableau Server Version change validation failed." 2273
 - Upgrade logs location 2274
 - Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error 2274
 - Upgrade stops or fails at 12%, 78%, or 92% 2274
 - Upgrading fails due to lack of disk space 2275
 - Upgrade fails on RebuildSearchIndex job 2275
 - Upgrade fails on 2020.4.0 or later 2276
- Common Settings Import Issues 2277
 - Import of settings file causes "not present on any node" validation error due to missing services 2277
 - Import of settings file causes "configuration value you specified does not match" error 2279
 - "You cannot directly modify instances of the Coordination Service" error 2280
 - If you see this error after importing a settings file: 2280
 - If you see the error when setting the process count for Coordination Service manually: 2281

Troubleshooting connections to TSM	2282
Unable to connect to TSM	2282
Starting Tableau Server	2282
Tableau Server cannot determine if it fully started	2282
Tableau Server doesn't start	2282
Reindexing Tableau Server Search & Browse	2283
Problems that can be solved by rebuilding Search & Browse index	2283
Activating Tableau Server	2283
Tableau Server license activation fails	2283
Confirm you can access the licensing server	2283
Verify the date and time	2285
Verify FlexNet Licensing Service has started	2285
Force the product key to be read again	2286
Send the contents of trusted storage to Tableau Support	2286
tabcmd Installation Problems	2287
Installing tabcmd separately	2287
Problems installing tabcmd on Linux	2287
Java is not installed	2287
Incorrect version of Java is installed	2288
Troubleshoot Server Sign in Problems	2288

 - 1. Set permissions defaults in the Default project 2574
- Why removing some default permissions makes your life easier 2576
- 2. Create a new project for a hypothetical Marketing department 2576
- Plan your groups and permissions 2577
 - 3. Create groups based on users' content needs 2577
 - 4. Create the temporary users for this exercise 2578
- What if you're using Active Directory? 2579
 - 5. Add the users to the groups 2580
 - 6. Assign permissions to the groups at the project level 2581
 - 7. Lock project permissions 2586
- How does project locking or unlocking affect permissions? 2588
 - View and test your work 2588
- Test permissions by publishing and interacting 2589

Next-level content management	2589
Connecting to Data Sources	2590
This is archived content	2590
Introduction	2591
Think about data in Tableau Server terms	2591
Think about optimizing data access and security	2592
Before you begin	2592
What do you need to do?	2594
Provide access to data sources	2594
Let users embed credentials (or not)	2595
Set data source permissions	2596
Share CSV, Excel, or Access files via a live connection	2597
Set up the shared network location	2598
Add the Excel file to the shared location	2599
Create a workbook that connects to the shared Excel file	2599
Keep data fresh	2600
Set refresh schedules that users can choose from	2601
Determine the frequency of scheduled refreshes	2602
Configure data connection caching	2603
Understand the tradeoffs between using a live connection and an extract	2604
Guiding principle: If performance is more important than data freshness, use an extract	2604

- Guiding principle: If real-time data is required for business decisions, use a live connection 2605
- Guiding principle: If a workbook contains sensitive data, use a live connection ... 2605
- Compare the performance of extracts and live connections 2606
 - Notifications, Monitoring, and Tuning 2607
 - This is archived content 2607
 - Introduction 2607
 - Alerts: Get notifications for server events 2607
- SMTP information you'll need 2608
 - Step 1: Configure SMTP information for Tableau Server 2609
 - Step 2: Set up notifications 2610
 - Subscriptions to views 2610
 - Server component events 2610
 - Low disk space 2611
 - Administrative views 2611
- Traffic to views 2612
- Background tasks for extracts 2613
- Stats for load times 2614
 - Windows performance monitoring 2615
 - Step 1: Create a new data collector set 2616
 - Step 2: Select performance counters 2616
 - Step 3: Save the data collector set 2619

Step 4: Run the data collector set	2619
Step 5: Allow Remote Access for Multiple Computers	2620
Tuning: Tweaking the server for better performance	2620
Optimize for user traffic	2621
Refresh the cache less often	2621
Increase the number of VizQL server processes	2621
Optimize for extract refreshes	2622
Adjust the extract refresh schedule	2622
Configure extract refreshes to run in parallel	2623
Increase backgrounder processes	2623
Additional resources	2623
Open for Business!	2624
This is archived content	2624

About Tableau Help

Addressing Implicit Bias in Technical Language

In an effort to align with one of our core company values, equality, we have changed terminology to be more inclusive where possible. Because changing terms in certain places can causing a breaking change, we maintain existing terminology in the following places:

- Tableau APIs: methods, parameters, and variables
- Tableau CLIs: commands and options
- Tableau Resource Monitoring Tool installers, installation directories, and terms in configuration files
- Third-party systems documentation

For more information about our ongoing effort to address implicit bias, see [Salesforce Updates Technical Language in Ongoing Effort to Address Implicit Bias](#) on the Salesforce website.

What's New and Changed in Tableau Server

Looking for Tableau Server on Linux? See [What's New in Tableau Server](#).

[Tableau Server Release Notes](#) | [Known Issues](#)

This topic lists all the new features and product changes for the latest release.

New in version 2021.4

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New Tableau Desktop and Web Authoring](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

Server authorization-to-run (ATR) service

Beginning with Tableau Server version 2021.4, server authorization-to-run (ATR) is now the default way to activate Tableau Server in any on-premises, cloud, container, or virtual environment. When impacted by underlying hardware changes (non-container environments), Server ATR reduces the occurrence of maximum activation errors. For more information, see [Activate Tableau Server using the authorization-to-run \(ATR\) service](#).

Increased ziplogs granularity, by time

Beginning with Tableau Server version 2021.4 the `tsm maintenance ziplogs` command now includes `H:mm` time options to specify start and end time when using the `--startdate` and `--enddate` options. This provides additional control for administrators who want to collect logs from a specific date and time segment. These options can result in faster creation of smaller ziplog archives.

For details, see `tsm maintenance ziplogs`.

New services in version 2021.4

Tableau Server version 2021.4 includes the following new services, used with Virtual Connections:

- Data Profiling service
- Extract service
- Minerva service
- Published Connections service
- Query Gateway microservice
- Query Policy service

For more information, see [Tableau Server Processes](#). For more details about Virtual Connections, see [About Virtual Connections and Data Policies](#).

Register an EAS to enable SSO for embedded content

Beginning in version 2021.4, you can register an external authorization server (EAS) to establish a trust relationship between Tableau Server and your external authorization server. By establishing a trust relationship, you're able to provide your users with a single sign-on (SSO) experience to Tableau content embedded in your custom applications through your identity provider (IdP). For more information, see [Register EAS to Enable SSO for Embedded Content](#).

This feature includes the following new `tsm` commands:

Tableau Server on Windows Help

- vizportal.oauth.connected_apps.max_expiration_period_in_minutes
- vizportal.oauth.external_authorization.enabled
- vizportal.oauth.external_authorization_server.blocklisted_jws_algorithms
- vizportal.oauth.external_authorization_server.issuer
- vizportal.oauth.external_authorization_server.jwks
- vizportal.oauth.external_authorization_server.max_expiration_period_in_minutes

Add-ons

Tableau Resource Monitoring Tool- part of the Server Management Add-on

Updated Performance Chart for Slow View Load Requests

The Slow View Load Requests chart shows when views are rendering more slowly than normal on Tableau Server making it easy to quickly identify performance issues related to rendering views. For more information see [Investigating Slow View Load Requests](#).

Run As User account for Agent

Starting in version 2021.4, for Windows installations, you must specify a Run As User account that will be used to access Tableau Server to gather monitoring information. This must be the same account that is used for the Tableau Run As User account. Previously, by default, the Local System User account was used to access this information, but this option allows you to specify a user that is not necessarily an admin on the Tableau Server node. You can specify this user during install or upgrade. For more information, see

[Install the Agent Using the Web Interface](#)

[Install the Agent Using Command Line](#)

[Upgrading Resource Monitoring Tool](#)

You can also update this information post-installation using [rmtadmin-service-setup](#).

New command to update service setup - `rmtadmin-service-setup`

Starting in version 2021.4, a new command has been added to allow you to update the setup information for the Resource Monitoring Tool services including RMT Server, Agent, Rabbit MQ, and PostgreSQL database. For more information, see [rmtadmin-service-setup](#).

Slow View incident updates

Starting in version 2021.4, you can specify thresholds to include all views or only certain views. Previously you could only specify duration and users, but now you can select which views you want the thresholds to apply to. For more information, see [Slow Views Incidents](#).

Tableau External Repository - part of the Server Management Add-on

Google Cloud Platform support

Starting in version 2021.4, you can use Google Cloud to setup Tableau Server External Repository. For more information, see [Create a PostgreSQL Instance on Google Cloud](#).

Enable or disable encryption between Tableau Server and External Repository

Starting in version 2021.4, `tsm security repository-ssl enable` command has been updated to include a new option so you can enable encrypted communication between Tableau Server and the External Repository. For more information, see [tsm security repository-ssl enable](#).

Starting in version 2021.4, you can use `tsm security repository-ssl disable` command to stop encrypting traffic between Tableau Server and External Repository. For more information, see [tsm security repository-ssl disable](#).

This change now allows you to update connection security for External Repository for an existing installation.

Tableau Content Migration Tool - part of the Advanced Management

Import user mappings from a CSV file

Starting in version 2021.4, you can import a CSV file with domain, user, and group mappings to quickly prepare your data for migration. Importing from a CSV file can reduce the manual steps required by allowing you to create and edit your mappings in bulk outside the Content Migration Tool. For more information, see [Migration Plans: User Permissions Mapping](#).

Support for Amazon Athena, Amazon EMR, and Salesforce data connection types

Content Migration Tool now supports Amazon Athena, Amazon EMR, and Salesforce data connection types. These connections can be modified during migration when applying Data Source Transformations for workbooks and published data sources. For a list of supported data connection types, see [Getting Started with Tableau Content Migration Tool](#).

Virtual connections and data policies - part of the Data Management Add-on

Virtual connections and data policies are included in the separately licensed Data Management Add-on for Tableau Server and Tableau Online. These new data management features enable you to provide a single, centralized connection to a database for your users, as well as define row-level security on the tables in the connection using a data policy. For more information, see [About Virtual Connections and Data Policies](#).

With virtual connections you get Quick Help

As you create and test your new virtual connection, help is just a click away. Delivered in the product, Quick Help shows relevant just-in-time help content based on where you are or what you're doing in the virtual connection editor. Simply click the ? icon on the top right of your screen to open the movable help window.

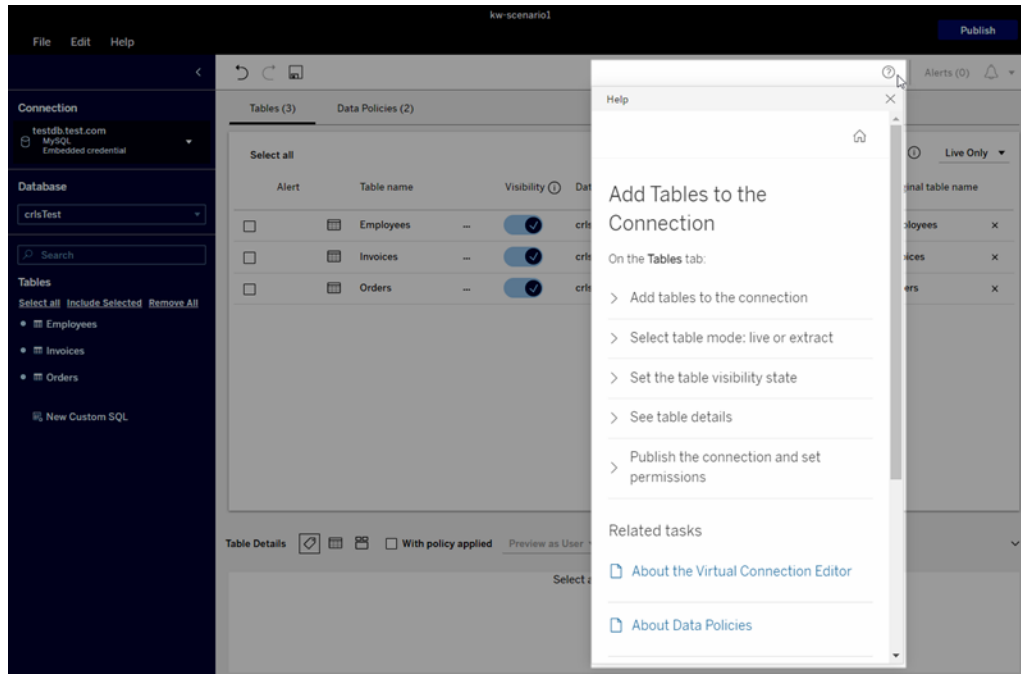

Tableau Catalog - part of the Data Management Add-on

Custom SQL information on content lineage pages - Catalog lineage pages show information that helps users understand more about custom SQL in their content.

- A banner on lineage pages identifies content that uses custom SQL.
- You can review the custom SQL query.
- A warning is shown for custom SQL queries that could result in incomplete lineage.

For more information, see [Supported lineage](#) in the Tableau Desktop and Web Authoring Help.

Tableau Catalog supports the T-SQL dialect in custom SQL queries - Support for the T-SQL dialect means Tableau Catalog can provide more complete lineage when custom SQL is used. For more information, see [Supported queries](#) in the Tableau Desktop and Web Authoring Help.

Data quality warnings links in email automatically open the Data Details pane - When you click a data quality warning in a subscription email, the view opens with the **Data**

Details pane shown. Also, a new embed parameter, `showDataDetails`, is available to open the view with the **Data Details** pane shown. For more information, see [Parameters for Embed Code](#) in the Tableau Desktop and Web Authoring Help.

Inherited descriptions appear in the fields list on lineage pages - When a description for a field exists upstream from the field, it now appears in the fields list on lineage pages with information about where the description is inherited from. For more information, see [How field descriptions are inherited](#) in the Tableau Desktop and Web Authoring Help.

Easily create Prep flows based on external assets - Now you can use databases and tables as starting points for new flows in Prep web authoring. For more information, see [Start a new flow](#) in the Tableau Prep Help.

Changed in 2021.4

Version 2021.4 includes the following changes you should know about before upgrading.

Increase in memory recommendations for production installations of Tableau Server

Beginning with Tableau Server 2021.4, the minimum amount of memory for a production installation of Tableau Server increases from 32 GB to 64 GB. This increase helps ensure a satisfactory experience with Tableau Server, and accounts for increased memory needs of newer features.

For customers wanting to do proof of concept testing, we recommend using a Tableau Online account, which will guarantee you a system running on adequate hardware. Tableau Online is also a good option for organizations that would otherwise be running Tableau Server on a single node (a one-computer installation).

For more information about Tableau Server system requirements, see [Before you install...](#)

Search using attributes, operators, and special characters is no longer supported

Beginning with Tableau Server 2021.4, search attributes, operators, and special characters cannot be used to limit search on Tableau Server and Tableau Online. You can limit the search results using filters. To learn more about searching on Tableau, see [Search Your Tableau Site](#).

IdP-initiated SLO support for server-wide and site-specific SAML

In addition to supporting service provider (SP)-initiated single log out (SLO) for both server-wide SAML and site-specific SAML, Tableau Server supports identity provider (IdP)-initiated SLO beginning with Tableau Server 2021.4. For more information about SAML configuration and requirements, see [SAML Requirements](#).

Offline activation process is simpler

Beginning with Tableau Server version 2021.4, offline activation has been made simpler, with fewer steps required to activate Tableau Server. In addition, the offline activation request file (`offline.tlq`) has been renamed `TableauOfflineActivationRequest.tlq`. The offline deactivation request file (`deactivate.tlq`) has been renamed `TableauOfflineDeactivationRequest.tlq`. For more information about offline activation, see [Offline Activation When Installing Tableau Server](#). For more information about offline deactivation, see [Deactivate Tableau Server Offline](#).

Features Introduced in Previous Versions of Tableau Server

Looking for Tableau Server on Linux? See [What's New in Tableau Server](#).

Added or changed in previous versions

Version 2021.3

Added in 2021.3

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New Tableau Desktop and Web Authoring](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

New configuration key for sharing embedded view links

Beginning with version 2021.3 we added a server configuration key that changes the behavior of the **Copy Link** option when sharing a view to be embedded in a web page.

In version 2019.4 the behavior of this option changed so that it did not include the "embed=y" parameter by default and you had to manually add it if you wanted to embed the view in a web page. This new configuration key allows you to configure Tableau Server so that it behaves as pre-2019.4 versions did and automatically includes the "embed=y" parameter. For more information, see `vizportal.alwaysUseEmbeddedShareLinks`.

For details about sharing views by embedded them in web pages, see [Embed Views into Webpages](#) in the Tableau Desktop and Web Authoring Help.

Set new permission capability for metrics

The Create/Refresh Metrics permission capability has been added for workbooks. For more information, see [Permission Capabilities and Templates](#) in the Permissions topic.

Prior to 2021.3, the Create/Refresh Metrics capability was controlled by the Download Full Data capability. On workbooks created prior to 2021.3, users who had the Download Full Data capability will have the Create/Refresh Metrics capability.

This new capability provides finer-grained control over your data, allowing you to grant users the ability to create metrics while denying the ability to view or download the full data for the view.

Control access to Explain Data with new site setting and Run Explain Data permission capability

Server administrators can now control the availability of Explain Data in site settings. Prior to 2021.3, the ability to enable or disable Explain Data was controlled at the server level only using the tsm configuration set option ExplainDataEnabled.

Authors can now control the availability of Explain Data at the workbook level using the Run Explain Data permission capability. For more information, see Explain Data in the Permissions topic.

Note: To make Explain Data available in viewing mode, a workbook author must also select the option **Allow Explain Data to be used in this workbook when viewed online** in the Explain Data Settings dialog box. For more information, see Control Access to Explain Data.

Limit the number of tags per item

A new setting allows you to limit the number of tags that users can add to Tableau content, such as workbooks and metrics, and external assets, such as databases and tables. This setting ensures that tags don't pose resource consumption problems. When you lower the tag limit, it prevents new tags from being added above the limit, but it doesn't remove existing tags on items in excess of the limit. For more information, see Site Settings Reference.

Integrate a Tableau Server site with a Slack workspace

The Tableau for Slack lets Tableau Server administrators connect a Tableau site with a Slack workspace. Once connected, Tableau users can see notifications in Slack when they're mentioned in a comment, when teammates share content with them, or when data meets a specified threshold in a data-driven alert. For more information, see [Integrate Tableau with a Slack workspace](#).

Manage data freshness

Cached data is great for the performance of live-connection workbooks, but seeing stale cached data in a viz can cause confusion and frustration for workbook users. Now with data freshness policies, you can strike a balance between performance and data freshness. Server administrators can [set a default caching policy for all sites on the server](#), and workbook owners can override the default caching policy by setting data freshness policies for specific workbooks. For more information, see [Set a Data Freshness Policy](#).

New configuration key for changing gateway logging levels

Beginning with version 2021.3 we added a server configuration key, `gateway.httpd.loglevel`, that allows you to change the logging level for the gateway process (Apache HTTPD) without needing to manually edit the `httpd.conf.temp` file. For information about the new key, see `gateway.httpd.loglevel`. For details about changing logging levels, see [Change Logging Levels](#). When changing logging levels, be aware of potential impact to disk space usage and performance. When you have gathered the information you need with a non-default logging level, change the logging back to the default level to minimize impact to Tableau Server.

Set up server-wide and site-level OAuth for Dremio and Salesforce CDP

Beginning with version 2021.3, you can set up server-wide or site-level OAuth for Dremio; and in version 2021.3.3, you can set up server-wide or site-level OAuth for Salesforce CDP. For more information, see the following:

- Set Up OAuth for Dremio
- Set Up OAuth for Salesforce CDP

Add-ons

Tableau Catalog - part of the Data Management Add-on

Inherited descriptions appear in web authoring - When a description for a field exists upstream from the field, it now appears in web authoring with information about where the description is inherited from. For more information, see [Describe fields in a published data source](#) in the Tableau Desktop and Web Authoring Help.

Assets in personal spaces are indexed - Tableau Catalog indexes assets in personal spaces, but users who browse through the lineage tool see **Permissions required** instead of information about workbooks in personal spaces.

Data quality warnings appear in subscription emails - Subscription emails can include data quality warnings for workbooks or views if their upstream assets have warnings. For more information, see Data quality warnings in subscriptions.

Resource Monitoring Tool - part of the Advanced Management

Agent Registration Security Improvements

Improvements include, providing a user name and password during Agent registration, and requiring a bootstrap file that is not older than 24 hours. Registration also requires both port 443 and 5672 to be open during Agent registration. For more information, see [Install the Agent Using the Web Interface](#) or [Install the Agent Using Command Line](#).

Session Time Limit

A new option has been added to the Resource Monitoring Tool Server setup to allow configuring the session expiration time. This can be done during initial install of the Resource Monitoring Tool Server in the web interface or through the command line. You can also update this as a post installation task at any time. For more information, see [rmtadmin Command Line Utility](#).

Tableau Server on Windows Help

Inclusive Language Update

In an effort to align with our company values of Equality, we have changed non-inclusive terminology, specifically, "Master Server" to "RMT Server" where possible. However, you may continue to see the terms in CLI commands and options and other instances. For more information, see [About Tableau Help](#).

Content Migration Tool - part of the Advanced Management

Copy project permissions and ownership settings

Content Migration Tool now includes project options for copying permissions and content ownership settings to the destination location. The migration process will also copy project descriptions and content permission settings by default. For more information, see [Migration Plans: Source Projects](#).

Apply saved credentials for data connections

The **Apply Saved Credentials** data source transformation allows you to apply saved credentials from your Account Settings page for data connections, making it easier to connect after migration. For more information, see [Migration Plans: Workbooks and Migration Plans: Published Data Sources](#).

Improved user and group mappings

The "User or Group Mapping" has been separated into individual User Mapping and Group Mapping transformations. Mappings now auto-populate a list of domains, users, and groups from the source and destination location to make finding users easier.

Beginning in 2021.3, you can apply user mapping to content permissions, in addition to content ownership of projects, workbooks, and data sources. For more information, see [Migration Plans: User Permissions Mapping](#).

Changed in 2021.3

Version 2021.3 includes the following changes you should know about before upgrading.

Python package is installed with Tableau Server

Beginning with Tableau Server 2021.3, The Tableau Server Setup program installs a Python package. Python will be used by future advanced analytics features. If you cannot or choose not to install Python with Tableau Server, you will not have access to any future features that require Python. For more information on how to opt out of installing the Python package, see the `/skippythoninstall` switch in Install Switches and Properties for Tableau Server.

Backup behavior changed

Beginning with Tableau Server 2021.3, when you run a backup of Tableau, the backup job skips any files that are newer than the start time of the backup job. This change impacts extract refreshes that run after the backup has begun. These will be skipped during the current backup. Other impacts to customers should be minimal except a reduction of the size of some backup files.

Tableau Server no longer supports Windows Server 12 or Windows Server 12 R2

Beginning with version 2021.3, in keeping with Microsoft's Windows Server support policy, Windows Server 12 and Window Server 12 R2 are no longer supported operating systems for Tableau Server. This change was originally scheduled to begin with version 2021.1 but was delayed until version 2021.3. For details of the announcement, see the [Tableau Blog](#).

For more information about supported versions of Windows, see Operating system requirements.

Tableau Server no longer supports Internet Explorer 11

Beginning with version 2021.3, we are ending our support for Internet Explorer (IE) for accessing Tableau Server. Tableau Server is fully compliant with Chrome, Firefox, Safari, and Edge. For details of the announcement, see the [Tableau Blog](#).

For more information about supported web browsers supported by Tableau Server, see [Tableau Tech Specs](#).

SP-initiated SLO support for site-specific SAML

In addition to supporting service provider (SP)-initiated single log out (SLO) for server-wide SAML, Tableau Server supports SP-initiated SLO for site-specific SAML beginning with Tableau Server 2021.3. For more information about SAML configuration and requirements, see [SAML Requirements](#).

Version 2021.2

Added in 2021.2

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New Tableau Desktop and Web Authoring](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

Multiple analytics extensions in a site

Beginning with version 2021.2, you can now create multiple analytics extensions connections for each site. This means that organizations with different language or connection requirements can use analytics extensions on the same Tableau Server site, with different workbooks using different connections. For more information on analytics extensions, see [Configure Connections with Analytics Extensions](#). **Note:** As of 2021.2, Einstein Discovery analytics extensions are still limited to one per site.

New Server service - Collections

Beginning with version 2021.2, a new service has been added to support the Collections feature. The new process is called the Collections service. For more information on what this service does, and guidance on how to configure this process for multi-node installations, see [Tableau Server Collections Service](#).

Collections are like playlists that let users organize content in a way that is meaningful to them. For more information on how to create and manage collections, see [Organize Items in a Collection](#) in the Tableau Desktop and Web Authoring Help.

Configure settings for extracts in web authoring

Beginning with version 2021.2, you can configure settings for extracts that you create in Web Authoring. Optionally, configure options to tell Tableau how to store, define filters for, and limit the amount of data in your extract. For more information, see [Create Extracts on the Web](#).

Streamlined site settings for Ask Data

Streamlined site settings for Ask Data now disable or enable the feature site-wide for all data sources. If it's enabled site-wide, indexing frequency remains customizable for each data source. For more information, see [Disable or Enable Ask Data for a Site](#).

Bring Einstein Discovery predictions into your Prep flows on the web

Beginning with version 2021.2, you can bring prediction models built in Einstein Discovery directly into your Prep flows on the web.

Note: You must have a Salesforce license and user account that is configured to access Einstein Discovery to use this feature.

Tableau Server on Windows Help

With the power of machine learning and artificial intelligence, you can bulk score your flow data and generate new fields for predicted outcomes at the row level, as well as add top predictors and recommended improvement fields to include data about which fields contributed to the predicted outcome. Add a Prediction step to your flow, sign into Einstein Discovery and choose from deployed models, and apply them to your flow data. Then generate your flow output and use the new data source to analyze the predicted outcomes in Tableau. This feature was first introduced in Tableau Prep Builder in version 2021.1.3. For more information, see [Add Einstein Discovery Predictions to your flow](#) in the Tableau Prep help and [Create and Interact with Flows on the Web](#).

Share explanations from Explain Data in published dashboards

Explain Data has a reimagined user interface optimized for a broader audience of business users. Authors (Creators or Explorers with editing permissions) can now enable Explain Data for viewers of dashboards and sheets in published workbooks. Viewers can select a mark of interest in the view and run Explain Data to explore their data more deeply than before.

Access to Explain Data in viewing mode is not enabled by default, so authors will need to enable this option. For information on how to enable Explain Data in viewing mode, see [Enable Explain Data in viewing mode in published workbooks and dashboards](#).

For more information on Explain Data, see [Discover Insights Faster with Explain Data](#), [Get Started with Explain Data](#), and [Control who can use Explain Data and what they can see](#).

Daily removal of embedded external assets without downstream connections

Beginning with version 2021.2, a background job for Tableau Catalog (or Tableau Metadata API) runs daily by default to delete embedded external assets without downstream connections to Tableau content. For more information, see [features.DeleteOrphanedEmbeddedDatabaseAsset](#) and `databaseservice.max_database_deletes_per_run`.

New Subscription jobs configuration key

Beginning in version 2021.2, a new configuration key, `back-grounder.timeout.single_subscription_notify`, changes how you configure the maximum time to complete for single subscription jobs. For more information, see "New configuration key for setting maximum time for single subscription job" in What's Changed in 2021.2.

Configure custom OAuth

You can now configure custom OAuth clients for a site to 1) override server-wide OAuth client settings if configured for the server or 2) enable support for securely connecting to data that requires unique OAuth clients. For more information, see [Configure custom OAuth for a site](#).

Add-ons

Tableau Catalog - part of the Data Management Add-on

Add Field Descriptions - You can add descriptions for fields in a published data source that then display in the Description column on the data source page Lineage tab. You can also see the description on the Data tab when you build a visualization. For more information, see [Describe fields in a published data source](#) in the Tableau Desktop and Web Authoring Help.

Data Quality Warning Updates

- **Formatted text support for warning messages** - When you create or edit a data quality warning message, you can format the text with bold, underline, and italics, and include a link or an image. For more information, see [Set a Data Quality Warning](#).
- **Message required for warnings** - When you create a data quality warning, you're now required to enter a message to display to users. (This doesn't apply to warnings generated when you set Tableau to monitor for extract refresh or flow failures.) For more information, see [Set a Data Quality Warning](#).

Tableau Server on Windows Help

Inherited descriptions appear in Tableau Desktop - When a description for a field exists upstream from the field, it now appears in Tableau Desktop with information about where the description is inherited from. For more information, see [Describe fields in a published data source](#) in the Tableau Desktop and Web Authoring Help.

Full table name appears - The table's full name has been added to the table page.

Filter by tags - You can now filter databases, files, and tables by tags in the Connect To dialog box.

Filter by embedded or non-embedded - On the External Assets page, you can filter databases, files, and tables by asset category: embedded or non-embedded.

Resource Monitoring Tool - part of the Server Management Add-on

Automated Process Discovery

Resource Monitoring Tool now supports hot topology changes on Tableau Server and automatically updates the processes information. You no longer have to configure the process information manually.

CLI support for Environment setup

New CLI commands are available to allow you to configure a new environment during install or updating an existing environment. Previously, you had to use the web interface to configure the Environment. Here are the new commands related to Environment setup:

- `rmtadmin create-env`: Creates a new Environment
- `rmtadmin update-env`: Updates an existing Environment:
- `rmtadmin bootstrap-file`: Downloads the bootstrap file to register Agents.

For more information, see [Install the RMT Server Using Command Line and rmtadmin Command Line Utility](#) .

New CLI commands

Several new CLI commands have been added to support environment setup and management. Here is a list of all the new commands added in this release:

- `rmtadmin agents`: Lists all the registered Agents on Tableau Server nodes for all environments.
- `rmtadmin create-env`: Creates a new Environment
- `rmtadmin bootstrap-file`: Downloads the bootstrap file to register Agents.
- `rmtadmin cleanup`: Deletes the log files that are older than a certain number of days.
- `rmtadmin delete-env`: Deletes a specific environment and all data that has been collected for that environment.
- `rmtadmin delete-server`: Deletes the configuration information of the Tableau Server node from the environment, deregisters the Agent on that node, and deletes all monitoring data collected specific to that node.
- `rmtadmin delete-server-data`: Deletes the data collected from one or more Tableau Server nodes.
- `rmtadmin deregister-agent`: Deregisters the Agent from the environment.
- `rmtadmin environments`: Lists all the environments.
- `rmtadmin servers` : Lists all the Tableau Server nodes across all environments or a specific environment.
- `rmtadmin test-env`: Tests the various connection points between and Tableau Server.
- `rmtadmin update-env`: Updates the environment settings.

For more information, see [rmtadmin Command Line Utility](#) .

Node Selector

If you have more than 5 Tableau Server nodes, you will now be able to navigate and filter by nodes. Previously on the Tableau Processes chart only showed information for 5 nodes.

Tableau Server on Windows Help

Agent Compatibility

Resource Monitoring Tool Agent should be on the same version as the Master Server or a compatible version. If you have one or more Agent on a non compatible version, an incident will be logged and reported. For more information, see Agent Incidents.

External Repository - part of the Server Management Add-on

You can now configure a stand-alone PostgreSQL database instance as the External Repository for Tableau Server. For more information, see [Create a PostgreSQL Database as a Stand-alone Installation](#)

Content Migration Tool - part of the Server Management Add-on

Content Migration Tool now supports personal access tokens as an authentication method for your source and destination servers. For more information, see [Migration Plans: Servers](#).

Changed in 2021.2

Version 2021.2 includes the following changes you should know about before upgrading.

Encrypted communication channel with Active Directory is required

Beginning with Tableau version 2021.2, Tableau Server no longer allows insecure connections with Active Directory. If your current instance of Tableau Server is communicating with Active Directory over a non-encrypted channel, upgrade will fail.

Run the following command to allow an insecure connection on your current version of Tableau Server before you upgrade:

```
tsm configuration set -k wgserver.domain.allow_insecure_connection -v true --force-key
```

After upgrade completes, we recommend securing the channel and then setting this option to `false`.

Note: By default (when `wgserver.domain.allow_insecure_connection` is set to `true`), Active Directory group synchronization will fail if the communication channel with Active Directory is not encrypted.

Secure SAML configuration is enforced

Beginning with version 2021.2, Tableau Server enforces secure SAML configuration for Server-wide and Site SAML.

Signature algorithm The certificate that you configure for SAML must use a secure signature algorithm, for example SHA-256. If you attempt to upgrade Tableau Server with a SAML certificate that uses SHA-1 signature hash, upgrade will fail.

We recommend that you upload a new certificate with SHA-256. See [Update SAML Certificate](#).

Alternatively, you can configure Tableau Server to accept the less-secure SHA-1 hash by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.

RSA key and ECDSA curve sizes The certificate used for SAML must either have an RSA key strength of 2048, or ECDSA curve size of 256. If you attempt to upgrade Tableau Server with a SAML certificate that uses less-secure key or curve sizes, upgrade will fail.

We recommend that you upload a new certificate with more secure key or curve size. See [Update SAML Certificate](#).

Alternatively you can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys, `wgserver.saml.min_allowed.rsa_key_size` and `wgserver.saml.min_allowed.elliptic_curve_size`.

Site SAML secure configuration verification

This release includes an updated `tabcmd` utility with the `validateidpmetadata` command. The `validateidpmetadata` command will scan your existing SAML sites and

Tableau Server on Windows Help

identify the signature algorithms and key sizes that are configured for each site. See `validateidpmetadata`.

Tableau Server on Windows installer logging changes

Beginning with Tableau Server 2021.2, due to internal changes to the installer, the logging behavior by the Tableau Server installer program has changed if you use the `/log` switch on the command line.

Prior to version 2021.2 you could use the `/log` switch to specify a log file name without a path, and the file was written to the current working directory. Starting in 2021.2, if you do not also specify a path, the file will be written to a temporary location that is deleted when the installation is done. If you use the `/log` switch, you must also specify both the path and the log file name in `<name>.<ext>` format if you want to preserve the log. If you do not include a file name, the installer will ignore the switch and save the log to `%TEMP%`.

The behavior is unchanged if you do not use the `/log` switch: the installer log is created in the logged in user's temp directory, `%TEMP%` using a naming convention of `Tableau_Server_<version_code>.log`.

For more information on command line switches for the installer, see [Install Switches and Properties for Tableau Server](#)

Tableau Prep Flow Service has been renamed to Tableau Prep Minerva Service

Beginning with version 2021.2, the Tableau Prep Flow Service (`flowqueryservice`) has been renamed to the Tableau Prep Minerva Service (`flowminerva`). This process appears on the TSM Status page and in the output of the TSM command `tsm status -v`. For more information, see [Tableau Server Processes](#).

New configuration key for setting maximum time for single subscription job

Beginning in version 2021.2, you now set the maximum time to complete a single subscription job using the new `backgrounder.timeout.single_subscription_notify` configuration key. This key replaces use of the `backgrounder.timeout_tasks` key for configuring timeouts on single subscription jobs. As of version 2021.2 the `backgrounder.timeout_tasks` key no longer uses the `single_subscription_notify` option. For more information, see `backgrounder.timeout.single_subscription_notify`.

Version 2021.1

Added in 2021.1

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New Tableau Desktop and Web Authoring](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

Integration of Einstein Discovery Predictions

Beginning with version 2021.1, you can integrate predictions directly into Tableau views and dashboards using models deployed by Einstein Discovery in Salesforce. For an introduction to Einstein Discovery in Tableau, see [Integrate predictions from Einstein Discovery into Tableau](#) in What's New in Tableau Desktop and Web Authoring help. Also see the [Einstein Discovery in Tableau](#) page and [demo](#) on [tableau.com](#).

To use Einstein Discovery predictions on Tableau Server, some server configuration is required. For more details, see [Configure Einstein Discovery Integration](#). For information

Tableau Server on Windows Help

on required licenses, access, and permissions in Salesforce and Tableau, see [Requirements for access](#).

For information on how to configure and use Einstein Discovery predictions in workbooks and dashboards, see [Integrate Einstein Discovery Predictions in Tableau](#) in Tableau Desktop and Web Authoring help.

Server authorization-to-run (ATR) service

Server authorization-to-run (ATR) enables you to activate Tableau Server in any cloud, container, or virtual environment without being impacted by underlying hardware changes that lead to maximum activation errors. For more information, see [Activate Tableau Server using the authorization-to-run \(ATR\) service](#).

Zero downtime licensing

With zero downtime licensing, you can apply most licensing changes to Tableau Server without needing to restart when license end dates, capacity, or installed features change. For more information, see [Zero downtime licensing](#).

Specify ports that should not be used during dynamic port allocation

Use the new configuration key `ports.blocklist` to specify ports in the dynamically assigned range that should **not** be used by Tableau. Setting this key with specific ports will cause Tableau Server to not use the ports when dynamically assigning ports on start up. For more information, see [Blocking specific ports within the range](#).

Block ingestion of complex content

Use the `tsm configuration set` command option `metadata.ingestor.blocklist` to troubleshoot content ingestion issues with Catalog or Metadata API. For more information, see [metadata.ingestor.blocklist](#).

Use personal access tokens for admin impersonation

Beginning with version 2021.1, you can enable Tableau Server personal access token impersonation. In this scenario, access tokens that are created by server administrators can be used for user impersonation when using the Tableau Server REST API. See [Server administrator impersonation](#).

Backup performance improvements

Beginning with version 2021.1, you can increase the number of threads the `tsm maintenance backup` command uses. This can significantly improve performance if your hardware supports it. Our testing suggests that the default option provides the best results, however should you choose to go beyond default multithreading option, you should limit the number of threads to the number of virtual processors on the computer, up to a recommended maximum of four. To increase the number of threads, set the `backup.zstd.thread_count` configuration key, and use the `--multithreaded` option with the `tsm maintenance backup` command. For more information about backing up Tableau Server, see [Back up Tableau Server data](#).

New Server Process - Content Exploration Service

Beginning with version 2021.1, a new server process has been added to enhance the searching and navigation capabilities in Tableau Server. The new process is called the Content Exploration Service. For more information on what this service does, and guidance on how to configure this process for multi-node installations, see [Tableau Server Content Exploration Service](#).

Redesigned notifications center now includes notifications for sharing and comments

Users can now see notifications for new comments and shares by selecting the bell icon in the top right corner of their Tableau site. The redesigned notification center also displays updates for flows and extract jobs. Users can also control where they receive notifications in their Account Settings—directly in Tableau, by email, or both. To configure notifications for

all site users, turn on notifications in Settings under Manage Notifications. For settings information, see Site Settings Reference. For more information on this change, see Changed in 2021.1.

Add-ons

Azure Key Vault - part of the Server Management Add-on

Tableau Server can use an Azure Key Vault as a Key Management System (KMS) beginning with version 2021.1. This requires the separately licensed Server Management Add-on for Tableau Server. For more information, see Azure Key Vault.

External File Store and External Repository- part of the Server Management Add-on

Enhanced snapshot backup - If you have both External File Store and External Repository configured for your Tableau Server, you now have additional options to manage backup and restore of your Tableau Server data. For more information, see Backup and Restore with External File Store.

Note: Beginning with Tableau Sever 2021.1, if you have both External File Store and External Repository enabled, Tableau Server Backup process no longer includes creating a backup file of the repository by default. If you are upgrading from a version earlier than 2021.1, and you have scripts to run or schedule your backups, and want to continue to include the repository backup, see Option 1: Include Repository in the Backup .

Resource Monitoring Tool - part of the Server Management Add-on

1. **Performance improvements**- The Resource Monitoring Tool can now provide real-time performance reporting for a Tableau Server deployment serving up to **5,500** views per hour.
2. **Filters** - New filter options are available in the web interface to improve navigation and help explore event monitoring.

- 3. SSL configuration for Tableau Server Repository** - You can now configure secure encrypted communications between Resource Monitoring Tool and Tableau Server Repository database. For more information, see Encrypted Data Collection.

Tableau Catalog- part of the Data Management Add-on

Automated data quality warning - You can set Tableau to monitor for extract refresh failures and for flow run failures. When a failure occurs, Tableau generates a data quality warning that displays to users. For more information, see Set a Data Quality Warning.

Quick search results expanded - Quick search results now include tags on external assets.

Changed in 2021.1

Version 2021.1 includes the following changes you should know about before upgrading.

Change in default behavior for snapshot backups

Note: If you have both External File Store and External Repository enabled and use scripts to do backups, this can potentially result in not having a backup of the repository.

Beginning with Tableau Sever 2021.1, if you have both External File Store and External Repository enabled, Tableau Server backup process no longer includes creating a backup file of the repository by default. If you are upgrading from a version earlier than 2021.1, and you have scripts to run or schedule your backups, and want to continue to include the repository backup, see Option 1: Include Repository in the Backup .

SHA-256 hash algorithm enforced for SAML assertions with IdP

Beginning with Tableau Sever 2021.1, Tableau Server will hash message signatures and digests with SHA-256 in SAML assertions to the IdP. To change this behavior, see `wgserv-er.saml.sha256`.

New SAML configuration keys

Beginning with Tableau Server 2021.1, Tableau Server includes three new SAML configuration keys:

- `wgserver.saml.blocklisted_digest_algorithms`: Specifies the digest algorithms that are not allowed as part of certificates used in SAML configuration or for signing SAML assertions. When set, assertions that are signed with a blocklisted algorithm will fail and certificates containing a blocklisted digest algorithm will fail. We recommend blocking the SHA-1(SHA1) algorithm. Before blocking SHA-1, confirm that your SAML certificates digest algorithms are not SHA-1, and that your SAML idP does not sign messages with SHA-1.
- `wgserver.saml.min.allowed.elliptic_curve_size`: Specifies the minimum elliptic curve size required for ECDSA certificates that uploaded and configured for Tableau Server. If Tableau Server is configured with an ECDSA certificate that does not satisfy this minimum curve size, Tableau Server may go into a degraded state. If you attempt to upload a certificate that does not meet the minimum curve size, Tableau Server will reject the certificate. We recommend a minimum curve size of 256.
- `wgserver.saml.min.allowed.rsa_key_size`: Specifies the minimum key size that required for RSA certificates that are uploaded and configured for Tableau Server. If Tableau Server is configured with an RSA certificate that does not satisfy this minimum key size, Tableau Server may go into a degraded state. If you attempt to upload a certificate that does not meet the minimum key size, Tableau Server will reject the certificate. . We recommend a minimum key size of 2048.

In future releases of Tableau Server, these keys will be configured with secure minimum defaults, as specified in the recommendations above. In future releases, if your SAML configuration is not configured with the minimum requirements, SAML functionality or upgrade may fail. In the meantime, we recommend that you update your SAML configuration to be in compliance with the recommendations above.

Client and CA certificates used for mutual SSL must meet minimum security requirements

Beginning with Tableau Server 2021.1, Tableau Server configured for mutual SSL authentication will enforce secure certificate requirements.

Client and certificate authority (CA) certificates used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

Tableau Server will fail mutual authentication requests from client certificates that do not meet these requirements.

Additionally, upgrade of Tableau Server will fail if the certificate authority (CA) certificate that is configured for mutual SSL does not meet these requirements.

- To update the CA certificate file for Tableau Server mutual SSL, upload the certificate as described in [Configure Mutual SSL Authentication](#).
- To disable the certificate security enforcement, see the Tableau KB topic, [Tableau Server Using Mutual SSL Authentication Fails to Start or Rejects Login After Upgrade to Tableau Server 2021.1 because Certificates Use Insecure Key Attribute](#).

Improvements to JVM maximum heap size scaling for Tableau Catalog ingestion and elastic server

Beginning with Tableau Sever 2021.1, JVM maximum heap size scales automatically for Catalog ingestion and elastic server. For more information, see `non-interactivecontainer.vmopts` and `elasticsearch.vmopts`.

Old notifications do not appear in new notifications center

When you upgrade to Tableau Server 2021.1, old notifications will not appear in the new notifications center. All existing email notifications will continue. To continue tracking older notifications, make sure the server setting for Notifications for Extract Jobs and Flow Runs is enabled before upgrading. For more information, see [What's New and Changed in Tableau Server](#).

Version 2020.4

Added in 2020.4

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

Enable and configure Catalog or Metadata API indexing limits for content

Use the following `tsm configuration set` command options to enable and configure Catalog or Metadata API indexing limits, also called event throttling, for new and updated content across all sites:

- `metadata.ingestor.pipeline.throttleEventsEnable`
- `metadata.ingestor.pipeline.throttleLimit`
- `metadata.ingestor.pipeline.throttlePeriodLength`

Activate and register multiple product keys

Beginning with version 2020.4.0, you can activate and register multiple product keys during installation. Tableau Services Manager checks licensing levels (cores versus product keys) and license types (creators versus explorers and viewers) to ensure the installation can be completed due to licensing. You can apply additional product key(s) to Tableau Server if necessary, to achieve the desired number of creator, explorer, and viewer seats, cores, and features to accommodate user capacity. For more information, see [Activate and Register Tableau Server](#).

Configure Tableau Server for offline maps

Beginning with version 2020.4.0, you can configure Tableau Server to use offline maps that are installed with Tableau. To do this, set the `vizqlserver.force_maps_to_offline` configuration key to `true` and apply pending changes. For more information, see [Displaying Maps in an Air-Gapped Environment](#).

Turn off Web Page objects

To prevent Web Page objects in dashboards from displaying target URLs, do either of the following:

- For a specific site, deselect **Enable Web Page Objects** in the [site settings](#).
- For an entire server, set the `vizqlserver.web_page_objects_enabled` configuration key to `false`.

Improved control of extract query workloads

You can now fine tune extract query workload management in a multi-node deployment by using the new node role, `extract-queries-interactive`. For more information, see [Workload Management through Node Roles](#). To use this feature, you must have a valid Server Management Add-on license activated on your Tableau Server.

Automatic configuration of query cache size

The size of the query cache is now automatically set based on the amount of available system memory. This improves the number of query results that will fit into the cache by default. For more information, see [General Performance Guidelines](#).

The default query cache settings are suitable for most situations but it is possible to manually configure them using the TSM command line interface. The TSM settings are: `native_api.InitializeQueryCacheSizeBasedOnWeights`, `native_api.QueryCacheMaxAllowedMB`, `native_api.LogicalQueryCacheMaxAllowedWeight`, `native_api.MetadataQueryCachMaxAllowedWeight`, `native_`

Tableau Server on Windows Help

`api.NativeQueryCacheMaxAllowedWeight`, and `native_api.QueryCacheEntryMaxAllowedInPercent`. For more information, see `native_api.InitializeQueryCacheSizeBasedOnWeights`.

Custom sign in note appears for server sign in errors

In 2020.4, sign in page notes added to the Sign In Customization setting will also appear when a user receives a sign in error, such as when a user attempts to log in with SSO (SAML, Site SAML, and Open ID). Server administrators can use this note to help users understand how to get a license or why they can't access a site. For more information, see [Customize Your Server](#). For more information, see [Customize Your Server](#).

New processes related to Tableau Prep flows

The 2020.4 release adds some new processes to Tableau Server. The Tableau Prep Flow Authoring (`floweditor`) and Tableau Prep Flow Service (`flowqueryservice`) processes now appear on the TSM Status page and in the output of the TSM command `tsm status -v`. For more information, see [Tableau Server Processes](#).

Ask Data Usage and Adoption admin view

You can now see how users engage with Ask Data on a site, using the new Ask Data Usage admin view. The dashboard highlights the top Ask Data users, data sources, and data source owners, along with headline value metrics. For more information, see [Ask Data Usage](#).

New tsm schedules commands

Version 2020.4.0 introduces new commands for managing scheduled jobs. For this first release you are limited to using the `tsm schedules` commands with backup jobs, but our intent is to expand the scope of these commands in future releases of Tableau Server. For more information, see [Scheduling and Managing Backups](#), [tsm schedules](#), and [tsm maintenance backup](#).

Checkpoint upgrades

Enhancements to the `upgrade-tsm` script give server administrators more options when faced with a failed upgrade. For more information, see "Changed in 2020.4" below.

Additional dynamically configurable keys for logging

Dynamic configuration was introduced in version 2020.2, and version 2020.3 added dynamically configurable logging options to those made available in 2020.2.0. Version 2020.4 continues to build on this with two new keys. When you make configuration changes with these keys, or configuration changes with these keys in combination with Tableau Server Dynamic Topology Changes, you do not have to restart Tableau Server.

New dynamically configurable keys in 2020.4:

- `tomcatcontainer.log.level`
- `vizportal.log.level`

For details viewing dynamically configurable keys, see `tsm configuration list-dynamic-keys`. For more information about the introduction of dynamic configuration in version 2020.2, see [Dynamic Configuration](#). For more on changing logging levels, see [Change Logging Levels](#).

Create extracts on the web

Now you can create extracts directly in web authoring, without using Tableau Desktop. For more information, see [Create Extracts on the Web](#). You can extract new workbooks in addition to existing workbooks. Optionally, the extract creation can run in the background and you can be notified when it's completed. This will let you close your authoring session while the extract is being created, which can be helpful with large extracts that might take a long time.

Create and interact with flows on the web

You can now create flows to clean and prepare your data using either Tableau Prep Builder, Tableau Server, or Tableau Online. Connect to your data, build a new flow, or edit an existing flow and your work is automatically saved every few seconds as you go. Create

Tableau Server on Windows Help

draft flows that are only available to you or publish your flow to make it available for others. Run your individual flows right from the web or run your flows automatically on a schedule using Tableau Prep Conductor if you have the Data Management Add-on. For more information, see [Create and Interact with Flows on the Web](#).

Add-ons

Tableau Resource Monitoring Tool updates- part of the Server Management Add-on

Resource Monitoring Tool is included in the separately licensed Server Management Add-on for Tableau Server. For more information, see [Get Started with Tableau Resource Monitoring Tool](#).

The following features are included in this release:

Linux Support - Resource Monitoring Tool **Master Server and Agents can now be installed on Linux platform**. For more information, see [Install the Tableau Resource Monitoring Tool](#).

SSL Certificates - You can now use a locally imported SSL Certificates.

- Windows: SSL Certificate Mode and Requirements.
- Linux: Install the Tableau Resource Monitoring Tool.
- Command Line installation are supported for both Linux and Windows installations.
 - Master: Install the RMT Server Using Command Line
 - Agent: Install the Agent Using Command Line

Agent OS Detection - Master Server can detect the OS that each Agent is installed on and will list it in the web interface. For more information, see [Install the Tableau Resource Monitoring Tool](#).

Tableau Server External Repository- part of the Server Management Add-on

Tableau External Repository is included in a separately licensed Server Management Add-on for Tableau Server. For more information, see [Tableau Server External Repository](#).

Azure Support - You can now configure Tableau Server External Repository on Azure Database. For more information, see [Create a Azure Database PostgreSQL Instance on Azure](#).

Upgrade - If you have External Repository configured, before upgrading your Tableau Server to 2020.4, you must make sure you are using PostgreSQL version 12 or later. For more information, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

Tableau Catalog updates - part of the Data Management Add-on

Tableau Catalog is included in the separately licensed Data Management Add-on for Tableau Server and Tableau Online. For more information, see [About Tableau Catalog](#).

The following features are included in this release:

Data Quality Warning History admin view - Site administrators can see how data quality warnings are being used on the site using the pre-built admin view, Data Quality Warning History. For more information see [Data Quality Warning History](#).

See quality warning details in Tableau Desktop - Tableau Desktop users can hover over the warning icon on the Data tab to see details about the data quality warnings affecting the data in their workbook. For more information, see [Set a Data Quality Warning](#).

Metrics appear in lineage and show data quality warnings - Data quality warnings now appear on metrics affected by a warning. Metrics also appear in the Lineage tool, enabling you to see how a metric might be affected by data changes when performing impact analysis. For more information, see [Create and Troubleshoot Metrics](#).

Tableau Prep Conductor updates - part of the Data Management Add-on

Now, the Data Management Add-on is only needed to schedule and monitor flows with Tableau Prep Conductor. Other flow-related tasks no longer require you to license the add-on. For more information, see Tableau Prep Conductor.

Changed in 2020.4

Version 2020.4 includes the following changes you should know about before upgrading.

SHA1 certificates disabled for SSL mutual authentication

Beginning with Tableau Server 2020.4, Tableau Server configured for mutual SSL authentication will block authentication of users with client certificates that use the SHA-1 signing algorithm.

Users who attempt to log in with SHA-1 client certificates encounter an "Unable to sign in" error, and the following error will be visible in the VizPortal logs:

```
Unsupported client certificate signature detected: [certificate  
Signature Algorithm name]
```

If the clients in your organization are connecting to Tableau Server using SSL mutual authentication and the clients are using certificates with the SHA-1 signing algorithm, then you must perform one of the following actions before upgrading:

- Update the certificates used by your clients. The certificates must use the SHA-256 (or stronger) signing algorithm, or
- Disable the SHA-1 blocklist before upgrading to Tableau Server 2020.4. To disable the blocking functionality, run the following TSM commands before you upgrade:

```
tsm configuration set -k "ssl.client_certificate_login.b-  
locklisted_signature_algorithms" -v ""
```

Note that the value (-v) includes an empty set of quotes to specify a null value.

For more information about how to reset this value after you have updated client certificates, see the Knowledge Base article, [Mutual SSL Fails After Upgrading if Certificates Signed with SHA-1](#).

For more information about why this change has been implemented, see the Tableau Community post, [Retiring Default Support for SHA-1 Signed Certificates Used During Mutual SSL Authentication in Customer-Managed Tableau Server 2020.4](#), and the National Institute of Standards and Technology policy statement, [NIST Policy on Hash Functions](#).

wgserver.domain.whitelist config key has been deprecated

Beginning with version 2020.4, the `wgserver.domain.whitelist` configuration key has been deprecated. Use the new key, `wgserver.domain.accept_list` to specify allowed domains.

All functionality of the older key has been transferred to the new key. As of 2020.4.0, existing installations configured with the old key will not be impacted, and the key can still be used, but you must include the `--force-keys` option when setting the key, and the key will be permanently removed in a future release. For all new configurations, use `wgserver.domain.accept_list` instead. For more information about the new configuration key, see `wgserver.domain.accept_list`.

CPU requirement update

Beginning with version 2020.4, Tableau Server requires all nodes to have CPUs that support SSE4.2 and POPCNT instruction sets. These CPUs have been common for more than 10 years and are installed on most newer computers. If you attempt to install or upgrade Tableau on a computer that does not support these instruction sets, the installer will not allow you to continue.

Checkpoint Upgrade for Tableau Server

Version 2020.4 of Tableau Server includes updates to the `upgrade-tsm` script that give you the ability to rerun the script when an upgrade fails. The script keeps track of successful progress, and when you rerun the script after an upgrade failure, restarts at the latest

Tableau Server on Windows Help

successful "checkpoint." This saves time because successful steps do not need to be repeated on rerunning the script. As a first troubleshooting step, rerun the `upgrade-tsm` script. Doing this can result in a successful upgrade if a momentary environmental problem or timing issue caused the initial failure.

Checkpoint upgrades also give experienced IT professionals the option to further troubleshoot the failure, and make corrections (for example, if there is a problem with disk space, or a permissions issue on a particular file or directory) before rerunning the upgrade script. For troubleshooting details, see [Upgrade fails on 2020.4.0 or later](#).

PostgreSQL upgrade

Version 2020.4 of Tableau Server includes a major-version update of the PostgreSQL database used for the Tableau repository. During the upgrade a temporary `pgsql-only` backup is created and this increases the length of time the upgrade takes as well as the amount of temporary disk space used.

If you have External Repository configured, before upgrading your Tableau Server to 2020.4, you must make sure you are using PostgreSQL version 12 or later. For more information, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

Visual improvements to user, group, and site dialogs

The 2020.4 release adds visual updates to administrator menus and dialogs to make managing users, groups, and sites easier in Tableau Server.

Changes to default JVM heap size for Tableau Catalog ingestion

Beginning with Tableau Server 2020.4, the default JVM heap size for Catalog ingestion is determined by and then scales based on system memory. To review the default values for Catalog ingestion, see `noninteractivecontainer.vmopts`.

Version 2020.3

Added in 2020.3

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

- Server "Pre-flight Check"
- New command to list dynamically configurable keys
- Set the Site Time Zone for Extracts
- Automatically Suspend Extract Refreshes for Inactive Workbooks
- Manage Licenses for User Groups with Grant Role on Sign In
- Use admin tools to get indexing status for Catalog and Metadata API
- [Tag stale content for archiving](#)

Add-ons

- Tableau Catalog updates - part of the Data Management Add-on
- Tableau Content Migration Tool updates - part of the Advanced Management

Server "Pre-flight Check"

Beginning in Tableau Server on Windows version 2020.3 a pre-flight check runs when you install or upgrade Tableau Server. This check, on install, looks at common permissions issues related to the install directory and data directory that cause problems when installing Tableau Server. On upgrades, permissions are checked, as well as potential port conflicts for key services. In addition, new `tsm maintenance preflight-check` commands have been added for both permissions and ports.

For more information see [Tableau Server Pre-Flight Check](#).

New command to list dynamically configurable keys

Version 2020.3 introduces a new TSM command to view all dynamically configurable keys. The command, `tsm configuration list-dynamic-keys`, displays a list of all configuration options you can change without needing to restart Tableau Server. This command helps you distinguish dynamically configurable keys from those that require a server restart, allowing you to decide when to set each.

Dynamic configuration was introduced in version 2020.2, and version 2020.3 adds additional dynamically configurable logging options to those in 2020.2.0. When you make configuration changes with these keys, or configuration changes with these keys in combination with [Tableau Server Dynamic Topology Changes](#), you do not have to restart Tableau Server.

New dynamically configurable keys include:

- `backgrounder.log.level`
- `clustercontroller.log.level`
- `dataserver.log.level`
- `filestore.log.level`
- `gateway.log.level`
- `tdsservice.log.level`
- `vizqlserver.log.level`

For details on the new command, see [tsm configuration list-dynamic-keys](#). For more information about the introduction of dynamic configuration in version 2020.2, see [Dynamic Configuration](#). For more on changing logging levels, see [Change Logging Levels](#).

Set the Site Time Zone for Extracts

The default time zone for extract-based data sources in a site is Coordinated Universal Time (UTC). Site administrators can now choose to set a different time zone.

For more information, see [Set the Site Time Zone for Extracts](#).

Automatically Suspend Extract Refreshes for Inactive Workbooks

To save resources, Tableau can automatically suspend extract refresh tasks for inactive workbooks. This feature applies to full extract refreshes only, not to incremental extract refreshes. This feature only applies to refresh schedules that run weekly or more often.

For more information, see [Automatically Suspend Extract Refreshes for Inactive Workbooks](#).

Manage Licenses for User Groups with Grant Role on Sign In

Administrators can set a minimum site role for user groups and choose **Grant role on sign in** when creating or modifying that user group. Enabling Grant role on sign in reduces manual work to manage licenses, since administrators can designate site role capabilities by group, and provision licenses when a user actually needs it. By waiting to grant licenses until users sign in, administrators can streamline license provisioning, without granting licenses to inactive users. For more information, see [Grant License on Sign In](#).

Tableau Catalog updates - part of the Data Management Add-on

Tableau Catalog is included in the separately licensed Data Management Add-on for Tableau Server and Tableau Online. For more information about Tableau Catalog, see [About Tableau Catalog](#).

The following features are included in this release:

See data quality warnings in Tableau Desktop - When you open a workbook in Tableau Desktop that has a data quality warning, the warning icon (either a blue circle or a yellow triangle with an exclamation point) appears on the Data tab on the sheet page of the workbook. For more information, see [Set a Data Quality Warning](#)

'Sensitive data' warning type added - You can use this new warning type to set a data quality warning for sensitive data in your organization. For more information, see [Set a Data Quality Warning](#)

Embedded assets are listed in External Assets - You can now see embedded assets listed in the External Assets page. For more information, see [Use Lineage for Impact Analysis](#).

Tag external assets - Add tags to databases, tables, and columns, which enables you to, among other things, tag tables and columns with personally identifiable information (PII). For more information, see [Tag Items](#) in Tableau Desktop and Web Authoring Help.

Use admin tools to get indexing status for Catalog and Metadata API

Tableau Server 2020.3 includes two admin tools to make it easier to get indexing status of Tableau Catalog and Tableau Metadata API:

- Monitor initial ingestion progress and validate its status using the Backfill API. For more information, see [Get Initial Ingestion Status](#).
- After initial ingestion, ensure indexing continues to work as expected using the Eventing API. For more information, see [Get Eventing Status](#).

Tableau Content Migration Tool updates - part of the Advanced Management

Tableau Content Migration Tool is included in the separately licensed Advanced Management for Tableau Server. For more information about Advanced Management, see [About Tableau Advanced Management](#).

The following features are included in this release:

- **Support for Tableau Online** - The Content Migration Tool now includes both Tableau Online and Tableau Server sign-in options when connecting to source and destination servers. To learn about the new sign-in experience, see [Migration Plans: Servers](#).
- **SAML and Single Sign-On** - As of version 2020.3, you can authenticate using SAML and Single Sign-On authentication types for non-scripted migration plans.
- **Tableau Bridge data sources** - Published data sources that are within a private

network (inaccessible to the public internet) can be migrated and allowed to refresh using Tableau Bridge. For more information, see [Migration Plans: Published Data Sources](#).

- **Tableau Prep Builder and Tableau Prep Conductor** - Content produced by Tableau Prep Builder or Tableau Prep Conductor (version 2020.2.x and later) can now be included in your migration plans.
- **Asynchronous publishing** - The Content Migration Tool now supports asynchronous publishing of data sources.
- **Resource optimization** - You can specify how many objects to process in memory in parallel with the new **Maximum Processing Concurrency** setting. The setting allows you to optimize resource usage of CPU and memory when performing migration operations, ultimately reducing your memory footprint. For more information, see [Tableau Content Migration Tool Settings](#).
- **Migrate more content** - The Content Migration Tool editor and console runner can now use up to 4 GB of RAM (increased from 2 GB), allowing you to migrate larger workbooks and data sources.

Tag Stale Content for Archiving

The Stale Content Admin view that was introduced in 2020.2, now has an added functionality that allows you to tag content as stale. You can then choose to archive the tagged content. For more information, see [Stale Content](#).

Changed in 2020.3

Version 2020.3 includes the following changes you should know about before upgrading.

Data Acceleration for Workbooks that use the Object Model Framework

Administrators can now also enable data acceleration for workbooks that use the Object Model framework. See [Data Acceleration](#).

Version 2020.2

Added in 2020.2

Help Design

- Combined What's New and What's Changed in Tableau Server
- Applies to label for Data Management and Server Management Add-ons

User

- Use Relationships to Combine Data for Multi-table Analysis
- Create Metrics to Track Data

Other new features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

- New Admin Views
- Changes to Create and Modify Schedule
- Data Acceleration
- Extract Query Load Balancing
- Dynamic Configuration

Add-ons

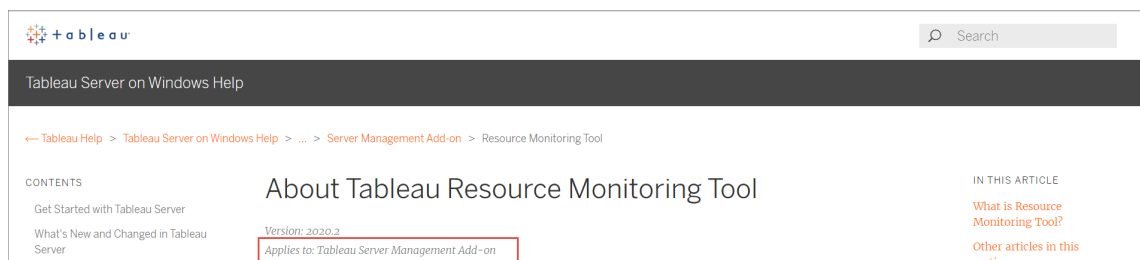

- Tableau Catalog updates - part of the Data Management Add-on

Combined What's New and What's Changed in Tableau Server

Beginning with version 2020.2, the "What's New" and "What's Changed" Help topics are combined in a single "What's New and Changed in Tableau Server" topic (this topic). The topic has been relocated in the Table of Content, and the old "What's Changed" topic now has a link to the combined file.

Applies to label for Data Management and Server Management Add-ons

Topics about add-on features list the add-on name in the Applies to section of the topic. For example:

Use Relationships to Combine Data for Multi-table Analysis

Relationships are a new, flexible way to combine data for multi-table analysis in Tableau. Data sources now support multi-table data models in a new logical layer. Tableau recognizes the separate tables in your data source and performs aggregations at the native level of detail for each table.

Creators can combine tables using relationships. Using relationships between logical tables makes it easier to explore and analyze multi-table data at the right level of detail, without having to write specialized calculations to control aggregations like averages and totals.

You do not need to specify join types for relationships; during analysis Tableau automatically selects the appropriate join types based on the fields and context of analysis in the worksheet.

Note: Your workbook must use an embedded data source for you to be able to edit relationships in the Data Source page in web authoring in Tableau Server or Tableau Online. You cannot edit the data model of a published data source.

In support of multi-table analysis, several parts of the Tableau interface have changed. The Data Source page (canvas, data grid), View Data window, and the Data pane in the worksheet have all been updated to support a multi-table analysis experience. For more information, see [Changes to different parts of the interface](#).

Note: View Data column order has changed in Tableau 2020.2 and later. This change is required to support relationships and logical tables. For details, see [View Data column order changes in Tableau 2020.2 and later](#).

For more information about relationships and changes to data sources, see these topics:

- [What's Changed with Data Sources and Analysis in 2020.2](#)
- [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#)
- [The Tableau Data Model](#)
- [Relate Your Data and Optimize Relationships Using Performance Options](#)
- [How Analysis Works for Multi-table Data Sources that Use Relationships](#)
- [Troubleshoot Multi-table Analysis](#)
- [Walkthrough: Don't Be Scared of Relationships](#)

Also see this Tableau blog post: [Relationships, part 1: Introducing new data modeling in Tableau](#)

Create Metrics to Track Data

Metrics help users track changes to their data. Users can create metrics from a view and use them to monitor key numbers like daily sales. For information on how users create metrics, see [Create and Troubleshoot Metrics](#).

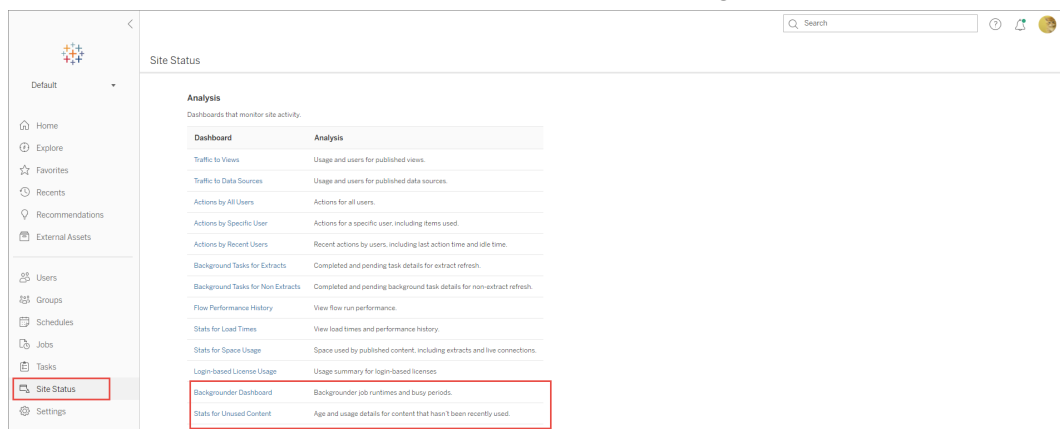

As a Tableau Server administrator, you have the ability to control how often metrics refresh and how failing refreshes are handled. You also can ensure that users are able to create metrics or disable metrics for particular sites. For more information, see [Set Up for Metrics](#).

New Admin Views

Two new pre-built administrative views are available in this release:

1. **Backgrounder Dashboard:** Use this view to understand the background job details such as, the number of jobs that have completed successfully, failed, or canceled. You can also identify when your Backgrounder is busy or overloaded. For more information, see [Backgrounder Dashboard](#).
2. **Stale Content aka Stats for Unused Content:** Identify content that hasn't been accessed or opened in a while and how much disk space is being used by stale content. For more information, see [Stale Content](#).

In previous versions of Tableau Server, admin views were all displayed in the same workbook, in separate tabs. However, the two new admin views are displayed as separate workbooks and not part of the existing admin view workbook. You can navigate to the new admin views from the Server or Site Status page:

Changes to Create and Modify Schedule

The web interface used to create and modify schedule has changed. You can now select more than one day when you create or modify monthly schedules. For more information

and updated screen shots of the new web interface, see [Create or Modify a Schedule](#).

Data Acceleration

Administrators can now enable data acceleration for specific workbooks. The workbook loads faster because Tableau Server precomputes the workbook's data in a background process. For more information, see [Data Acceleration](#).

Extract Query Load Balancing

Improvements to load balancing for extract-based queries are now available in Tableau Server. For more information, see [Extract Query Load Balancing](#).

Dynamic Configuration

Version 2020.2 introduces dynamic configuration for certain configuration options or keys. When you make configuration changes with these keys, or configuration changes with these keys in combination with Tableau Server Dynamic Topology Changes, you do not have to restart Tableau Server. This step toward more flexible server management includes dynamic configuration keys for changing logging levels for some Tableau Server processes, and changing some TSM base file paths.

Dynamically configurable keys include:

- `tsm.log.level`
- `tsm.controlapp.log.level`
- `tabadmincontroller.auth.expiration.minutes`
- `basefilepath.site_import.exports`
- `basefilepath.site_export.exports`
- `basefilepath.backuprestore`

For more information see [Change Logging Levels and tsm File Paths](#).

Tableau Catalog updates - part of the Data Management Add-on

Tableau Catalog is included in the separately licensed Data Management Add-on for Tableau Server and Tableau Online. For more information about Tableau Catalog, see [About Tableau Catalog](#).

The following features are included in this release:

Raise the visibility of important warnings - You can set a data quality warning to be highly visible, so that users of a visualization that's affected by the warning see a notification, and the warning displays in a more prominent yellow color elsewhere in Tableau. For more information, see [Set a Data Quality Warning and "Use Data Details to see visualization information"](#) in [Explore and Analyze Data in a View](#) in the Tableau Desktop and Web Authoring Help..

Dashboards appear in the Lineage pane - When you select the Dashboards item in the lineage, you can see a list of downstream dashboards. For more information, see [Use Lineage for Impact Analysis](#).

Filter external assets on Certified and data quality warnings - In addition to using search to narrow down your choices on External Assets, you can now filter databases, files, and tables by Certified and by data quality warnings.

More filters when connecting - When you connect to data, you can filter databases and table on connection type.

Changed in 2020.2

Version 2020.2 includes the following changes you should know about before upgrading.

Analytics extensions (external service) connections must be reconfigured

Tableau supports a set of functions that your users can use to pass expressions to analytics extensions for integration with R and Python. Previously, this feature was referred to "external services."

In previous versions of Tableau Server, the analytics extensions configuration applied to the Tableau Server global configuration and was administered with TSM.

Beginning with version 2020.2, you can configure a different analytics extensions connection for each site. Administration of the analytics extensions connection has moved out of TSM and to Tableau Server administrator. Additionally, configuring an analytics extensions connection no longer requires a restart of Tableau Server.

However, if you have configured Tableau Server with an analytics extensions connection, then you must reconfigure that connection after you upgrade Tableau Server to version 2020.2.

Before upgrading, document the existing analytics extensions configuration. On previous versions (2019.1-2020.1) you can run the `tsm security vizql-extsvc-ssl list` command to list the existing connection details. To retrieve the password that is stored for the analytics extensions connection (if any), run the following tsm command:

```
tsm configuration get -k vizqlserver.rserve.password
```

After you have upgraded, configure the analytics extension connection. See [Configure Connections with Analytics Extensions](#).

Oracle data source connections require updated driver

Beginning with version 2020.2, Oracle data sources use a new JDBC driver. You must download and install this driver on Tableau Server to enable existing content relying on Oracle connections to properly display. Until this driver is downloaded and installed on Tableau Server, existing content will not display or refresh. Follow the instructions on the [Driver Download](#)

page to get and install the new driver. For details on the changes and how they impact Tableau authors, see [Oracle](#) in the Tableau Desktop and Web Authoring Help.

WDC behavior change if Run As service account has admin group privileges

Beginning with version 2020.2, because of changes to the QTWebEngine component used by Tableau Server, if you use Web Data Connectors (WDCs) and Tableau is configured with a Run As service account in a local administrators or domain administrators group, you may run into problems using WDCs. Our recommendation has been and continues to be to use a domain User account for the Run As service account. This is a good security practice.

For more information on possible issues, see the [Tableau Knowledge Base](#). For details on suggested best practices when creating a Run As service account, see [Creating the Run As service account](#).

Tableau Resource Monitoring Tool Updates

- **Installers:** Starting in 2020.2, the Master Server installer installs both the prerequisites and the Master Server. You no longer need to install the prerequisites separately. For more information, see:
 - [Install the RMT Server Using Web Interface](#)
 - [Upgrading Resource Monitoring Tool](#)
- **Installation Experience:** The steps to create an environment after installing the Master Server, and the steps to install and register Resource Monitoring Tool Agent on Tableau Server nodes have changed. For more information, see :
 - [Install the RMT Server Using Web Interface](#)
 - [Install the Agent Using the Web Interface](#)
- **OS Requirements:** Starting in 2020.2, Windows Server 2012 is no longer supported. The minimum supported operating system is now Windows Server 2012 R2.

The Startup Values of some TSM services have changed

Beginning in maintenance versions, the startup values of several TSM services have been changed from "Automatic" to "Automatic (Delayed Start)" to help address some occasional

Tableau Server on Windows Help

issues in timing. This change should not have a significant impact. Services affected: Tableau Server Administration Agent, Tableau Server Administration Controller, Tableau Server Client File Service, Tableau Server Coordination Service, Tableau Server License Manager, and Tableau Server Service Manager.

If you are running an older version of Tableau Server you can leave the startup values as they were originally configured ("Automatic"), but updating them to the new values ("Automatic (Delayed Start)") will not negatively impact Tableau Server. For more information about service startup values, including the specific maintenance releases where this change took place, see [Verify Tableau Service Settings](#) in our current documentation.

Version 2020.1

Added in 2020.1

User

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

- Run Now Server and Site Setting
- New configuration options for Hyper
- Support for Login-based License Management
- Support for Kerberos delegation with Vertica data source
- Support for managing site role limits
- Updates for Permission Dialog
- Lock nested projects

Add-ons

- Tableau Catalog updates - part of the Data Management Add-on
- Tableau Server External File Store (Server Management Add-on)

Run Now Server and Site Setting

This new setting allows Server Administrators to configure whether to allow or block users from manually running extract refreshes, flows runs, and subscriptions. This can be set at the server level to apply to all the sites on Tableau Server or at a site level to apply to only certain sites. For more information, see [Server Settings \(General and Customization\)](#).

New configuration options for Hyper

You can use these new tsm configuration set options to configure Hyper to control resource consumption and improve stability:

- `hyper.memory_limit`
- `hyper.memtracker_hard_reclaim_threshold`
- `hyper.memtracker_soft_reclaim_threshold`
- `hyper.network_threads`
- `hyper.objectstore_validate_checksums`
- `hyper.query_total_time_limit`
- `hyper.session_memory_limit`
- `hyper.temp_disk_space_limit`

For more information, see [tsm configuration set Options](#).

Support for Login-based License Management

Login-based license management, helps you manage licensing for users with Creator roles on Tableau Server and Tableau Online. Users with Explorer or Viewer roles cannot use this feature. If you're using Role Based Subscriptions with Tableau Server or Tableau Online, you can simplify your license management using login-based license management to eliminate separate Tableau Desktop and Tableau Prep Builder product keys. You only need to manage one or more product keys for on-premises Tableau Server, or in the case of Tableau Online, you don't need to manage any product keys at all.

Support for Kerberos delegation with Vertica data source

You can now authenticate to Vertica data sources with Kerberos delegation. To configure Kerberos delegation on Tableau Server, see [Enable Kerberos Delegation](#). To enable Kerberos for Vertica in Active Directory, see [Enabling Kerberos Delegation for Vertica](#).

Support for managing site role limits

Server administrators can now set a maximum number of Creator, Explorer, and Viewer licenses available for a site. Site administrators can use those quotas to allocate licenses for users on their site. For a site that has user-based licensing with no licensing limits set by the server administrator, maximums for each role are determined by the number of available licenses. To learn more, see [Manage Site Role Limits](#). Server admins can also configure site role quotas via the [REST API](#).

Updates for Permission Dialog

Set permissions faster with the new permissions dialog. New permission [templates](#) and capability groupings match common user scenarios. Editing permission rules is easier than ever with direct editing—double click to enter edit mode. Search for groups and users simultaneously without preselecting your choice. [Copy](#) a custom permission rule and paste it for another group or user. And hand off project management to [Project Leaders](#) more intuitively with the new setting. For more information on permissions, see [Permissions](#).

Lock nested projects

Regulating permissions is now more flexible. Project permissions can be locked independently for nested projects. Top-level projects can act as organizational containers for projects with different permission models. Non-admins can create new locked projects. For more information, see [Lock content permissions](#).

Tableau Server External File Store (Server Management Add-on)

You can now configure Tableau Server to use a SAN or NAS to store File Store data. Using a network attached storage for your File Store data provides some benefits like reduced

backup times, by using the snapshot backup technologies. For more information see, [Tableau Server External File Store](#)

Tableau Catalog updates - part of the Data Management Add-on

Tableau Catalog is included in the separately licensed Data Management Add-on for Tableau Server and Tableau Online. For more information about Tableau Catalog, see [About Tableau Catalog](#).

The following features are included in this release:

Added connectors - Connect to more data from external assets. We've added support for the following connectors: Google Big Query, Google Drive, Google Sheets, Box, Dropbox, and OneDrive.

Create workbooks - Create a workbook from the External Assets page or from a database or table page for Catalog-supported connections. For more information, see "Tableau Catalog users create workbooks from external assets" in [Creators: Get Started with Web Authoring](#) in the Tableau Desktop and Web Authoring Help.

Filter on Certified and data quality warnings - Filter data sources, databases, files, and tables by Certified, filter data sources by connections, and filter databases and tables by data quality warnings. For more information, see "Open the Connect to Data page" in [Creators: Connect to Data on the Web](#), or "Connect from Tableau Desktop" in [Connect to Data by Using Tableau Server or Tableau Online](#) in the Tableau Desktop and Web Authoring Help.

Enhanced Data Details pane -

- See a sparkline with the number of times a sheet or dashboard was viewed over the last 12 weeks.
- Easily see that there are Warnings on a view.
- Expand a field to see its metadata, such as a description or calculation.
- When a field in a workbook inherits its description, see where the description comes from.

For more information, see "Use Data Details to see visualization information" in [Explore and Analyze Data in a View](#) in the Tableau Desktop and Web Authoring Help.

Changed in 2020.1

Version 2020.1 includes the following changes you should know about before upgrading.

- Tableau Server no longer supports Windows 7 or Windows 2008
- `tableau-server-obliterate` script now preserves backup and log files
- Improvements to the `tsm topology deploy-coordination-service` command
- Large statistical file extracts consume system resources

Tableau Server no longer supports Windows 7 or Windows 2008

Beginning with version 2020.1, in keeping with Microsoft's Windows Server support policy, Windows 7 and Windows 2008 are no longer supported operating systems for Tableau Server.

For more information about supported versions of Windows, see [Operating system requirements](#).

`tableau-server-obliterate` script now preserves backup and log files

In previous versions of Tableau Server, running the `tableau-server-obliterate` script deleted all content from the Data directory. Beginning with version 2020.1, the default behavior of the `tableau-server-obliterate` script has changed: the script copies and saves Tableau Server backup and log files to the `logs-temp` directory. The default location for the `logs-temp` directory is at `\ProgramData\Tableau\logs-temp`. You can set options on the script to disable this new functionality.

See [Remove Tableau Server from Your Computer](#).

Improvements to the `tsm topology deploy-coordination-service` command

Beginning with version 2020.1, the command to deploy a new coordination service ensemble waits for the ensemble to be properly deployed and removes the old ensemble before returning control to the command prompt. This simplifies the process for deploying a new coordination service ensemble and eliminates the chances of continuing on with other commands or actions before Tableau Server is properly configured for the new ensemble. You no longer need to run the `tsm topology cleanup-coordination-service` command after deploying a new ensemble in version 2020.1.0 and later.

Note: With this change, all coordination service ensemble commands require input for a "y/n" prompt confirming that a server restart will take place. To run these commands without input, include the `--ignore-prompt` option.

For more information about deploying a coordination service ensemble, see [Deploy a Coordination Service Ensemble](#).

Large statistical file extracts consume system resources

Beginning with Tableau Server 2020.1, a change to the Statistical File (SAS) library may cause large SAS-based extract refreshes to fail. The following connection error will be visible in the backgrounder logs, along with spikes in system memory consumption.

"exceeded per-process memory threshold"

To work around the issue, run the following TSM commands after upgrading Tableau Server:

```
tsm configuration set -k features.ReadStat -v false
tsm pending-changes apply
```

For more information and steps to work around the issue in Tableau Desktop, see the Knowledge Base article, [Large Sas File Extract Refresh Failed And Huge Memory Consumption Observed After Upgraded Tableau Server To 2020.3.1](#).

Added in 2019.4

User

- Request access

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

- Configure recommendations for views
- Enable or disable Ask Data for a site
- Personal access tokens
- Secure SMTP
- Test Email Configuration
- Create Extracts on the Web
- New Installers for Tableau Server and tabcmd
- Custom welcome banner
- Limit visibility of user information
- Manage Sandboxed Extensions

Request access

Users can now request access to see a project, workbook, or view when they don't have viewing permission. When someone requests access to content, Tableau routes an email to the person who controls permissions for that content with information about the request and instructions on making access changes. For information on managing permissions, see [Permissions](#).

Configure recommendations for views

Tableau Server now recommends views to help users discover relevant content. Recommendations for views are an expansion of the system that provides recommendations for data sources and tables.

- To control whether the recommendations feature is enabled for your server, use the tsm configuration set options `recommendations.enabled` and `recommendations.vizrecs.enabled`. For more information, see [tsm configuration set Options](#).
- To schedule when the recommendations trainer runs on your server, adjust the server settings under **Recommendations Training Schedule**. For more information, see [Server Settings \(General\)](#).
- To hide all recommendations on a particular site, or to hide user names from appearing on the recommendation tooltips for a particular site, adjust the site settings under **Recommendations for Views**.

Enable or disable Ask Data for a site

As a site administrator, you can control the availability of Ask Data in the **General** area of site settings. For more information, see [Disable or Enable Ask Data for a Site](#).

Personal access tokens

Personal access tokens provide Tableau Server users the ability to create long-lived authentication tokens. The tokens allow users to run automation with Tableau REST APIs without requiring hard-coded credentials or interactive login. More information about using personal access tokens with Tableau REST APIs is at [Signing In and Out \(Authentication\)](#).

As an administrator, you can revoke and track usage of the tokens. See [Personal Access Tokens](#).

Secure SMTP

You can now configure Tableau Server to connect with your email server over a secure connection. You can encrypt and optionally authenticate with a certificate that you upload and

Tableau Server on Windows Help

configure on Tableau Server. See [Secure SMTP](#).

Test Email Configuration

After you configure an SMTP connection, use the new command, `tsm email`, to validate it.

Create Extracts on the Web

Now you can create extracts in the browser, without using Tableau Desktop. For more information, see [Create Extracts on the Web](#) . You can also use the new `createextracts` and `deleteextracts` commands in `tabcmd` to create or delete extracts for a published workbook or data source. For more information, see [tabcmd Commands](#).

New Installers for Tableau Server and `tabcmd`

Tableau Server 2019.4 introduces completely rewritten Setup programs for both Tableau Server and `tabcmd`. For more information, see [What's Changed - Things to Know Before You Upgrade](#).

Custom welcome banner

You can add a custom message to the welcome banner on the home page for all server users to see. Add up to 240 characters of text and hyperlinks to provide important support information or resource to help server users get started. You can also turn off the default Tableau home banner for all server users. For more information, see [Customize Your Server](#).

Limit visibility of user information

The User Visibility site setting lets administrators manage if users with Viewer and Explorer site roles see other users and groups on the site, which can be important for sites that are used by multiple clients. When User Visibility is set to **Limited**, Explorers and Viewers cannot see information about other users, including aliases, project ownership, comments, and more. Creators and administrators (including Site Administrator Explorers) can still view

user information. By default, User Visibility is set to Full. For more information, see [Manage Site User Visibility](#).

Manage Sandboxed Extensions

Tableau now supports Sandboxed extensions, which are a new type of dashboard extension that run in a protected environment hosted by Tableau. Like Network-enabled extensions, Sandboxed extensions are web applications that run in custom dashboard zones and can interact with the rest of the dashboard using the [Tableau Extensions API](#). While Network-enabled extensions have full access to the web, Sandboxed extensions can't share data or make network calls outside of the hosting Tableau Server. Sandboxed extensions provide a new level of security for Tableau users and administrators.

To learn more about controlling extensions, see [Manage Dashboard Extensions in Tableau Server](#). To learn more about extension security and strategies for deployment, see [Extension Security - Best Practices for Deployment](#).

Changed in 2019.4

Version 2019.4 includes the following changes you should know about before upgrading.

- Tableau Server installer has been rewritten
- New tabcmd installer for Windows
- Updates to Tableau Server Job management
- Updates to tsm maintenance cleanup command
- Changed behavior for Copy Link when sharing a view

Tableau Server installer has been rewritten

The 2019.4 release of Tableau Server features a newly rewritten Setup program for Tableau Server.

This update changes some of the command line switches and options available for the installer. If you have automated the installing or upgrading of Tableau Server, be sure to

Tableau Server on Windows Help

review the current command line options for the Server Setup program. See [Changes to Command Line Install Options for Tableau Server Setup](#) for more information.

New tabcmd installer for Windows

The 2019.4 release of Tableau Server features a newly rewritten Setup program for installing tabcmd on Windows.

This update changes some of the command line options. If you have automated the installation of tabcmd, be sure to review the current command line options for the tabcmd Setup program. For more information, see [tabcmd and Install Switches and Properties for tabcmd \(Windows\)](#)

Updates to Tableau Server Job management

The Job management page has several updates and new options including the following:

- The **Jobs** page now includes **Average Run** and **Average Queue** time information for each job.
- Improved job cancellation experience. Server and Site admins can now enter customized notes as well as pick recipients of the e-mail when cancelling a job.
- More information is provided in the job detail dialog box, such as: the last time the job was run successfully, and the name of the job creator.
- Canceling flow run jobs is now supported. Previously, in Tableau Server version 2019.3, only extract refreshes and subscriptions were supported.
- New **Task Type** has been added: Encryption jobs.
- Failed jobs now includes jobs that have been suspended. Suspended jobs are a sub-status of the failed jobs and have their own icon to distinguish them from other failed jobs.

For more information, see [Managing Background Jobs in Tableau Server](#).

Updates to tsm maintenance cleanup command

The `tsm maintenance cleanup` command now includes an option to clear the image cache.

In addition, the `--verbose` option has been removed from the command. Running the command with the `--verbose` option will result in an error. If your organization has automated task using the `tsm maintenance cleanup` command with the `--verbose` option, update your automation scripts.

Changed behavior for Copy Link when sharing a view

Beginning with version 2019.4, the behavior of the **Copy Link** option of the **Share** button in a view no longer includes the "embed=y" parameter by default. To include this parameter you need to edit the copied URL before adding it to your web page code. For more information sharing views by embedding them in web pages, see [Embed Views into Webpages](#) in the Tableau Desktop and Web Authoring Help. For details about the parameter, see [URL parameters for iframe tags](#) in the Tableau Desktop and Web Authoring Help.

Version 2019.3

Added in 2019.3

Version 2019.3 includes the following new features.

User

- Add PDF Attachments to Subscription Emails
- Tableau Catalog features—part of the Data Management

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

Tableau Server on Windows Help

- Support for Embedded Credentials in Bootstrap Files
- Tableau Catalog on the server—part of the Data Management
- Tableau Metadata API
- Advanced Management
- Extract Encryption at Rest
- Date-range Support for Ziplogs
- Tableau Server Usage Data
- Add a Note to Tableau Server Sign In Page
- Support added for Italian
- Job Management

Add PDF Attachments to Subscription Emails

You can give your users the option to attach PDF renderings for views and workbooks subscription emails. You must enable attachment functionality on the server. See [Configure Server Event Notification](#).

Tableau Catalog features—part of the Data Management

Tableau Catalog is included in the separately licensed Data Management Add-on for Tableau Server and Tableau Online, making a variety of features available to you in the data management space. You can use Tableau Catalog to discover data, curate data assets, communicate data quality, perform impact analysis, and trace the lineage of data used in Tableau content. For more information, see [About Tableau Catalog](#).

Tableau Catalog on the server—part of the Data Management

Tableau Catalog is included in the separately licensed Data Management. For more information, see [License the Data Management Add-on](#).

You can give your users access to metadata and features like expanded search, data details, and lineage when you Enable Tableau Catalog. To learn more about how Tableau Catalog and metadata permissions work, see [Manage Permissions for External Assets](#).

Tableau Metadata API

If you're a developer and interested in accessing metadata indexed by or surfaced through Tableau Catalog, see the [Tableau Metadata API Help](#).

Job Management

You can now view, monitor, and manage backgrounder jobs on Tableau Server. For more information, see [Managing Background Jobs in Tableau Server](#).

Support for Embedded Credentials in Bootstrap Files

You can now include embedded credentials when generating bootstrap file. This allows you to add a new node to your Tableau Server installation from the command line without needing to provide TSM administrative credentials when installing the node, and can be especially useful if you automate installation of Tableau. This feature is enabled by default and the embedded credentials are valid for a predetermined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie.

Embedded credentials apply when adding a node from the command line, and are designed to provide you with flexibility, so you can choose how you use this feature. You can choose to not include embedded credentials any time you generate a bootstrap file. You can also disable the feature entirely using the `features.PasswordlessBootstrapInit` option with the `tsm configuration set` command. When credentials are not included, you are prompted, when adding a node, for the name and password of a user with administrative permissions on the computer where Tableau Services Manager is installed.

Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. The file can also embedded credentials which are valid for a predetermined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie. We strongly recommend that you take additional measures to secure the bootstrap file.

For more information, see `tsm topology nodes get-bootstrap-file`.

Advanced Management

Advanced Management is a separately licensed Add-on which will provide enhanced security, manageability, and scalability capabilities for Tableau Server.

- **Improved scalability:**
 - For Tableau Server deployments hosted on AWS, you can now choose to host your metadata repository externally with Amazon RDS Postgres. Amazon RDS offers scalability, reliability, high availability and security built-in for PostgreSQL. By integrating with AWS, you will be able to take advantage of these additional benefits of deploying the cloud. For more information, see [Tableau Server External Repository](#).
 - You can also tune your Tableau Server processes by customizing which nodes process data engine queries and background jobs. For more information, see [Workload Management through Node Roles](#).
- **Increased operational efficiency:**
 - New Resource Monitoring Tool and Content Migration Tool which were acquired from Interworks are included as part of Advanced Management:
 - The Resource Monitoring Tool provides increased visibility into hardware utilization, and server processes, and makes it easier to understand and tune the performance of your Tableau Server installation. For more information, see [About Tableau Resource Monitoring Tool](#).
 - The Content Migration Tool helps streamline your workbook and data source content work flows. You can manage the movement of content between development and production or between other environments. For more information, see [About Tableau Content Migration Tool](#)
- **Enhanced security:**

If your organization will be enabling extract encryption at rest, you can also integrate Tableau Server with AWS Key Management Service to provide an enhanced level of integration and security. For more information, see [Tableau Server Key Management System](#).

Extract Encryption at Rest

Extract encryption at rest is a data security feature that allows you to encrypt .hyper extracts while they are stored on Tableau Server.

Tableau Server administrators can enforce encryption of all extracts on their site or allow users to specify to encrypt all extracts associated with particular published workbooks or data sources. See [Extract Encryption at Rest](#).

Date-range Support for Ziplogs

Two new date options for the `tsm maintenance ziplogs` command, `--startdate` and `--enddate`, give you the ability to specify a date range for the logs being gathered. These options must be used together, and cannot be used with the `--minimumdate` option. For more information, see [tsm maintenance ziplogs](#).

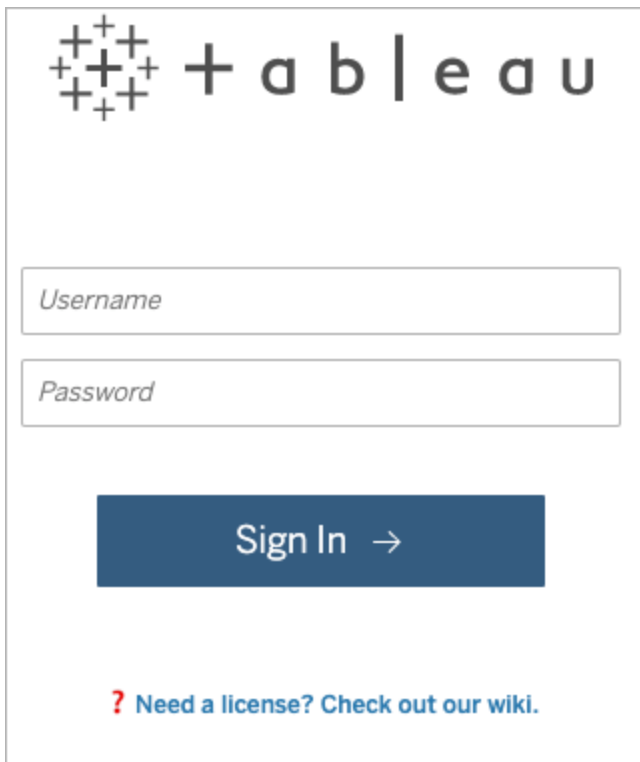

Tableau Server Usage Data

Beginning with Tableau Server 2019.3, server usage data is sent to Tableau by default. This is the case for new installs and upgrades and can be disabled. You can opt out during installation, upgrade, or at any time after Tableau Server has been installed. For more information about usage data, see [What's Changed - Things to Know Before You Upgrade](#) in the [What's Change](#) article, and the general overview, [Server Usage Data](#).

Add a Note to Tableau Server Sign In Page

You can add an optional note and URL to your server's sign in page to help new users gain server access or for server-wide announcements. The setting also supports emojis. To set a custom note, sign in to a site on Tableau Server. On the left-side navigation pane, select **Manage all sites** from the drop-down site list. Select **Settings** to and add a message to

Sign In Customization. For more information about customizing Tableau Server, see [Customize Your Server](#).

A screenshot of the Tableau sign-in interface. At the top left is the Tableau logo, which consists of a cluster of plus signs followed by the word 'tableau' in a lowercase, sans-serif font. Below the logo are two input fields: the first is labeled 'Username' and the second is labeled 'Password'. Below these fields is a dark blue button with the text 'Sign In →' in white. At the bottom of the form, there is a red question mark icon followed by the text 'Need a license? Check out our wiki.' in blue.

tableau

Password

Sign In →

? Need a license? Check out our wiki.

Support added for Italian

Tableau has added support for Italian. You can now set Tableau to display the user interface in one of eleven languages:

- Chinese (Simplified)
- Chinese (Traditional)
- English (United Kingdom)
- English (United States)
- French
- German
- Italian
- Japanese
- Korean

- Portuguese
- Spanish

For more information, see [Language and Locale for Tableau Server](#).

In addition to supporting Italian in all Tableau products, the help is also available in these languages. To read the help in your preferred language, navigate to the bottom of the main [Tableau Help](#) page, and select the language from the footer.

Changed in 2019.3

Version 2019.3 includes the following changes you should know about before upgrading.

- Default cipher suite no longer includes default support for old ciphers
- Tableau Server Usage Data
- Upgrade without needing to provide a password
- Some tsm command options are no longer configurable

Default cipher suite no longer includes default support for old ciphers

The 2019.3 version of Tableau Server no longer includes default support for Triple-DES, IDEA, and CAMELIA ciphers for SSL connections. These ciphers are no longer considered adequately secure. In the previous versions of the Security Hardening Checklist, we included a recommendation to disable the Triple-DES cipher, which was enabled by default.

Tableau Server on Windows Help

Depending on your environment, you may need to make additional configurations before our after upgrading:

- If you disabled the Triple-DES cipher as documented in the Checklist, then we recommend running the following commands before you upgrade to 2019.3:

```
tsm configuration set -k ssl.ciphersuite -d  
  
tsm pending-changes apply
```

This command reverts Tableau Server to the 2019.2 (and older) default cipher suite configuration. After you have upgraded to 2019.3, Triple-DES, IDEA, and CAMELIA will be removed from the default supported ciphers.

Do not run the command if you made other changes to the `ssl_ciphersuite` key.

- If you did not change the `ssl_ciphersuite` key, then Setup will update the key value to the new default as part of the upgrade process. The new default value for the `ssl_ciphersuite` key is

```
HIGH:MEDIUM:!aNULL:!MD5:!RC4:!3DES:!CAMELLIA:!IDEA:!SEED.
```

- If your users still require support for Triple-DES, then we recommend upgrading to more recent browsers that support more secure ciphers. If that is not an option, then you can run the following commands after you have upgraded. The first command sets the `ssl_ciphersuite` key to the pre-2019.3 configuration, which supports Triple-DES:

```
tsm configuration set -k ssl.ciphersuite -v  
"HIGH:MEDIUM:!aNULL:!MD5:!RC4"  
  
tsm pending-changes apply
```

Usage data is sent to Tableau

Beginning with Tableau Server 2019.3, server usage data is sent to Tableau by default. This is the case for new installs and upgrades. You have the ability to opt out during installation,

upgrade, or at any time after Tableau Server has been installed. For more information about usage data, see [Server Usage Data](#).

To disable the sending of server usage data:

- If you are installing Tableau Server for the first time, you can disable this feature during the configuration of initial node settings. For details, see [Configure Initial Node Settings](#).
- If you are upgrading Tableau Server, the `upgrade-tsm` script will let you know about the option and how to disable it.
- If you want to have installed or upgraded Tableau Server and want to disable the sending of server usage data, you can do this from the TSM Maintenance page, or from the command line. For details, see [Server Usage Data](#).

Upgrade without needing to provide a password

Beginning with Tableau Server 2019.3, when you upgrade from version 2019.2 or later, the `upgrade-tsm` script no longer requires you to specify a user and password. Version 2019.3 and later take advantage of the [What's New and Changed in Tableau Server](#) feature and uses the account you have logged in as to authenticate the upgrade. You can override this behavior with the `--user` option, to specify an administrative user. When you do this, you can also provide a password using the `--password` option, or enter a password when prompted. Upgrades from versions earlier than 2019.2.0 will still prompt you for a password.

Some tsm command options are no longer configurable

Beginning with Tableau Server 2019.3, the following options are enabled on install and are no longer configurable:

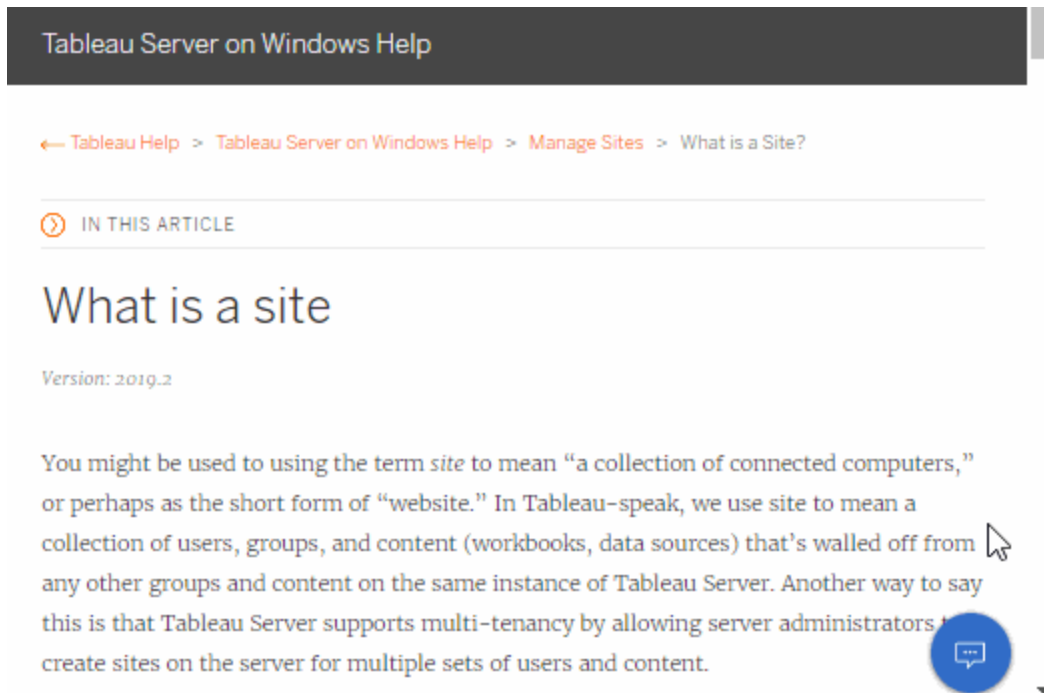

- `backgrounder.enable_sort_jobs_by_job_rank`
- `backgrounder.enable_task_run_time_and_job_rank`

Added in 2019.2

Version 2019.2 includes the following new features.

Help Design

A blue **Send feedback** icon is displayed in the bottom right corner of every Help page to make it easier for you to send feedback about the content in a topic. Click the icon to let us know if a topic is helpful to you, and also to comment on what needs improvement.

User

- New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

- Direct access with TSM CLI
- Local authentication password policy improvements
- Select from ten different languages for Tableau
- Set a site-level start page
- Windows Server 2019
- Elastic Server on multiple nodes
- SSL connection to TabPy external service
- Configuring the threshold for suspending data-driven alerts
- Configuring logging levels for TSM processes

Direct access with TSM CLI

Beginning in the 2019.2 release of Tableau Server, running tsm commands will not require you to enter a password if the following are true:

- The account you are running commands with is a member of the TSM-authorized group, which is the local Administrators group on the Windows computer.
- You are running commands locally on the Tableau Server that is running the Tableau Server Administration Controller service. By default, the Tableau Server Administration Controller service is installed and configured on the initial node in a distributed deployment.

See [Authenticating with tsm CLI](#).

Local authentication password policy improvements

Beginning in the 2019.2 release of Tableau Server, you can now set password policies for Tableau Server that is configured for local authentication. For example, you can specify password length, expiry, and complexity. Additionally, you can set accounts to be locked out after too many failed sign-in attempts. You can also enable users to reset their own passwords. See [Local Authentication](#).

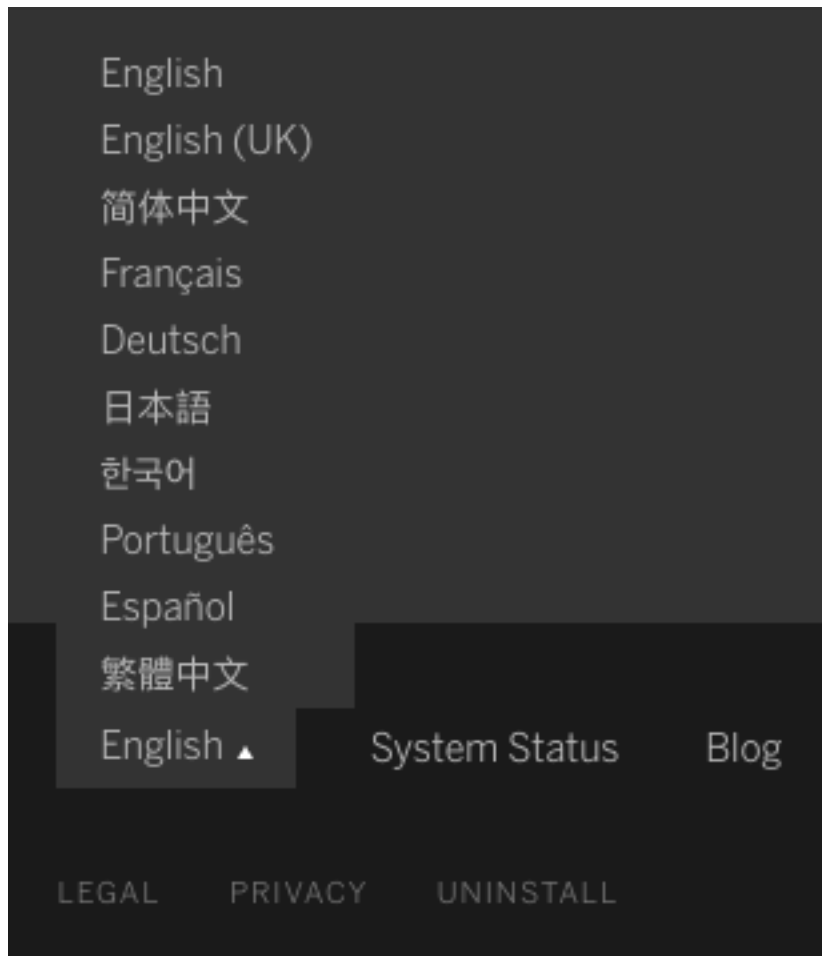

Select from ten different languages for Tableau

Tableau has added support for two new languages, Chinese (Traditional) and English (United Kingdom). You can now set Tableau to display the user interface in one of ten languages:

- Chinese (Simplified)
- Chinese (Traditional)
- English (United Kingdom)
- English (United States)
- French
- German
- Japanese
- Korean
- Portuguese
- Spanish

For more information, see [Language and Locale for Tableau Server](#).

In addition to supporting two new languages in all Tableau products, the help is also available in these languages. To read the help in your preferred language, navigate to the bottom of the main [Tableau Help](#) page, and select the language from the footer.

Set a site-level start page

Beginning in the 2019.2 release of Tableau Server, you can set a start page for all site users, so that they land on a particular page when they sign into Tableau Server. Previously, server administrators could only set a start page at the server-level. See [Set the Default Start Page for All Users](#).

Windows Server 2019

Beginning in the 2019.2 release of Tableau Server, you can install Tableau Server on Windows Server 2019. For more information about requirements, see [Before you install...](#)

Elastic Server on multiple nodes

Elastic Server is used by Ask Data to index data. You can now run Elastic Server processes on more than one node in a cluster. It is recommended to have an odd number of Elastic Server processes running. For more information, see [Tableau Server Processes](#).

SSL connection to TabPy external service

In previous versions, SSL connections to TabPy were not supported. In Tableau Server 2019.2, you can configure SSL connections. Configuring external services is done with tsm commands at tsm security.

Configuring the threshold for suspending data-driven alerts

By default, an alert is suspended after 350 consecutive alert failures. Server administrators can configure the threshold number of alert failures before an alert is suspended. For more information, see [Set Up for Data-Driven Alerts](#).

Configuring logging levels for TSM processes

You can now easily change the logging levels of Tableau Services Manager (TSM) processes. This allows you to increase logging levels to troubleshoot issues (if you are working with Tableau Support for example). For more information, see [Change Logging Levels](#).

Changed in 2019.2

Version 2019.2 includes the following changes you should know about before upgrading.

- Minimum hardware requirements have changed
- Upgrade requires at least 15% free disk space on each node
- "Referrer-Policy" HTTP header added
- Map-related internet addresses have changed

Minimum hardware requirements have changed

Beginning with version 2019.2, Tableau Server requires a minimum of 4 cores and 16 GB of RAM in order to install. The installation program will check that the computer you are installing on satisfies these minimums before you can install. If the computer does not meet these hardware minimums, Tableau cannot be installed. For details, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#). For more information about this change, see this Tableau blog post: [Updated machine requirements for Tableau Server trials](#).

Upgrade requires at least 15% free disk space on each node

Upgrading to version 2019.2 includes a version update to the PostGRES database that Tableau uses internally. This update means that a backup of the database is done before upgrading, and that requires a minimum of 15% free space on each node.

"Referrer-Policy" HTTP header added

Beginning in 2019.2, Tableau Server includes the ability to configure Referrer-Policy HTTP header behavior. This policy is enabled with a default behavior that will include the origin URL for all "secure as" connections (policy no-referrer-when-downgrade). In previous versions, the Referrer-Policy header was not included in responses sent by Tableau Server. This change is not likely to impact user scenarios for most browsers. However, we recommend testing browser-based user scenarios after you upgrade to 2019.2. In the event a user scenario is effected, you can disable or change this header behavior. See [HTTP Response Headers](#).

Map-related internet addresses have changed

Beginning in 2019.2, Tableau Server needs access using port 443 to two new map locations:

- mapsconfig.tableau.com
- api.mapbox.com

Tableau Server on Windows Help

These replace the address used by previous versions: maps.tableau.com. For details on configuring Tableau Server for proper internet access, see [Configuring Proxies for Tableau Server](#).

Version 2019.1

Added in 2019.1

Version 2019.1 includes the following new features.

Changes to Tableau Help

Updates have been made to help you navigate our content, including a new right-hand menu to quickly scan and select different topics on a page. We've also created content within tabs, to easily show how to complete tasks for web or command line interface.

User

- New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).
- Web authoring auto recovery

Server or site administrator

- Microservice Container Processes
- TSM client authentication
- Ask Data and Elastic Server Processes
- Tableau Prep Conductor Server Process
- Node roles for Background Process
- Tableau Data Management Add-On
- SSL connection to Rserve external service

Web authoring auto recovery

With Tableau Server 2019.1, editing and authoring content on the server will auto-recover in the event of a process failure. As you make changes to content, Tableau Server will intermittently (and silently) save changes. In previous versions, a process failure results in lost changes if you did not save them prior to the failure. In Tableau Server 2019.1, changes you make prior to a failure will be persisted when you reconnect to the content.

By default, Tableau Server will save content after you make five changes to it. Your server admin can adjust this interval with the `vizqlserver.NumberOfWorkbookChangesBetweenAutoSaves` option using `tsm configuration set Options`. File size limit (`vizqlserver.WorkbookTooLargeToCheckpointSizeKiB`) and recovery attempts per session (`vizqlserver.RecoveryAttemptLimitPerSession`) can also be configured.

Microservice Container Processes

The 2019.1 release adds some new processes to Tableau Server. Two container processes, Interactive Microservice Container and Non-Interactive Microservice Container now appear on the TSM Status page and in the output of the TSM command `tsm status -v`. These processes contain microservices and cannot be configured independently by administrators. For more information, see [Tableau Server Microservice Containers](#).

TSM client authentication

In the 2019.1 release, certificate trust and management for TSM clients (Web UI and CLI) have been updated to make encrypted connections to Tableau Server easier to manage. See [Connecting TSM clients](#).

Ask Data and Elastic Server Processes

With Tableau Server 2019.1, Ask Data and Elastic Server processes have been added to Tableau Server to support the new Ask Data feature. For more information, see [Tableau Server Processes](#).

Tableau Server on Windows Help

The Ask Data process is installed and configured automatically. It cannot be configured manually. Logs are stored in the `nlp` directory. For more information, see [Tableau Server Logs and Log File Locations](#).

The Elastic Server process is installed and configured automatically. The Elastic Server heap size can be configured by using the `elasticserver.vmopts` TSM configuration option. For more information, see [tsm configuration set Options](#). Only one Elastic Server process can be running and it can optionally be moved to any node in the cluster.

Tableau Prep Conductor Server Process

Tableau Prep Conductor is a new server process that has been added to Tableau Server to support automation of running and managing flows. Tableau Prep Conductor leverages the scheduling and tracking functionality of Tableau Server so you can automate running flows to update the flow output instead of logging into Tableau Prep to manually run individual flows as your data changes. For more details, see [Tableau Prep Conductor](#).

Tableau Prep Conductor is licensed through Tableau Data Management Add-on. For more information, see [Licensing Tableau Prep Conductor](#).

Tableau Data Management Add-On

The Data Management Add-on is a new license that includes Tableau Prep Conductor. For more information, see [Licensing Tableau Prep Conductor](#).

Node roles for Backgrounder Process

A new `tsm topology` command that gives you the ability to specify the type of tasks that backgrounder can perform has been added. In 2019.1, using the new command, you can isolate certain nodes to run only flow tasks or run all tasks other than flows. This is useful if you are planning to use Tableau Prep Conductor to publish, run and schedule flows. For more information, see [Workload Management through Node Roles and Tableau Prep Conductor](#).

SSL connection to Rserve external service

In previous versions, SSL connections to Rserve and TabPy were not supported. In Tableau Server 2018.3, you can configure SSL connections. In addition, connecting to external services is now enabling, disabling, and configuring is now done with native tsm commands under tsm security.

Changed in 2019.1

Version 2019.1 includes the following changes you should know about before upgrading.

- High-resolution thumbnails
- Project card images

High-resolution thumbnails

In version 2019.1 and later, workbooks and views use higher resolution thumbnails. When you upgrade to Tableau Server version 2019.1 or later, the Backgrounder runs the Enqueue Thumbnails Upgrade job and the Upgrade Thumbnails job, which refreshes thumbnails for any views that have not been edited or published since Tableau version 2018.2 and converts them from low resolution thumbnail images (192 x192 pixels) to high resolution thumbnail images (300 x 300 pixels), as shown in the figure below.

Tableau Server on Windows Help

When the Upgrade Thumbnails job refreshes the thumbnail images, the modified date of the view is changed to match the thumbnail update date. The Upgrade Thumbnails job does not change the modified date of workbooks when it updates the contained view's thumbnails.

Thumbnails may appear blurry until the Upgrade Thumbnails job is complete. Depending on the number of workbooks you have, this could a few minutes to a few hours. You may also notice that thumbnail images may appear in low resolution for up to a week after upgrading to Tableau Server 2019.1. For more information, see [Upgrade Thumbnails Job](#).

Project card images

In version 2019.1 and later, project card images will not appear on the project card unless they are added as the last item in the project description and encapsulated with ! (exclamation marks). For more information, see [Add a Project Image](#).

Version 2018.3

Added in 2018.3

Version 2018.3 includes the following new features.

Changes to Tableau Help

Search results within the product help have been expanded to include results for all Tableau products and help articles. Help layout and navigation, such as table of contents placement and breadcrumbs, have been updated to create a more consistent cross-product help experience.

User

- New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).
- Secure extract data at the row level

Server or site administrator

- Materialize calculations in extracts already published to Tableau Server
- Improved content browsing (in-release beta)
- Support for Content Security Policy
- Improved support for LDAP
- SSL connection to Rserve external service
- SAML now supports PKCS#8 key files
- Improved key and secrets refresh process
- Backup without compression (added in version 2018.3.2)

Materialize calculations in extracts already published to Tableau Server

If you need to retroactively materialize calculations in extracts that have already been published to Tableau Server, you can use `tabcmd` to refresh the published extract with the `--addcalculations` option. For more information about materializing calculations in extracts, see [Materialize Calculations in Your Extracts](#) in the Tableau User Help. For more information about the `tabcmd` command option, see `refreshextracts workbook-name or datasource-name`.

Secure extract data at the row level

Secure your extract data at the row level using existing approaches for implementing row-level security in Tableau. For more information, see [Restrict Access at the Data Row Level](#) in the Tableau User Help.

Improved content browsing (in-release beta)

With Tableau Online and Tableau Server 2018.3, you and your web users can get a sneak preview of our reorganized content browsing experience. The new experience lets you see multiple content types—views, workbooks, data sources, flows, projects—in one grid or list. For example, you can now see all content inside a particular project and its sub-projects.

This new experience intends to make content discovery more intuitive, and it's the first in a set of planned changes that are aimed at improving self-service and governance of your Tableau content.

Tableau Server on Windows Help

To try the new browsing experience, enable the site-level setting we've provided for it. For more information, see [Preview the Updated Content Browsing Experience](#).

After you enable the new experience, encourage your users to sign in to our [Early Feedback](#) site, share their thoughts with us, and see our regular development updates.

Support for Content Security Policy

Tableau Server supports the Content Security Policy (CSP) standard. CSP is intended to be an additional layer of security against cross-site scripting and other malicious web-based attacks. CSP is implemented as a HTTP response header that allows you to specify where external resources, such as scripts and images, can be safely loaded from.

See [Content Security Policy](#).

Improved support for LDAP

Tableau Server 2018.3 includes improved support for LDAP, such as connection pooling, more flexible root configuration, and commas in object class names. See the new topic, [External Identity Store Configuration Reference](#).

Connections to external services support SSL

In previous versions, SSL connections to Rserve and TabPy were not supported. In Tableau Server 2018.3, you can configure SSL connections. In addition, connecting to external services is now enabling, disabling, and configuring is now done with native tsm commands under tsm security.

SAML now supports PKCS#8 key files

You can now use password-protected key files with SAML. See [Configure Server-Wide SAML](#). The passphrase is encrypted at rest along with other server secrets. See [Manage Server Secrets](#).

Improved key and secrets refresh process

In previous versions of Tableau Server, refreshing server secrets, keys, and tokens required that admins manually copied the keystore to each node in distributed deployments.

In Tableau Server 2018.3, the keystore is distributed to all nodes when you run the `tsm security regenerate-internal-tokens` command.

Backup without compression (added in version 2018.3.2)

Tableau Server version 2018.3.2 introduced a new option for the `tsm maintenance backup` command that allows you to disable compression when doing the backup. This can be beneficial for customers who have backups that take a long time. Using the option speeds up the time for the backup, but results in a larger backup file. If using this command option in a multi-node installation, we strongly recommend you have a File Store instance configured on your initial node to reduce the need to backup across nodes. To learn more about TSM backup, see `tsm maintenance backup`.

Changed in 2018.3

Version 2018.3 includes some changes you should know about before upgrading.

- Connecting to secondary trusted Active Directory domains may result in error
- Floating worksheet captions become transparent
- Changes to some Data Engine `tsm` configuration set options
- SSL Off-loading and SAML

Connecting to secondary trusted Active Directory domains may result in error

A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. Tableau Server will attempt to connect to secondary domains for user and group synchronization. But in some cases, Tableau Server

Tableau Server on Windows Help

will be unable to connect to the secondary domain, which will result in the error, "Domain not in whitelist (errorCode=101015)."

Setting the `wgserver.domain.whitelist` option in TSM is required by a fix for the security vulnerability, [\[Important\] ADV-2020-003: Tableau Server Forced Authentication](#). As of February 2020, the fix for this vulnerability is included in all latest versions and maintenance releases of Tableau Server. See `wgserver.domain.whitelist`.

Floating worksheet captions become transparent

To make a floating caption visible again, content authors will need to change the caption background to a color.

Changes to some Data Engine tsm configuration set options

Two new configuration tsm set configuration options have been added: `hyper.hard_concurrent_query_thread_limit` and `hyper.soft_concurrent_query_thread_limit`

The new options replace the `hyper.num_job_worker_threads` and `hyper.num_task_worker_threads` options available in Tableau Server versions 2018.3 and earlier. The `hyper.num_job_worker_threads` and `hyper.num_task_worker_threads` have been deprecated and will no longer work in 2019.1 and later.

SSL Off-loading and SAML

Beginning with version 2018.3, Tableau Server validates SAML response message returned from the IdP. If your organization terminates SSL connections from the IdP at a proxy server before sending the authentication request to Tableau Server, then users may be unable to login with SAML after you upgrade from 2018.2.

In this scenario, SSL is "off-loaded" at the proxy server, which means the https request is terminated at the proxy server and then forwarded to Tableau Server over http. Since SSL is off-loaded at the proxy, Tableau Server will validate with the protocol that it receives (http), but the IdP response is formatted with https, so validation will fail unless your proxy server

includes the X-Forwarded-Proto header set to `https`. See [Configure Tableau Server to work with a reverse proxy server](#).

Version 2018.2

Added in 2018.2

Version 2018.2 includes the following new features.

User

- Include colleagues on data conversations with @mentions

New features and enhancements related to web authoring and interacting with views on the web are listed in [What's New in Tableau for Users](#) and [Web Authoring and Tableau Desktop Feature Comparison](#). For topics related to web authoring and interacting with views, see [Using Tableau on the Web](#).

Server or site administrator

- Tableau Services Manager
- Dynamic topology support
- Lightweight Directory Access Protocol (LDAP) support
- Support for using SAML SSO with Kerberos database delegation
- Manage Dashboard Extensions in Tableau Server

Include colleagues on data conversations with @mentions

To engage people in a conversation about compelling data you find in a view, @mention them in comments. As you begin to type a name, matching people with Tableau accounts at your organization appear in a list you can choose from. For more information, see [Comment on Views](#) in Tableau User Help.

Site administrators can disable @mentions in the General section of site settings.

Tableau Services Manager

Tableau Server version 2018.2 introduced our new web-based server configuration and management application, Tableau Services Manager (TSM). TSM replaces tabadmin and the Server configuration utility from earlier versions. To learn more about TSM, see [Tableau Services Manager Overview](#).

Dynamic topology support

The introduction of TSM enables support for dynamic, or "hot" topology changes. This allows you to change the number of Backgrounder and VizQL processes running on nodes that already have these processes - without the need to restart Tableau Server. To learn more about these and other Tableau Server processes, see [Tableau Server Dynamic Topology Changes](#).

Lightweight Directory Access Protocol (LDAP) support

Tableau Server now supports Lightweight Directory Access Protocol (LDAP). To learn more about LDAP support in Tableau Server, see [Identity Store](#).

Support for using SAML SSO with Kerberos database delegation

In a Windows Active Directory (AD) environment, you can enable SAML single sign-on (SSO) to Tableau Server, along with Kerberos database delegation. This provides authorized users direct access to Tableau Server, as well as to the underlying data defined in their published workbooks and data sources. See [Use SAML SSO with Kerberos Database Delegation](#).

Manage Dashboard Extensions in Tableau Server

Dashboard extensions are web applications that provide users new ways to interact with data from other applications directly in Tableau. You can control the dashboard extensions that you allow to run in Tableau. You can manage an extension's access to data and can block extensions to prevent them from running. To learn more about controlling extensions, see [Manage Dashboard Extensions in Tableau Server](#).

Changed in 2018.2

Version 2018.2 includes some significant changes you should know about before upgrading. The following sections summarize the significant changes to Tableau Server 2018.2 and provide links for additional information.

- [Tableau Services Manager](#)
- [Moving the repository in a two-node cluster not supported](#)
- [Updates to Tableau Server Apache Logs](#)
- [The Read Only site role is now deprecated](#)
- [The tabcmd initialuser command prompts for password](#)

Tableau Services Manager

Beginning with version 2018.2, Tableau Server on Windows is available with Tableau Services Manager (TSM). TSM is the web-based server configuration and management utility that replaces the Server Configuration utility and the `tabadmin` command line utility. For server administrators who are familiar with earlier versions of Tableau, this means a lot of changes. You can learn about TSM and how it differs from the earlier configuration utility and `tabadmin`, by reading these topics:

- [Comparing Functionality of `tabadmin` and TSM](#)
- [Migrate from `Tabadmin` to the TSM CLI](#)

Upgrading from an earlier version of Tableau Server (version 2018.1 or earlier) requires some special steps. If this is your situation, be sure to read this topic:

- [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#)

Moving the repository in a two-node cluster not supported

With the introduction of Tableau Services Manager (TSM), you can no longer move the repository off the initial (primary) node in a two-node cluster. In versions 2018.1 and earlier, you could add a second repository to your second node and then remove the first repository. With TSM you cannot add a second repository on a two-node cluster, and this means you cannot move the repository off the initial node.

Updates to Tableau Server Apache Logs

Apache log files stored in `/logs/httpd` now contain records with several formatting improvements, including the following:

- Server names are shown according to the `UseCanonicalName` setting, which makes it easier to distinguish between nodes in a multi-node server deployment.
- Date and time are now tracked in a single date-and-time string that can be readily recognized as a single value by a variety of data analysis tools, including Tableau Desktop.

- Time zones are now easier to parse
 - On Linux, the numerical offset from UTC is provided.
 - On Windows, the name of the timezone is enclosed in quotes

Date, time and time zone formatting changes are illustrated by an example log entry from Tableau Server version 2018.1 and earlier releases:

```
::1 - - 2018-05-09 08:51:48.872 GMT Daylight Time 80 "POST
/vizql/w/Re-
gional/v/Obesity/sessions/A971A92AF77A4F4A9813065BDCEB24D6-0:0/-
commands/tabsrv/render-tooltip-server HTTP/1.1" "-" 200 445
"593" 135021 WvKolPH4UcM5KrzUblI8EwAAA@E
```

For purposes of comparison, here is a log entry from Tableau Server version 2018.2:

```
10.210.24.3 127.0.0.1 - 2018-05-09T16:07:58.120 "GMT Daylight
Time" 80 "POST /vizql/w/Su-
per-
store/v/Over-
view/-
bootstrapSession/sessions/185CCDC854A44765BB0298E93B403879-0:3
HTTP/1.1" "-" 200 136026 "784" 2370951 WvMOzgKIh-
fzh9kFWO@ow2gAAA1Y
```

The Read Only site role is now deprecated

The **Read Only** site role that was introduced in Tableau Server version 2018.1 is now deprecated. Any users assigned to the **Read Only** site role in version 2018.1 are reassigned to the **Viewer** site role after an upgrade to version 2018.2. To learn more about site roles, see [Set Users' Site Roles](#).

The `tabcmd initialuser` command prompts for password

In previous versions, the `tabcmd initialuser` command required a `--password` parameter to set the initial administrator password. In the `tabcmd` included with this version of

Tableau Server on Windows Help

Tableau Server, you can leave the `--password` parameter out of the command to be prompted in the shell instead. See `initialuser`.

Plan Your Deployment

The articles in this section provide information on planning a Tableau Server deployment.

In addition to consulting the articles in this section, we recommend that you review [Tableau Blueprint](#) as a first step in your planning workflow. Tableau Blueprint is a step-by-step guide to becoming a data-driven organization.

Comparing Functionality of tabadmin and TSM	95
Server Administrator Overview	108
Tableau Services Manager Overview	117
Infrastructure Planning	120

Comparing Functionality of tabadmin and TSM

The 2018.2 version of Tableau Server on Windows includes an updated management tool set called Tableau Services Manager (TSM), which replaces the legacy tabadmin CLI and GUI tool sets. Most of the functionality that was included with the legacy tool sets has been ported to TSM. The following list describes legacy functionality that has either not been ported directly or is no longer implemented in Tableau Server.

Note: Looking for tabadmin or Configuration Utility content for older versions of Tableau Server on Windows? See the archived online help on the [Tableau Help](#) page.

TSM is used to manage server-level configurations of Tableau Server. Access to TSM is available with a command-line interface (CLI) or a web interface. It replaces the following tools from previous versions of Tableau Server:

- Tableau Server Configuration utility
- tabadmin command-line utility

- Tableau Server Monitor

As a shorthand, this topic refers to these legacy tools as "tabadmin." In previous versions of Tableau Server on Windows, for example, you used tabadmin to perform the following tasks that are now performed with TSM:

- Initial configuration of Tableau Server after installation
- Ongoing configuration management, including editing settings and changing the server topology
- Running administrative tasks such as backup, restore, ziplogs, and more

To learn more about how to interact with and use TSM, see [Tableau Services Manager Overview](#).

To see the mapping between the legacy tabadmin CLI commands and the TSM commands, see [Migrate from Tabadmin to the TSM CLI](#).

Features only available from the TSM command line

The features and functionality described in this section were previously available in the Tableau Server Configuration utility. The features and functionality below are not exposed in the TSM web UI and must therefore be configured with the TSM CLI.

Preferred active repository

The Tableau Server Configuration utility had an option to set the preferred active repository. With TSM you need to do this using the CLI command `tsm configuration set -k postgresql.preferred_host`. For more information, see "Preferred active repository" in [Tableau Server Repository](#).

Data cache configuration

In previous versions, the Tableau Server Configuration utility provided a graphical UI to configure data caching. In the TSM version of Tableau Server, you must configure caching with the TSM CLI. See [Configure Data Cache](#).

Initial install-only settings

In previous versions, the Tableau Server Configuration utility provided a graphical UI to change the gateway port and to install samples, even after installation. With TSM, you can still specify these options in the Web UI during installation, but after install is complete, you can only change them with command-line tools.

See Tableau Services Manager Ports and publishesamples.

Initial SQL

In previous versions of Tableau Server, you could configure server to ignore initial SQL statements by selecting the **Ignore initial SQL statements for all data sources** option on the **Data Connections** tab of the Tableau Server Configuration utility. This configuration option is not included in the TSM Web UI. To configure server to ignore initial SQL statements, use the tsm configuration set command:

```
tsm configuration set -k vizqlserver.initialsql.disabled -v true
```

Site SAML

While the core SAML configuration options are included in the TSM web UI, to configure site SAML, you must use the TSM CLI. See Configure Site-Specific SAML.

SAP HANA SSO

See Configure SAP HANA SSO.

Rebuilding the Search Index

In Tableau Server versions prior to 2018.2, the Status page in Tableau Server included an option to rebuild the Search & Browse index. This was not the recommended way to rebuild the index, and the option has been removed beginning with 2018.2. Instead, use the `TSM maintenance reindex-search` command. For details, see `tsm maintenance reindex-search`.

Differences in functionality

This section describes the difference of functionality in TSM implementation as compared to the admin experience in the legacy tabadmin versions of Tableau Server on Windows.

Host name configuration

With TSM you cannot change the hostname after Tableau Server has been installed.

Archive logs requires local administrator privilege

In the legacy tabadmin versions of Tableau Server, site admins could generate archive log snapshots from the Tableau Server Admin Pages. In the TSM version of Tableau Server, the log snapshot functionality is restricted to administrators with TSM access. The account running TSM web UI or CLI must be a member of the local administrators group on the Windows computer running Tableau Server. See [Log File Snapshots \(Archive Logs\)](#).

Windows Firewall configuration

Setup no longer attempts to configure the Windows Firewall. Before you install Tableau Server, verify that the appropriate ports are open on the local firewall. See [Local firewall configuration](#).

Backup and restore process

In the TSM version of Tableau Server, you have more control over what Tableau Server data is backed up. With TSM, you use the `tsm maintenance backup`, `tsm settings export`, and `tsm settings import` commands to back up and restore your installation of Tableau Server. The `tsm maintenance backup` command will not back up server configuration data, and the `tsm maintenance restore` command will not restore configuration data (even if you are restoring a backup created by tabadmin). See [Perform a Full Backup and Restore of Tableau Server](#).

Backup and restore processes write and read files to and from fixed locations. Unlike with Tableau Server 2018.1 and earlier, you cannot specify a file location when you run the command. For more information, see [Fixed file locations](#) below.

Asset keys

Asset keys are now included with backup files. If you are restoring a backup where you included regenerated asset keys in legacy tabadmin, then you'll need to import that .yaml file as part of the TSM restore process. See [Perform a Full Backup and Restore of Tableau Server](#).

Configuration import and export

In the legacy tabadmin versions of Tableau Server, configuration and topology information was managed as part of the backup and restore process. With the introduction of TSM, you can now export and import your configuration and topology information using the tsm settings commands.

Kerberos configuration

In the legacy versions of Tableau Server, the Tableau Server Configuration utility included an option on the Kerberos tab that generated a configuration bat script for your domain admin to run. This script set service principal names and created keytab files for the Run As service account. In the TSM version of Tableau Server, we have documented this bat script so you can prepare it for your admin. See [Understanding Keytab Requirements](#).

File storage

In the TSM version of Tableau Server, a new process called client file service (CFS) handles distributing files in a multi-node deployment. You must use TSM CLI or web interface to upload files that are managed by CFS. See [Tableau Server Processes](#).

Ziplogs collects two days of log files

By default the `tsm maintenance ziplogs` command collects up to the last two days of log files instead of up to the seven days collected by `tabadmin ziplogs`. You can change this behavior using command line switches for the command. See `tsm maintenance ziplogs`.

TSM is a batch file

TSM is a batch file. When you run TSM commands at the command line, you are invoking a batch file (`TSM.cmd`). This means that if you are scripting or automating server maintenance or configuration in a batch file, you need to use the `call` command (for example, `call tsm maintenance ziplogs`) so that control is returned to the batch file.

You need to authenticate to use TSM

Unlike with `tabadmin`, where you could only run commands on the local computer where Tableau was installed, TSM allows you to run commands remotely, either from the Web UI or the CLI. This flexibility means that you need to sign in to TSM before running any commands. To sign in to the Web UI, open the TSM web page: `https://<tsm_computer>:8850` and sign in when prompted. To sign in to the CLI, use the `tsm login` command.

Cleanup and clear cache

In the TSM version of Tableau Server, clearing the cache, and other optional clean up operations are included in the `tsm maintenance cleanup` command.

Web Data Connectors

In the legacy `tabadmin` versions of Tableau Server, you could both import Web Data Connectors (WDCs) and add them to a safe list. In the TSM version of Tableau Server, you can add WDCs to a safe list using the `tsm data-access web-data-connectors add` command and the `web-data-connector-settings` Entity. To learn more about WDC support in Tableau Server, see [Web Data Connectors in Tableau Server](#).

Uninstall and remove Tableau Server

In the legacy `tabadmin` versions of Tableau Server, you uninstall using Windows Control Panel, and the uninstall process leaves behind files and other Tableau Server configurations.

With TSM, uninstalling Tableau Server differs in these ways:

- You should not uninstall Tableau Server while upgrading from a TSM version (2018.2.x or later) to a TSM version. After the upgrade is complete, you can uninstall your previous version using Windows Control Panel.
- Do not use Windows Control Panel to uninstall Tableau Server if your install or upgrade attempt fails. In these situations, use the `tableau-server-obliterate` script described below to completely remove Tableau Server from your computer.
- Using Windows Control Panel to uninstall Tableau Server does not create a backup of your data. You should create a backup using the `tsm maintenance backup` command and save the backup file to a safe location on a computer that is not part of your Tableau installation.
- To *completely* remove Tableau Server, use the `tableau-server-obliterate.bat` script. This removes all Tableau Server files and configurations. As a best practice, you should restart the computer after running the `obliterate` script.

For more information about uninstalling and removing Tableau Server, see [Uninstall Tableau Server](#).

Tableau Server \bin directory

The `\bin` directory has moved.

- In `tabadmin` installations, the default `\bin` directory is `\Program Files\Tableau\Tableau Server\<version>\bin`.

- In TSM installation, the default `\bin` directory is `\Program Files\Tableau\Tableau Server\packages\bin.<version_code>`.

Tableau Server installation directory

Tableau now is installed into a `\packages` folder.

- In tabadmin installations, the default installation location is `C:\Program Files\Tableau\Tableau Server\<version>`.
- In TSM installation, the default installation location is `\Program Files\Tableau\Tableau Server\packages\` with a versioned subfolder for each process or service. For example: `C:\Program Files\Tableau\Tableau Server\packages\bin.20182.18.1214.0751`

Fixed file locations

In tabadmin you could specify a file location for files generated or used by commands such as backup, restore, and ziplogs. With TSM you cannot specify the location when running the equivalent command, but you can set the fixed file location before running the command by using a `basefilepath` variable. For details on which commands read from or write to a fixed file location, and how to change that location, see [tsm File Paths](#).

Log file snapshots

The location you go to generate a log file snapshot has changed with TSM. With versions of Tableau Server on Windows prior to 2018.2, you could generate a log file snapshot and download it from the Status page of Tableau Server. With TSM you do this on the TSM Maintenance page. New in TSM is the ability to upload a log file snapshot directly to Tableau Support. For more information on how these two features work in TSM, see [Log File Snapshots \(Archive Logs\)](#).

Changes in high availability and distributed deployments

With TSM, we've changed the language we use to describe the Tableau Server nodes in a distributed installation. Prior to the release of TSM we referred to the first node as the "primary" node, and any additional nodes as "worker" nodes. With TSM the nodes are more similar to each other than in prior releases, so we refer to the first node as the "initial" node, and other nodes as "additional" nodes. The initial node includes some TSM-specific processes that are not installed on additional nodes, including the TSM Controller and the License Server. Tableau includes a script to move these key processes over to another node in your installation if a problem occurs on the initial node. For details, see [Recover from an Initial Node Failure](#).

The installation process for distributed deployments has also changed.

- **Common installer file**—In version 2018.1 and earlier, deployments required two separate installers. With 2018.2 and TSM, you run the same installer for all nodes and indicate if you are installing on the initial node or additional nodes.
- **No auto-discovery of nodes**—With versions of Tableau Server prior to 2018.2, once you installed all nodes, you ran the Server Configuration utility and added worker nodes to the primary. With TSM, after installing the initial node, you generate a bootstrap configuration file and use this when you install all additional nodes. For more information about installing a multi-node cluster, see [Distributed and High Availability Tableau Server Installations](#).
- **Coordination Service installation**—When you configure a multi-node installation of Tableau Server you need to also deploy a Coordination Service ensemble to your additional nodes. In versions of Tableau Server on Windows prior to 2018.2, additional instances of the Coordination Service were automatically added as you added a total of three or five nodes. Now you need to manually deploy the Coordination Service. For more information on how to do this, see [Deploy a Coordination Service Ensemble](#).
- **No "backup primary"**—There is no longer a need for a "backup primary" node, and

TSM does not support creating a backup for the initial node. With TSM, if your initial node encounters a problem, you move the key processes from that node to another of your cluster nodes using a script. For more information on how to do this, see [Recover from an Initial Node Failure](#).

Upgrade process changes

Your upgrade steps depend on which version you are upgrading from. Upgrading from legacy tabadmin Tableau Server (2018.1.x or earlier) to a TSM version (2018.2 or later), requires special steps.

- **Upgrading from version 2018.1 or earlier:** If you are upgrading from Tableau Server on Windows version 2018.1 or earlier to Tableau Server on Windows version 2018.2 or later, read the key aspects below, then see [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#) for detailed upgrade instructions.

- **Upgrading from version 2018.2 or later:** If you are upgrading from Tableau Server on Windows version 2018.2 or later, read [Upgrading from 2018.2 and Later \(Windows\)](#). Do not follow the steps for a pre-TSM to TSM upgrade.

Below are key aspects of upgrading Tableau Server from version 2018.1 or earlier to version 2018.2 or later that you need to be aware of.

All upgrades:

- **Local administrator**—Sign in as a local administrator. You need to be signed into the Tableau Server computer as a "local admin" to run the Tableau Server Setup program, and to run scripts related to upgrading. A "local admin" is a user who's a member of the Administrators group in the Local Users and Groups management console in Windows.
- **Local security policy**—Verify that your local security policy will allow "log on as a

service" and "log on locally" permissions for the Run As service account. For details, see [Verify the Local Security Policy](#).

- **Run As**—Read and understand these Run As service account requirements: [Required Run As Service Account Settings](#).
- **Windows Accounts and Permissions**—Read and understand these Windows account requirements: [Windows Accounts and Permissions](#).
- **Ports**—Before upgrading, read and understand the requirements for ports: [Tableau Services Manager Ports](#).
- **Licenses**—
 - **Trial product keys**—You cannot directly upgrade a server that is running a trial product key from one major version to another (for example, from version 10.5.x to version 2018.x). To upgrade from one major version to another with a trial product key, install the new version of Tableau Server on a separate machine, activate a trial key there, and restore a backup from your existing version. For more information, see [Server Upgrade - Verify Licensing Status](#).
 - **Expired maintenance**—You cannot upgrade a server with a product key whose maintenance has expired or expires on a date earlier than the release date of the version you are upgrading to. If you attempt to upgrade a server in this state, your server will be unlicensed and the upgrade may fail. If your maintenance has expired or is too old, use the **Manage Product Keys** application to refresh your product key *before* you uninstall your original version. If refreshing the key does not update maintenance to a valid date, check in the Tableau Customer Portal for a Tableau Server key with current maintenance.
 - **Uninstall**—Use Windows Control Panel to uninstall your existing pre-TSM version of Tableau Server before upgrading. This special-case upgrade is unlike upgrades in earlier versions, which automatically uninstalled the previous version of Tableau

Server. When you upgrade from version 2018.1 or earlier to version 2018.2 or later, you *must uninstall* your earlier version yourself. If you have not uninstalled your earlier version, you will be prompted to do so when you attempt to install your new version. This is specific to upgrades from 2018.1 or earlier to 2018.2 or later.

- **Backup**—Save a backup of your earlier version to a safe place on a different computer. Uninstalling your previous version of Tableau Server will create a backup in the Tableau data directory (by default: `C:\ProgramData\Tableau\Tableau Server`). We **strongly** recommend you copy this backup to a computer that is not part of your Tableau Server installation before upgrading. This provides you with an up-to-date version of your data you can use if you need to go back to your earlier version of Tableau Server. For more information on properly preparing for an upgrade, see [Preparing for Upgrade](#).

Backups from versions of Tableau Server older than version 9.x cannot be used with version 2018.2.x or later. If you are running an older version of Server, you may need to do an intermediate upgrade to version 9.x through 10.x before upgrading to version 2018.2 or later.

- **Firewall management**—Firewall management is manual. Unlike earlier versions of Tableau Server, you must manage the local firewall on any computers where you run Tableau Server. For more information, see [Local firewall configuration](#).
- **Upgrade script**—After installing the new version, complete the upgrade and switch to the new version by running the `upgrade-tsm.cmd` script. The script is installed in the `\scripts.<version_code>` folder of the new version you just installed. By default: `C:\Program Files\Tableau\Tableau Server-\packages\scripts.<version_code>\`

Tableau Server must be stopped to complete the upgrade. If Tableau Server is not stopped when you run the script, the script will let you know, and will offer to stop the server. You can also choose to stop the server before running the script using the `tsm stop` command.

Tableau Server on Windows Help

- **Antivirus software**—Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Multi-node upgrades:

- **Multi-node terminology**—With TSM, we've changed the language we use to describe the Tableau Server nodes in a distributed installation. Prior to the release of TSM we referred to the first node as the "primary" node, and any additional nodes as "worker" nodes. With TSM the nodes are more closely peers, so we refer to the first node as the "initial" node, and other nodes as "additional" nodes.
- **Uninstall**—Use Windows Control Panel to uninstall your existing pre-TSM version of Tableau Server from all nodes before upgrading. If you have not uninstalled your earlier version, you will be prompted to do so when you attempt to install your new version.
- **Node installation**—Run the Setup program on all nodes in a cluster. Unlike some distributed installation upgrades in versions prior to 2018.2.0, there is no automatic upgrade of any additional nodes.
- **Single installer**—Use the same Setup program on all nodes. Starting with 2018.2.0 you use the same installer on all nodes, and specify when prompted whether you are upgrading the initial (primary) node, or an additional (worker) node. There is no separate installer for the additional nodes.
- **Upgrade script**—After installing the new version on all nodes in your cluster, complete the upgrade and switch to the new version by running the `upgrade-tsm.cmd` script on the initial node in the cluster.

Tableau Server must be stopped to complete the upgrade. If Tableau Server is not stopped when you run the script, the script will let you know, and will offer to stop the

server. You can also choose to stop the server before running the script using the `tsm stop` command.

Functionality that is not implemented in TSM

- Restore config data from a backup file (.tsbak). The legacy version of `tabadmin` backup included configuration data by default. The analogous TSM command, `tsm maintenance backup`, does not include config data. To back up and restore config data in TSM, use the `tsm settings` commands.
- With the introduction of Tableau Services Manager (TSM), you can no longer move the repository off the initial (primary) node in a two-node cluster. In versions 2018.1 and earlier, you could add a second repository to your second node and then remove the first repository. With TSM you cannot add a second repository on a two-node cluster, and this means you cannot move the repository off the initial node.

Server Administrator Overview

Tableau Server on Windows integrates with a number of components in your IT infrastructure to provide a unique self-service data analytics culture for your users. It's important that you, as a server administrator, understand how Tableau Server fits into your IT infrastructure.

The topics in this section provide information on planning, deploying, tuning, and managing Tableau Server.

If you are new to Tableau Server, and you want to deploy it in your organization, we encourage you to deploy Tableau Server as a single server in a test environment first. The easiest way to do a single-server installation and to understand the essential requirements is to follow the steps in [Everybody's Install Guide](#).

If you are deploying Tableau Server as part of a broader effort to transform your organization into a data-driven culture, see [Tableau Blueprint](#). Tableau Blueprint is a step-by-step guide to becoming a data-driven organization, whether your organization is new to modern,

Tableau Server on Windows Help

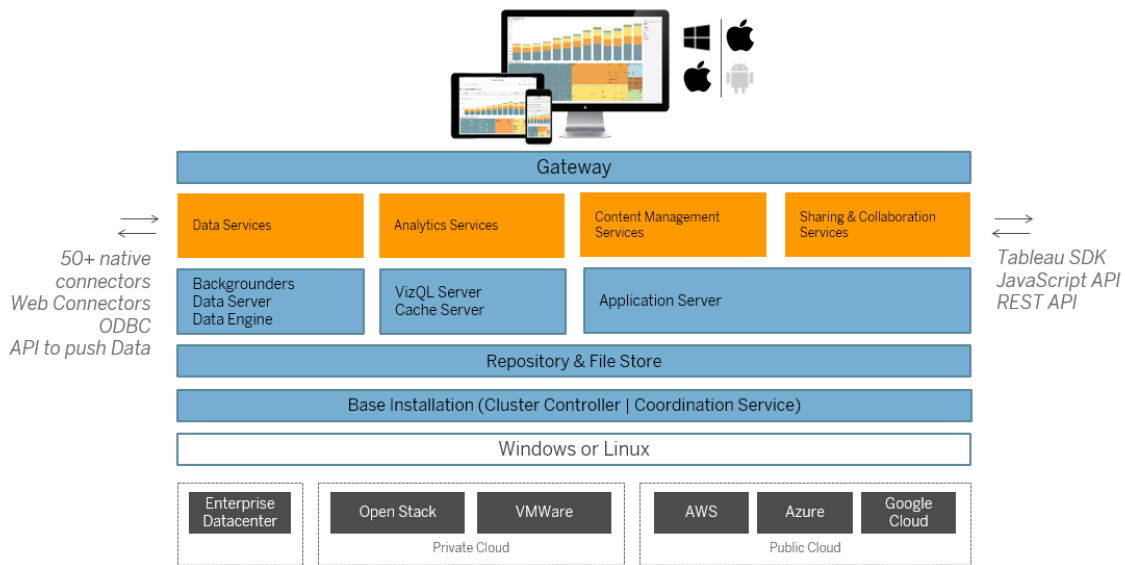

self-service analytics or you've already deployed and need to broaden, deepen, and scale the use of data.

This topic provides a brief overview of how to think about Tableau Server and how it interacts with your existing IT infrastructure.

Looking for Tableau Server on Linux? See [Server Administrator Overview](#).

Architectural overview

Tableau Server is a collection of processes that work together to provide a full self-service analytic platform for your users. The following diagram shows a high-level architectural view of Tableau Server.

Multiple server processes (shown in blue above) work together to provide services at various tiers. The Gateway process is the component that redirects traffic from all Tableau clients to the available server nodes in a cluster.

Data Services is a logical grouping of services that provide data freshness, shared meta data management, governed data sources, and in-memory data. The underlying processes that power Data Services are the Backgrounder, Data Server and Data Engine processes.

Analytics Services, composed of the VizQL and Cache Server processes, provide user-facing visualization and analytics services and caching services.

Sharing and Collaboration, and Content Management Service are powered by the Application Server process. Core Tableau Server functionality such as user login, content management (projects, sites, permissioning, etc.) and administration activities are provided by the Application Server process.

All of the above services use and rely on the Repository process, which contains structured relational data like metadata, permissions, workbooks, data extracts, user info, and other data. The File Store process enables data extract file redundancy across the cluster and ensures extracts are locally available on all cluster nodes. Under heavier loads, extract files are available locally across the cluster for faster processing and rendering.

Tableau's architecture is flexible, allowing you to run the platform just about anywhere. You can install Tableau Server on-premises, in your private cloud or data center, on Amazon EC2, on Google Cloud Platform, or on MS Azure. Tableau analytics platform can also run atop virtualization platforms. We recommend you follow the best practices for each virtualization platform to ensure the best performance from Tableau Server.

Tableau and your data

When you install Tableau Server into your organization, it becomes a core component of the analytics pipeline to the data your users need. It's important to understand how Tableau Server interacts with your business data. Specifically, Tableau Server can store extracts of data in your organization. It can also connect to live data sources. How you choose to provide the data to your Tableau users is informed by a number of variables: data source type, user scenario, performance and access requirements, and infrastructure conditions.

Tableau Server on Windows Help

Tableau Server has not been architected as a data warehouse server where static, native data files are housed. In fact, using Tableau Server as a traditional data warehouse is a poor use of your investment. Rather, when it comes to data storage, we recommend hosting optimized data extracts on Tableau Server. While a data extract is often a subset of a larger data source in your organization, you can also create extracts for data sources that are over-taxed during work hours by [scheduling the extract refresh](#) for off-hours.

Extracts are also useful for modeling data or to enable highly-performant visualization authoring. For example, to improve visualization authoring and interaction performance you may optimize extracts by filtering the source data to the essential fields for a given department or project. Extracts can be resource intensive. If your organization plans to make heavy use of extracts, review the topic, [Optimize for Extracts](#).

Tableau Server also provides direct, authorized access to live data sources, allowing users to build and run complex filtered queries against a variety of connected data sources. For this scenario, Tableau requires highly performant network access to the data sources in your organization and to those in the cloud. Tableau Server and the target data sources also need to be properly sized to handle the processing load required by high-volume, complex data operations. You can optimize performance for live data connections with caching configurations and specifying initial SQL commands.

User access

Tableau Server is also a web-based collaboration platform, where users connect to share, view, and interact with data visualizations and data sources from a variety of devices. This means that Tableau Server must be accessible to Tableau users within your local protected network. You can also extend access to data visualizations to desktop, mobile, and authenticated web users outside your organization.

Tableau Server integrates with the following user [authentication](#) solutions: Active Directory, SAML, OpenId, and Kerberos.

Where should I install Tableau Server in my network?

Because of the highly-sensitive nature of most data that organizations manage with Tableau Server, and because Tableau Server requires access to internal data stores, Tableau Server must be run inside a protected network. Authenticated access from the internet is configured to connect to Tableau Server through a **reverse proxy** or a VPN solution.

Some organizations embed Tableau views in public webpages, or, for internal users, on generic web servers on the internal network.

Tableau Server can be configured to support such scenarios with either authenticated or anonymous access. For authorized access, where users can only view underlying data to which they have permission, you can configure trusted tickets with a generic web server. In this scenario, Tableau Server authorizes access to the underlying data in an embedded view. This scheme enables you to host interactive data visualizations on a web server in a DMZ or outside the protected network.

Anonymous access to embedded Tableau views requires that you enable "**guest user**" for Tableau Server. Guest user also requires that you license Tableau Server according to the number of cores you are running, rather than a named-user (interactor) model.

Sizing and scalability

Depending on the size and data usage in your organization, you can scale Tableau Server up or out. As you scale your server, you can also selectively allocate resources to meet your data needs and user needs.

When you scale up Tableau Server, you add hardware resources to a single server. For example, you might increase the memory and processing power of the computer running Tableau Server.

When you scale out Tableau Server, you add computers (or nodes). To create a highly available deployment with failover, you need at least three nodes. For example, you might run most CPU-intensive server processes on two nodes and use the third node for the gateway and coordination controller services.

Whether you scale up or scale out, you can selectively allocate resources by configuring the number and type of server processes that run. If your organization has a lot of data and creates a lot of data extracts, you can increase the number of processes that are dedicated to refreshing and storing extracts. Alternatively, if your organization wants to optimize for heavy user loads, you can increase the number of processes dedicated to responding to user requests. Additionally, you can integrate Tableau Server into industry-standard network load balancers to further optimize your server for user requests.

Tableau Server management model

Tableau Server has been designed to support a management scheme with two high-level administrators: server administrator and site administrator. In small organizations, these roles may be assumed by the same person or team, but in larger organizations, the roles often diverge.

In this model, server administrators are IT professionals who maintain and deploy heterogeneous server solutions. Essential areas for server administrators may include networking, hardware tuning and maintenance, security and access, and managing users and

directory services. The tools and documentation that we deliver with Tableau Server for the server administrator support these core server IT areas.

Site administrator, on the other hand, is an administrative role specific to Tableau Server or Tableau Online deployments. The Tableau site administrator is fundamentally concerned with data content. The site administrator manages users and their access to projects, workbooks, and data sources. To learn about sites and how to plan your deployment for them, see [What is a site](#)

Administrative roles

In some small organizations a single administrator may manage the entirety of Tableau Server. But for bigger enterprise organizations, Tableau Server usually requires at least three administrative roles for management at scale.

Tableau Server administrator

The Tableau Server administrator has access to administrative pages for creating and editing sites, adding users and setting roles, and many content-related tasks after the Tableau Server installation is complete. The Tableau Server administrator also creates and manages other server and site administrators, who in turn may manage sites, user groups, and projects.

For information about signing into Tableau Server as a Tableau Server administrator, see [Sign in to the Tableau Server Admin Area](#).

TSM administrator

Tableau Services Manager (TSM) is a tool that gives server administrators command-line and web-based options for installing, upgrading, configuring, and maintaining Tableau Server. The TSM administrator installs the server and performs server-related administrative task like backing up server data, restoring backups, creating log archives, and managing multi-node clusters.

Tableau Server on Windows Help

The TSM administrator must be an administrator on the local computer. See [Sign in to Tableau Services Manager Web UI](#).

Common tasks performed by the TSM administrator include:

- Initial configuration of Tableau Server after installation
- Ongoing configuration management, including editing settings and changing the server topology
- Running administrative tasks such as backup, restore, and ziplogs

To learn more about TSM, see [Tableau Services Manager Overview](#).

Tableau portal administrator

An important administrative role in a Tableau Server deployment is the Tableau customer portal administrator. The portal administrator manages licensing and the associated keys for the Tableau deployment. As the portal administrator, your first step is to purchase licenses on the [Tableau Customer Portal](#). When you purchase licenses, the portal will return corresponding product keys. To renew your license, visit the [Tableau renewal](#) web page.

Tableau has a number of products (e.g. Desktop, Server, Prep Builder, Add-ons, etc). Each of the Tableau products require that you activate licenses by updating the Tableau software with the product keys that are purchased and stored on the Tableau Customer Portal. As the administrator who is tasked with activating Tableau licenses, it important that you understand the relationship between licenses and keys. See [Understanding License Models and Product Keys](#).

Management tools

Tableau Server includes a number of toolsets for managing the system:

- **Tableau Server administrator page:** This is the web-based administrative site that is installed on each Tableau Server instance. Tasks performed on the administrator page are day-to-day tasks for both server and site administrators. Server-related tasks include creating sites and site administrator accounts, optionally importing users, setting up synchronization with directory services, setting up extract refresh schedules, monitoring server performance and usage, and other global settings.

Site-related tasks include managing content and assign permissions, running extract refreshes, create groups and projects, monitoring site activity, optionally adding users, and other content-related tasks.

See [Navigate the Admin Areas of the Tableau Web Environment](#).

Permissions required for the Tableau Server administrator page are based on site roles. The site roles are generated and managed by Tableau Server.

- [tsm Command Line Reference](#) - This is the primary interface for server-wide configurations. Many configurations made with TSM CLI are rarely revisited after initial configuration. For example: SSL, subscriptions, data caching, service account, SMTP alerting, user authentication, and single-sign on configuration are all performed with TSM CLI.
- You can also Sign in to Tableau Services Manager Web UI.
- **tabcmd**: You can use the tabcmd command-line utility on a Windows or Linux computer to create scripts to automate administrative tasks on your Tableau Server sites. For example, use tabcmd for creating or deleting users, projects, and groups.
- **REST API**: With the Tableau Server REST API you can manage and change Tableau Server resources programmatically, via HTTP. The API gives you simple access to the functionality behind the data sources, projects, workbooks, site users, and sites on a Tableau server. You can use this access to create your own custom applications or to script interactions with Tableau Server resources.

Security

As an application server connecting to data that may be highly-sensitive, Tableau Server supports and implements a number of industry security standards. Our server admin documentation includes best practices and implementation for user authentication, authorization, data security, and network security. While our default installation is secure by design, we also recommend following the [security hardening checklist](#) to further lock down your deployment.

For more information about security audit compliance, vulnerability reporting, and other security resources, visit <http://www.tableau.com/security>.

Tableau Services Manager Overview

This article provides an overview of Tableau Services Manager (TSM), which you can use to configure and administer Tableau Server. Beginning with version 2018.2, TSM is available for Tableau Server on Windows, both as a CLI and as a Web UI.

- [Functionality](#)
- [Components](#)
- [Authentication](#)
- [Connecting](#)

Functionality

TSM gives server administrators command-line and web-based options for configuring and maintaining Tableau Server, including performing administrative tasks like backing up server data, restoring backups, creating log archives, and managing multi-node clusters. For example, you use TSM to perform the following tasks:

- Initial configuration of Tableau Server after installation
- Ongoing configuration management, including editing settings and changing the server topology
- Running administrative tasks such as backup, restore, and ziplogs

For administrators familiar with earlier versions of Tableau Server, TSM replaces the following tools from previous versions of Tableau Server:

- Tableau Server Configuration utility
- tabadmin command line utility
- Tableau Server Monitor

To see a list of differences between these legacy administrative tools and TSM, see [Comparing Functionality of tabadmin and TSM](#).

To learn about how tabadmin commands map to TSM command-line commands, see [Migrate from Tabadmin to the TSM CLI](#).

Components

TSM consists of *services* (called *processes* in this documentation) and *clients*. TSM processes are administrative services which manage Tableau Server processes. TSM processes run continuously after TSM is initialized, even when the rest of Tableau Server is offline.

TSM processes that run, even when Tableau Server is stopped include:

- Administration Agent
- Administration Controller
- Client File Service
- Coordination Service (based on Apache Zookeeper™)
- Service Manager
- Licensing Service

For more information about TSM processes and Tableau Server processes, see [Tableau Server Processes](#).

TSM Authentication

Whether you use the TSM Web UI, the command line interface, or the TSM API, you need to authenticate to Tableau Server before you can perform administrative tasks. This user account is distinct from Tableau Server user accounts, including Tableau Server administrators and site administrators.

You authenticate to TSM with a user that exists on the Tableau Server computer. The TSM user account must use password-based authentication. By default, the TSM user account must be a member of the Administrators group on the computer where Tableau Server is running. Alternatively, you can specify a Windows group for TSM administration after you have installed Tableau Server. See [Configure a Custom TSM Administration Group](#).

Connecting TSM clients

As a security measure, you can only connect to TSM with clients (CLI, Web UI, Rest API) over HTTPS. This is because TSM allows you to perform administrative tasks and to

connect to TSM from other computers.

When you are connecting with a TSM client, you must connect to the Tableau Server instance running the TSM Administration Controller service.

Note: The TSM CLI tool does not require admin credentials in some scenarios. Specifically, if the account you are logged in as is a member of the TSM-authorized group, you do not need to provide credentials to run commands when running tsm CLI locally. For more information, see [Authenticating with tsm CLI](#).

TSM HTTPS connections rely on a self-signed certificate generated by the Tableau Server installer. This certificate is the Tableau installation CA certificate that signs the SSL certificates Tableau creates for encrypting traffic over HTTP. The Tableau installation CA certificate must be trusted by the systems connecting to TSM Administration Controller.

The TSM CLI client validates certificate trust from a different store than the TSM Web UI uses. The TSM CLI client refers to the trusted store in the local Java keystore to validate trust for CA certificates. Since the TSM Web UI must establish connection with a web browser, trust is validated with the operating system's trusted keystore. The difference in how CA certificates are stored determines different trust configuration scenarios as outlined here:

- For TSM Web UI and CLI communications on Tableau Server, the certificate trust is configured by default as part of the installation, node bootstrap, and upgrade processes. The Tableau installation CA certificate is added to the trusted store in both the Java keystore and in the Windows trusted root keystore. This allows you to access TSM from any computer in the cluster without additional configuration.
- For TSM CLI connections from remote computers, you will be prompted to trust the Tableau installation CA certificate the first time you connect to the Tableau Server running TSM Administration Controller. You can choose to trust the CA certificate, in which case you will not be prompted again on that computer until the certificate expires (default is 3 years). Or you can connect with a one-time trust by running your TSM command with the `--trust-admin-controller-cert` flag.
- For TSM Web UI connections from remote computers, the browser will prompt you to trust the host running TSM Administration Controller service.

Infrastructure Planning

Before you install Tableau Server, you should review the disk requirements, recommended configurations, user accounts, security, and networking requirements.

Before you install...

Note: You can find additional information about technical specifications for Tableau Server on the Tableau web site, [here](#).

This topic includes requirements and recommendations that you must consider before you install Tableau Server into a production environment.

- If you want to install a single server, or if you want to do a minimal installation for test purposes, refer to our single-server installation guide, [Everybody's Install Guide](#).
- If you are deploying Tableau Server in a distributed cluster, review Distributed Requirements in addition to the requirements and recommendations described in this topic.

Hardware recommendations for production installations

The following list describes the minimum hardware recommendations for a production use, single- node installation of Tableau Server:

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> • 64-bit (x64 chipsets) • Must support SSE4.2 and POPCNT 	8-core, 2.0 GHz or higher	<ul style="list-style-type: none"> • 64 GB (version 2021.4.0 and later) • 32 GB (versions prior to 	50 GB

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
---------------------	------------------	------------	------------	------------------------

- | | | | | |
|--|--|--|-----------|--|
| | instruction sets | | 2021.4.0) | |
| | <ul style="list-style-type: none"> ARM-based processors are not supported | | | |

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Multi-node and enterprise deployments

Contact Tableau for technical guidance.

Nodes must meet or exceed the minimum hardware recommendations, except:

- Nodes running backgrounder, where 4 cores may be acceptable.
- Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the [Option 2: Backup Repository Separately](#) topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

To see the full list of recommendations and to see the minimum requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

Tableau Server on Windows Help

For public cloud deployments on Amazon Web Services and Google Cloud Platform, their “vCPU” is actually a CPU hyper-thread, and not a full CPU core. When sizing cloud instances, you will need twice as many vCPU as the Tableau Server CPU core requirements given (8 vCPU required for a minimum trial installation, 16 vCPU recommended for a single-node installation).

Operating system requirements

The following 64-bit Microsoft Windows Server operating systems are supported:

- Tableau Server 2021.3.0 and later:
 - Windows Server 2016
 - Windows Server 2019

Earlier versions:

- Tableau Server 2020.1.0 - 2021.2.x:
 - Windows Server 2012
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019
- Tableau Server 2019.1.0 - 2019.x:
 - Windows Server 2008 R2
 - Windows Server 2012
 - Windows Server 2012 R2

- Windows Server 2016
- Windows Server 2019

Note: All nodes in a multi-node cluster must have the same type of operating system. You cannot install a multi-node instance of Tableau Server on a combination of Linux and Windows nodes.

Installation directory

By default, Tableau Server will install on the system drive. The drive where Windows is installed is the system drive. In most cases, the system drive is the C:\ drive. In this default case, Tableau Server will install into the following directories:

- `C:\Program Files\Tableau\Tableau Server\packages`
- `C:\ProgramData\Tableau\Tableau Server`

Do not specify a symbolic link or a data directory location on a Network File System (NFS) volume.

Non-default installation locations

Rather than install onto the system drive, some organization install applications on a separate drive. During setup (or with automated installation), you can specify a different installation location. If you select a different installation drive or folder location during setup, then the data directory for Tableau Server will install into the same path. This means that if you install to a non-default location, the default `C:\ProgramData\Tableau\Tableau Server` path will not be created.

When you install to a non-default location, you must take the following into consideration:

- You may need to configure Run As service account permissions manually. If you do not use the predefined local account, `NetworkServices`, as the Run As service

Tableau Server on Windows Help

account, then you will need to set permissions for the account that you will be using. You must set these permissions after you install Tableau Server. See [Verify Folder Permissions](#).

- **Log files are stored at** `<installation path or drive>\data\tabsvc\logs`. The `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs` path in a default installation is converted to `<installation path or drive>\data\tabsvc\logs`.
- You may need to specify the same location when you upgrade to newer versions of Tableau Server. For more information on upgrading, see [Upgrade Tableau Server Overview](#).

Note: If you run Tableau Server on a VM, either locally, or in the cloud, be aware of the potential for complications related to licensing. This applies whether you are running Tableau Server as a standalone or in a cluster. If you are simply upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment can end up with an untrusted license, and any attempts to upgrade will fail.

To clone a VM, make sure the Tableau Server is unlicensed (all licenses are deactivated). After cloning the VM, activate the Tableau license on the cloned VM and proceed with the upgrade.

- When installing a multi-node instance of Tableau Server, the installation location (path) must be the same on every node.

Tableau Prep Conductor

Tableau Prep Conductor is one of the processes on Tableau Server. It runs a flow, checks connection credentials, and sends alerts if a flow fails. Tableau Prep Conductor leverages the scheduling and tracking functionality of Tableau Server so you can automate running flows

to update the flow output instead of logging into Tableau Prep Builder to manually run individual flows as your data changes.

Tableau Prep Conductor is licensed separately and is available through the Data Management Add-on license. For more information on Tableau Prep Conductor licensing, see [License the Data Management Add-on](#).

We recommend you enable Tableau Prep Conductor on a dedicated node. For more information:

- If you are installing a new Tableau Server, see [Step 1 \(New Install\): Install Tableau Server with Tableau Prep Conductor](#).
- If you are adding Tableau Prep Conductor to an existing installation of Tableau Server, see [Step 1 \(Existing Install\): Enable Tableau Prep Conductor](#).

Additional requirements

Make sure that your environment also meets the following additional requirements:

Hostname

- Tableau Server must be able to resolve the hostname to an IP address either using the domain name server (DNS) or with a local host file on the computer running Tableau Server. By default, host files are stored at `\Windows\System32\Drivers\etc\hosts`.
- The hostname of the server must not change after you start Tableau Services Manager during the setup process. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.
- Hostnames that include underscores (`_`) are not supported by Tableau Server.

Static IP address

The computer where you install Tableau Server must have a static IPv4 or IPv6 address.

Database drivers

Tableau Server on Windows Help

To connect to specific data sources, the computer where you install Tableau Server must have the correct database drivers installed. For more information, see Database Drivers.

Available ports

TSM and Tableau Server each require an available TCP port in order for you to access them. TSM defaults to port 8850, and the Tableau Server Gateway service defaults to port 80. We strongly recommend that you ensure that both port 8850 and 80 are not in use on your system before installing Tableau Server. If those ports are not available, the TSM and gateway ports may be dynamically remapped to different port numbers, and there is currently no interface for displaying which port they have been remapped to.

If you are installing Tableau Server on a computer that's also running IIS (not a recommended deployment), you should modify the Tableau's gateway port number to avoid conflict with IIS. You can specify a different gateway port number during the setup process.

See Tableau Services Manager Ports.

Local firewall configuration

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 can be changed.

Port	TCP/UDP	Used by ...	TYPE OF INSTALLATION	
			All	Distributed / High Availability
80	TCP	Gateway	X	
443	TCP	SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port.	X	

Port	TCP/UDP	Used by ...	TYPE OF INSTALLATION	
			All	Distributed / High Availability
8850	TCP	Tableau Services Manager.	X	
8060	TCP	PostgreSQL database.	X	
8061	TCP	PostgreSQL backup verification port	X	
8000-9000	TCP	Range of ports reserved by default for dynamic mapping of Tableau processes		X
27000-27009	TCP	Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.	X	

See [Tableau Services Manager Ports](#)

For information about configuring the local Windows firewall, refer to the Microsoft product documentation.

Local administrator

The account that you use to run Setup must be a member of the Local Administrators group on the Windows computer where Tableau Server is installed.

By default, you must also use an account with local administrator rights to run Tableau Services Manager (TSM) Web UI and CLI tools. However, after you have installed Tableau Server, you can specify a Windows group for TSM administration. See [Configure a Custom TSM Administration Group](#).

Tableau Server on Windows Help

Use TSM to configure the Tableau Server components that rely on OS-level access, such as processes, authentication, log files, licensing, and alerts. See [TSM Authentication](#).

Tableau-specific administration, such as importing users, creating sites, web authoring, etc. is performed by Tableau Server administrators. You can configure these administrative accounts by assigning roles to users after you install. The initial Tableau Server administrator account is created as part of the installation process. See [Add an Administrator Account](#).

Run As service account

A Run As service account for the Tableau Server service to run under is useful if you're using NT Authentication with data sources or if you're planning on doing SQL Server impersonation. For more information, see [Run As Service Account](#) and [SQL Server Impersonation](#).

In some organizations, Group Policy or other system management solutions are used to standardize permissions and accounts on application servers. If your organization runs a such a solution, be sure to configure the system to accommodate the folder permissions required by the Run As service account. See [Verify Folder Permissions](#).

Antivirus software

Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Continue to the next step: [Install and Configure Tableau Server](#).

Disk Space Requirements

In general, when estimating the amount of additional disk space to allocate for Tableau Server for day-to-day usage, you must consider whether or not extracts will be published to Tableau Server, and consider the number of workbooks that you expect to publish to

Tableau Server . If you anticipate using extracts, Tableau recommends that you begin with a few hundred gigabytes (GB). If you do not anticipate using extracts, you may only need around 50 GB to fulfill your usage needs. To setup drive space alerts, see [Configure Server Event Notification](#).

Looking for Tableau Server on Linux? See [Disk Space Requirements](#).

It is critical for Tableau Server to have adequate disk space. If you run out of disk space on any node in a Tableau Server installation, you can experience erratic performance, including not being able to access Tableau Server or the TSM Web UI. For troubleshooting steps, see [Troubleshoot Disk Space Usage on Tableau Server Nodes](#) in the Tableau Knowledgebase.

Here are the factors that affect disk space requirements and where you might choose to install Tableau Server:

Drive size and type of partition

The type of partition used on your Tableau Server drive can impact the amount of space available to your Tableau Server installation.

- Master Boot Record (MBR) partitions support partitions and hard drives up to 2 terabytes (2T) and can be used on boot drives.
- GUID partition table (GPT) partitioning support partitions and hard drives up to 18 exabytes in size but cannot be used on boot drives. These are a good choice when installing Tableau Server on an additional drive because they provide for so much disk space, allowing enterprises to scale up over time.

Publishing extracts to Tableau Server

Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out

how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.

Refreshing extracts

Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.

While there may be some cases where .hyper extracts become bigger after an extract upgrade, there are other cases when .hyper extracts become smaller after an extract upgrade. In general, the overall disk size requirements should be the same for .hyper extracts as it was for .tde extracts.

Creating many workbooks

If using workbooks, consider the number of workbooks that will be published to Tableau Server. Individual workbooks tend to take up a small amount of disk space. However, if you anticipate thousands of workbooks being published, you may want to allocate additional disk space to accommodate those workbooks.

Logging

To assist with daily management and troubleshooting, Tableau Server creates log files as a part of its normal operations. Depending on the level at which the logging is configured, it can significantly impact the amount of disk space necessary on the Tableau Server computer.

Backup and restore processes

The free disk space required to create a backup varies depending on the amount of data in the Tableau Server repository and file store services, and their collocation with the tabadmincontroller service. During backups, the background tasks for cleaning up old extracts are temporarily paused. This means that, for the duration of the backup, extract refreshes will leave extra files in place, adding to disk space usage. If your backup takes a long time, or if

your organization uses many extracts that are regularly updated, this can result in a significant amount of temporary disk space usage. These temporary files will be removed after the backup is complete.

The following table lists the disk space requirements for backup based on whether the node hosts the repository, file store, controller, or some combination of them.

Repository	File Store	Controller	Disk Space Required
✓			<p>3x repository data + 250 MB</p> <p>To obtain an estimate of the repository data, check the size of <data directory>/pgsql/data/base directory.</p> <p>To obtain the exact size of the repository data, open the backup file and use the size of the workgroup.pg_dump file.</p>
	✓		<p>1.5x file store data</p> <p>To obtain an estimate of file store data (extracts, flows, etc.), check the size of <data directory>/dataengine directory.</p>
		✓	<p>3x repository data + 250 MB + 2.5x file store data</p>
✓	✓		<p>3x repository data + 250 MB + 1.5x file store data</p>
	✓	✓	<p>3x repository data + 250 MB + 1.5x file store data</p>

Tableau Server on Windows Help

			3x repository data + 250 MB + 2.5x file store data
			3x repository data + 250 MB + 1.5x file store data

Restore disk space requirements

You must have adequate disk space for the database restore process to run successfully.

To restore Tableau Server:

- On controller nodes, you need free space equal to at least the size of the backup archive.
- On repository nodes, you need free space equal to at least three times the size of the repository data in the backup archive, plus 250 MB, plus the size of the pgsql data directory.
- On file store nodes, you need free space equal to at least twice the size of the dataengine folder in the backup archive.

Recommended Baseline Configurations

Determining the topology (number of nodes, number of Tableau Server processes) of your Tableau Server deployment requires you to consider these variables: your environment, sources of data and management to provide self-service data access, workload, and usage. However you may not have enough information about these variables when you deploy Tableau Server for the first time. This topic describes three baseline architectures that can be used as starting points for your Tableau Server installations.

Hardware recommendations for production installations

The hardware recommendations for production Tableau Server installations below are based on the hardware that the Tableau team uses to test Tableau Server scalability. We suggest that you use these recommendations as starting points for your production

deployments. For Proof of Concept (PoC) deployments, we recommend you use Tableau Online. For more information, see [Minimum hardware requirements for installation](#).

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single Server	64-bit (x64) ARM-based processors are not supported.	8 physical cores (16vCPUs), 2.0 GHz or higher	64 GB (8GB/physical Core)	500 GB - 1 TB

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 physical cores (8 vCPUs), and 16 GB of RAM.

Multi-node and enterprise deployments	Nodes must meet or exceed the minimum hardware recommendations, except in the following scenarios where a node can be configured with 4 physical cores (8 vCPUs):
---------------------------------------	---

- Dedicated node for Backgrounder.
- Dedicated node for Tableau Prep Conductor.
- Move all the licensed process from the initial node to additional nodes.

Note: For deployments using virtual machines, Tableau recommends dedicated CPU affinity. If you are running Tableau Server in a virtual environment, use your VM host's best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host. Typically 2 vCPUs = 1 physical core for Tableau Server. For example, for AWS installations, the 4 core minimum recommendation is equivalent of 8 AWS vCPUs. Similarly, follow the best practices provided by your virtual infrastructure provider to make sure Tableau Server has access to the appropriate compute, memory, and data resources. If you are installing Tableau Server in a virtual environment or a

cloud-based deployment, see [Virtual Machines and Public Cloud Deployments](#) section later in this topic.

Estimating Disk Space

There are several factors that affect disk space requirements, including whether or not you will be publishing extracts, flows, and the number of workbooks to Tableau Server. For more information see [Disk Space Requirements](#).

Baseline Configurations

- Single Server Installations
- Two Node Installation - Specialized for extract heavy environments
- Two Node Installation - Specialized for flow environments
- High Availability Installations (HA)

Single Server Installations

Recommendations

We recommend using a single machine to install your Tableau Server for initial deployments with limited usage and are not mission critical. Single Server installations can also be expanded to multi-node installation as your workloads grow.

Here are some instances when a single server installation may not be right for you:

- If your system is considered mission critical and needs to be highly available. High availability is about minimizing the system downtime. It is achieved by eliminating single points of failure, and having a reliable failover mechanism. Tableau Server requires a minimum of a three-node configuration to provide redundancy and eliminate the single points of failure. This is one of the primary reasons to move to a multi-node configuration.
- If you have a lot of active users and a lot of extract refreshes, the two types of loads

may be competing for the same resources on the machine. In such a scenario, a single server configuration may not be the right option as you may need additional specialized nodes to isolate the difference workloads.

Note: Active users represent the interactive, concurrent requests made to Tableau Server, including consuming dashboards on a laptop or mobile device, web authoring, and connecting to and querying Published Data Sources.

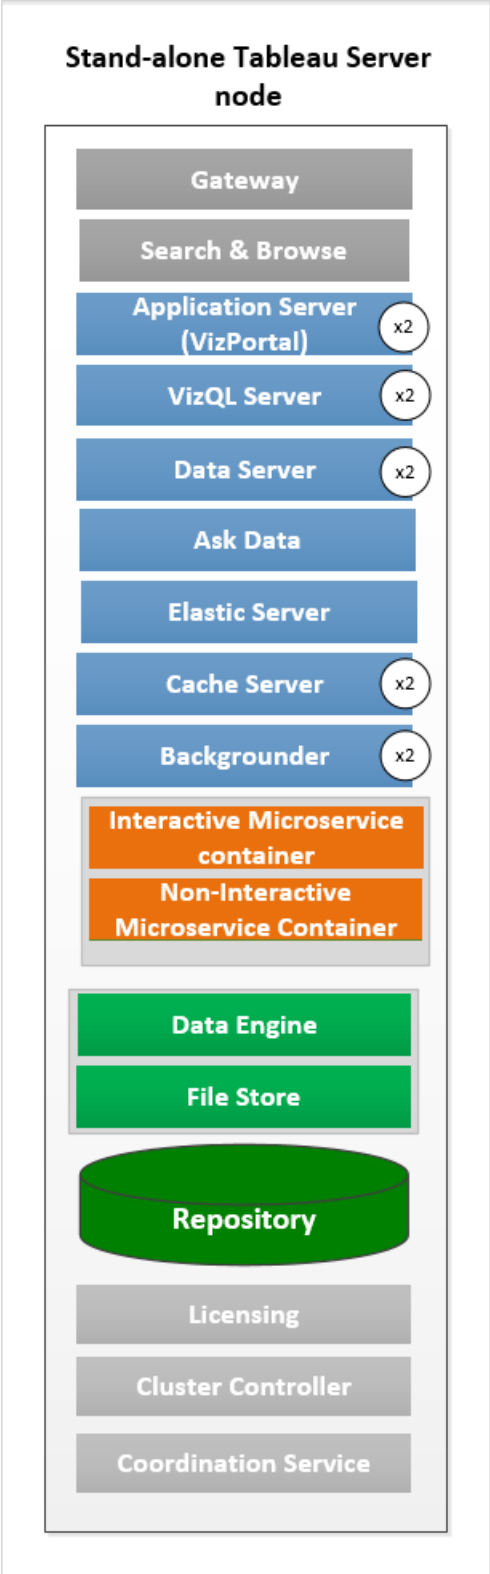

Tableau Server on Windows Help

- Stand-alone single server node with all the processes installed on one machine.
- By default Tableau Server installer configures the number of process instances based on the hardware on the machine. We recommend that you keep the default configuration as your starting point. Below are the number of processes for an 8 core machine.
 - VizQL Server: Set to 2 instances (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
 - Backgrounder, Cache Server, and Data Server: Set to 2 instances.
 - All other processes, only one instance of the process is installed, regardless of hardware.

Note: One instance of Tableau Prep Conductor is automatically configured with Backgrounder, when you have the Data Management Product Key activated on your server. However, it is recommended that you have a dedicated node for Tableau Prep Conductor. If you plan to have flows on your Tableau Server, it is recommended that you use two or more nodes and dedicated one of these nodes to run only flows. The example configuration described above does not include Tableau Prep Conductor since it is a single node server.

Multi-Node Installations

Running Tableau Server on more than one machine is called a multi-node installation, or a cluster. There are various reasons why you might want to have a multi-node installation. For example, you may have heavy extract environments which can mean dedicating some hardware resources to Backgrounder process. For systems that have high availability requirements, you need a multi-node environment that has at least three nodes.

Two Node Installation - Specialized for extract heavy environments

Recommendations

Start with a two node configuration when the following conditions apply to you:

- **Extract heavy environment:** Majority of your data sources are extracts. Having just a few, extremely large extracts could put your deployment in this category, as would having very many small extracts.
- **Frequent extract refreshes:** Refreshing an extract is a CPU-intensive task. Deployments where extracts are frequently refreshed (for example, several times a day during business hours) are often helped by more emphasis on the background process, which handles refresh tasks.

Important: Two-node configurations do not meet the minimum requirements for high availability. If you need a system that is highly available, see High Availability Installations (HA).

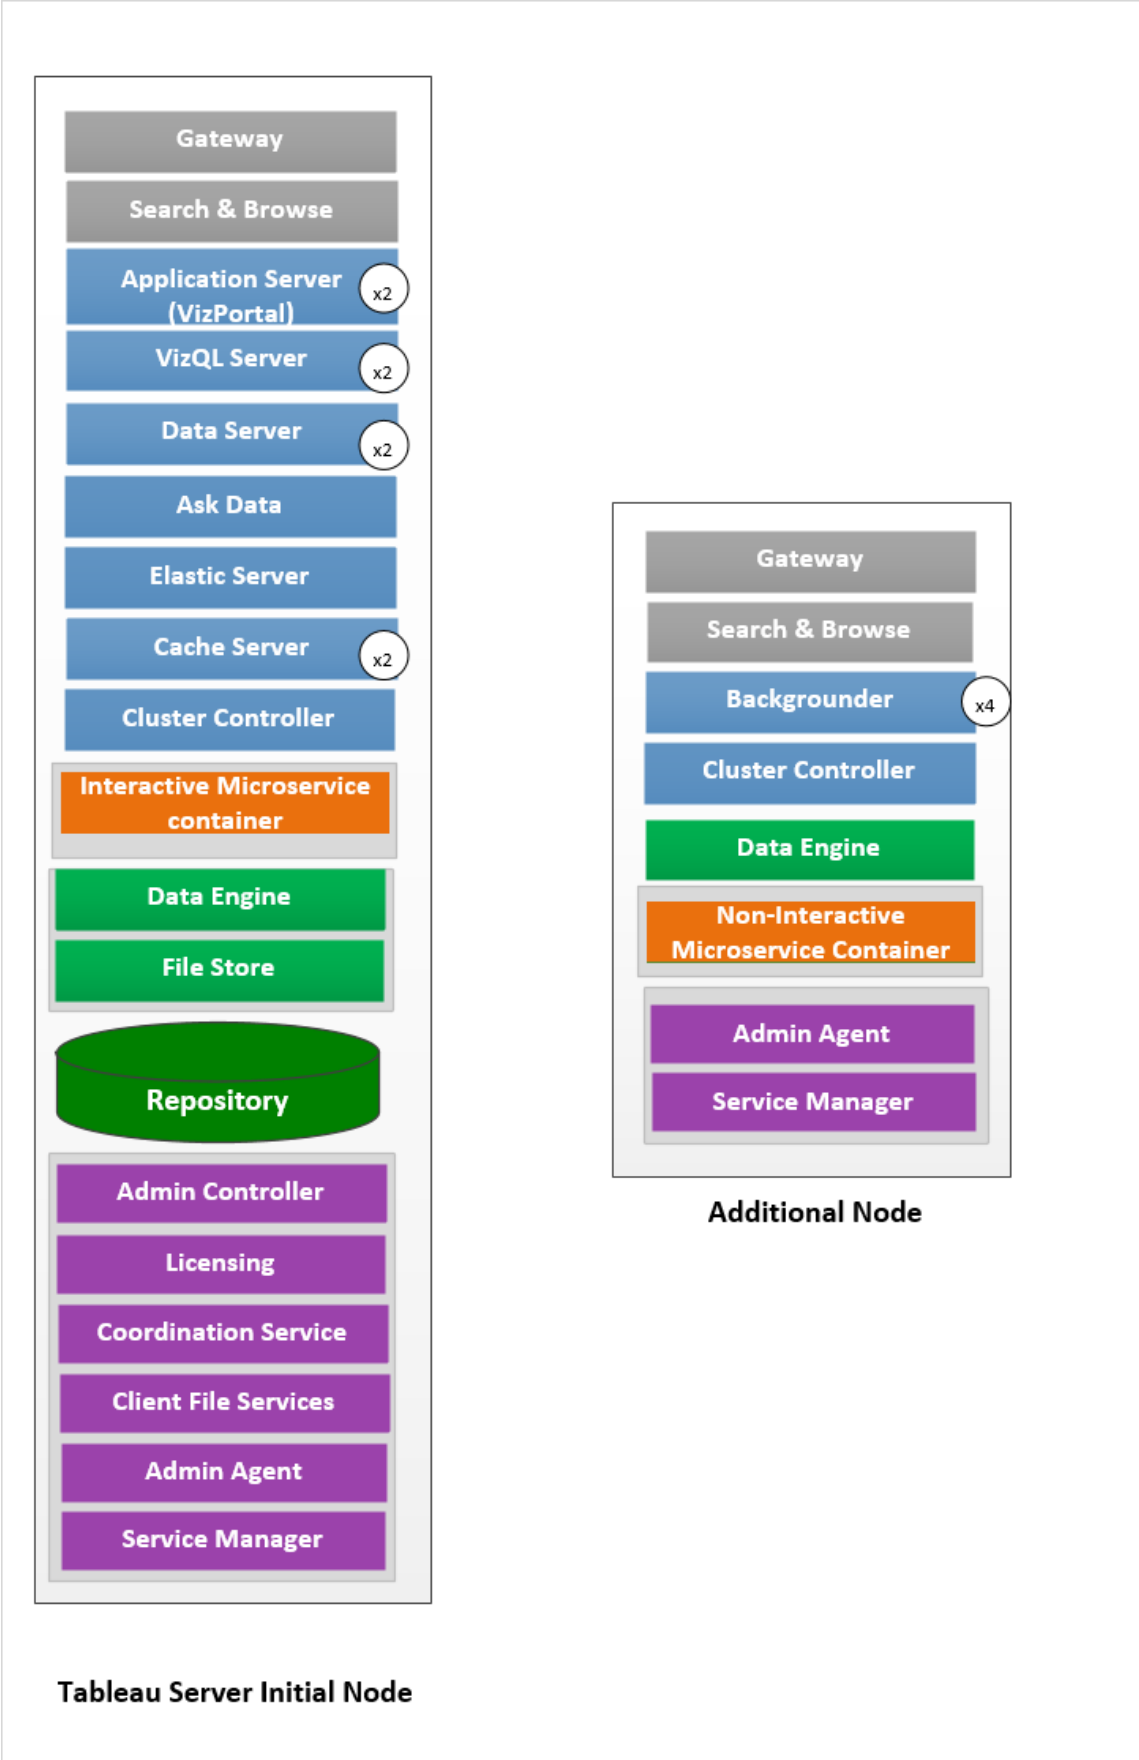

Tableau Server on Windows Help

- On the initial node, install all the processes except for the backgrounder. Below is the number of instances of the processes for an 8 core machine:
 - VizQL Server: Set to 2 instances. (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
 - Cache Server, and Data Server: Set to 2 instances. One instance of Ask Data is automatically configured on the node that has Data Server.
 - Elastic Server: Elastic Server memory is configured to 1GB by default and can be configured to improve performance by using the `elasticserver.vmopts` TSM configuration option. For more information, see [tsm configuration set Options](#).
 - All other processes, only one instance of the process is installed, regardless of hardware. One instance of Interactive Microservice Container is installed on a node that has Application Server enabled, and one instance of Non-Interactive Microservice Container is installed on a node that has Backgrounder enabled.
- Isolate backgrounder on the additional node. To calculate the minimum number of backgrounder processes to run on this node, divide the computer's total number of physical cores by 4. To calculate the maximum number, divide the computer's total physical cores by 2. In the example shown above, both the nodes are on machines with 8 physical cores. When you install the backgrounder, Tableau Server automatically installs one instance of the Data Engine.

Note: This configuration assumes that you do not have Tableau Prep Conductor enabled on your Tableau Server. If are using Tableau Prep Conductor to schedule and manage flows, and have an extract heavy environment, we recommend that you have at least 3 nodes and use the 3 node configuration described later in this topic.

As you monitor and gather data about the performance and usage, you can fine tune and configure the number of instances for these processes. For example, on the node where it is

dedicated to running backgrounder, initially, you can set the number of backgrounders to minimum (total number of cores divided by four), and increase the number of backgrounder processes later if you find that:

- Extract refreshes are taking a long time to complete
- Subscriptions and alerts are not completing on time

For more information on performance tuning, see Performance Tuning topic.

Two Node Installation - Specialized for flow environments

Start with a two node configuration if you are planning to publish, schedule, and manage flows on your Tableau Server.

Important: Two-node configurations do not meet the minimum requirements for high availability. If you need a system that is highly available, see High Availability Installations (HA).

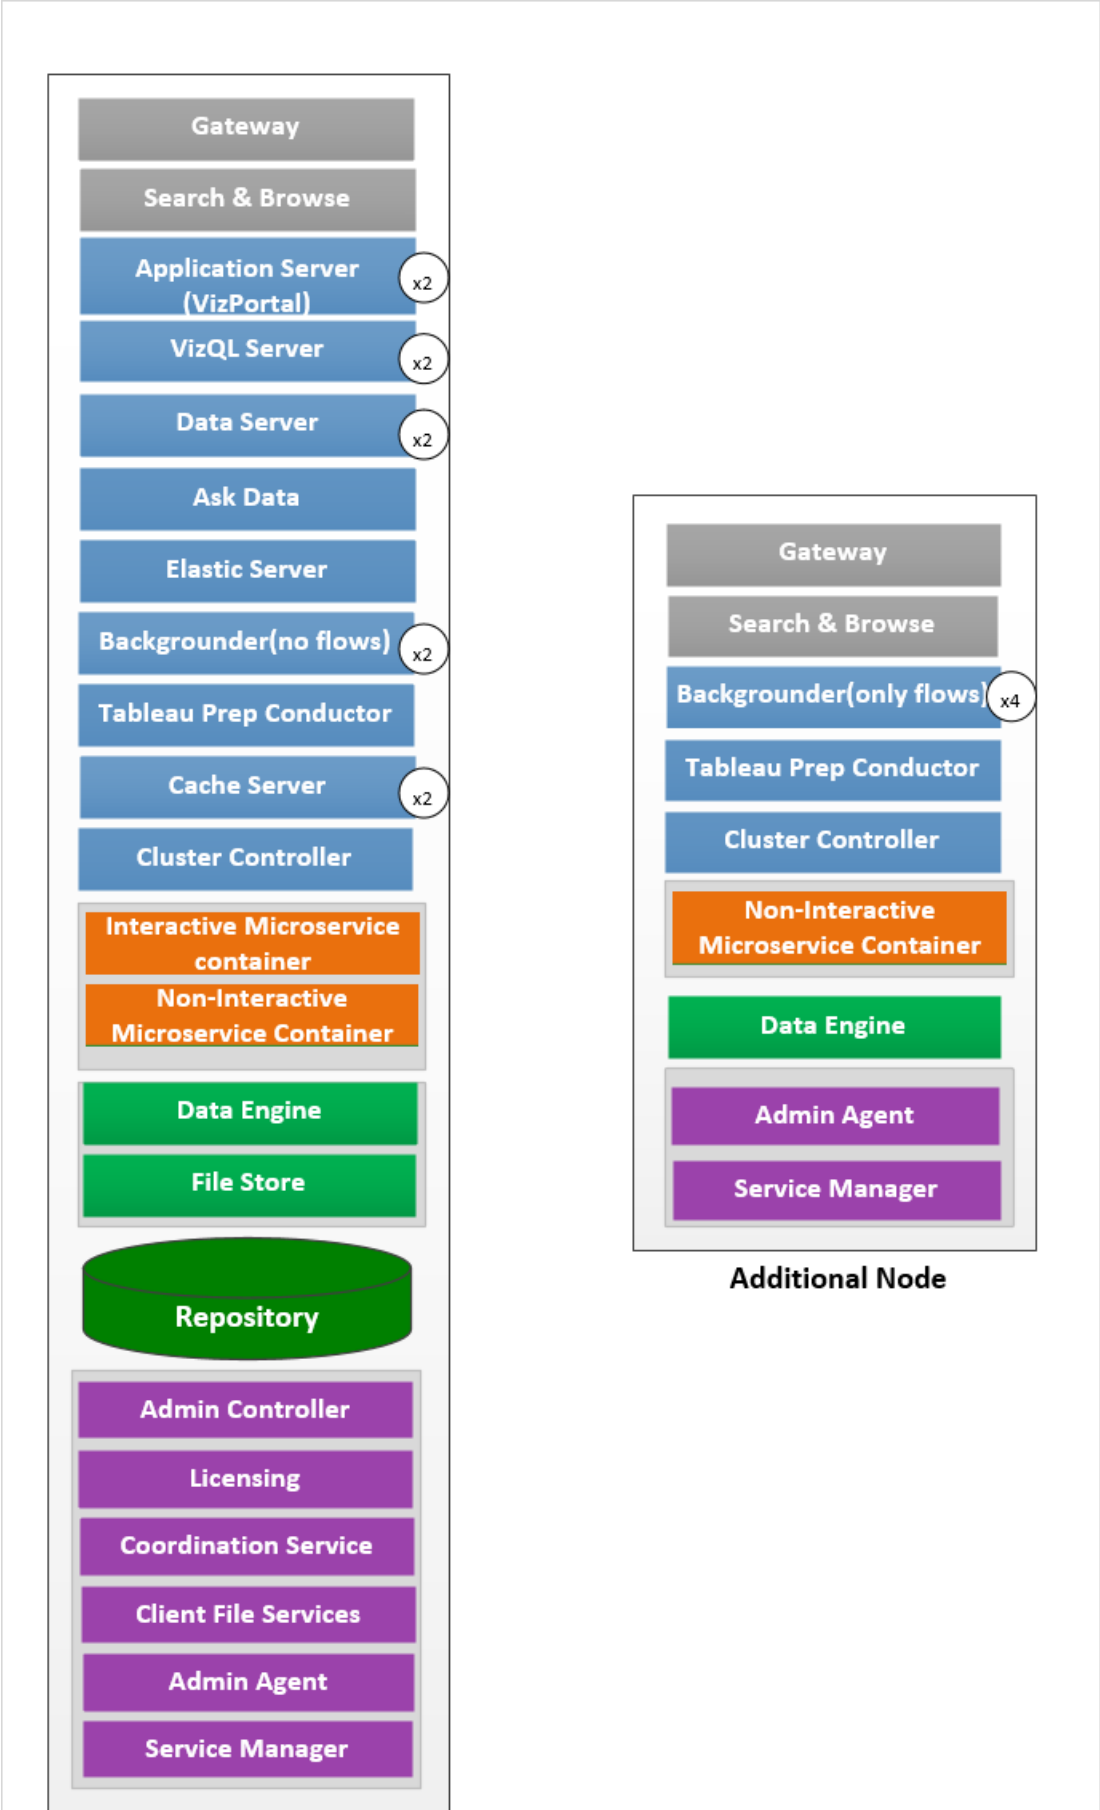

Tableau Server on Windows Help

- On the initial node, install all the processes. Below is the number of instances of the processes for an 8 core machine:
 - VizQL Server: Set to 2 instances. (default calculation: Number of physical cores divided by 4, up to a maximum of 4).
 - Cache Server, and Data Server: Set to 2 instances. One instance of Ask Data is automatically configured on the node that has Data Server.
 - Backgrounder: Minimum 2, maximum 4. The diagram above shows the maximum for an 8 core node. Tableau Prep Conductor is automatically configured on the node where you have backgrounder installed. On the initial node, set the Backgrounder node role to run all job types including flows using the `tsm topology set-node-role` tsm configuration. For more information, see `tsm topology set-node-role`
 - Elastic Server: Elastic Server memory is configured to 1GB by default and can be configured to improve performance by using the `elast-icserver.vmopts` TSM configuration option. For more information, see `tsm configuration set Options`.
 - All other processes, only one instance of the process is installed, regardless of hardware. One instance of Interactive Microservice Container is installed on a node that has Application Server enabled, and one instance of Non-Interactive Microservice Container is installed on a node that has Backgrounder enabled.
- Isolated the backgrounder on the additional node to run only flows. Use the `tsm topology set-node-role` tsm configuration to configure this setting. For more information, see `tsm topology set-node-role`

Note: If you have both a heavy extract environment, and schedule and manage flows on your server, we recommend that you use the 3 node configuration described below.

High Availability Installations (HA)

Recommendations

A highly available installation of Tableau Server is a distributed installation that is designed to maximize the availability of Tableau Server. High availability basically means that the system is available with minimal amount of downtime. To build in redundancy for HA related items such as repository, file redundancy, and failover, you need a **minimum of three nodes**. The tolerance for downtime will vary for each organization and depends on the SLAs you have established in your organization.

High availability is achieved by eliminating single points of failure and detecting failures and setting up a reliable failover system. HA in Tableau Server is mainly achieved by:

- File redundancy with multiple File Store/Data Engine instances.
- Active/Passive Repository across two nodes.
- Adding an external load balancer to make sure your installation is robust to Gateway failures and make sure that requests only get routed to functioning Gateway processes.

Server Configuration

Three-node configuration:

- To build in redundancy, you need to add additional nodes to host instances of the repository and File Store/Data Engine processes. You can add instances of other processes, including multiple instances of a process on a node.

- To build redundancy for the type of backgrounder jobs, have one of the nodes (initial node in this example) run all type of jobs. Backgrounders run all types of jobs by default. On one of the additional nodes, set the backgrounder to run only flows, and the other additional node to run all jobs except for flows.
- The successful functioning of Tableau Server depends on a properly functioning Coordination Service. For server installations of three or more nodes, we recommend that you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems. For more information, see [Deploy a Coordination Service Ensemble](#) .
- Elastic Server memory is configured to 1GB by default and can be configured to improve performance by using the `elasticserver.vmopts` TSM configuration option. For more information, see [tsm configuration set Options](#).
- To reduce the system's vulnerability, you can run multiple gateways and additional instances of some of the server processes. The fewest number of computers required to achieve this configuration is three.
- The repository has also been moved from the initial node to one of the additional nodes, and a second, passive instance has been added to the other new node.
- One instance of Interactive Microservice Container is installed on a node that has Application Server enabled, and one instance of Non-Interactive Microservice Container is installed on a node that has Backgrounder enabled.

NOTE: In certain circumstances you may want to limit the processes running on your initial node. Reasons for doing this include wanting to run as few processes as possible on the node to limit processing requests on the node. You might also remove licensed Tableau Server processes from the node if you have a core-based license and do not want the initial node cores to count against your core use. For more information on Tableau Server licensed processes, see [Tableau Server Processes from the node](#).

Tableau Server on Windows Help

Virtual Machines and Public Cloud Deployments

In general, the considerations and recommendations described in this topic apply to virtual environment and cloud deployments.

If you are running Tableau Server in a virtual environment, use your VM host's best practices for vCPU allocation in relation to the number of physical CPU cores on the VM host. Typically 2 vCPUs = 1 physical core for Tableau Server. For example, for AWS installations, the 4 core minimum recommendation is equivalent of 8 AWS vCPUs.

For more information on cloud-based deployments, see:

- [Install Tableau Server in the Cloud.](#)

Beyond Baseline Configurations

If you are planning a system whose configuration is beyond the limits documented here, contact [Tableau Professional Services](#).

Disaster Recovery Considerations

While HA configurations reduce downtime, you may still encounter failures in case of a disaster or hardware failures. In addition to the above considerations, you should evaluate the importance of disaster recovery in your organization and plan for a deployment that helps you meet your disaster recovery goals and objectives.

When planning for disaster recovery (DR) in your Tableau environment, there are two main factors to consider:

- Recovery Time Objective (RTO), a measure of how much downtime your business can accept before a full recovery.
 - Influences how often you restore your backups to an alternative cluster and the amount of infrastructure investment.
- Recovery Point Objective (RPO), a measure of how much data loss your business can tolerate.

- Influences how often you will need to take backups of your system.
- For Tableau Server the RPO cannot be shorter than the time it takes to complete a full backup of your server.

The diagram below illustrates how to plan for a range of RTO requirements:

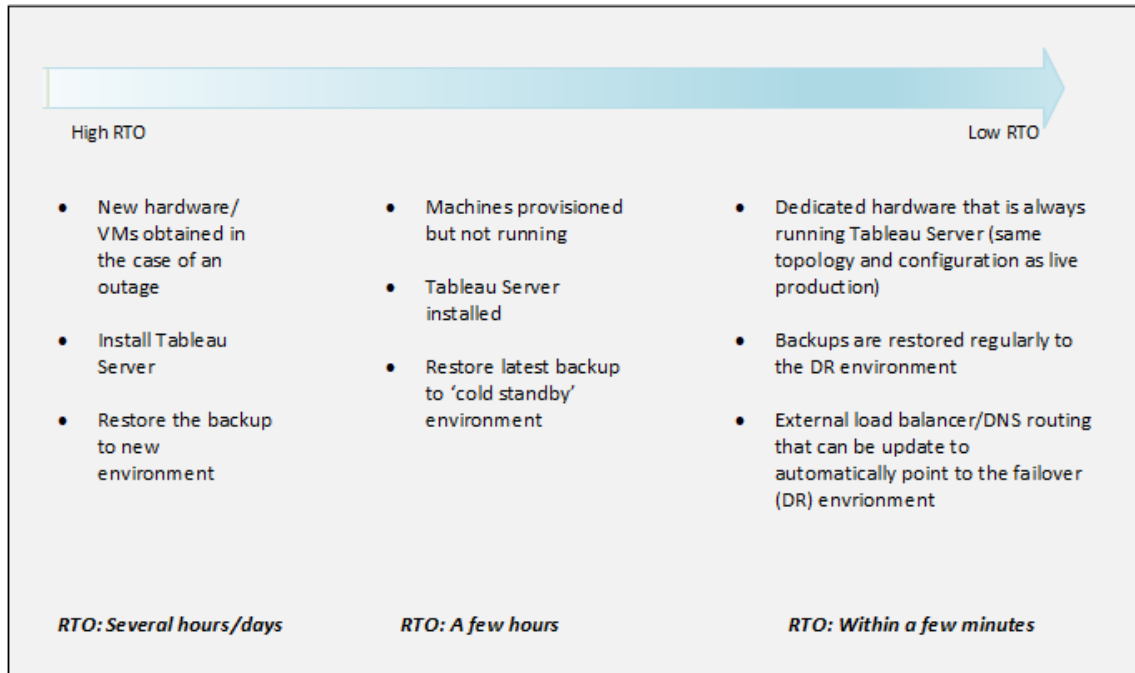

Tableau Server Scalability

These baseline configurations may not be enough as your needs change and grow, and you might need to scale your Tableau Server beyond these configurations. Like other enterprise platforms, Tableau Server scales up by adding processor, memory, and disk to existing node, and scales out by adding more nodes to a cluster. However, scalability and performance are heavily dependent on external systems and user activity. The configuration of your Tableau Server can be different depending on your requirements and variables:

Tableau Server on Windows Help

For more information on Tableau Server scalability and the variables affecting scalability, see [Tableau Server Scalability whitepaper](#).

Run As Service Account

The *Run As* service account is a Windows account that Tableau Server uses ("runs as") when it accesses resources. For example, Tableau Server reads and writes files on the computer where Tableau Server is installed. From the perspective of Windows, Tableau Server is doing this as the Run As service account. In some cases, Tableau Server may use the Run As service account to access data from external sources, such as databases or files on a shared network directory.

As you plan your Tableau Server deployment, you need to determine if the default Run As service account, configured to run under the context of the local Network Service account (NT Authority\Network Service), will suffice for your needs. If it does not, then you will need to update the Run As service account to run under a domain account that has access to the resources in your Active Directory domain(s).

In either case, it's important to understand the security implications of the account that Tableau Server uses for the Run As service account. Specifically, if Tableau Server needs to access other servers, file shares, or databases that use Windows authentication, then the account that is configured for Run As service account will be used to access those resources. The account that is configured for Run As service account must also have elevated permissions to the local Tableau Server. A general best security practice is to limit the scope of all user accounts to the minimum required permissions. We make the same recommendation to you as you plan Run As service account. For more information, see [Data Access with the Run As Service Account](#)

The account you use for the Run As service account should not be a member of the Local Administrators or Domain Administrators account. Instead we recommend using a domain user account that is not an administrator for the Run As service account. Using a domain account that is not a member of these administrator groups is a good security practice and can help avoid access to certain data sources and folders. For information on best practices when creating a Run As service account, see [Creating the Run As service account](#).

You can set the Run As service account during Tableau Server installation, or you can update the Run As service account using the TSM Web UI. Tableau Services Manager sets permissions for the Run As service account, but if you are unsure if the account you want to use for Run As service account satisfies the requirements, or if you have changed the Run As service account and are getting permission errors, see [Required Run As Service Account Settings](#).

Default Run As service account: Network Service

The Network Service account is a predefined local account with limited permissions that exists on all Windows computers. While it has limited administrative access to the local computer on which it runs, it does have more access to resources than members of the Active Directory default Users group. For example the Network Service group can write to the registry, the event log, and has special rights to log on for application services.

By default, the Run As service account is set to a local account called Network Service. Use the default Network Service account when:

- You are using local authentication for Tableau Server.
- All users in your organization include extracted data in the workbooks that they are uploading to Tableau Server.

Tableau Server on Windows Help

- You are running Tableau Server in a single-server deployment.
- External data sources that your users access through Tableau Server do not require Windows NT integrated security or Kerberos. In most data-access scenarios, Microsoft SQL Server, MSAS, Teradata, and Oracle databases require Windows NT integrated security.

While the Network Service account can be used to access resources on remote computers within the same Active Directory domain we do not recommend using the default account for such scenarios. Instead, configure a domain account for Run As service account if Tableau Server must connect to data sources in your environment. See [Change the Run As Service Account](#).

Run As service account: Domain user

For all Active Directory scenarios, we recommend updating the Tableau Server Run As service account with a domain user account. Update the Run As service account to a domain user account when data sources accessed through Tableau Server require Windows NT integrated security or Kerberos.

If you have deployed a distributed deployment of Tableau Server, then you can update the Run As service account with either a domain user or a Windows workgroup user. In either case, you must use the same user account for all server nodes. See [Distributed Requirements](#) for more information.

To configure your environment to use a domain account, see [Change the Run As Service Account](#).

Data Access with the Run As Service Account

When Windows Authentication is configured, the Run As service account requires read and query permissions to the databases that are accessed by Tableau Server. As designed, Run As service account permissions result in access to the same databases by Tableau Server users with the *Creator* role or the *Explorer (Can Publish)* role. Users with these roles can access and view the databases with the same level of access as the Run As service account when connecting to the databases using Windows Authentication option on Tableau Server.

For example, a user with the Creator role can view all databases that have been granted access to the Run As service account.

If the Creator-user specifies the database host name and selects Windows Authentication when creating a new data source from a web browser, then the user will be able to view the databases that have been permissioned for the Run As service account.

View access to database assets are not restricted to users who connect to Tableau Server with a web browser. Sophisticated users, who have the same roles noted above and who have knowledge of database server names, can also craft workbooks with Tableau Desktop that can view the databases that have been permissioned for the Run As service account.

The functionality described here is universal for all data sources that are accessed by the Run As service account, regardless of how users authenticate with Tableau Server. For example, even if users authenticate to Tableau Server with Kerberos or SAML, their access to all Run As-configured data sources will be the same. Users with Creator or Explorer (Can Publish) are able to access all data that is permissioned for the Run As service account.

Recommendations

Whether user access to databases in these scenarios is acceptable must be assessed by your organization. Generally, reducing the usage and scope of the Run As service account will reduce the likelihood of inadvertent user access to database content. However, reducing the usage and scope of the Run As service account may also impose more credential management to you and your users.

Evaluate the following recommendations in context of your business needs and data access policies.

- Firstly, be sure that you trust all users who have Creator roles or Explorer (Can Publish) roles. You will rely on these users to perform actions in Tableau with integrity.
- If you cannot trust all of your users who have publishing rights on data sources that are accessed by the Run As service account, then you should consider embedding credentials for those data sources.

Tableau Server on Windows Help

- If a data source is not set up for automated extract refreshes, that is, the data source is primarily accessed as a live connection, then you may be able to use Kerberos Delegation. For requirements, see Enable Kerberos Delegation.

Configure Data Source Connection Settings

To automatically authenticate your users when the workbook they're accessing connects to a live, Windows-authenticated data source, configure your Tableau data connection with the **Use Windows Authentication** option selected:

Windows Authentication

Authenticates with the server's Run As user service account

Username and Password

Each Tableau Server user is prompted for database credentials

The image displays two side-by-side screenshots of the 'Microsoft SQL Server' connection configuration dialog in Tableau. Both screenshots show the same fields: 'Server' (mssql.example.com), 'Database' (Optional), and a section for signing in to the database. In the left screenshot, the 'Use Windows Authentication (preferred)' radio button is selected. In the right screenshot, the 'Use a specific username and password:' radio button is selected, and the 'Username' field contains 'jsmith' and the 'Password' field is masked with dots. Both screenshots have 'Require SSL' and 'Read uncommitted data' checkboxes unchecked. The right screenshot includes a 'Sign In' button in the bottom right corner.

It's important to understand how the Run As service account accesses data on behalf of the users in your organization. In some cases, users may inadvertently access data that their users accounts are not explicitly permissioned for. Before allowing users to access data with the Run As service account, review [Data Access with the Run As Service Account](#).

Change the Run As Service Account

Depending on your environment and data access requirements, you may want or need to change the Run As service account. There are two main scenarios where you change the Run As service account:

- Replacing the default Run As local account (NetworkService) with a domain account. If you are operating in an environment where a majority of your data sources are authenticated in the context of Active Directory (Windows NT integrated security) then you will need to configure the Run As service account to use a domain account, not the local account (NetworkService).
- Changing an existing domain Run As service account to a different account.

This topic describes both scenarios and describes how to update the Run As service account password.

The account you use for the Run As service account should not be a member of the Local Administrators or Domain Administrators account. Instead we recommend using a domain user account that is not an administrator for the Run As service account. Using a domain account that is not a member of these administrator groups is a good security practice and can help avoid access to certain data sources and folders. For information on best practices when creating a Run As service account, see [Creating the Run As service account](#).

Replacing the default Run As local account (NetworkService) with a domain account

If you are going to replace the default NetworkService account with a domain account, we recommend using a dedicated account for the Run As service account. Follow these steps:

1. Create the Run As service account in Active Directory
2. Configure Tableau Server to use the Run As service account

Tableau Server on Windows Help

Creating the Run As service account

Follow these best practices:

- It's important to understand how the Run As service account accesses data on behalf of the users in your organization. In some cases, users may inadvertently access data that their users accounts are not explicitly permissioned for. Before you create a Run As service account, review [Data Access with the Run As Service Account](#).
- Create a dedicated account in Active Directory for the Tableau Server Run As service account. In other words, don't use an existing account. By using a dedicated account you can be sure that the data resources that you permission for Tableau Server are only accessible by Tableau Server Run As service account.
- The Run As service account is used to query users and group membership in Active Directory. By default, the NetworkServices account and default domain users have permission to query Active Directory. Do not restrict read or query permissions for the Run As service account.
- Do not use an account with any kind of domain administrative permissions. Specifically, when you create an account in Active Directory, create an account in the domain User Group. Do not add the account that you create to any Active Directory security groups that needlessly elevate the permissions for the account.
- Permission the data sources in your directory for this one account. The account that you'll use for Run As service account only needs Read access to the appropriate data sources and network shares.
- If users in your organization authenticate with smart cards, disable the smart card logon option for the Run As service account.
- If you have installed Tableau Server on a drive other than the system drive, then you will need to configure the system drive to allow the Run As service account additional permissions. The system drive is the drive where Windows is installed. For example, if you have installed Windows on the C:/ drive, then C:/ is your system drive. If you install Tableau Server on any other drive (D:/, E:/, etc), then you will need to configure permissions for the Run As service account on the system drive. See [Required Run As Service Account Settings](#) for more information.

Configuring the Run As service account in Tableau Server

After you have created the Run As service account in Active Directory, configure Tableau Server to use that account.

Use the TSM Web UI to configure the Run As service account for the first time.

To configure the Run As service account

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Security** tab, and then click the **Run As Service Account** tab.
3. Select **User Account** and then enter the user name and password for the service account. Specify the domain name as `domain\account`, where domain name is the NetBIOS name of the domain where the user resides:

The screenshot shows the 'Run As Service Account' configuration window. It features three tabs: 'Run As Service Account', 'External SSL', and 'Repository SSL'. The 'Run As Service Account' tab is active. Under this tab, there are two radio button options: 'NT AUTHORITY\NetworkService' and 'User Account'. The 'User Account' option is selected. Below the radio buttons, there are two input fields: 'Username' and 'Password'. The 'Username' field contains the text 'EXAMPLE\runas-user'. The 'Password' field contains a series of dots representing a masked password. At the bottom of the window, there are two buttons: 'Cancel' and 'Save'.

4. Click **Save** to verify the user name and password.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

After you update the Run As service account, Tableau Server will automatically configure permissions on the local computer for the account that you have entered.

Tableau Server on Windows Help

Changing an existing domain Run As service account to a different account

To change an existing domain Run As service account to a different account, you must apply permissions to that new account. To apply permissions to your new Run As service account, you must first reset permissions by applying them to the default NetworkService account.

Before you begin, verify that the new account that you will be using for the Run As service account complies with the best practices noted previously in the section, [Creating the Run As service account](#).

This procedure requires you to restart Tableau Server services twice, so run this procedure during off hours.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Security** tab, and then click the **Run As Service Account** tab.
3. Under **User Account**, select **NT Authority\NetworkService**.
4. Click **Save**.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.
6. After the server restarts, open TSM and navigate to the **Run As Service Account** tab.
7. Select **User Account** and then enter the user name and password for the service account. Specify the domain name as `domain\account`, where domain name is the NetBIOS name of the domain where the user resides:

8. Click **Save** to verify the user name and password.
9. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.
10. Revoke the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).

Use the TSM CLI

1. Reset the Run As service account to NetworkService. Run the following command:

```
tsm configuration set -k service.runas.username -v "NT
AUTHORITY\NetworkService"
```

2. Run the following command to save this change and restart:

```
tsm pending-changes apply
```

3. Set the Run As service account to the new account. Run the following commands:

Tableau Server on Windows Help

```
tsm configuration set -k service.runas.username -v  
<domain\username>
```

```
tsm configuration set -k service.runas.password -v "<pass-  
word>"
```

Enclose the password with double quotes to ensure special characters in the string are processed correctly. To view the password as it will be stored, run the following command:

```
tsm pending-changes list
```

The password will be validated with Active Directory. If valid, then the password will be encrypted and saved. TSM will not report success or failure.

4. Run the following command to save and restart:

```
tsm pending-changes apply
```

Troubleshooting:

- Verify that the server has started. If it is in a degraded state, then you may have entered an incorrect password. View the stored password by running the `configuration get` command. This command will decrypt and display the password in the shell. Run the following command:

```
tsm configuration get -k service.runas.password
```

If the previous password is displayed, then you did not enter a valid password.

- Enter the correct password (see Step 3), and then run the following command to save and restart:

```
tsm pending-changes apply
```

5. Revoke the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).

Updating the Run As service account password

If the Run As service account password has been updated in Active Directory you must update it for Tableau Server. The Run As service account password is encrypted and stored on Tableau Server. For more information, see [Manage Server Secrets](#).

If you are running Tableau Server in a distributed deployment, then you only need to update the password with TSM on the initial node in the cluster. TSM will distribute this configuration to each node automatically.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Security** tab, and then click the **Run As Service Account** tab.
3. Under **User Account**, enter the password for the service account.
4. Click **Save** to verify the password.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

Use the TSM CLI

1. Set the new password. Run the following command:

```
tsm configuration set -k service.runas.password -v "<password>"
```

Tableau Server on Windows Help

Enclose the password with double quotes to ensure special characters in the string are processed correctly. To validate that special characters were escaped correctly, run the following command to view the password as it will be stored:

```
tsm pending-changes list
```

The password will be validated with Active Directory. If valid, then the password will be encrypted and saved. TSM will not report success or failure.

2. Run the following command to save and restart:

```
tsm pending-changes apply
```

Troubleshooting:

- Verify that the server has started. If it is in a degraded state, then you may have entered an incorrect password. View the stored password by running the `configuration get` command. This command will decrypt and display the password in the shell. Run the following command:

```
tsm configuration get -k service.runas.password
```

If the previous password is displayed, then you did not enter a valid password.

- Enter the correct password (see Step 1), and then run the following command to save and restart:

```
tsm pending-changes apply
```

Troubleshooting: Update the password in the Microsoft Services console

In some cases, you may see service failures after updating the Run As service account password. If so, then you may need to manually update the password for the **Tableau Server Services Manager** service. Update the password in the Microsoft Services management console.

If you are running Tableau Server in a distributed deployment, then you must perform the following procedure on each node in the cluster.

1. Stop Tableau Server.

- To use the TSM CLI, run the following command:

```
tsm stop
```

- To use the TSM Web UI, on the top-right of the page, click the drop-down list next to the status, and then click **Stop Tableau Server**:

2. Open the Services MMC snap-in on the Windows computer that is running Tableau Server.
3. Double-click the **Tableau Server Services Manager** service to open the properties page.
4. On the **Tableau Server Services Manager Properties** page, click the **Log On** tab, and then enter the password for the service account.
5. Click **Apply**, then click **OK**.
6. Restart the **Tableau Server Services Manager** service by right-clicking on the service name and then clicking **Restart**.
7. Start Tableau Server.

Tableau Server on Windows Help

- To use the TSM CLI, run the following command:

```
tsm start
```

- To use the TSM Web UI, on the top right of the page, click the drop-down list next to the status, and then click **Start Tableau Server**.

Related tasks

The Run As service account is central to many operations on Tableau Server, especially those that are involved with remote data access. To avoid access errors, review the tasks here and follow the links for those that apply to your scenario.

- If you are running Tableau Server in an organization with multiple Active Directory domains, see [Domain Trust Requirements for Active Directory Deployments](#).
- Enabling Kerberos single sign-on requires additional configuration related to the Run As service account. To enable Kerberos single sign-on with Tableau Server, see [Kerberos](#).
- Enabling impersonation requires additional configuration related to Run As service account. To deploy and enable impersonation with Microsoft SQL Server, see [Impersonate with Embedded SQL Credentials](#).
- If you have installed Tableau Server onto the non-system drive, then you will need to manually set some permissions for the Run As service account. See [Required Run As Service Account Settings](#) for more information.
- If you have changed the Run As service account, then we recommend revoking the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).
- If your organization uses a forward proxy solution, then you may need to reconfigure the local LAN settings on the Tableau Server with the Run As service account. See [Configure a forward proxy server](#) for more information. In this scenario, the Run As service account must also be temporarily configured as the log on account for Tableau Server Administrative Controller for product key operations. See [Configure Product Key Operations with Forward Proxy](#).

Troubleshoot Run As User

As discussed in the topic, [Run As Service Account](#), Tableau Server requires administrative-like access to the machine on which it is installed. Therefore, when you update the Run As service account, a background process will configure permissions on the Tableau computer for that account. However, in some complex deployment scenarios you may need to verify or manually configuration the Run As service account permissions on the local Tableau Server computer. Use this section to verify how permissions are configured on the machines running Tableau Server in your deployment. This section also includes procedures that describe how to set permissions and configure security policies for the Run As service account.

Required Run As Service Account Settings

The Run As service account needs permissions that allows it to modify files and registry settings. In addition, because the Run As service account is used as the security context for the Tableau Server Application Manager service (tabsvc), the account must also be given rights to log on as a service.

These permissions are set automatically when you update the Run As service account in Tableau Server Configuration as described in the topic, [Change the Run As Service Account](#).

If you have changed the Run As service account, then we recommend revoking the permissions for the previous account. See [Revoke Run As Service Account Permissions](#).

The account you use for the Run As service account should not be a member of the Local Administrators or Domain Administrators account. Instead we recommend using a domain user account that is not an administrator for the Run As service account. Using a domain account that is not a member of these administrator groups is a good security practice and can help avoid access to certain data sources and folders. For information on best practices when creating a Run As service account, see [Creating the Run As service account](#).

Tableau Server on Windows Help

If you have recently changed Run As service account or are getting permission errors, use this section to confirm that Tableau Server meets the permission requirements that are detailed here. If you're running a distributed installation, all Run As service account permission configurations must be the same across all nodes.

Note: Do not hide the files created by the Tableau Server installer.

Verify Folder Permissions

The account the Tableau Server service runs under is referred to as the Run As service account. The Run As service account needs permission to specific folder resources on the Windows computer.

This topic provides:

- An accounting of the permissions that are required by the Run As service account.
- Information about installing Tableau Server in non-default locations.
- How to reapply permissions on an existing Run As service account using TSM.

This topic refers to the drive where Windows is installed as the *system drive*. The system drive is equivalent to the Windows environmental variable, %WINDIR%. The drive where Tableau Server is installed is referred to as the *install drive*.

Resource	System or install drive	File Path	Permissions required
folder	system	SYSTEMROOT:\windows\system32	Read, List folder contents
executable	system	SYSTEMROOT:\windows\system32\cmd.exe	Read & execute
Drive root	install	root, for example, Local Disk (C:)	Read, List

			folder contents
folder	install	PROGRAMFILES\Tableau\Tableau Server	Modify
folder	install (on system drive)	\ProgramData\Tableau\Tableau Server\	Modify
folder	install (on non-system drive)	\Tableau\Tableau Server\data\	Modify

When you update the Run As service account in TSM, a background process will configure the folder permissions on the Tableau computer for the Run As service account that you specify.

In this case, where you are installing on the system drive into the default folder (C:\Program Files\Tableau), the configuration of folder permissions will be handled by TSM. You do not need to verify or change any folder permissions for this scenario. If you install Tableau Server onto a different drive, you will need to manually configure some permissions.

Installing in a non-default location

If you are installing Tableau Server in a non-default location on a different drive, then you will need to configure permissions on the installation folder for Run As service account as well as the predefined local accounts: Network Service, Local Service, and System.

The following table describes the permissions that are applied if you install Tableau Server in a non-default location. All of these permissions are set on the installation folder, and are inherited by the subfolders and files in the installation folder. These permissions are configured by the Tableau Setup program and are also reconfigured whenever you upgrade

Tableau Server on Windows Help

Tableau Server to a new version. Changing permissions on these folders may impair functionality.

For more information about different accounts used by Tableau Server, see [Windows Accounts and Permissions](#).

Set permissions for this account:	Permissions required
The user account that is used to install and upgrade Tableau Server	Full control
The user account that is used to run TSM commands	Full control
System account	Full control
Run As service account, Network Service, and Local Service	Read & execute

Reapplying folder permissions

In some organizations, Group Policy or other system management solutions are used to standardize permissions and accounts on application servers. If your organization runs a such a solution, be sure to configure the system to accommodate the folder permissions required by the Run As service account. If the folder permissions for the Run As service account have been changed, you can use TSM to reapply the permissions. See [Changing an existing domain Run As service account to a different account](#).

Verify Registry Permissions

The account the Tableau Server service runs under needs permission to modify the registry on the local machine.

In a multi-node cluster, the registry permissions are only granted on the tsm node in the cluster.

When you update the Run As service account, TSM will configure the registry permissions on the Tableau computer for the account you specify. It's unlikely that you will need to apply these permissions manually.

Verify that the Run As service account has been granted permissions to the `HKEY_LOCAL_MACHINE\Software\Tableau` registry branch. If the account that you have specified as the Run As service account is a member of the local administrative group or a member of the Domain Admins security group, then the account will not be displayed on the Permissions page.

Permissions

TSM will grant Read permission and the following Special permissions to these branches:

- Query Value
- Set Value
- Create Subkey
- Enumerate Subkeys
- Notify
- Write DAC
- Write Owner
- Read Control

To view or edit permissions on registry directories:

1. Open the Registry Editor by entering `regedit` in Windows Run, and then clicking **OK**.
2. In Registry Editor, navigate to the directory where you want to view or edit permissions. Right-click the directory, and then click **Permissions...**
3. In Permissions, on the Security tab, select the Run As service account, and then click **Advanced**.
If you are adding your Run As service account, then click **Add** and follow the Windows process for adding a user account to the Security tab. After you have added the account, then select the Run As service account, and then click **Advanced**
4. In Advanced Security Settings, on the Permissions tab, select the Run As service account, and then click **Edit**.

Tableau Server on Windows Help

5. On the Permission Entry, under Basic permissions, verify that **Read** and **Special permissions** are selected. Verify that **Only apply these permissions to objects and/or containers within this container** is not selected.
6. To view or edit Special permissions, click **Show advanced permissions**.
7. Under Advanced permissions, verify that the permissions enumerated at the beginning of this topic are selected. Verify that **Only apply these permissions to objects and/or containers within this container** is not selected.
8. If you have set new permissions, then click **OK** through the multiple windows to finish. If you have viewed permissions and not edited anything, then click **Cancel** to close all windows.

Verify the Local Security Policy

After you specify a Run As service account in Tableau Services Manager (as described in the topic, [Change the Run As Service Account](#)), TSM will update the local security policy on the computer running Tableau Server. TSM will update the local security policy to give "log on as a service" and "log on locally" permissions to the Run As service account. This elevated policy is required because the Run As service account is used as the security context for the Tableau Server Application Manager service (tabsvc).

Note: If the Run As service account that you specify in TSM is a member of the local administrators or a domain administrator, then TSM may not update the local security policy. Updating the Run As service account with an account that is a member of local administrators or domain administrators is not a good security practice. We recommend using a domain User account for the Run As service account.

In some cases, you may need to manually set security policy for your Run As service account. For example, some organizations run Windows Group Policy that remove "Log on as a service" or "Allow log on locally" rights that have been set on user accounts. Or an organization may run a policy that creates a permission conflict by specifying "Deny log on as a service." If your organization does this, then you will need to disable or edit such Group Policies so that your Run As service account is not affected. For details on best practices when creating a Run As service account, see [Creating the Run As service account](#).

The following procedure describes how to configure security policies, **Log on as a service** and **Allow log on locally**, manually. You can also use the procedure below to verify that your Run As service account is appropriately configured with local security policy rights. For example, you should verify that the Run As service account is not specified on the **Deny log on as a service** policy.

If you are running a distributed installation, then configuration must be the same across the initial and all additional nodes.

To verify or update the local security policy:

1. Select **Start > Control Panel > Administrative Tools > Local Security Policy**.
2. In Local Security Policy, open **Local Policies**, select **User Rights Assignments**.

To verify or set Log on as a service policy:

Tableau Server on Windows Help

- a. Right-click **Log on as a service** policy and then click **Properties**.

- b. In **Log on as a service Properties** , click **Add User or Group**.
- c. Type the <domain>\<username> for the Tableau Server Run As service account (for example: MYCO\tableau_server), and click **Check Names**.
- d. When the account resolves correctly, it is underlined. Click **OK**.

To verify or set **Allow log on locally** policy:

- a. Right-click **Allow log on locally** policy and then click **Properties**.
- b. Verify that the Run As service account is specified. If it is not, follow the procedure above to add the Run As service account.

To verify **Run As service** account is not specified in the **Deny log on as a service** policy:

- a. Right-click **Deny log on as a service** policy, and then click **Properties**.
 - b. In **Deny log on as a service Properties**, verify that the Run As service account is not listed. If it is, remove it. When you are finished, click **OK**.
3. Click **OK** to close the Local Security Settings windows.

Verify Tableau Service Settings

Confirm that Tableau services are assigned the correct Log On and Startup values. If you are running a **distributed installation** of Tableau Server, perform these steps on all nodes in the cluster.

Note: The Startup Values for TSM services changed in these maintenance releases: 2020.215, 2020.3.10, 2020.4.6, and 2021.1.3. Values changed from "Automatic" to "Automatic (Delayed Start)" for the following TSM services: Tableau Server Administration Agent, Tableau Server Administration Controller, Tableau Server Client File Service, Tableau Server Coordination Service, Tableau Server License Manager, and Tableau Server Service Manager. If you are running older versions of Tableau Server you do not have to change these values from "Automatic" but can do so without negative impact.

1. Log on as administrator to the computer running Tableau Server.
2. On the Tableau Server computer, select **Start > Control Panel > Administrative Tools > Computer Management > Services and Applications > Services**.
3. Open Services and Applications, then click **Services**. Confirm that the following services have the correct settings:

Service Name	Logon Value	Startup Value
FLEXnet Licensing Service 64	Local System	Automatic

Tableau Server on Windows Help

Service Name	Logon Value	Startup Value
Secondary Logon	Local System	Manual
Tableau Server Administration Agent	Local System	Automatic (Delayed Start)
Tableau Server Administration Controller	Network Service	Automatic (Delayed Start)
Tableau Server Client File Service	Network Service	Automatic (Delayed Start)
Tableau Server Coordination Service	Network Service	Automatic (Delayed Start)
Tableau Server License Manager (Runs on initial node only)	Local Service The License Manager relies on default Windows folder permissions that are applied to the Local Service. In more secure environments, you must modify the permissions on the Tableau installation directory. Otherwise, you may encounter licensing errors. See Verify Folder Permissions for more information.	Automatic (Delayed Start)
Tableau Server Service Manager	<domain>\<username> This is the Run As service account. See below. If you have not specified a Run As service account, then the Network Service system account is used.	Automatic (Delayed Start)

Note: Do not change the default settings on the **Recovery** tab of the **Tableau Server Service Manager Properties** dialog box; leave the settings for failure recovery as **Restart the Service**.

Changing the Log On Value

To change the **Log On** value for Tableau Server (tabsvc) to the Run As service account, see [Change the Run As Service Account](#).

Revoke Run As Service Account Permissions

Changing the Run As service account in Tableau Server Configuration Utility does not remove the permissions from the previous account. Therefore, after you change the Run As service account, we recommend manually revoking permissions from the previous account as a secure best practice. Follow the procedure below to revoke permissions from the previous Run As service account.

If you have changed your Run As service account and your organization uses a forward proxy solution, then you may need to reconfigure the local LAN settings with the new Run As service account. See [Configure a forward proxy server](#) for more information.

You must be logged onto the Tableau Server computer with an administrator account to perform the following procedures.

Remove folder permissions

Tableau Server configures permissions on Windows folders according to the location where you install Tableau Server. Before you remove folder permissions, review [Verify Folder Permissions](#) to identify the resources for which you will need to remove permissions. Run the following procedure for each of the resources you have identified:

1. For each resource (drive, folder, executable), right-click the resource, and then click **Properties**.
2. On the resource property page, click the **Security** tab, and then click **Edit** to change permissions.

Tableau Server on Windows Help

3. On the Permissions page, select the previous Run As service account and then click **Remove**.
4. Click **OK**.

Remove registry permissions

Remove the previous Run As service account from the following registry locations:

- HKEY_CURRENT_USER\Software\Tableau
- HKEY_LOCAL_MACHINE\Software\Tableau

Warning: Editing the Windows registry incorrectly can have harmful effects on your computer.

1. Open the Registry Editor by entering `regedit` in Windows Run, and then clicking **OK**.
2. For each registry directory, right-click the **Tableau** folder, and then click **Permissions**.
3. In the **Permissions for Tableau** page, select the previous Run As service account, and then click **Remove**.
4. Click **OK**.

Remove security policies

Remove the previous Run As service account from the following security policies:

- “Log on as a service” policy
 - “Allow log on locally” policy
1. Select **Start > Control Panel > Administrative Tools > Local Security Policy**.
 2. In **Local Security Policy**, open **Local Policies**, select **User Rights Assignments**.
 3. For each policy:
 - a. Right-click the policy and then select **Properties**.
 - b. On the policy property page, select the previous Run As service account, and then click **Remove**.
 - c. Click **OK**.

Identity Store

Tableau Server requires an identity store to manage user and group information. There are two kinds of identity stores: local and external. When you install Tableau Server you must configure either a local identity store or an external identity store.

For information about configuration options for the identity store, see [identityStore Entity and External Identity Store Configuration Reference](#).

Local identity store

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

External identity store

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the authoritative source for all user and group data.

If you have configured the Tableau Server identity store to communicate with an external LDAP directory, then all users (including the initial admin account) that you add to Tableau Server must have an account in the directory.

When Tableau Server is configured to use an external LDAP directory, you must first import user identities from the external directory into the Tableau Server repository as system users. When users sign in to Tableau Server, their credentials are passed to the external directory, which is responsible for authenticating the user; Tableau Server does not perform this authentication. However, the Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. Therefore, after authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

Tableau Server on Windows Help

Active Directory is an example of an external user store. Tableau Server is optimized to interface with Active Directory. For example, when you install Tableau Server on an Active Directory domain-joined computer using the Configure Initial Node Settings, Setup will detect and configure most Active Directory settings. If, on the other hand, you are using TSM CLI to install Tableau Server, you must specify all the Active Directory settings. In this case, be sure to use the LDAP - Active Directory template to configure identity store.

If you are installing into Active Directory, you must install Tableau Server onto a computer that is joined to the Active Directory domain. Additionally, we recommend that you review [User Management in Deployments with External Identity Stores](#) before you deploy.

For all other external stores, Tableau Server supports LDAP as a generic way to communicate the identity store. For example, OpenLDAP is one of several LDAP server implementations with a flexible schema. Tableau Server can be configured to query the OpenLDAP server. To do so, the directory administrator must provide information about the schema. During setup, you must use Configure Initial Node Settings to configure a connection to other LDAP directories.

LDAP bind

Clients that wish to query a user store using LDAP must authenticate and establish a session. This is done by binding. There are multiple ways to bind. Simple binding is authenticating with a username and password. For organizations that connect to Tableau Server with simple bind, we recommend configuring an SSL encrypted connection, otherwise the credentials are sent over the wire in plaintext. Another type of binding Tableau Server supports is GSSAPI binding. GSSAPI uses Kerberos to authenticate. In Tableau Server's case, Tableau Server is the client and the external user store is the LDAP server.

LDAP with GSSAPI (Kerberos) bind

We recommend binding to LDAP directory with GSSAPI using a keytab file to authenticate to the LDAP server. You will need a keytab file specifically for the Tableau Server service. We also recommend encrypting the channel with the LDAP server using SSL/TLS. See [Configure Encrypted Channel to LDAP External Identity Store](#).

If you are installing into Active Directory, and the computer where you are installing Tableau Server is already joined to the domain, then the computer may already have a configuration file and a keytab file. In this case, the Kerberos files are for the operating system functionality and authentication. Strictly speaking, you can use these files for GSSAPI bind, but we don't recommend using them. Instead, contact your Active Directory administrator and request a keytab specifically for the Tableau Server service. See [Understanding Keytab Requirements](#).

Assuming your operating system has a properly configured keytab for authentication to the domain, then the Kerberos keyfile for GSSAPI bind is all you need for the base installation of Tableau Server. If you plan to use Kerberos authentication for users, then [configure Kerberos for user authentication](#) and [Kerberos delegation to data sources](#) after installation is complete.

LDAP over SSL

By default, LDAP with simple bind to arbitrary LDAP servers is not encrypted. User credentials that are used to establish the bind session with the LDAP server are communicated in plaintext between Tableau Server and the LDAP server. We strongly recommend that you encrypt the channel between Tableau Server and the LDAP server.

If your organization uses an LDAP directory other than Active Directory, see [Configure Encrypted Channel to LDAP External Identity Store](#).

Authenticating clients

Basic user authentication in Tableau Server is by username and password sign-in for both local and external user stores. In the local case, user passwords are stored as a hashed password in the repository. In the external case, Tableau Server passes the credentials to the external user store and awaits a response as to whether the credentials are valid.

External user stores can also handle other kinds of authentication like Kerberos or SSPI (Active Directory only), but the concept is still the same, Tableau Server delegates the credentials or user to the external store and awaits a response.

You can configure Tableau Server such that username-password sign-in is disabled. In these scenarios other authentication methods, such as trusted authentication, OpenID, or SAML can be used. See [Authentication](#).

In some cases, you may need to update LDAP external directories to allow bind operations with username + DN format from Tableau Server. See [User binding behavior on sign in](#).

User Management in Deployments with External Identity Stores

This topic describes important technical details that you should be familiar with if you use an external identity store to manage users for Tableau Server. Tableau Server supports connecting to an external directory using LDAP. In this scenario, Tableau Server imports users from the external LDAP directory into the Tableau Server repository as system users.

Arbitrary LDAP directories

The system username in Tableau is whatever attribute you set as part of LDAP configuration, for example "cn". This is true for both individual user import and group sync functionality. See [External Identity Store Configuration Reference](#).

User binding behavior on sign in

You may need to update your LDAP configuration to allow binding with usernames appended with the DN. Specifically, you will need to update your LDAP configuration when Tableau Server is configured with an arbitrary LDAP directory. (e.g., OpenLDAP) that uses UPN or Email addresses as usernames.

Tableau Server will search for a given user based on the username that is supplied during sign in. Tableau Server will then attempt to bind with the username appended with the DN. In the case where Tableau Server has been configured with GSSAPI, then the username@REALM (domain name) will be used.

Active Directory

This content in rest of this topic assumes that you are familiar with Active Directory user management and basic Active Directory schema and domain concepts.

If you are installing into Active Directory, you must install Tableau Server onto a computer that is joined to the Active Directory domain.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Active Directory user authentication and Tableau Server

Tableau Server stores all user names in the Tableau Server identity store, which is managed by the repository. If Tableau Server is configured to use Active Directory for authentication, you must first import user identities from Active Directory to the identity store. When users sign in to Tableau Server, their credentials are passed to Active Directory, which is responsible for authenticating the user; Tableau Server does not perform this authentication. (By default, NTLM is used for authentication, but you can enable Kerberos or SAML for single sign-on functionality—however, in all these cases, authentication is left to Active Directory.) However, the Tableau user names stored in the identity store are associated with rights and permissions for Tableau Server. Therefore, after authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

Active Directory user name attributes and Tableau Server

Active Directory uniquely identifies user objects using several attributes. (For details, see [User Naming Attributes](#) on the MSDN website.) Tableau Server relies on two Active Directory user naming attributes:

Tableau Server on Windows Help

- `sAMAccountName`. This attribute specifies the logon name that was originally designed for use with older versions of Windows. In many organizations, this name is combined with the NetBIOS name for authentication, using a format like `example\j-smith`, where `example` is the NetBIOS name and `j-smith` is the `sAMAccountName` value. Due to the original design in Windows, the `sAMAccountName` value must be less than 20 characters.

In the Windows **Active Directory Users and Computers** administrative console, this value is in the field labeled **User logon name (pre-Windows 2000)** on the **Account** tab of the user object.

- `userPrincipalName` (UPN). This attribute specifies a user name in the format `j-smith@example.com`, where `j-smith` is the UPN prefix and `@example.com` is the UPN suffix.

In the Windows **Active Directory Users and Computers** administrative console, the UPN is a concatenation of two fields on the **Account** tab of the user object: the **User logon name** field, and the domain drop-down list next to it.

Adding users from Active Directory

You can **add users individually** from Active Directory, either by typing them in the server environment or by creating a CSV file and importing the users. You can also add Active Directory users by **creating a group via Active Directory** and importing all of the group's users. The result can be different depending on which approach you're using.

Importing UPN prefix as username

The user name that Tableau Server will import into the identity store will be the `sAMAccountName` value unless one of the following is true:

- If the UPN prefix of the user specified is greater than 20 characters, and the search string matches the full UPN, and is entered with the Windows login format (domain\UPN).

Consider a user with the following Active Directory attributes:

- UPN: `jsmith123456789012345@example.lan`
- sAMAccountName: `jsmith`

To import this user so that the UPN prefix (`jsmith123456789012345`) is used as the Tableau Server username, specify this search string when importing the user:

```
example.lan\jsmith123456789012345@example.lan
```

(To import this user so that sAMAccountName is used, simply specify `jsmith` when importing).

- If the user name you specify includes an @symbol in the UPN prefix (`jsmith@domain`) and the search string you enter is either in the Windows domain login format (`example.lan\jsmith@domain`) or is the full UPN.

Consider a user with the following Active Directory attributes:

- UPN: `jsmith@domain@example.lan` (in this case, the UPN prefix is `jsmith@domain` and the UPN suffix is `example.lan`)
- sAMAccountName: `jsmith`

To import this user so that the UPN prefix (`jsmith@domain`) is used as the Tableau Server username, specify either one of the following search strings when importing the user:

- `example.lan\jsmith@domain`
- `jsmith@domain@example.lan`

(To import this user so that sAMAccountName is used, simply specify `jsmith` when importing).

If user names were inadvertently imported using UPN names, you can delete the accounts in Tableau Server and then reimport those accounts using the sAMAccountName value for the user name, as shown in **User logon name (pre-Windows 2000)** in the **Windows Active Directory Users and Computers** administrative console.

In all cases, the Tableau Server Users page will present user names with the prefix of the UPN only. The full UPN is not displayed in the Tableau Server Users page.

Tableau Server on Windows Help

Adding user groups

If you import an Active Directory user group, Tableau will import all users from the group using the `sAMAccountName`.

Sync behavior when removing users from Active Directory

Users cannot be automatically removed from Tableau Server through an Active Directory sync operation. Users that are disabled, deleted, or removed from groups in Active Directory remain on Tableau Server so that you can audit and reassign the user's content before removing the user's account completely.

However, Tableau Server will act upon user objects differently based how the status of that user object changes in Active Directory. There are two scenarios: deleting/disabling users in Active Directory or removing users from synchronized groups in Active Directory.

When you delete or disable a user in Active Directory and then synchronize that user's group on Tableau Server, the following occurs:

- The user is removed from the Tableau Server group you synchronized.
- The user's role is set to "unlicensed."
- The user will still belong to the All Users group.
- The user is unable to sign in to Tableau Server.

When you remove a user from a group in Active Directory and then synchronize that group on Tableau Server, the following occurs:

- The user is removed from the Tableau Server group you synchronized.
- The user's role is retained: it is not set to "unlicensed."
- The user will still belong to the All Users group.
- The user will still have permission to the Tableau Server with access to everything that the All Users group is granted permission to use.

In both instances, to remove a user from Tableau Server, the server administrator must delete the user from the Server Users page in Tableau Server.

Domain nicknames

In Tableau Server, domain nickname is equivalent to the Windows NetBIOS domain name. In a Windows Active Directory forest, a fully qualified domain name (FQDN) can have an arbitrary NetBIOS name. The NetBIOS name is used as the domain identifier when a user logs in to Active Directory.

For example, the FQDN `west.na.corp.lan` might be configured with a NetBIOS name (nickname) of `SEATTLE`. The user `jsmith` in that domain could log on to Windows using either of the following user names:

- `west.na.corp.example.com\jsmith`
- `SEATTLE\jsmith`

If you want your users to sign in to Tableau Server with a NetBIOS name instead of the FQDN, then you'll need to verify that the nickname value for each domain where users log in is set. See `editdomain` for information on how to view and set the nickname value for each domain.

Support for multiple domains

You can add users and groups from a domain that's different from the domain of the Tableau Server computer in these cases:

- Two-way trust has been established between the server's domain and the users' domain.
- The server's domain trusts the users' domain (one-way trust). See [Domain Trust Requirements for Active Directory Deployments](#).

The first time you add a user or group from the non-server domain, you must specify the fully qualified domain name with the user/group name. Any additional users or groups you add from that domain can be added using the domain's nickname, provided the nickname matches the NetBIOS name. If Tableau Server connects to multiple domains, you must also specify the other domains that Tableau Server connects to by setting the `wgserver.domain.whitelist` (version 2020.3 and earlier) or

Tableau Server on Windows Help

`wgserver.domain.accept_list` (version 2020.4 and later) option with TSM. For more information, see `wgserver.domain.whitelist` or `wgserver.domain.accept_list`.

Duplicate display names

If user display names are not unique across multiple domains, then managing users with the same display name in Tableau can be confusing. Tableau Server will display the same name for two users. For example, consider an organization with two domains, `example.lan` and `example2.lan`. If user John Smith exists in both domains, then adding that user to groups and other administrative tasks will be confusing in Tableau Server. In this scenario, consider updating the display name in Active Directory for one of the users to differentiate the accounts.

Sign in to Tableau Server with NetBIOS name

Users can sign in to Tableau Server using the domain nickname (NetBIOS name), for example, `SEATTLE\jsmith`.

Tableau Server cannot query for NetBIOS name for a given FQDN. As a result, Tableau sets the nickname of a given FQDN according to the first entry in the namespace. For example, given the FQDN `west.na.corp.lan`, Tableau sets the nickname to `west`.

Therefore, you might need to update the domain nickname on Tableau Server before users can sign in using the nickname. If you do not update the nickname, users will have to sign in using a fully qualified domain name. For more information, see [Users From New Domain Unable to Log In and Do Not Appear in User List](#) in the Tableau Knowledge Base.

Domain Trust Requirements for Active Directory Deployments

When you run Tableau Server in an Active Directory environment across multiple domains (either in the same Active Directory forest or in different forests), some Tableau functionality is dependent on the trust relationship between the domains. For example, some administrators manage users in domains that are separate from where they deploy server applications, such as Tableau Server. In other organizations, a Tableau Server deployment might be shared with external partners or with different partners in the organization. Finally,

Windows-authenticated data sources, such as SQL Server, MSAS, or Oracle, that Tableau Server connects to may also be in other domains.

If it's feasible, we recommend configuring two-way trust between all domains that interact with Tableau Server. If this is not possible, Tableau Server can be configured to support user authentication where a one-way trust has been configured. In this case, a one-way trust between domains is supported when the domain in which Tableau Server is installed is configured to trust the domain where user accounts reside.

The following illustration shows one-way trust between the domain where Tableau Server is installed and the domain where user accounts reside:

In this scenario, Tableau Server is in the dev.local domain, and users from the users.lan Active Directory domain are imported into Tableau Server. A one-way trust is required for this scenario; specifically, the dev.local domain is configured to trust the users.lan domain.

Users in the users.lan domain can access Tableau Server in the dev.local with their normal Active Directory credentials. However, you may need to update the domain nickname on Tableau Server before users log on with the nickname. Refer to the [Tableau Knowledge Base](#) for more information.

When you configure Tableau Server for this scenario, specify the primary user domain during installation. See [Configure Initial Node Settings](#). To ensure that Tableau Server can connect to other Active Directory domains, you must also specify other domains that Tableau

Tableau Server on Windows Help

Server connects to by setting the `wgserver.domain.accept_list` option with TSM. For more information, see `wgserver.domain.accept_list`.

The Run As service account must also have query (Read) access to each domain from which users will be imported.

Kerberos single sign-on is supported in this one-way trust scenario.

Review [User Management in Deployments with External Identity Stores](#) to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

Connecting to live data in one-way trust scenarios

In the one-way trust scenario, users connecting to Tableau Server can connect to live data that's hosted in the cloud or on any other data source on premises that does not rely on Windows authentication.

Data sources that require Windows-authentication might have additional authentication requirements that complicate the scenario, or that can even prevent Tableau Server users from connecting. This is because Tableau Server uses the Run As service account for authentication with such data sources. If you are running Tableau Server in a different domain than data sources that use Windows authentication, verify that the Run As service account that is used for Tableau Server can access the data source.

Communicating with the Internet

In most enterprises, Tableau Server needs to communicate with the internet. Tableau Server was designed to operate inside a protected internal network. Do not set up Tableau Server directly on the internet or in a DMZ. Instead, communications between your network and the internet should be mediated using proxy servers. If the computer running Tableau Server cannot access the internet directly, then you may need to deploy forward proxy servers to mediate traffic from inside the network to targets on the internet. Tableau Server doesn't support pass-through or manual proxy authentication.

For inbound traffic, we recommend running Tableau Server behind reverse proxy servers.

How Tableau communicates with the internet

Tableau Server requires outbound access to the internet for these scenarios:

- Working with maps. Tableau uses map data that is hosted externally.

Tableau Server needs to connect to the following internet locations with port 443 to use maps:

- mapsconfig.tableau.com
- api.mapbox.com

If Tableau cannot make these connections, maps may fail to load.

You can test connectivity by accessing each of those addresses in a browser:

<https://mapsconfig.tableau.com/v1/config.json> and <https://api.mapbox.com/> will prompt you to download a json file.

If you use a proxy to connect to the internet and are unable to connect to api.mapbox.com, see [Working with firewalls](#) on the Mapbox website.

For Tableau Server version 2019.1 and earlier, see the documentation for your version: [Tableau Help](#)

- Connecting to the Tableau send-logs server.

You can upload log files to Tableau when working with Support. See [tsm maintenance send-logs](#). To successfully upload files to Tableau, your Tableau Server must be able to communicate with the send-logs server on port 443:

report-issue.tableau.com:443

- Sending Basic Product Data.

The domain, prod.telemetry.tableausoftware.com, is used by Tableau to receive the Basic Product Data about process launch and shutdown. It is also used for the more general Product Usage Data.

Tableau Server on Windows Help

Traffic to this domain will occur on port 80 (for initial registration of our Product Data clients) and on port 443 (for all subsequent traffic).

prod.telemetry.tableausoftware.com:80

prod.telemetry.tableausoftware.com:443

- Licensing. Tableau products connect to the internet to activate product keys. Unless you activate Tableau software with the [Offline Activation Tool](#), all Tableau products must have access to the internet to validate licenses. Specifically Tableau requires internet access during the following licensing operations: activation, deactivation, and on the refresh maintenance date. For more information about these operations, see [Manage Licenses](#).

Tableau Server needs to connect to the following internet locations for licensing purposes:

- atr.licensing.tableau.com:443
- licensing.tableau.com:443
- register.tableau.com:443
- s.ss2.us
- ocsp.rootg2.amazontrust.com
- ocsp.rootca1.amazontrust.com
- ocsp.sca1b.amazontrust.com
- crt.sca1b.amazontrust.com
- crt.rootca1.amazontrust.com
- ocsp.sca0a.amazontrust.com

- crt.sca0a.amazontrust.com
- ocsp.sca1a.amazontrust.com
- crt.sca1a.amazontrust.com
- ocsp.sca2a.amazontrust.com
- crt.sca2a.amazontrust.com
- ocsp.sca3a.amazontrust.com
- crt.sca3a.amazontrust.com
- ocsp.sca4a.amazontrust.com
- crt.sca4a.amazontrust.com
- crl.rootca1.amazontrust.com
- crl.rootg2.amazontrust.com
- crl.sca1b.amazontrust.com

Requests to the above domains may be on port 80 or 443. Port 80 is used for certificate validation (revocation, certificate chain, etc). Port 443 is used for SSL connections.

If Tableau Server cannot make a connection while attempting to activate its license, you will be prompted to do an offline activation.

- Working with external or cloud-based data.

Tableau Server needs to connect to the following internet location for Box, Dropbox, OneDrive, Google Drive, Google Sheets, and Anaplan services:

```
galop.connectors.tableau.com:443
```

Tableau Server can run without internet access. For more information about deploying Tableau Server in organizations without access to the internet, see [Install Tableau Server in a Disconnected \(Air-Gapped\) Environment](#).

In many enterprises, users also need to access Tableau Server from outside the network (that is, from the internet). For example, in many enterprises, users want to be able to reach Tableau Server from their mobile devices in order to interact with views that are stored on the server. To configure access to Tableau Server from the internet or from mobile devices, you should use a reverse proxy. See [Configuring Proxies for Tableau Server](#).

Configuring Proxies for Tableau Server

In most enterprises, Tableau Server needs to communicate with the internet. Tableau Server was designed to operate inside a protected internal network. Do not set up Tableau Server directly on the internet or in a DMZ. Instead, communications between your network and the internet should be mediated using proxy servers. Forward proxy servers mediate traffic from inside the network to targets on the internet. Reverse proxy servers mediate traffic from the internet to targets inside the network.

Who should read this article?

This article is for IT professionals who are experienced with general networking and gateway proxy solutions. The article describes how and when Tableau requires internet access, and describes how to configure your network and Tableau to use forward and reverse proxy servers for access to and from the internet. There are many third-party proxy solutions available, so some of the content in the article is necessarily generic.

Before you configure a proxy server, see [Communicating with the Internet](#).

Configure a forward proxy server

To enable communication from Tableau Server to the internet, deploy Tableau Server behind a forward proxy server. When Tableau Server needs access to the internet, it doesn't send the request directly to the internet. Instead, it sends the request to the forward proxy,

which in turn forwards the request. Forward proxies help administrators manage traffic out to the internet for tasks such as load balancing, blocking access to sites, etc.

If you use a forward proxy, you must configure the computers that run Tableau Server inside the network to send traffic to the forward proxy. Tableau Server doesn't support pass-through or manual proxy authentication.

If you are running OpenID authentication with a forward proxy solution, additional configurations are required. See [Configure OpenID to work with a forward proxy](#).

Configuring Tableau Server on Windows to work with a forward proxy

The steps for configuring internet options on the Tableau Server computer depend on which of these scenarios describes your enterprise:

- **Your organization doesn't use a forward proxy solution.** If your organization is not running a proxy solution and the computer where you are installing Tableau Server can communicate with the internet, you don't need to follow the procedures here.
- **A proxy solution is deployed, and automatic configuration files define connection settings.** If your organization uses automatic configuration files (such as PAC or `.ins` files) to specify internet connection information, you can use this information in the Local Area Network (LAN) Settings dialog box in Windows. For more information, see [Enable Automatic Detection and Configuration of Browser Settings](#) on the Microsoft support site.
- **A proxy solution is deployed, but automatic configuration files are not deployed.** For this scenario, you must configure LAN settings on the Windows computer that is running Tableau Server so that connections to your proxy server are run under the security context of the Run As User account. You must also configure `localhost` and other internal Tableau Server instances as exceptions.

The following procedure describes the steps for the last scenario—a proxy solution without automatic configuration files, where Tableau Server is running on Windows Server.

Note: If you are using a distributed installation of Tableau Server, perform the following procedures on the initial server node and on each additional node.

Step 1: Add the Run As service account to the Local Administrators group

To perform this procedure, you must log onto the Tableau Server computer with the as the Run As service account. By default, the "log on locally" policy is not applied to the Run As service account. Therefore, you must temporarily add the Run As service account to the Local Administrators group.

If you haven't installed Tableau Server on the computer yet, see [Change the Run As Service Account](#). If you already installed Tableau Server and configured the Run As service account, then you can determine the Run As service account name by signing into TSM Web UI. The Tableau Server Run As service account is listed on the **Security** tab of the **Configuration** window. See [Sign in to Tableau Services Manager Web UI](#).

Add the Run As service account to the Local Administrators group using steps in [Add a member to a local group](#) on the Microsoft website. When you've finished configuring the forward proxy information, you'll remove the Run As service account from the Local Administrators group.

Step 2: Configure the proxy server in Windows LAN Settings

1. Using the Run As service account, log onto the computer where Tableau Server is installed or will be installed.
2. Open the **Local Area Network (LAN) Settings** dialog box. (A quick way to get to this dialog box is to search for `Internet Options` in the Windows Start menu. In the **Internet Properties** dialog box, click the **Connections** tab, and then click **LAN settings**.)
3. Under **Proxy server**, select **Use a proxy server for your LAN**, enter the proxy

server address and port, and then select **Bypass proxy server for local addresses**.

Leave this dialog box open and continue to the next step.

Step 3: Add exceptions to bypass the proxy server

You add exceptions to this proxy configuration to guarantee that all communications within a local Tableau Server cluster (if you have one now or will have one later) do not route to the proxy server.

1. In the LAN settings dialog box, click **Advanced**. (This button is available only if you've selected the option to use a proxy server for your LAN.)
2. In the **Proxy Settings** dialog box, in the **Exceptions** field, enter the following:

Tableau Server on Windows Help

- `localhost`
- Server host names and IP addresses of other Tableau Server computers in the same cluster.

Use semicolons to separate items.

3. Close the proxy settings dialog box and the Local Area Network (LAN) Settings dialog box.
4. In the **Internet Properties** dialog box, click **OK** to apply the settings.

Stay logged onto the computer and continue to the next step.

Step 4: Verify proxy settings do not conflict with Windows environment variables

Some organizations configure forward proxy settings as environment variables in the Windows operating system. If such settings are configured on the computer that is running Tableau Server, then you must verify that they do not conflict with the configurations you've completed here.

1. On the computer that is running Tableau Server, enter "advanced system settings" in the search box and then click Enter to open the **System Properties** box.
2. On the **Advanced** tab, click **Environment Variables**.
3. Scroll through the **System variables** field.

If `http_proxy` or `https_proxy` are specified, verify that the values do not conflict with the proxy server address that you configured in the previous step.

- If the existing settings do not conflict, then go to "Step 5: Test the proxy configuration."
- If the existing settings do conflict, then create a new variable named `no_proxy`, and enter:

- the host name,
- IP address, and
- port of the Tableau Server for the value

For example, `localhost`, `192.168.0.10`:80. For more information see the Microsoft MSDN article, [Set Environment Variables](#).

4. Click **OK**.

Step 5: Test the proxy configuration

To test the new configurations, while still logged in with the Run As service account on the Tableau Server computer, open a web browser and test the following Tableau URLs:

`https://mapsconfig.tableau.com/v1/config.json` and `https://api.mapbox.com/` will prompt you to download a json file.

Step 6: Remove the Run As service account from the Local Administrator group

After you have tested the proxy settings, remove the Run As service account from the Local Administrators group. Leaving the Run As service account in the administrator group elevates the permissions of the Run As service account and is a security risk.

Restart Tableau Server to ensure that all changes are implemented.

Server crash reporter

If your organization uses a proxy server to connect to the internet then you must configure Tableau Server's crash reporter to use the proxy. Even if you have already configured Tableau Server to use a proxy, you must also configure server crash reporter separately. To configure proxy for server crash reporter, see [Configure Server Crash Reporter](#).

How a reverse proxy works with Tableau Server

A reverse proxy is a server that receives requests from external (internet) clients and forwards them to Tableau Server. Why use a reverse proxy? The basic answer is security. A reverse proxy makes Tableau Server available to the internet without having to expose the

Tableau Server on Windows Help

individual IP address of that particular Tableau Server to the internet. A reverse proxy also acts as an authentication and pass-through device, so that no data is stored where people outside the company can get to it. This requirement can be important for organizations that are subject to various privacy regulations such as PCI, HIPAA, or SOX.

The following diagram illustrates the communication path when a client makes a request to Tableau Server that is configured to work with a reverse proxy server.

1. An external client initiates a connection to Tableau Server. The client uses the public URL that's been configured for the reverse proxy server, such as `https://tableau.example.com`. (The client doesn't know that it's accessing a reverse proxy.)
2. The reverse proxy maps that request in turn to a request to Tableau Server. The reverse proxy can be configured to authenticate the client (using SSL/TLS) as a precondition to passing the request to Tableau Server.
3. Tableau Server gets the request and sends its response to the reverse proxy.
4. The reverse proxy sends the content back to the client. As far as the client is concerned, it just had an interaction with Tableau Server, and has no way to know that the communication was mediated by the reverse proxy.

Proxy servers and SSL

For better security, you should configure reverse proxy servers to use SSL for any traffic that's external to your network. This helps to ensure privacy, content integrity, and authentication. Unless you've deployed other security measures to protect traffic between your

internet gateway and Tableau Server, we also recommend configuring SSL between the gateway proxy and Tableau Server. You can use internal or self-signed certificates to encrypt traffic between Tableau Servers and other internal computers.

Mobile access

Tableau Server adds an X-header to all HTTP responses for Tableau Mobile sessions. By default, most proxy solutions will preserve X-headers. If your proxy solution does not preserve X-headers, then you will need to configure your proxy server to preserve the following header to all HTTP responses for Mobile client sessions: `X-Tableau: Tableau Server.`

If you have configured authentication at the proxy server gateway, then your proxy server must respond to Tableau Mobile HTTP requests with a HTTP 302 response. The 302 must include a redirect to the identity provider login page. To view a diagram that describes the 302 authentication sequence, see [Tableau Mobile Authentication Sequence](#) in the Tableau Community.

Reverse proxy and user authentication

Tableau Server will always authenticate users. This means that even if you are authenticating inbound connections at the gateway for your organization, Tableau Server will still authenticate the user.

However, not all clients will support user authentication with a reverse proxy:

- For supported web browsers, you can use SAML, OpenID Connect, Kerberos, Trusted Tickets or manual authentication with a reverse proxy. However, we recommend a transparent scenario where user requests are not prompted for authentication at the gateway. This recommendation doesn't prohibit using SSL for client/server system-level authentication at the gateway proxy, in fact, we strongly recommend SSL system-level authentication.
- Tableau Mobile supports SAML or manual authentication with a reverse proxy. The

Tableau Server on Windows Help

iOS version of Tableau Mobile additionally supports Kerberos with a reverse proxy. The same recommendation above applies.

- Tableau Desktop and Tableau Prep do not support authentication with a reverse proxy. For remote access, use a VPN solution or configure your reverse proxy to route traffic from Tableau Desktop or Tableau Prep directly to Tableau Server for authentication.

If your organization is authenticating with Active Directory:

- Active Directory with Enable automatic logon (SSPI) is not supported with a reverse proxy.
- Tableau Server must be configured for reverse proxy before configuring Tableau Server for Kerberos. For more information, see [Configure Kerberos](#).

Configure Tableau Server to work with a reverse proxy server

Before you configure Tableau Server, you'll need to collect the following information about the proxy server configuration. To configure Tableau Server, you use the `tsm configuration set` command. The information you need to collect corresponds to options you'll need when you run `tsm`.

Most of the following `tsm` options are also used to configure Tableau Server deployments that operate behind a load balancer. For more information, see [Add a Load Balancer](#).

Item	Description	Corresponding <code>tsm configuration set</code> option
IP address or CNAME	<p>You can either enter an IP address or a CNAME for this option.</p> <p>The public IP address or addresses of the proxy server. The IP address must be in IPv4 format, such as <code>203.0.113.0</code>, and it must be a static IP.</p>	<code>gateway.trusted</code>

Item	Description	Corresponding <code>tsm configuration set option</code>
	<p>If you are unable to provide a static IP, or if you are using cloud proxies or external load balancers, you can specify the CNAME (Canonical Name) DNS value that clients will use to connect to Tableau Server. This CNAME value must be configured on your reverse proxy solution to communicate with Tableau Server.</p>	
FQDN	<p>The fully qualified domain name that people use to reach Tableau Server, such as <code>tableau.example.com</code>. Tableau Server doesn't support context switching for this option. For example, the following URL is not supported: <code>example.com/tableau</code>.</p>	<code>gateway.public.host</code>
Non-FQDN	<p>Any subdomain names for the proxy server. In the example of <code>tableau.example.com</code>, the subdomain name is <code>tableau</code>.</p>	<code>gateway.trusted_hosts</code>
Aliases	<p>Any public alternative names for the proxy server. In most cases, aliases are designated using CNAME values. An example would be a proxy server <code>bigbox.example.com</code> and CNAME entries of <code>ftp.example.com</code> and <code>www.example.com</code>.</p>	<code>gateway.trusted_hosts</code>

Tableau Server on Windows Help

Item	Description	Corresponding <code>t-sm configuration set option</code>
Ports	Port numbers for traffic from the client to the reverse proxy server.	<code>gateway.public.port</code>

If you are using a distributed installation of Tableau Server, then run the following `t-sm` commands on the initial node in your cluster.

1. Enter the following command to set the FQDN that clients will use to reach Tableau Server through the proxy server, where *name* is the FQDN:

```
t-sm configuration set -k gateway.public.host -v "name"
```

For example, if Tableau Server is reached by entering `https://tableau.example.com` in the browser, enter this command:

```
t-sm configuration set -k gateway.public.host -v "tableau-example.com"
```

2. Enter the following command to set the address or the CNAME of the proxy server, where *server_address* is the IPv4 address or CNAME value:

```
t-sm configuration set -k gateway.trusted -v "server_ip_address"
```

If your organization uses multiple proxy servers, enter multiple IPv4 addresses, separating them with commas. IP ranges are not supported. To improve start up and initialization of Tableau Server, minimize the number of entries for `gateway.trusted`.

3. Enter the following command to specify alternate names for the proxy server, such as its fully qualified domain name, any not fully qualified domain names, and any aliases. If there's more than one name, separate the names with a comma.

```
t-sm configuration set -k gateway.trusted_hosts -v "name1, name2, name3"
```

For example:

```
tsm configuration set -k gateway.trusted_hosts -v
"proxy1.example.com, proxy1, ftp.example.com, www.ex-
ample.com"
```

4. If the proxy server is using SSL to communicate with the internet, run the following command, which tells Tableau that the reverse proxy server is using port 443 instead of port 80:

```
tsm configuration set -k gateway.public.port -v 443
```

Note: If the proxy server is using SSL to communicate with Tableau Server, SSL must be configured and enabled on Tableau Server.

5. Enter the following command to commit the configuration change:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Configure the reverse proxy server to work with Tableau Server

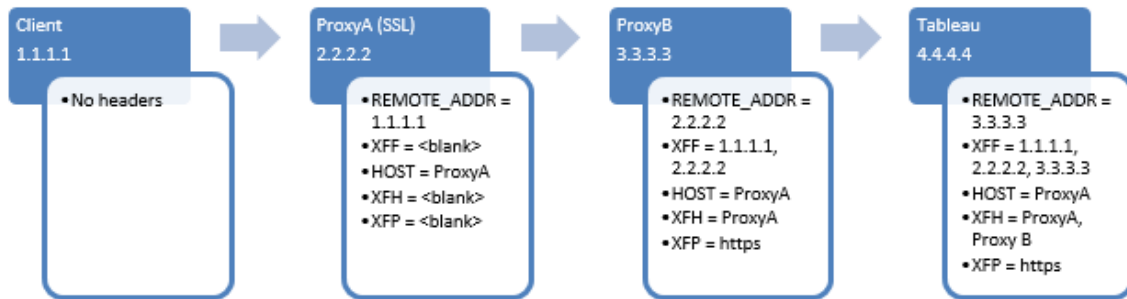

When a client accesses Tableau Server through a reverse proxy, specific message headers have to be preserved (or added). Specifically, all proxy servers in the message chain must be represented in the `gateway.trusted` and `gateway.trusted_hosts` settings.

The following graphic shows example headers for a single-hop message chain, where the proxy server is communicating directly with Tableau Server:

Tableau Server on Windows Help

The following graphic shows example headers for a multiple-hop message chain, where the message traverses two proxy servers before connecting to Tableau Server:

The following table describes what these headers are and how they relate to the configuration settings on Tableau Server:

Headers	Description	Related Tableau Server settings
REMOTE_ADDR and X-FORWARDED-FOR (XFF)	Tableau Server needs these headers to determine the IP address of origin for requests. X-FORWARDED-FOR header must present IP address chain to Tableau Server in the order the connections have occurred.	The IP address that you set <code>ingateway.trusted</code> must match the IP presented in REMOTE_ADDR. if you sent multiple addresses <code>ingateway.trusted</code> , one of them must match the IP presented in REMOTE_ADDR.
HOST and X-	These headers are used to generate	The host names that are

FORWARDED HOST (XFH)	absolute links to Tableau Server when it replies to the client. X-FORWARDED-HOST header must present host names to Tableau Server in the order the connections have occurred.	presented in X-FORWARDED-HOST header must be included in the host names that you specify in <code>gateway.trusted_hosts</code> .
X-FORWARDED-PROTO (XFP)	<p>This header is required if SSL is enabled for traffic from the client to the proxy, but not for traffic from the proxy to Tableau Server.</p> <p>The X-FORWARDED-PROTO headers are important for scenarios where HTTP or HTTPS is not maintained along each hop of the message route. For example, if the reverse proxy requires SSL for outside requests, but traffic between the reverse proxy and Tableau Server is not configured to use SSL, X-FORWARDED-PROTO headers are required. Some proxy solutions add the X-FORWARDED-PROTO headers automatically, while others do not. Finally, depending on your proxy solution, you might have to configure port forwarding to translate the request from port 443 to port 80.</p> <p>Related KB article: "Unable to Sign In" and "Invalid username or pass-</p>	<p>Port configuration on reverse proxy (inbound connections from client and outbound connections to Tableau Server) must be specified in the corresponding parameter: <code>gateway.public.port</code>, which is the port clients use to connect to the proxy.</p> <p>If the proxy server is using SSL to communicate with Tableau Server, SSL must be configured and enabled on Tableau Server.</p>

	word" Error With SAML After Upgrading.

Install and Configure Tableau Server

The topics referenced at the bottom of this page describe the steps to install and configure Tableau Server. If you are installing a distributed deployment (cluster), use the steps in this topic to install the initial node, then, to install additional nodes, see [Distributed and High Availability Tableau Server Installations](#).

After you run the installation, you must then continue setup by activating a license, registering Tableau Server, and configuring various settings including authentication.

What version are you installing or upgrading to?

Beginning with Tableau Server on Windows version 2019.4.0, a new Setup program is used to install and upgrade Tableau Server. If you are installing or upgrading to version 2019.3.x or earlier, see the [2019.3 Server Help for instructions](#).

Other installation methods

There are a few alternative methods that you can use to install Tableau Server.

- If you want a quick start procedure to install Tableau Server in a non-production environment, see [Jump-start Installation](#).
- The topics included in this installation section describe how to install Tableau Server on Windows using the interactive installer. If you want to install Tableau Server using a command line, see [Automated Installation of Tableau Server](#).
- If you are installing Tableau Server in an environment without a connection to the internet, see [Install Tableau Server in a Disconnected \(Air-Gapped\) Environment](#).
- You can also install Tableau Server onto various cloud platforms. See [Install Tableau Server in the Cloud](#).
- For single-server installations in departments or small businesses, see [Everybody's Install Guide](#).

Before you begin

To install Tableau Server you must have a computer that satisfies the hardware requirements. You will get an informational message if your computer meets the minimum requirements but does not satisfy the recommended minimum requirements. In this case, your computer hardware can handle a trial installation of Tableau but is not adequate for a production environment. For more information, see [Before you install...](#)

Installation steps

The following steps describe how to install Tableau Server on a single computer. Use the steps to install Tableau Server in a single server deployment. Use the steps to install the initial node in a multi-node Tableau Server deployment. Run the steps sequentially.

1. Install TSM
2. Activate and Register Tableau Server
3. Configure Initial Node Settings
4. Add an Administrator Account

Before you install...

Note: You can find additional information about technical specifications for Tableau Server on the Tableau web site, [here](#).

This topic includes requirements and recommendations that you must consider before you install Tableau Server into a production environment.

- If you want to install a single server, or if you want to do a minimal installation for test purposes, refer to our single-server installation guide, [Everybody's Install Guide](#).

- If you are deploying Tableau Server in a distributed cluster, review Distributed Requirements in addition to the requirements and recommendations described in this topic.

Hardware recommendations for production installations

The following list describes the minimum hardware recommendations for a production use, single- node installation of Tableau Server:

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> • 64-bit (x64 chipsets) • Must support SSE4.2 and POPCNT instruction sets • ARM-based processors are not supported 	8-core, 2.0 GHz or higher	<ul style="list-style-type: none"> • 64 GB (version 2021.4.0 and later) • 32 GB (versions prior to 2021.4.0) 	50 GB

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Multi-node and enterprise deployments	<p>Contact Tableau for technical guidance.</p> <p>Nodes must meet or exceed the minimum hardware recommendations, except:</p> <ul style="list-style-type: none"> • Nodes running backgrounder, where 4 cores may be acceptable.
---------------------------------------	--

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
---------------------	------------------	------------	------------	------------------------

- Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the [Option 2: Backup Repository Separately](#) topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.

- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

To see the full list of recommendations and to see the minimum requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

For public cloud deployments on Amazon Web Services and Google Cloud Platform, their "vCPU" is actually a CPU hyper-thread, and not a full CPU core. When sizing cloud instances, you will need twice as many vCPU as the Tableau Server CPU core requirements given (8 vCPU required for a minimum trial installation, 16 vCPU recommended for a single-node installation).

Operating system requirements

The following 64-bit Microsoft Windows Server operating systems are supported:

- Tableau Server 2021.3.0 and later:
 - Windows Server 2016
 - Windows Server 2019

Earlier versions:

Tableau Server on Windows Help

- Tableau Server 2020.1.0 - 2021.2.x:
 - Windows Server 2012
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019
- Tableau Server 2019.1.0 - 2019.x:
 - Windows Server 2008 R2
 - Windows Server 2012
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019

Note: All nodes in a multi-node cluster must have the same type of operating system. You cannot install a multi-node instance of Tableau Server on a combination of Linux and Windows nodes.

Installation directory

By default, Tableau Server will install on the system drive. The drive where Windows is installed is the system drive. In most cases, the system drive is the C:\ drive. In this default case, Tableau Server will install into the following directories:

- `C:\Program Files\Tableau\Tableau Server\packages`
- `C:\ProgramData\Tableau\Tableau Server`

Do not specify a symbolic link or a data directory location on a Network File System (NFS) volume.

Non-default installation locations

Rather than install onto the system drive, some organization install applications on a separate drive. During setup (or with automated installation), you can specify a different installation location. If you select a different installation drive or folder location during setup, then the data directory for Tableau Server will install into the same path. This means that if you install to a non-default location, the default `C:\ProgramData\Tableau\Tableau Server` path will not be created.

When you install to a non-default location, you must take the following into consideration:

- You may need to configure Run As service account permissions manually. If you do not use the predefined local account, `NetworkServices`, as the Run As service account, then you will need to set permissions for the account that you will be using. You must set these permissions after you install Tableau Server. See [Verify Folder Permissions](#).
- Log files are stored at `<installation path or drive>\data\tabsvc\logs`. The `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\logs` path in a default installation is converted to `<installation path or drive>\data\tabsvc\logs`.
- You may need to specify the same location when you upgrade to newer versions of Tableau Server. For more information on upgrading, see [Upgrade Tableau Server Overview](#).

Note: If you run Tableau Server on a VM, either locally, or in the cloud, be aware of the potential for complications related to licensing. This applies whether you are running Tableau Server as a standalone or in a cluster. If you are simply

upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment can end up with an untrusted license, and any attempts to upgrade will fail.

To clone a VM, make sure the Tableau Server is unlicensed (all licenses are deactivated). After cloning the VM, activate the Tableau license on the cloned VM and proceed with the upgrade.

- When installing a multi-node instance of Tableau Server, the installation location (path) must be the same on every node.

Tableau Prep Conductor

Tableau Prep Conductor is one of the process on Tableau Server. It runs a flow, checks connection credentials, and sends alerts if a flow fails. Tableau Prep Conductor leverages the scheduling and tracking functionality of Tableau Server so you can automate running flows to update the flow output instead of logging into Tableau Prep Builder to manually run individual flows as your data changes.

Tableau Prep Conductor is licensed separately and is available through the Data Management Add-on license. For more information on Tableau Prep Conductor licensing, see [License the Data Management Add-on](#).

We recommend you enable Tableau Prep Conductor on a dedicated node. For more information:

- If you are installing a new Tableau Server, see [Step 1 \(New Install\): Install Tableau Server with Tableau Prep Conductor](#).
- If you are adding Tableau Prep Conductor to an existing installation of Tableau Server, see [Step 1 \(Existing Install\): Enable Tableau Prep Conductor](#).

Additional requirements

Make sure that your environment also meets the following additional requirements:

Hostname

- Tableau Server must be able to resolve the hostname to an IP address either using the domain name server (DNS) or with a local host file on the computer running Tableau Server. By default, host files are stored at `\Windows\System32\Drivers\etc\hosts`.
- The hostname of the server must not change after you start Tableau Services Manager during the setup process. For example, this might happen if you use the cloud-init package to initialize a virtual machine, and you install Tableau Server on that virtual machine.
- Hostnames that include underscores (`_`) are not supported by Tableau Server.

Static IP address

The computer where you install Tableau Server must have a static IPv4 or IPv6 address.

Database drivers

To connect to specific data sources, the computer where you install Tableau Server must have the correct database drivers installed. For more information, see [Database Drivers](#).

Available ports

TSM and Tableau Server each require an available TCP port in order for you to access them. TSM defaults to port 8850, and the Tableau Server Gateway service defaults to port 80. We strongly recommend that you ensure that both port 8850 and 80 are not in use on your system before installing Tableau Server. If those ports are not available, the TSM and gateway ports may be dynamically remapped to different port numbers, and there is currently no interface for displaying which port they have been remapped to.

If you are installing Tableau Server on a computer that's also running IIS (not a recommended deployment), you should modify the Tableau's gateway port number to avoid conflict with IIS. You can specify a different gateway port number during the setup process.

Tableau Server on Windows Help

See Tableau Services Manager Ports.

Local firewall configuration

If you are running a firewall on the computer where you will be installing Tableau Server, then you will need to open the following default ports for Tableau Server traffic. All port numbers, except 443 can be changed.

Port	TCP/UDP	Used by ...	TYPE OF INSTALLATION	
			All	Distributed / High Availability
80	TCP	Gateway	X	
443	TCP	SSL. When Tableau Server is configured for SSL, the application server redirects requests to this port. Do not change this port.	X	
8850	TCP	Tableau Services Manager.	X	
8060	TCP	PostgreSQL database.	X	
8061	TCP	PostgreSQL backup verification port	X	
8000-9000	TCP	Range of ports reserved by default for dynamic mapping of Tableau processes		X
27000-27009	TCP	Range of ports used by Tableau Server for License service. This range must be open on the node running the License service and accessible from other nodes. By default, the initial node runs the License service.	X	

See Tableau Services Manager Ports

For information about configuring the local Windows firewall, refer to the Microsoft product documentation.

Local administrator

The account that you use to run Setup must be a member of the Local Administrators group on the Windows computer where Tableau Server is installed.

By default, you must also use an account with local administrator rights to run Tableau Services Manager (TSM) Web UI and CLI tools. However, after you have installed Tableau Server, you can specify a Windows group for TSM administration. See [Configure a Custom TSM Administration Group](#).

Use TSM to configure the Tableau Server components that rely on OS-level access, such as processes, authentication, log files, licensing, and alerts. See [TSM Authentication](#).

Tableau-specific administration, such as importing users, creating sites, web authoring, etc. is performed by Tableau Server administrators. You can configure these administrative accounts by assigning roles to users after you install. The initial Tableau Server administrator account is created as part of the installation process. See [Add an Administrator Account](#).

Run As service account

A Run As service account for the Tableau Server service to run under is useful if you're using NT Authentication with data sources or if you're planning on doing SQL Server impersonation. For more information, see [Run As Service Account](#) and [SQL Server Impersonation](#).

In some organizations, Group Policy or other system management solutions are used to standardize permissions and accounts on application servers. If your organization runs a such a solution, be sure to configure the system to accommodate the folder permissions required by the Run As service account. See [Verify Folder Permissions](#).

Antivirus software

Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Continue to the next step: [Install and Configure Tableau Server](#).

Minimum Hardware Requirements and Recommendations for Tableau Server

The following minimum hardware requirements and recommendations apply to all computers running Tableau Server, including physical hardware and virtual machines (VMs):

- **Minimum requirements for installation** reflect the minimum hardware your computer must have in order to install Tableau Server. We do not recommend you attempt run Tableau Server on servers with these values, even if you are just testing. Depending the features you have licensed and are using, you may experience poor performance and an unrealistic experience. In certain cases Tableau Server may not start without at least 20GB of memory.

For prototyping and Proof of Concept (PoC) testing, we recommend you use Tableau Online. This will give you an opportunity to experience Tableau Server on appropriately sized hardware.

- **Minimum recommendations for production** go beyond minimum installation requirements, and represent the minimum hardware configuration you should use for installation on most production nodes. If your computer meets the minimum installation requirements but does not meet these recommendations, the Setup program will warn you but you can continue the installation. For certain nodes dedicated to specific tasks and processes such as backgrounder, or Prep, you may be able to use servers that do not meet this minimum recommendation.

In addition, Tableau Server should not be installed on a physical computer or on a VM instance that is also running resource-intensive applications such as databases or application servers.

Note: If you install Tableau Server on a computer that meets the minimum requirements but does not have at least 8 cores and 16 GB of system memory, the default number of all processes installed is reduced to one of each process by design. For more information about processes, see [Server Process Limits](#)

Looking for Tableau Server on Linux? See [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

Minimum hardware requirements for installation

We strongly recommend any Proof of Concept (PoC) testing or prototyping be done using Tableau Online. This guarantees you will be running on systems with adequate resources.

The computer on which you are installing or upgrading Tableau Server must meet the minimum hardware installation requirements. If the Setup program determines that your computer does not meet the following requirements, you will not be able to install Tableau Server. Meeting these requirements does not guarantee you a good experience testing Tableau Server

For more information on how the Setup program determines hardware, see [Determining Computer Hardware](#).

Minimum Hardware Requirements	Processor	CPU	RAM	Free Disk Space
Note: These minimum requirements are for installing Tableau Server. They do not guar-	<ul style="list-style-type: none"> 64-bit (x64 chipsets) 	4- core	16 GB	15 GB

Minimum Hardware Requirements	Processor	CPU	RAM	Free Disk Space
--------------------------------------	------------------	------------	------------	--------------------------------

antee successful testing or use. For production minimum recommendations, see Minimum production hardware recommendations.

- Must support SSE4.2 and POPCNT instruction sets
- ARM-based processors are not supported

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.

Minimum production hardware recommendations

For production use, the computers on which you install or upgrade Tableau Server should, in most cases, meet or exceed the minimum hardware recommendations. These recommendations are general. Actual system needs for Tableau Server installations can vary based on many factors, including number of users and the number and size of extracts, as well as the features you have licensed. If the Setup program determines that your computer does not meet the following recommendations, you will get a warning, but you can continue with the installation process. For more information, see the Hardware recommendations for production installations.

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> 64-bit (x64 chipsets) Must support SSE4.2 and POPCNT instruction sets ARM-based processors are not supported 	8-core, 2.0 GHz or higher	<ul style="list-style-type: none"> 64 GB (version 2021.4.0 and later) 32 GB (versions prior to 2021.4.0) 	50 GB

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Multi-node and enterprise deployments	<p>Contact Tableau for technical guidance.</p> <p>Nodes must meet or exceed the minimum hardware recommendations, except:</p> <ul style="list-style-type: none"> Nodes running backgrounder, where 4 cores may be acceptable. Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM.
---------------------------------------	--

Important: The disk space requirement cannot be checked until you initialize TSM.

Tableau Server on Windows Help

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the [Option 2: Backup Repository Separately](#) topic.

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.

- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

For hardware recommendations for Tableau Server in the cloud, see the following:

- Selecting an AWS Instance Type and Size in the [Tableau Server on Windows in the AWS Cloud Administrator Guide](#)
- Selecting a Google Compute Engine Virtual Machine Type and Size in the [Tableau Server on Windows in the Google Cloud Platform Administrator Guide](#)
- Selecting a Microsoft Azure Virtual Machine Type and Size in the [Tableau Server on Windows in Microsoft Azure Administrator Guide](#)

Determining Computer Hardware

To determine how many physical cores a computer has, the Tableau Server setup program queries the operating system. To view hardware information that the setup program detected on your computer, open the `app-install.log` file in the following folder on the computer where you are installing Tableau Server:

```
<install directory>\ProgramData\Tableau\Tableau Server-
\logs\app-install.log
```

In the `app-install.log` file, look for lines similar to the following. These lines provide information about the physical cores that the setup program detected and that it used to determine the core count that is being used for licensing, as well as the amount of system memory that was detected.

```
2020-11-24 17:40:43.842 +0000 main : DEBUG com.t-
ableau-
soft-
ware.tabad-
min.configuration.builder.BootstrapConfigurationBuilder -
System processor count = 8
```

Tableau Server on Windows Help

```
2020-11-24 17:40:43.842 +0000 main : DEBUG com.tableau-  
ableau-  
soft-  
ware.tabad-  
min.configuration.builder.BootstrapConfigurationBuilder - System  
memory = 64383MB
```

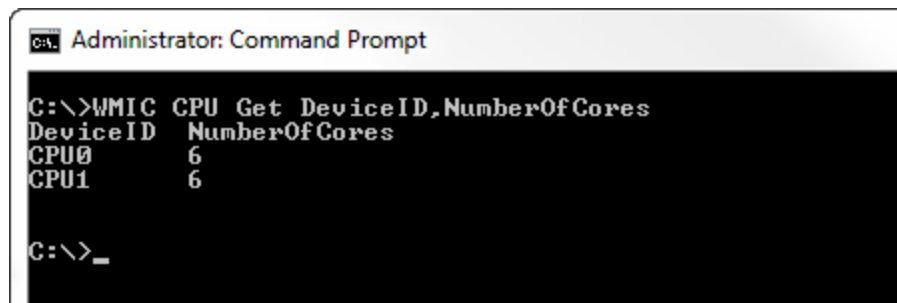

Manually determining the number of cores on your computer

To determine manually how many physical cores your server has, you can use the Windows Management Instrumentation Command-line tool (WMIC). This is useful if you do not know whether your computer will meet the minimum hardware requirements for installing Tableau Server.

1. Open a command prompt.
2. Enter the following command:

```
WMIC CPU Get DeviceID,NumberOfCores
```

The output will display the device ID or IDs and the number of physical cores the computer has.

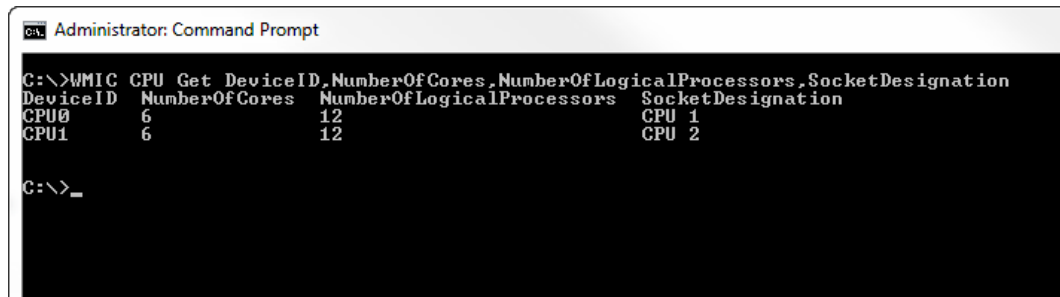

```
Administrator: Command Prompt  
C:\>WMIC CPU Get DeviceID,NumberOfCores  
DeviceID  NumberOfCores  
CPU0      6  
CPU1      6  
C:\>_
```

In this example, there are two CPUs, each with six cores, for a total of twelve physical cores. This computer would satisfy the minimum hardware requirements for installing Tableau Server.

The following command shows a longer version that lists the logical processors as well as the physical cores.

```
WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
```

```
Administrator: Command Prompt
C:\>WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
DeviceID    NumberOfCores    NumberOfLogicalProcessors    SocketDesignation
CPU0        6                12                           CPU 1
CPU1        6                12                           CPU 2
C:\>_
```

In the above example, the server has a total of twelve physical cores, resulting in 24 logical cores.

Install TSM

This topic guides you through the process of installing Tableau Server Tableau Services Manager (TSM).

Important: Do not install a beta version of Tableau Server in your production environment. You should also never restore a production Tableau Server installation using a backup of a beta version.

What version are you installing or upgrading to?

Beginning with Tableau Server on Windows version 2019.4.0, a new Setup program is used to install and upgrade Tableau Server. If you are installing or upgrading to version 2019.3.x or earlier, see the [2019.3 Server Help for instructions](#).

Prerequisites

Before proceeding, review the topic, [Before you install....](#)

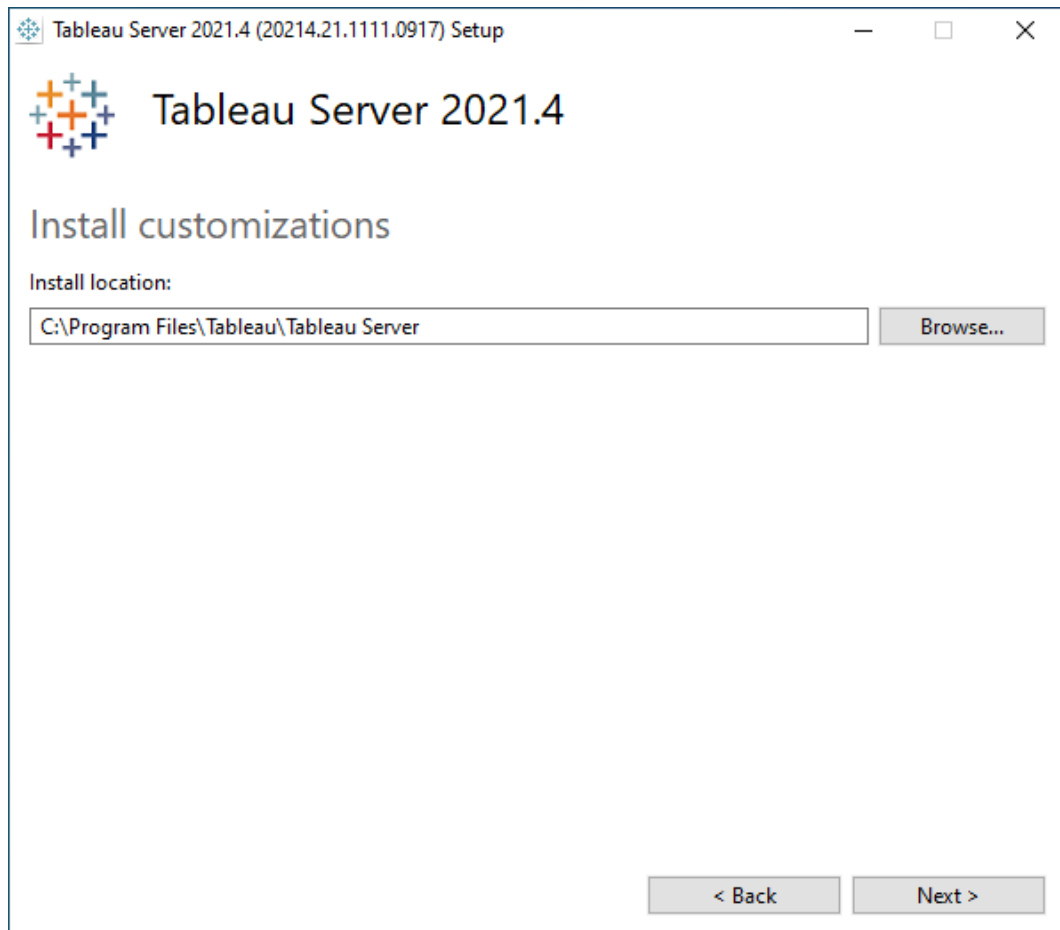

Use the TSM web interface

Running Setup

After you download the Tableau Server installation file, follow the instructions below to install the server.

Important: Do not install a beta version of Tableau Server in your production environment. You should also never restore a production Tableau Server installation using a backup of a beta version.

1. Sign in as a user with administrator access to the computer where you want to install Tableau Server and double-click the installation file.
2. Follow the on-screen instructions to complete Setup and install the application.

The default installation path is `C:\Program Files\Tableau\Tableau Server\<version>`. The Setup program displays the install path without the version, like this: `C:\Program Files\Tableau\Tableau Server`. You can choose a different location, including a different drive, either by browsing to or typing in a new path. Be aware that if you browse to a location, the Setup program appends `\Tableau Server` to the end of the path. You can remove this if it is not the location you want.

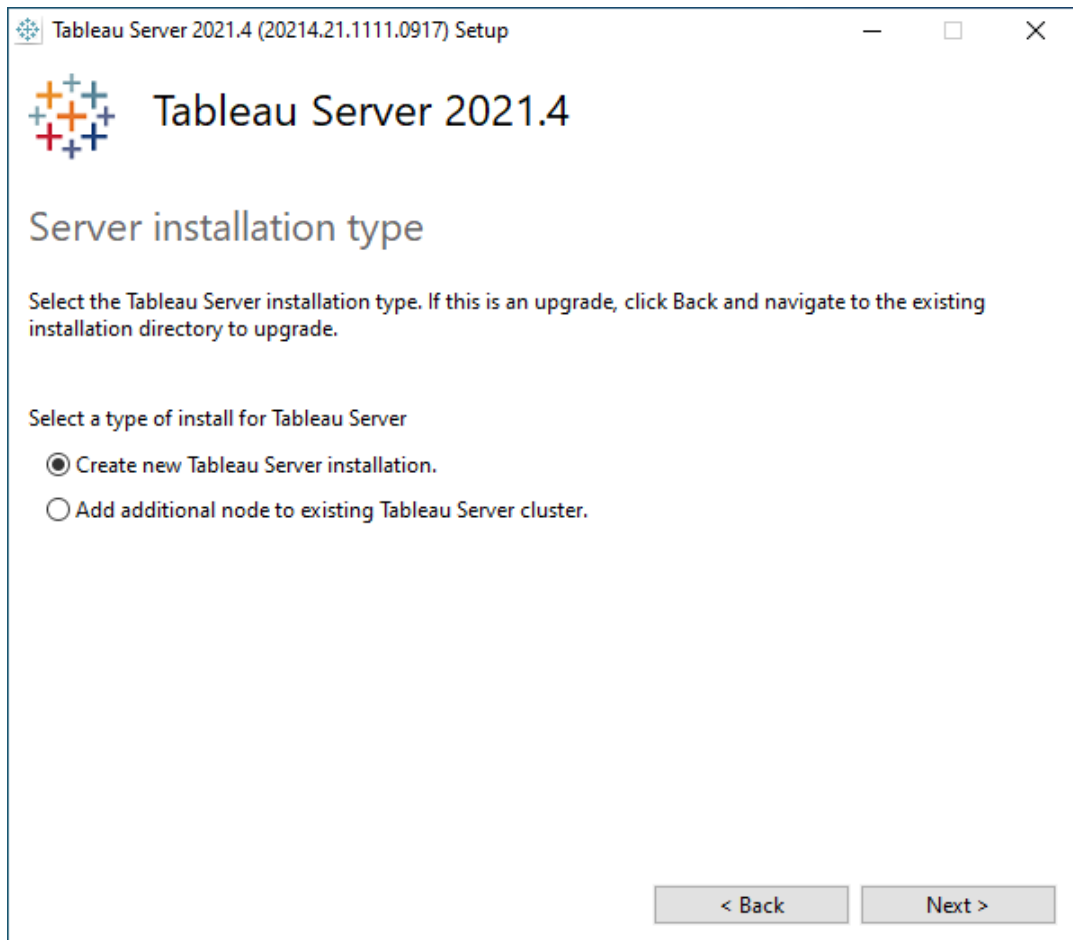

If you are upgrading from Tableau Server version 2018.1 or earlier and Tableau was installed to a non-default location, you need to specify the location of your existing version. Upgrade steps vary depending on your target version and install location. See

Tableau Server on Windows Help

Upgrade Tableau Server Overview for information on how to choose your upgrade steps.

Note: If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

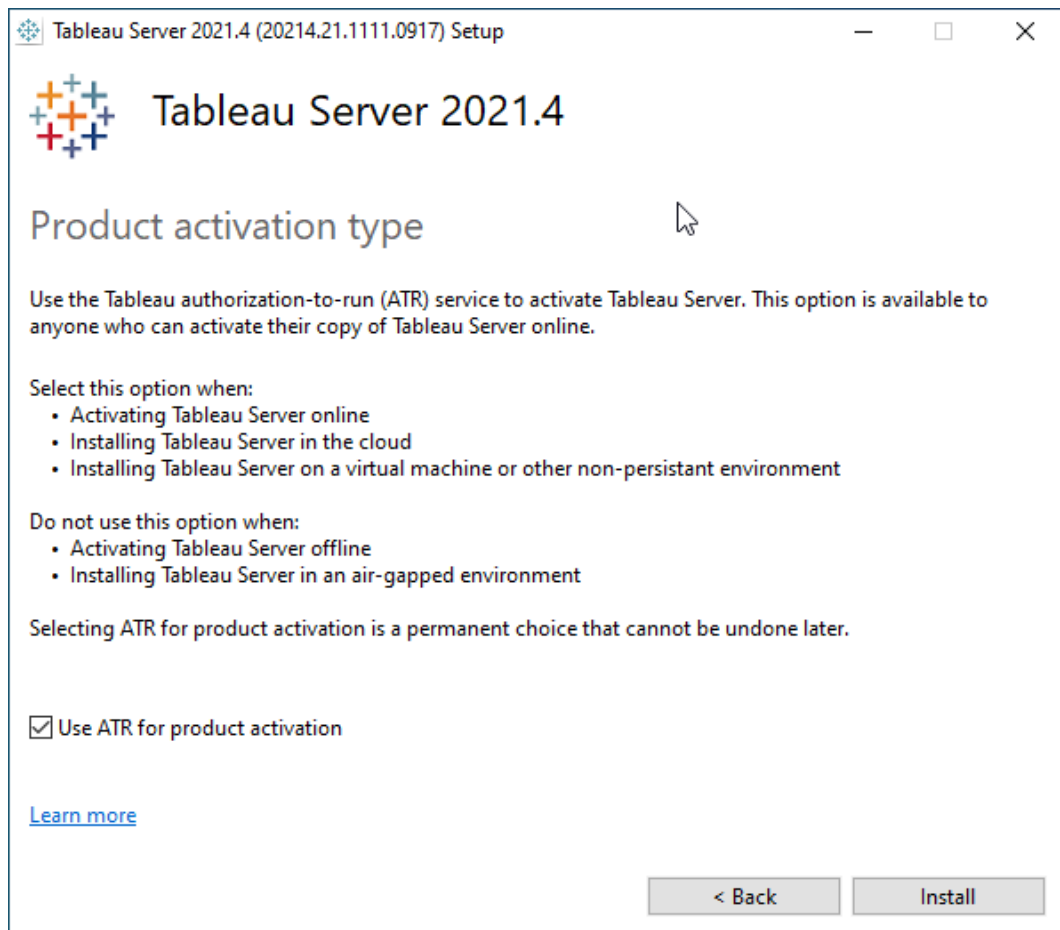

3. Click **Next**.

On the **Server installation type** page, you can specify whether you are installing the first node of a Server installation, or additional nodes in a multi-node installation. You

do not need to change this from the default (Create new Tableau Server installation.) unless you are installing a multi-node Tableau Server. If you are installing a multi-node Tableau Server, see [Install and Configure Additional Nodes](#).

4. Click **Next**.

On the **Product activation type** page, select whether you want to use the Tableau authorization-to-run (ATR) service to activate Tableau Server (the default), and then click **Install**. For more information about the Tableau authorization-to-run (ATR) service, see [Activate Tableau Server using the authorization-to-run \(ATR\) service](#).

5. After the installation completes, click **Finish**. Setup will then open the TSM configuration web page on the computer where you are installing Tableau Server.

Tableau Server on Windows Help

If you need to support characters that are not the Latin-1 set, install the Windows Language Packs via **Control Panel > Regional and Language Options**. The language packs will need to be installed on the initial server as well as any additional nodes.

Use the TSM CLI

Install Tableau Server

1. Open a command prompt as a user with administrator access to the computer where you want to install Tableau Server.
2. Download the Setup program from the [Tableau Server Downloads and Release Notes](#) page.
3. Navigate to the directory where you copied the Setup program.
4. Run the Setup program from the command line using the `/silent` flag (run unattended and silently with no UI prompts), `ACCEPTTEULA` (accept the End User License Agreement), and `ACTIVATIONSERVICE` (use Server ATR to activate Tableau Server) properties:

```
TableauServer-64bit-<version>.exe /silent ACCEPTTEULA=1  
ACTIVATIONSERVICE="1"
```

Note: There are a number of different installation options you can specify during CLI installation, for example, to change installation and logging paths, or to specify the TSM controller port. For a complete list of switches that you can specify during CLI installation, see [Install Switches and Properties for Tableau Server](#).

5. Close the command window and open a new one, then confirm that TSM is installed and running:

```
tsm status -v
```

The status will be `STOPPED` but the tsm-specific processes will be running:

```
node1: localhost
Status: STOPPED
'Tableau Server Coordination Service 0' is running.
'Tableau Server Administration Agent 0' is running.
'Tableau Server Administration Controller 0' is running.
'Tableau Server License Manager 0' is running.
'Tableau Server Client File Service 0' is running.
```

Configure Tableau Server for a forward proxy

If your organization uses a forward proxy solution to access the internet, then configure Tableau Server to use the proxy server. Tableau Server must access the internet for map data and for default licensing functionality.

We recommend configuring Tableau Server for a forward proxy solution at this point of the installation process. See [Configuring Tableau Server on Windows to work with a forward proxy](#).

Next step

- [Activate and Register Tableau Server](#)

Activate and Register Tableau Server

Before you can use Tableau Server, you must activate and register it.

Tableau Server requires at least one product key that both activates the server and specifies the number of license levels you can assign to users. You can access your product keys from the [Customer Portal](#).

If you need to activate Tableau Server on a computer that is offline, see [Activate Tableau Server Offline - Adding a License](#). If you need to activate additional product keys to add capacity to an existing Tableau Server installation, see [Add Capacity to Tableau Server](#).

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in *Install and Configure Tableau Server*:

- Install TSM
- TSM uses port 8850. If you are running a local firewall, open port 8850.
- Configure Product Key Operations with Forward Proxy

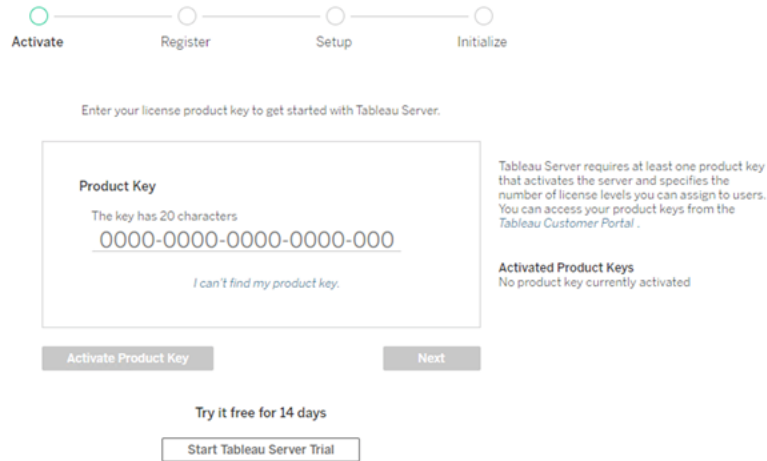

Use the TSM web interface

1. If the computer where you are installing Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, *Configure Product Key Operations with Forward Proxy*, before continuing.
2. Sign in to Tableau Services Manager Web UI.

The account you use must have administrative privileges on the computer where TSM is installed.

3. On the **Activate** page, Enter or paste your product key and click **Activate Product Key**.

After your product key is activated, it appears under **Activated Product Keys**.

4. To activate another product key, type over the key you just entered to add the new product key, and then click **Activate Product Key**. After your product key is activated, it appears under **Activated Product Keys**. Continue adding product keys in this manner until you're done.
5. When you're finished activating product keys, click **Next**.

Note: If the product keys you have activated don't have the necessary capacity, such as not enough cores or only a Viewer role product key, Tableau Services Manager displays the **Insufficient licenses applied** dialog box. Click **Activate Another Product Key** to add another product key and increase capacity on your Tableau Server installation.

Tableau Server on Windows Help

Insufficient licenses applied

You have not activated enough product keys for your Tableau Server deployment.

If you try to activate Tableau Server using these licenses, it may not run properly. We recommend that you activate additional licenses to support this Tableau Server deployment

[Tableau Customer Portal Troubleshooting](#)

[Activate Another Product Key](#)

6. On the **Register** page, enter your information into the fields and click **Register**.

● ——— ○ ——— ○ ——— ○
Activate Register Setup Initialize

Register with Tableau. All fields are required.

Register

Use the TSM CLI

Configure for forward proxy

If the computer where you are installing Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, [Configure Product Key Operations with Forward Proxy](#), before continuing.

Activate Tableau Server

To activate Tableau Server for production use, you must have a product key.

To activate a product key, run the following command:

```
tsm licenses activate -k <product key>
```

To activate a two-week trial, run the following command:

```
tsm licenses activate -t
```

If you are unable to activate Tableau, for example, if you get an error like this:

```
License Server not available
```

see [Activate Tableau Server Offline - Adding a License](#).

What if I get an access denied error when I attempt to run TSM commands?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Register Tableau Server

After activation, you need to register Tableau Server. To do this, create a registration file and then pass it as an option with the `tsm register` command.

1. Generate a template that you can edit by running the following command:

```
tsm register --template > /path/to/<registration_file>.json
```

2. Edit the template file to create your completed registration file.

Here is an example of a registration file in the required format:

```
{
  "zip" : "97403",
  "country" : "USA",
  "city" : "Springfield",
  "last_name" : "Simpson",
  "industry" : "Energy",
  "eula" : "yes",
  "title" : "Safety Inspection Engineer",
  "phone" : "5558675309",
  "company" : "Example",
  "state" : "OR",
  "department" : "Engineering",
  "first_name" : "Homer",
  "email" : "homer@example.com"
}
```

3. After saving changes to the file, pass it with the `--file` option to register Tableau Server:

```
tsm register --file /path/to/<registration_file>.json
```

For example:

```
tsm register --file C:\Users\mwatson\Documents\tableau-
reg-file.json
```

If you have a product key for Add-on license, you must activate that product key to be able to use the features included in each Add-on. Product keys for add-on licenses should only be activated after at least one capacity product key has been activated on the server.

- For license information on Tableau Data Management see, License the Data Management Add-on.

Tableau Server on Windows Help

- For license information on Tableau Advanced Management, see About Tableau Advanced Management.

Next step

- Configure Initial Node Settings

Activate Tableau Server Using the Authorization-To-Run (ATR) Service

You can use the Server authorization-to-run (ATR) service to activate Tableau Server deployed in on-premises, cloud, container, or virtual environments without running out of license activations. The ATR service achieves this by providing short-term leases of configurable duration (ATR duration) that ties the license to the device until product key expiration date is met. ATR handles activation capacity tracking so that when there is an underlying hardware change, maximum activation errors don't occur. This option is ideal for cloud-based or virtual environments, but is available to anyone who can activate their copy of Tableau Server online because Tableau Server needs to connect to various internet locations for licensing purposes. For more information, see [Communicating with the Internet](#).

Select this option if:

- You plan to activate Tableau Server online
- You plan to install Tableau Server in the cloud
- You plan to install Tableau Server on a virtual machine or other non-persistent environment
- You frequently test Tableau Server installations
- You often experience maximum activation errors

Do not use this option if:

- You plan to activate Tableau Server offline
- You plan to install Tableau Server in an air-gapped environment

Selecting ATR for product activation is a permanent choice that cannot be easily undone. To change this later, you must backup, remove, and then reinstall Tableau Server.

Note: When using Server ATR with subscription licenses, you do not need to refresh product keys in Tableau Server. To renew an expired subscription or make licensing changes, you must identify the new product key in the Tableau Customer Portal and activate it.

Select the Server ATR option

You can select the Server authorization-to-run (ATR) option when installing Tableau Services Manager (TSM) using the TSM web interface or the TSM CLI. For more information, see [Install TSM](#).

Set or change the Server ATR duration

When using Server authorization-to-run (ATR) to activate Tableau Server, you can change the ATR duration and use a setting different than the default of 432000 seconds (5 days). The ATR duration is the length of time that Tableau Server is authorized to run and will refresh while Tableau Services Manager (TSM) processes are up, requiring no new activation until the key(s) have reached their expiration date. If you're creating a test server or virtual machine (VM) that will have a short lifespan, you might want to shorten the ATR duration. Similarly, if you have a server that will remain for a long time, you might want to lengthen the ATR duration. The license refresh duration varies from hourly to daily, depending on the ATR duration. You should keep your Tableau Server running for at least 50 percent of the ATR duration. Otherwise if the Tableau Server is left shut down too long, you may need to reapply your license.

To change the ATR duration, you use the `tsm licenses atr-configuration set -duration <value_in_seconds>` command. For more information, see [tsm licenses atr-configuration set](#).

ATR duration in seconds	Minimum	Maximum	Default
Tableau Server (non-container)	14400 (4 hours)	7776000 (90 days)	432000 (5 days)

To set ATR duration and manually start the Activation Service, run the following

Tableau Server on Windows Help

commands:

Note: You must run these commands as an administrator from a command prompt. Depending on how your computer is configured, you may need to run them in the C:\Windows\System32 folder.

1. On the initial node, open a command prompt as administrator, and then use the following commands.
2. `tsm licenses atr-configuration set --duration <value_in_seconds>`
3. `tsm pending-changes apply`
4. `net stop activation-service_0`
5. `net start activation-service_0`

Move a Server ATR license to another Tableau Server

If you want to stop using your license on an existing Tableau Server and use it on a new installation of Tableau Server, you can move your Server ATR license. You might want to move licenses when:

- Switching between development or pre-production environments.
- Moving Tableau Server to upgraded hardware.
- Moving Tableau Server to cloud infrastructure.
- Using an ephemeral Tableau Server, such as a virtual machine (VM) or container.

How do ATR leases work?

When you sign into Tableau Server and activate it using your product key, your ATR lease remains active as long as the Administration Controller, also called the TSM Controller, and the Activation Service are running. If you stop using Tableau Server, such as when you shut

down the computer where Tableau Server is installed, you are automatically logged out and the ATR lease expires. Tableau reclaims the license and frees the capacity for new use after the ATR lease duration has elapsed.

Activate the same license on another Tableau Server

You can have one production and two non-production installations per license. If you have unused activations on a license, you can activate the same license on another Tableau Server. If you're out of activations, you can still activate the license after its lease expires.

1. You have an existing Tableau Server that is licensed using Server ATR.
2. Stop the existing Tableau Server from refreshing its leased activation. You can do this using any of the following methods:
 - Shut down your existing Tableau Server.
 - Uninstall the existing Tableau Server.
 - Disconnect the existing Tableau Server from the Internet by unplugging the ethernet cable or disconnecting wifi.
3. After the ATR lease expires, you can reuse the license on another Tableau Server.
4. On the new computer, install Tableau Server.

When prompted, activate Tableau Server using the same license.

Remove product keys that were activated using Server ATR

You can remove product key(s) that were activated using Server ATR when you want to reclaim license capacity from one Tableau Server installation and use it on another. For more information about reclaiming a product key, see [Deactivate Product Key](#).

Stop using Server ATR for activation

If you no longer want to use the Server ATR activation method for a specific Tableau Server, you must perform a backup, delete the existing Tableau Server, install a new

Tableau Server, and then restore from backup.

1. Perform a full backup of your Tableau Server. For more information, see [Perform a Full Backup and Restore of Tableau Server](#).
2. Completely remove Tableau Server using the `tableau-server-obliterate` script with the `-l` option. For more information, see [Remove Tableau Server from Your Computer](#).
3. Install and configure Tableau Server. When installing TSM, on the **Product Activation** page, clear the **Use ATR for product activation** check box. For more information, see [Install and Configure Tableau Server](#).
4. Restore from backup. For more information, see [Perform a Full Backup and Restore of Tableau Server](#).

Offline Activation When Installing Tableau Server

When you install Tableau Server, you have to activate at least one product key, but we recommend that you activate all Tableau Server licenses found in the Tableau Customer Portal. Doing this activates the server, and specifies the number of license levels you can assign to users. There are also times you may need to activate licenses after Tableau Server is installed, for example, if you add capacity to your server, or get a new product key. If you don't have your product key, you can get it from the [Tableau Customer Account Center](#).

In most cases, you can activate your key directly from Tableau, either during installation, or later, using the Tableau Services Manager (TSM) Licenses page, but there are some circumstances that don't allow you to do this. If your computer is not connected to the internet for example, or has a firewall that restricts access outside your intranet. In these cases you need to do an offline activation.

- Offline activation when adding a license—To complete an offline activation when you are adding a license to Tableau Server, see [Activate Tableau Server Offline - Adding a License](#).
- Offline activation of licenses during install—To complete an offline activation when you are installing Tableau Server, follow the steps below.

Offline activation overview and prerequisites

Offline activation of Tableau Server involves the following steps:

1. Generate an offline activation request file (`Tableau-OfflineActivationRequest.tlq`).
2. Upload the offline activation request to Tableau and download the resulting activation file (`activation.tlf`) to activate Tableau Server.

In this article

Use the TSM web interface

Use the TSM CLI

Use the TSM web interface

If you are unable to do an activation of your product key from within the TSM Setup UI, you can do an offline activation. This might be necessary if you are installing on a computer that is isolated without internet access. If you attempt to activate your product key and see a dialog that says online activation is unavailable, you can activate the key offline. Click **Activate License Offline**.

Tableau Server on Windows Help

Tableau displays instructions for the activation process.

1. Create an offline file for each product key you want to activate.

Create an offline file you will upload to Tableau. If your product key is not pre-filled in the form, enter your key and click **Create Offline File** to generate an offline file (TableauOfflineActivationRequest.tlq) on the local computer.

Step 1: Create, Upload, and Submit an Offline File

Enter a product key then create, save, and move the TableauOfflineActivationRequest.tlq file to a computer connected to the Internet. You will then need to upload and submit the offline file to Tableau (Step 2).

The key has 20 characters

Access a computer connected to the Internet and go to <http://www.tableau.com/support/activation>. Upload and submit the TableauOfflineActivationRequest.tlq file created above. This will generate the first activation.tlf file to upload in Step 2.

Leave the Tableau Server install program open and copy the Tableau-OfflineActivationRequest.tlq file to a computer with internet access. You need to upload this file to Tableau to generate an activation file.

2. Upload and submit the offline file.

On the computer where you copied the Tableau-OfflineActivationRequest.tlq file, open a browser and go to <http://www.tableau.com/support/activation> to open the Tableau Support Activation page. You will upload and submit the TableauOfflineActivationRequest.tlq file to Tableau. This automatically generates an activation file (activation.tlf) that you can download and copy back to the Tableau Server computer.

- a. On the Offline Activation page, click **Choose File** to select the Tableau-OfflineActivationRequest.tlq file.
- b. Click **Upload Activation File** to submit the file to Tableau.

- c. Click the [here](#) link to download the `activation.tlf` file to your computer.

Offline Activation

The activation was successful. Please click [here](#) to download your activation file.

For help creating the offline activation file, see [Activate Tableau Desktop Offline](#) or [Activate Tableau Server Offline](#). ([Linux](#))

- d. Copy the `activation.tlf` file to the computer where Tableau Server is installed.

3. Upload the activation file.

On the Tableau Server computer, click **Upload Activation File** to upload the file to Tableau Server. When you do this successfully, the **Activate Product Key** button is enabled.

Step 2: Upload Activation File

Upload the activation file (activation.tif) you downloaded from <http://www.tableau.com/support/activation> to activate your license.

activation.tlf

After activating product key, you can go back to Step 1 to enter another product key.

4. Click **Activate Product Key** to complete the offline activation and continue with the installation process.

Use the TSM CLI

Log in to Tableau Services Manager

Before you can proceed you must log in to Tableau Services Manager (TSM).

To log in to TSM, run the following command:

```
tsm login -u <username>
```

What if I can't log in?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Step 1 - Generate an offline activation request file

1. On the initial node, open a command prompt as administrator.
2. Type this command to get your offline activation file:

```
tsm licenses get-offline-activation-file -k <product-key> -  
o <target-directory>
```

You can get your product key from the [Tableau Customer Portal](#). The target directory must already exist.

3. Copy the offline activation file (`TableauOfflineActivationRequest.tlq`) from the target directory to a computer that has internet access.

Step 2 - Upload the offline activation request to Tableau

1. On the computer that has internet access, go to the Tableau [Product Activations](#) page.
2. Complete the instructions to upload your `Tableau-OfflineActivationRequest.tlq` file.

This creates an activation file, `activation.tlf`.

3. Download the resulting activation file from Tableau.

Step 3 - Initialize or activate your license

1. Copy the activation file (`activation.tlf`) to a location accessible from your Tableau Server computer.
2. Run the following command:

```
tsm licenses activate -f <path-and-activation-file>
```

3. (Skip this step if you are installing Tableau Server for the first time.)

Restart the server for licensing changes to take effect:

```
tsm restart
```

To verify that all licenses are activated, you can run this command:

```
tsm licenses list
```

If you have completed the steps above, you should see a success message:

```
Activation successful.
```

Tableau Server is activated. If you need additional assistance, contact [Tableau Technical Support](#).

Deactivate Tableau Server Offline

If Tableau Server does not have Internet access, you can use the instructions in this topic to deactivate Tableau Server. You will need to use a second computer that is able to access the Internet to complete this activation process.

Note: These instructions require you to save a file that you will use for deactivation. You must complete these steps using a browser other than Microsoft Edge, such as Google Chrome. If you use Edge, the product key return file used for deactivation is not created. To prevent existing users from becoming unexpectedly unlicensed, do not restart Tableau Server until you have activated a new license or transferred the site role for the users.

1. On the Tableau Server initial node, create a directory to store the offline deactivation file that is created in the next step.
2. Log in to TSM using a Tableau Administrator account, and then run the following

Tableau Server on Windows Help

command:

```
tsm licenses get-offline-deactivation-file -k <productkey>
-o <deactivation-file-directory>
```

3. Move the `TableauOfflineDeactivationRequest.tlq` file from the deactivation file directory that you specified in the previous command to a trusted computer that has Internet access.
4. On the trusted computer that has Internet access, open a web browser and visit the Tableau [Product Activations](#) page. Follow the instructions on that page to submit your `TableauOfflineDeactivationRequest.tlq` file.
5. When prompted, save the product key return file (`return.tlr`) from the **Product Activations** page.
6. Move the product key return file (`return.tlr`) from the trusted computer that has Internet access to the Tableau Server initial node that runs the Licensing Server service.
7. Log in to TSM using a Tableau Administrator account, and then run the following command:

```
tsm licenses deactivate -f <path-to-license-key-return-
file>
```

Configure Product Key Operations with Forward Proxy

If the computer where Tableau Server is installed has been configured to connect with a forward proxy server, then you must run the procedure in this topic to activate, refresh, or deactivate product keys for Tableau Server.

Alternatively, you can activate a product key offline, see [Activate Tableau Server Offline - Adding a License](#).

To access and subsequently configure product key information for your Tableau Server installation, the Windows service, **Tableau Server Administrative Controller**, must run under the Run As service account. For normal operation, this service runs under the Network Service system account. This procedure describes how to specify the Run As service account as the temporary account used to log on for the **Tableau Server Administrative Controller** service. After you have successfully run the product key operation, you must then change the log on credentials back to the Network Service system account.

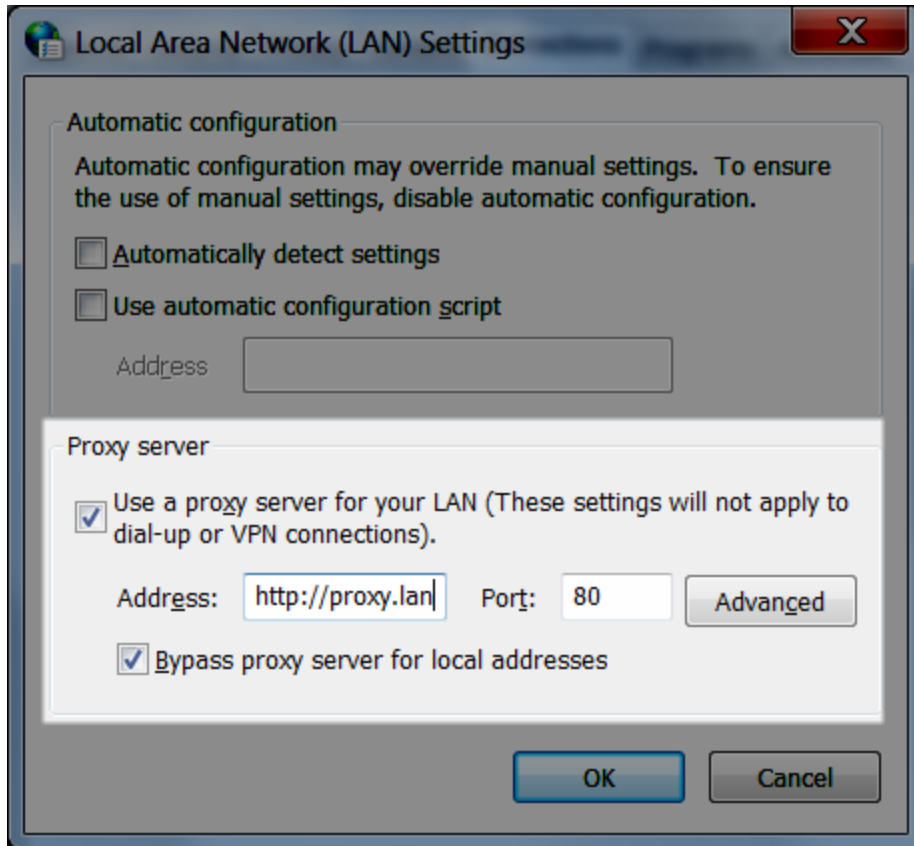

Before you begin

- If you are running a distributed deployment of Tableau Server, run the procedure in this topic on the initial node in the cluster.
- To run this procedure, you must know the Run As service account name and password. See [Change the Run As Service Account](#).
- Review your forward proxy configuration. The procedures below are for organizations that have set up the forward proxy using the "Internet Properties" on the Windows computer where Tableau Server is running. See [Configuring Proxies for Tableau Server](#).

Step 1: Verify proxy configuration

1. Log onto the computer where Tableau Server is installed or will be installed.
2. Open the **Local Area Network (LAN) Settings** dialog box. (A quick way to get to this dialog box is to search for `Internet Options` in the Windows Start menu. In the **Internet Properties** dialog box, click the **Connections** tab, and then click **LAN settings**.)
3. Under **Proxy server**, verify that **Use a proxy server for your LAN** is selected and

that the proxy server address and port has been specified.

Step 2: Temporarily change log on account for Tableau Server Administrative Controller service

1. Log onto the same computer that you verified in Step 1 above,
2. Open the **Services (Local)** Microsoft Management Console. (A quick way to get to this console is to search for `Services` in the Windows Start menu.)
3. Right-click **Tableau Server Administrative Controller**, click **Properties**. On **Tableau Server Administrative Controller Properties** page, click the **Log On** tab.
4. On the **Log On** tab, change `Network Service` to your Run As service account. Enter the password and then click **OK**.

5. In the **Services (Local)** Microsoft Management Console, right-click **Tableau Server Administrative Controller**, and then click **Restart**.

Step 3: Activate, refresh, or deactivate Tableau product keys

While the Tableau Server Administrative Controller is running under your Run As service account, you can activate, refresh, or deactivate your Tableau product key.

- To activate as part of the setup process, see [Activate and Register Tableau Server](#).
- To refresh a product key, see [Refresh Expiration Date for the Product Key](#).
- To deactivate a product key, see [tsm licenses deactivate](#).

Step 4: Revert the log on account back to Network Service

After you have completed your product key operation, you must change the log on account for Tableau Server Administrative Controller back to the `Network Service` account.

1. Open the **Services (Local)** Microsoft Management Console.
2. Right-click **Tableau Server Administrative Controller**, click **Properties**. On **Tableau Server Administrative Controller Properties** page, click the **Log On** tab.
3. On the **Log On** tab, click the **Browse** button.
4. On the **Select User** dialog box, enter `Network Service`, and then click **OK** to resolve the name and return to the **Log On** tab.
5. On the **Log On** tab, clear the passwords from the `Network Service` account, and then click **OK**.
6. In the **Services (Local)** Microsoft Management Console, right-click **Tableau Server Administrative Controller**, and then click **Restart**.

Configure Initial Node Settings

Looking for the Tableau Configuration Utility? As of version 2018.2, the Configuration Utility has been replaced by Tableau Services Manager (TSM). For more information about TSM, see [Comparing Functionality of tabadmin and TSM](#).

This topic describes how to configure essential server settings as part of the initial Tableau Server installation process.

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in [Install and Configure Tableau Server](#):

- Install TSM
- Activate and Register Tableau Server

Use the TSM web interface

After you have activated and registered Tableau Server, the installation program will display the Setup page.

Note: If you need to configure Tableau Server to connect to an LDAP directory that is not Active Directory, then you must use the TSM CLI.

The settings below are all you need to get started.

Identity Store

You cannot change the identity store after initializing.

- Local
- Active Directory

Run As Service Account

- NT AUTHORITY\NetworkService
- User Account

Gateway Port

Port Number: (Default)

Product Usage Data

- Disable sending usage data to Tableau

Include samples

- Include sample workbooks

Initialize

Tableau Server on Windows Help

Identity store settings

You must configure the identity store settings for the Tableau Server computer. The identity store manages Tableau Server accounts. You can configure the identity store to synchronize with an external directory (for example, OpenLDAP or Active Directory) or you can configure the identity store to manage and store accounts on Tableau Server. If you will be using a single sign on solution (OpenID, SAML, Kerberos, etc) then review the following topics before configuring the identity store:

- Identity Store
- Authentication

Important: After you have configured and applied settings for the identity store, it cannot be changed.

Identity Store

You cannot change the identity store after initializing.

Local

Active Directory

Domain	NetBIOS (Nickname)
<input type="text" value="example.lan"/>	<input type="text" value="EXAMPLE"/>

Allow unencrypted communication with Active Directory if an encrypted session cannot be established (Not recommended)

If you select **Active Directory**, Tableau Server will populate the **Domain** and **NetBIOS** fields from the computer on which you are running Setup. In some cases, Setup may not display these attributes. For more information about how Tableau Server connects and communicates with Active Directory, see User Management in Deployments with External Identity Stores.

Allow unencrypted communications with Active Directory

Your Active Directory infrastructure should manage certificates and trust with domain-joined computers. As such, the channel communication between Tableau Server and Active Directory resources should be encrypted. By default, Tableau Server requires an encrypted channel to Active Directory. We do not recommend allowing unencrypted communications with Active Directory, as this configuration is vulnerable to man-in-the-middle attacks. However, in some deployment scenarios, organizations do not encrypt the channel during initial configuration. Should you need to temporarily allow unencrypted communication with Active Directory, you can re-enable enforcement of encrypted communication later by running the tsm command, `wgserver.domain.allow_insecure_connection`, or by logging into TSM UI and toggling the setting under **User Identity & Access > Identity Store**.

Run As service account

By default, Tableau Server runs under the Network Service account. To use an account that will accommodate NT authentication with data sources, specify a user name and password. See Run As Service Account to learn more about creating and using a specific user account.

Important: Include the domain name with the user name—for example, `example\tableaurunas`.

Enter the password that you created for this account.

Tableau Server on Windows Help

Gateway port

The default port for web access to Tableau Server (via HTTP) is port 80. If the installation program determines that port 80 is in use when you first install Tableau Server, an alternate port (for example 8000) is used and shown in the Port number box.

You may need to change the port for other networking needs, for example, if you have a hardware firewall or proxy in front of the Tableau Server host, this might make running a back-end system on port 80 undesirable.

Product usage data

By default, Tableau Server shares usage data with Tableau that helps us better understand how you use our products, improve your overall experience, and build highly intelligent features that make Tableau even more powerful.

Clear this option if you do not want usage data sent to Tableau.

Product Usage Data

Disable sending usage data to Tableau

You can also change this setting after installation, on the TSM Maintenance tab in the TSM Web UI, or using the TSM CLI. For more information, see [Server Usage Data](#).

Sample workbook installation

By default, Tableau Server will install sample workbooks in the Default site when you initialize the server.

Include samples

Include sample workbooks

Alternatively, you can publish samples after installation by using the `publishsamples tabcmd` command.

Initializing install

After you have configured the options on this page, click **Initialize**.

The initialization process can take a while. When initialization is complete the following page is displayed:

Use the TSM CLI

First, configure identity store, gateway settings, and sample workbook installation. Then apply the changes, optionally verify your LDAP connection, and then initialize Tableau Server

Configure identity store settings

You must configure the identity store settings for the Tableau Server computer.

Important: After you have configured and applied settings for the identity store, it cannot be changed.

Use the json template in identityStore Entity to create a json file. After you have filled in the options with the appropriate values, you can then pass the json file with this command:

```
tsm settings import -f path-to-file.json.
```

Configure gateway settings (optional)

Depending on your network requirements, you may need to configure the gateway settings for the Tableau Server computer. For example, if you are enabling SSL or configuring access to Tableau Server with a reverse proxy, you may need to configure gateway settings. See `gatewaySettings` Entity for more information.

Use the json template in `gatewaySettings` Entity to create a json file. After you have filled in the options with the appropriate values, you can then pass the json file with this command:

```
tsm settings import -f path-to-json-file.json.
```

Configure product usage data (optional)

By default, Tableau Server shares usage data with Tableau to help us better understand how you use our products. This allows us to improve your overall experience and build highly intelligent features that make Tableau even more powerful.

Tableau collects only behavioral and usage data, never any of your confidential database values, and your usage data will never be shared or sold; its sole purpose is to improve your Tableau experience.

If you do not want to share product usage data, use the json template in `shareProductUsageDataSettings` Entity to create a json file, and specify a value of `false`. Then pass the json file with this command:

```
tsm settings import -f path-to-json-file.json.
```

You can also change this setting after installation, on the TSM Maintenance tab or using the TSM CLI. For more information, see [Server Usage Data](#).

Configure sample workbook installation (optional)

By default, Tableau Server will install sample workbooks in the Default site when you initialize the server.

Tableau Server on Windows Help

If you do not want to install sample workbooks during installation, run the following command:

```
tsm configuration set -k install.component.samples -v false
```

You can publish samples after installation by using the `publishsamples tabcmd` command.

Apply pending configuration changes

Now that you've created and set initial configuration, you must apply them. When you apply configuration changes, `tsm` will verify the settings you've set before committing them.

To apply configuration changes to Tableau Server, run this command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Once this command has completed, TSM processes are running, and Tableau Server is configured but is not running.

Verify LDAP configuration (Optional)

If your identity store uses LDAP, then we recommend verifying LDAP connectivity before proceeding.

To do so, run the following commands before you initialize the server:

```
tsm user-identity-store verify-user-mappings -v <user name>
```

```
tsm user-identity-store verify-group-mappings -v <group name>
```

User and group names must be valid names that exist in the LDAP server that you are connecting to. If your LDAP connection is set up correctly, then the user or group attributes will be returned to the shell. If your connection is not set up correctly, then an error will be returned.

Initialize and start Tableau Server

- To initialize and start Tableau Server, use the `--start-server` option:

```
tsm initialize --start-server --request-timeout 1800
```

This saves time by starting the server running after initialization.

- If you are going to reconfigure Tableau Server after initialization, leave the `--start-server` option off:

```
tsm initialize --request-timeout 1800
```

This stops the server after initialization.

Start Tableau Server. If you did not use the `--start-server` option during initialization and are finished configuring Tableau Server, use this command to start the server:

```
tsm start --request-timeout 900
```

Next Step

After initialization is complete, create the Tableau Server administrator user account. See [Add an Administrator Account](#).

Configuration File Example

This article provides an example of a complete JSON configuration file, with `gatewaySettings` and `identityStore` entities specified. In addition, a configuration key sets the gateway timeout to 900 seconds.

Your configuration file will look different depending on the options you need to set.

Tableau Server on Windows Help

You might set multiple .json configuration files during installation. To set the values for each file in Tableau Server, you run the following command, once for each configuration file:

```
tsm settings import -f path-to-file.json
```

After you set the configuration files, run `tsm pending-changes apply` to apply the changes from all of the .json files you've set.

```
{
  "configEntities": {
    "gatewaySettings": {
      "_type": "gatewaySettingsType",
      "port": 80,
      "publicHost": "localhost",
      "publicPort": 80
    },
    "identityStore": {
      "_type": "identityStoreType",
      "type": "local",
      "domain": "example.lan",
      "nickname": "EXAMPLE"
    }
  },
  "configKeys": {
    "gateway.timeout": "900"
  }
}
```

Entities vs keys

As shown in the example above, there are two classes of configuration parameters: `configEntities` and `configKeys`.

configEntities

Certain types of configuration are done through entity sets that map to specific scenarios, such as the identity store and gateway configurations. When you pass a set of `configEntities`

with the `tsm settings import -f path-to-file.json` command, TSM validates the configuration. If values passed are invalid, TSM will provide an error. This enables you to make changes during the configuration process, rather than experience a configuration failure at initialization or run time.

Entities can be set only by including a `configEntities` block in a `.json` file.

Important: All files that are referenced in `configEntities` must be located on the local computer. Do not specify UNC paths.

configKeys

Entities cover only a small portion of the configuration values that can be set. Hundreds of keys correspond to parameters stored in `.yaml` files. Tableau Server uses these parameters to store all of the configuration information for all services.

You can set individual keys with the `tsm configuration` command. But during deployment, setting them along with other configuration scenarios in JSON files, as shown above, is more convenient.

Unlike `configEntities`, `configKeys` are not validated.

Note: We do not recommend setting parameters that are not documented in `tsm configuration set Options`.

Server Usage Data

The Tableau Server administrator can control whether or not usage data from Tableau Server is sent to Tableau. By default this option is enabled, and can be disabled at initial install, or after installing Tableau Server, using the TSM Web UI or command line. For details about this usage data, see [Tableau Product Usage Data](#).

Tableau Server on Windows Help

In addition to product usage data, Tableau products send Basic Product Data to Tableau. This data is sent whether or not you have disabled the sending of product usage data. You can disable the sending of Basic Product Data separately. For details, see [Basic Product Data](#).

Disable Usage Data Sharing

You can disable the sharing of usage data when you install Tableau Server, or at any time after installation.

Disabling the sharing of usage data at install

To disable the sharing of usage data with Tableau when you are installing Tableau Server, clear the option during the initial configuration of server. For details, see [Product usage data](#).

Disabling the sharing of usage data after install

Use the TSM web interface

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Maintenance** tab.
3. Under Other Maintenance Tasks, in Server Usage Data, clear **Send usage data to improve Tableau features**:

Product Usage Data

4. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

Use the TSM CLI

If you do not want to share product usage data, disable the option using this tsm configuration command:

```
tsm configuration set -k shareproductusagedata.enabled -v false
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Basic Product Data

By default Tableau products send usage data to Tableau so that we can understand how customers use our software, and gain insights into where they are successful and where they might run into problems that we can address. For example, this data can help us learn

Tableau Server on Windows Help

where upgrades are commonly failing and allow us to make product changes to address those issues, or identify what portion of our user base needs informed about a security issue that applies to a specific version of Tableau Server. You can disable the sending of this data at installation time, or later. For details on how to do this, see the instructions for [Tableau Desktop](#) or [Tableau Server](#).

Even when you disable the sending of product usage data, certain basic product data is sent to Tableau. This Basic Product Data includes information about products and their processes, including which product or process is running, when they start up, what operating system they are running on, licensing information, which machine or cluster of machines has sent the data (using unique pseudonymized identifiers), and whether the product is configured to send product usage data.

You can disable the sending of Basic Product Data at the machine level, or at the enterprise level, by blocking traffic sent to **prod.telemetry.tableausoftware.com**.

Disabling sharing of Basic Product Data on individual computers

Important: This procedure involves modifying your local `hosts` file. If you do not know what this is, you should not change it. You should only make this change if you understand the implications of making changes to the file, know how to change the file, and have made a backup of the file for safety.

Modifying `hosts` files changes network behavior for computers. Detailed instructions for modifying `hosts` files are provided by operating system providers such as Microsoft, Apple or Linux Distributions.

1. Make a copy of your existing `hosts` file and save it to a computer that is not your Tableau computer. This is your backup, in case you need to reverse your changes. Do not start modifying the file until you have made a backup copy of it.
2. Modify your computer's `hosts` file to include these lines:

```
# Stops sending Product Usage to Tableau (prod.tele-  
metry.tableausoftware.com) .  
# Learn more here: http:\\tableau.com\derived-data  
127.0.0.1    prod.telemetry.tableausoftware.com
```

The first and second lines are comments, explaining the third line.

The third line prevents all traffic to `prod.telemetry.tableausoftware.com` (`http://prod.telemetry.tableausoftware.com/`) from leaving your local machine by sending it to the Internal host loopback address. The data does not get sent outside the computer.

Disabling the sharing of Basic Product Data at the enterprise level

To disable sending of Basic Product Data on an enterprise level, modify your Network Firewall to prevent outbound traffic to `prod.telemetry.tableausoftware.com`.

This domain is used by Tableau to receive the Basic Product Data about process launch and shutdown. It is also used for the more general Product Usage Data. Blocking traffic to this domain it you will prevent both kinds of data from being sent.

Traffic to this domain will occur on Ports 80 (for initial registration of our Product Data clients) and on Port 443 (for all subsequent traffic). To completely prevent product data from being sent, block all traffic to this domain.

For details on how to configure your network firewall, refer to your vendor or your internal IT department. Tableau cannot provide these instructions.

Add an Administrator Account

The final step in activating Tableau Server is to add the initial administrator account. The administrator will have all access to the server including the ability to manage users, groups, and projects.

The server must be running when you create the initial admin user.

Tableau Server on Windows Help

If you have configured the Tableau Server identity store to use LDAP or Active Directory, then the initial administrative user that you specify must be an account in the directory. The initial administrative user is generally distinct from the user account on the Tableau Server computer that you use to run `t-sm`.

However, these accounts can be the same if you have configured the Tableau Server identity store to use Active Directory and the initial admin user is a member of the local administrator group on the Tableau Server computer.

Prerequisites

Before proceeding with the procedures in this topic, complete the following prerequisites as outlined in *Install and Configure Tableau Server*:

- Install TSM
- Activate and Register Tableau Server
- Configure Initial Node Settings

Use web UI

After Tableau Server is finished initializing, the installation program will display a page to create the Tableau Server administrator.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.
- The `username` value cannot include an at sign (`@`) unless the user name suffix matches Tableau Server's primary domain. For example, if Tableau Server connects to domain "myco.com", a user name of "user@example.com@myco.com" cannot be used.

If you are installing remotely, then you must sign in to TSM on the physical computer where Tableau Server is installing, or you can access the computer remotely and run the `tabcmd initialuser` command from a shell.

Use `tabcmd` CLI

You must create the initial administrative account for Tableau Server.

- If you configured a local identity store during setup, then specify a name and password that you want to use.
- If you configured a LDAP or Active Directory identity store during setup, then you must specify a user account that is a member of the directory.
- The `username` value cannot include an at sign (`@`) unless the user name suffix matches Tableau Server's primary domain. For example, if Tableau Server connects to domain "myco.com", a user name of "user@example.com@myco.com" cannot be used.

To create the initial user, run the following `tabcmd` command:

```
tabcmd initialuser --server http://localhost --username "<new-admin-username>"
```

For example:

```
tabcmd initialuser --server http://localhost --username "tableau-admin"
```

If you are running the HTTP protocol on a port other than 80, specify the port after the host name, for example: `--server http://localhost:8080`.

After you run the command, the shell will prompt for an administrative password.

Next steps

After you have created the Tableau Server administrator account, continue your deployment by working through the configuration topics at Post Installation Tasks.

Initial Node Installation Defaults

By default, the Tableau Server installer configures the number of process instances that Tableau Server runs based on the hardware detected by the installer. The default configuration applies to single-server installations and to the initial server of a multi-node installation.

You can calculate the default configuration based on the following rules for each process, where the "number of cores" refers to the number of logical processors:

Process Name	Number of Processes
VizQL Server	Equal to the number of cores divided by four, up to a maximum of four process instances.
Backgrounder	Set to two unless the number of cores is fewer than eight.
Cache Server	Set to two unless the number of cores is fewer than eight.
Data Server	Set to two unless the number of cores is fewer than eight.

For all other process types, the number of process instances is set to one, regardless of the hardware.

Here's an example default configuration for a computer with 16 cores:

Process Name	Number of Processes
VizQL Server	4
Application Server	1
Backgrounder	2
Cache Server	2
Data Server	2
File Store	1

Process Name	Number of Processes
Data Engine	1

Jump-start Installation

This topic provides all of the steps required to perform a basic, quick-start installation of Tableau Server. The purpose of the configuration described here is to provide the quickest, simplest path to a Tableau Server installation. Use this procedure as practice, to try out the Tableau Server installation, management, and user experience before your actual server deployment.

Important: Do not use this procedure as a stand-alone resource for deploying Tableau Server into a production environment. To deploy Tableau Server into a production environment, refer to the content at [Install and Configure Tableau Server](#).

The procedures in this topic will install an instance of Tableau Server for Windows using a local identity store.

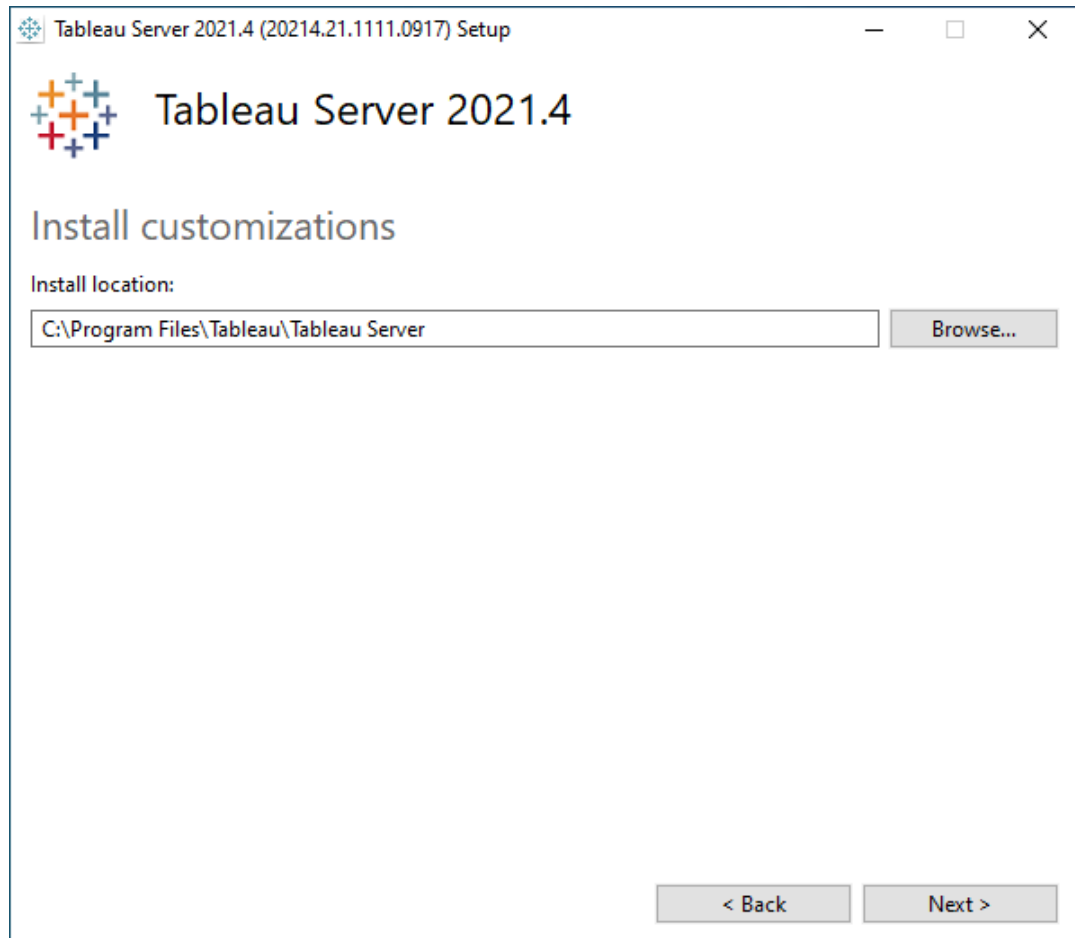

Before you begin

Review the topic, [Before you install....](#) The procedure here assumes that you have installed Windows on conforming hardware and according to the environmental requirements specified in that topic.

Note that the computer you install on must meet the minimum hardware requirements specified in [Minimum Hardware Requirements and Recommendations for Tableau Server](#). The setup program will not install Tableau Server onto systems that do not meet the minimum hardware requirements.

Step 1: Install Tableau Server and start Tableau Services Manager

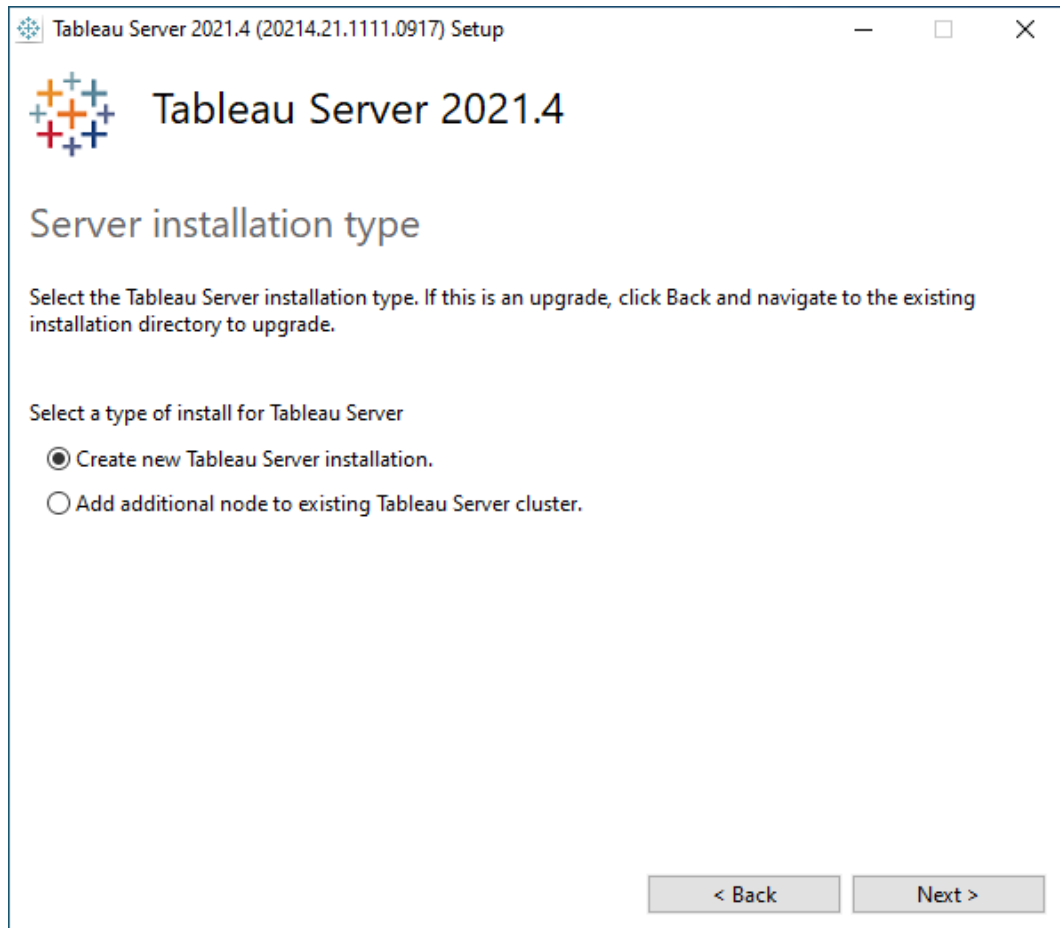

1. Double-click the installation file.
2. Follow the on-screen instructions to complete Setup and install the application.

The default installation path is `C:\Program Files\Tableau\Tableau Server`. You can choose a different location, including a different drive, either by browsing to or typing in a new path.

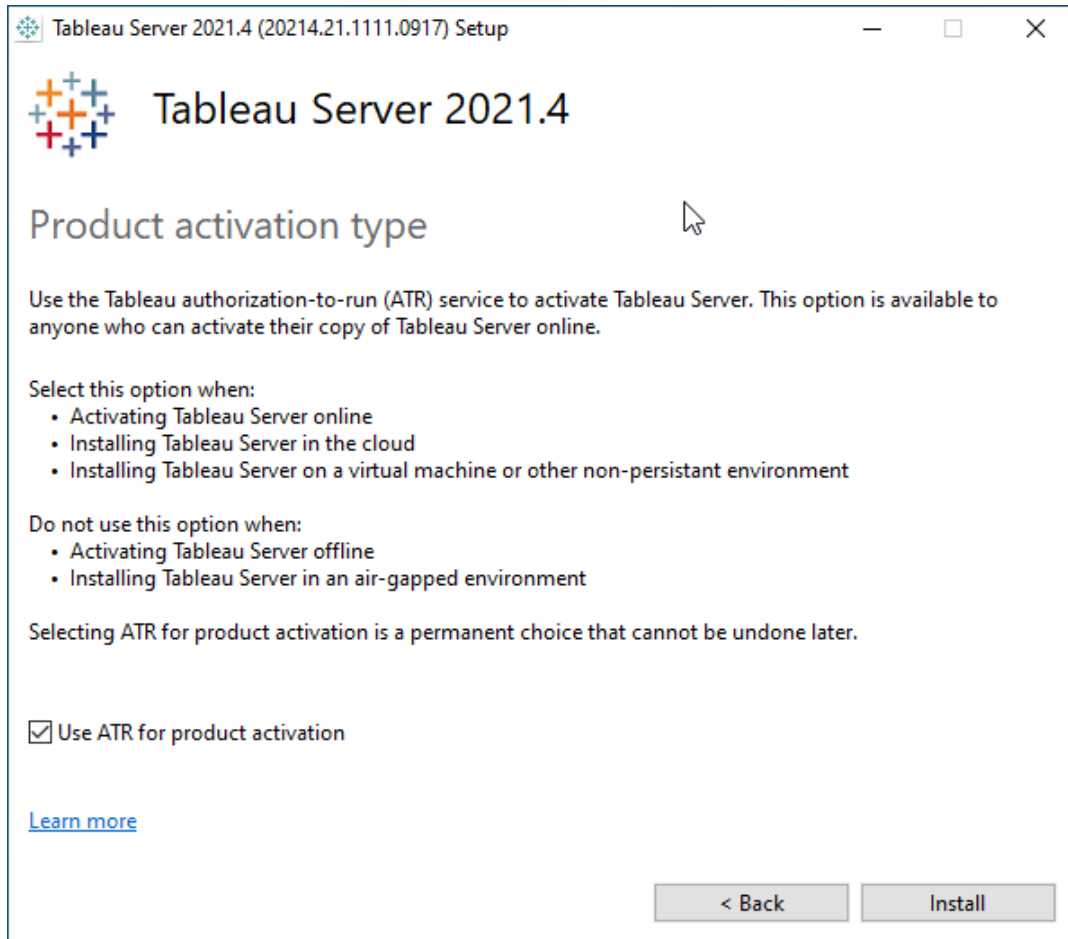

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

3. Click **Next**.

On the **Server installation type** page, you can specify whether you are installing the first node of a Server installation, or additional nodes in a multi-node installation. You do not need to change this from the default (Create new Tableau Server installation.) unless you are installing a multi-node Tableau Server. If you are installing a multi-node Tableau Server, see [Install and Configure Additional Nodes](#).

4. Click **Next**.

On the **Product Activation Type** page, select whether you want to use the authorization-to-run (ATR) service to activate Tableau Server, and then click **Install**.

5. After the installation completes, click **Finish**. Setup will then open the TSM configuration web page on the computer where you are installing Tableau Server.

Step 2: Activate and register Tableau Server

Before you can configure Tableau Server you must activate a license and register. For more details, see [Activate and Register Tableau Server](#).

1. Sign in to Tableau Services Manager Web UI.
2. On the **Activate** page, enter or paste your product key and click **Activate Product**

Key.

After your product key is activated, it appears under **Activated Product Keys**.

Enter your license product key to get started with Tableau Server.

Product Key
The key has 20 characters
0000-0000-0000-0000-000
[I can't find my product key.](#)

Tableau Server requires at least one product key that activates the server and specifies the number of license levels you can assign to users. You can access your product keys from the [Tableau Customer Portal](#).

Activated Product Keys
No product key currently activated

Activate Product Key Next

Try it free for 14 days
Start Tableau Server Trial

3. To activate another product key, enter the new product key, and then click **Activate Product Key**. After your product key is activated, it appears under **Activated Product Keys**.
4. When you're finished activating product keys, click **Next**.

Note: If the product keys you have activated don't have the necessary capacity, such as not enough cores or only a Viewer role product key, Tableau Services Manager displays the **Insufficient licenses applied** dialog box. Click **Activate Another Product Key** to add another product key and increase capacity on your Tableau Server installation.

Tableau Server on Windows Help

Insufficient licenses applied

You have not activated enough product keys for your Tableau Server deployment.

If you try to activate Tableau Server using these licenses, it may not run properly. We recommend that you activate additional licenses to support this Tableau Server deployment

[Tableau Customer Portal Troubleshooting](#)

[Activate Another Product Key](#)

5. On the **Register** page, enter your information into the fields and click **Register**.

● ——— ○ ——— ○ ——— ○
Activate Register Setup Initialize

Register with Tableau. All fields are required.

Contact Information

First Name _____ Last Name _____

Phone Number _____ Email _____

City _____ Postal Code _____

Country/Region _____ ▼ State/Province _____ ▼

Register

Step 3: Configure local identity store

You must configure the identity store settings. This procedure simplifies installation by setting the identity store to local authentication. For more details on customizing these defaults, see [Configure Initial Node Settings](#).

The settings below are all you need to get started.

Identity Store

You cannot change the identity store after initializing.

- Local
- Active Directory

Run As Service Account

- NT AUTHORITY\NetworkService
- User Account

Gateway Port

Port Number: (Default)

Product Usage Data

Disable sending usage data to Tableau

Include samples

Include sample workbooks

Initialize

Tableau Server on Windows Help

After you have configured the options on this page, click **Initialize**.

The initialization process can take a while. When initialization is complete the following page is displayed:

Step 4: Add administrator account

The final step in activating Tableau Server is to add the initial administrator account. The administrator will have all access to the server including the ability to manage users, groups, and projects. More details are at [Add an Administrator Account](#).

After Tableau Server is finished initializing, the installation program will display a page to create the Tableau Server administrator.

Specify a name and password that you want to use for the administrative account.

If you are installing remotely, then you must sign in to TSM on the physical computer where Tableau Server is installing, or you can connect remotely to the computer and run the `tabcmd initialuser` command from a shell.

Use the administrator account that you created in this step to access the Tableau Server admin web pages. See [Sign in to the Tableau Server Admin Area](#).

Step 5: Validate your installation

This is an optional step, but a good way to validate that Tableau Server is installed and running properly is to look at the built-in Administrative Views in Tableau Server.

Install Switches and Properties for Tableau Server

You can use the following installer switches when installing Tableau Server on Windows from the command line.

Note: Beginning with version 2019.4.0, the Tableau Server Setup program is new. The switches and properties below only apply for version 2019.4.0 and later. If you are installing an earlier version of Tableau Server and need information about command line options, see [Install Switches for Tableau Server \(2019.3 and earlier\)](#) in the 2019.3 Server Administrator Guide. If you are upgrading to version 2019.4.0 or later and have been using install switches in earlier versions, see [Changes to Command Line Install Options for Tableau Server Setup](#) for details on specific changes.

Switch	Description	Comments
<code>/install /repair /uninstall /layout "<directory>"</code>	Run Setup to either install, repair, or uninstall Tableau Server, or with <code>/layout</code> , create a complete local copy of the installation bundle in the directory spe-	Default is to install, displaying UI and all prompts. If no directory is specified on a fresh install, <code>C:\Program Files\Tableau\Tableau Server</code> is assumed. If Tableau Server is already installed, Setup will assume the same location as the current installation.

	releases of Tableau Server to support advanced analytics features. If you choose to skip installation of Python, Tableau Server users will not have access to those advanced analytics features when those features are available.	
--	--	--

Automated Installation of Tableau Server

You can use `SilentInstaller.py`, a **community supported** Python script, to automate a new install of Tableau Server. You can download the script and use it as written, or modify it for your specific needs.

Benefits of using the automated installer

- With a single command, you can install, configure, and run a working instance of Tableau Server.
- The `SilentInstaller.py` script can be run without user input making it suitable

for automation.

- The configuration can be set once and used for all your installations, making this a repeatable process.

When not to use the automated installer

- If you are installing Tableau Server for the first time, we recommend that you manually test your installation before automating the process. Any issues that block installation are easier to resolve interactively. After you have resolved these issues, you can perform an automated installation of Tableau Server using the `SilentInstaller.py` script.
- If you are testing or trying new configuration parameters such as authentication methods, we recommend that you manually run the installation first. Tableau Services Manager (TSM) validates configuration entities and rejects configuration parameters that are not valid. Once you have the correct parameters identified, you can use the automated installer.
- If you are unable to or do not want to enter passwords into the secrets file, using the automated installer might not be an option for you.

Before you begin

Review [Before you install...](#) to make sure you have installed Microsoft Windows Server on a computer that meets the operating system requirements and the minimum hardware requirements for Tableau Server.

Note: If you are installing Tableau Server in a production environment, review the minimum hardware **recommendations**. The recommendations represent the minimum hardware configuration you should use for a production installation of Tableau Server.

Tableau Server on Windows Help

To perform an automated installation, you use the `SilentInstaller.py` script, which relies on the Tableau Server install package as an input. Before you begin, we recommend that you download the following packages:

1. Download [Python 3.5](#) or later and install it on the computer where you want to install Tableau Server.
2. Download both the `SilentInstaller.py` script and the Tableau Server installer package:
 - a. Download the `SilentInstaller.py` script from [GitHub](#), along with `config.template.json`, `registration.template.json`, `secrets.template.json`, and the three bootstrap templates (`bootstrap.template.json`, `topologyBootstrap.template.json`, and `workerBootstrap.template.json`).
 - b. Select and download the appropriate **Tableau Server installer package** from the [Tableau Server Product Downloads and Release Notes](#) page. The one you choose depends on the version of Microsoft Windows Server you want to use.
3. Copy the packages and templates to a location on or accessible from the computer where you are going to install Tableau Server.

How to use the `SilentInstaller.py` script

The `SilentInstaller.py` script installs the Tableau Server installer package, creates the directories, sets the permissions required to run Tableau Server, and starts the Tableau Services Manager (TSM) setup. After TSM setup is complete, the `SilentInstaller.py` script runs `tsm` commands to install, configure, and start Tableau Server. By default, the `SilentInstaller.py` script activates a trial license during installation. If you have an actual product key, you can provide the product key at the command line or activate the product key after you run the `SilentInstaller.py` script. Most of the command line options in the automated installer are the same as the options used by the `tsm initialize` command.

You can run the `SilentInstaller.py` script in three modes: install the initial node, install additional nodes, and update cluster topology. When doing an installation for a distributed cluster, you'll run `SilentInstaller.py` with the options to install the initial node on the initial node. You'll run `SilentInstaller.py` with the options to install additional nodes on each additional node. Lastly, you'll run `SilentInstaller.py` with the options to update cluster topology on the initial node.

The `SilentInstaller.py` script is meant to be run without user interaction, so you must input all parameters into the required arguments that are passed to the `SilentInstaller.py` script. Alternatively, you can also put the required arguments into the bootstrap file. You can use the Configuration, registration, and secrets file templates provided.

Use the following steps to perform an unattended installation:

Step 1: Install the automated installer

1. Log onto the computer as a user with administrator access.
2. Download and install the `SilentInstaller.py` script, templates, and bootstrap files.

Step 2: Create files to provide additional configuration information required to run the automated install

Since the `SilentInstaller.py` script is meant to run without user interaction, you must provide the following additional information:

1. Copy the templates, **`config.template.json`**, **`registration.template.json`**, and **`secrets.template.json`**, to another directory like your home directory. We don't recommend that you edit the template files directly.
2. Edit the **`config.template.json`** file and provide the initial node configuration settings. You must provide identity store settings for the Tableau Server computer. Depending on your network requirements, you may need to also provide the gateway settings. The caching option is set to cache and reuse data for as long as possible. Sample

Tableau Server on Windows Help

workbooks are installed by default. The template includes the minimum required information, so the template is a starting point. For more information on configuration settings, see [Configure Initial Node Settings](#).

3. Edit the **registration.template.json** file and provide the information needed to register Tableau Server. For more information, see [Activate and Register Tableau Server](#).
4. Edit the **secrets.template.json** file and provide the user name and password for the TSM administrator and Tableau Server administrator accounts.
 - The TSM administrator account should be the same user as the Windows administrator running the script.
 - The Tableau Server administrator account is the initial account that is created by the installer and is used to administer Tableau Server.

Step 3: Run the automated install

1. Log onto the computer as a user with administrator access.

Install the initial node

The `SilentInstaller.py` script runs the proper commands to install, activate license, configure, and start Tableau Services Manager. Run `SilentInstaller.py -h` and `SilentInstaller.py install -h` to see the full list of options and their default values.

To install the initial node:

On the initial node, at a Python prompt, type:

```
SilentInstaller.py install --secretsFile secrets.json --configFile myconfig.json --registrationFile registration.json TableauServer-64bit-<version>.exe
```

Or alternatively:

```
SilentInstaller.py --bootstrapFile <bootstrap file path>
```

Script Option	Description
Required switches	
--configFile <file path>	The relative or absolute path to the Server Configuration JSON file.
--secretsFile <file path>	<p>The relative or absolute path to the Secrets File that describes the credentials of the Windows account to authenticate to Tableau Services Manager (TSM), and the username/password of the initial administrator user for Tableau Server. The secrets file also includes the product key you want to use to activate Tableau Server. By default, the secrets file template contains a trial license.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note: Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</p> </div> <p>The automated installer package includes the template for the secrets file.</p>
--registrationFile <file path>	The relative or absolute path to the Server Registration file containing the Tableau Server registration information.

Tableau Server on Windows Help

Script Option	Description
	The automated installer package includes the template for the registration file.
<installer executable file path>	The relative or absolute path to the Tableau Services Manager (TSM) installer.
Optional switches	
--installDir <file path>	The Tableau Server installation directory. If you don't provide a path, the default directory C:\Program Files\Tableau\Tableau Server will be used.
--dataDir <file path>	The location where the Tableau Server software configuration and data are stored. If you don't provide a path, the default directory C:\ProgramData\Tableau is used for the configuration and data files.
--installerLog <file path>	The existing directory where the installer's log files are written. If you don't provide a path, the log files will be written to your TEMP directory.
--controllerPort <port number>	The port on which the Tableau Services Manager (TSM) Controller should run.
--coordination-service-client-port <port number>	The ZooKeeper client port.
--coordination-service-peer-port <port number>	The ZooKeeper peer port.

Script Option	Description
<code>--coordinationserviceLeaderPort <port number></code>	The ZooKeeper leader port.
<code>--start</code>	Whether the server should be started when setup is complete.

Install additional nodes

The `SilentInstaller.py` script runs the proper commands to install Tableau Services Manager (TSM) on the additional node. Run `SilentInstaller.py installWorker -h` to see the full list of options and their default values.

To install additional nodes:

On each additional node, at a Python prompt, type:

```
SilentInstaller.py workerInstall --secretsFile secrets.json --nodeConfigurationFile nodeConfiguration.json TableauServer-64bit-<version>.exe
```

Option	Description
<code>--secretsFile <file path></code>	Required. The relative or absolute path to the Secrets File that describes the credentials of the Windows account to authenticate to Tableau Services Manager (TSM), and the username/password of the initial administrator user for Tableau Server. The secrets file also includes the product key you want to use to activate Tableau Server. By default, the secrets file template contains a trial license.

Option	Description
	<p>Note: Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</p> <p>The automated installer package includes the template for the secrets file.</p>
<p>--nodeCon- figurationFile <file path></p>	<p>Required. Path to the node configuration file for installing the additional node.</p>
<p>(installer executable) <file path></p>	<p>Required. The final argument to the script is simply the path, absolute or relative, to the Tableau Services Manager installer executable, acquired through usual channels such as downloaded from the Tableau Website. This script is only supported for use with Tableau Services Manager.</p>
<p>--installDir <file path></p>	<p>Optional. The Tableau Server installation directory. If blank, the default directory C:\Program Files\Tableau\Tableau Server will be used.</p>
<p>--dataDir <file path></p>	<p>Optional. The location where the Tableau Server software configuration and data are stored. If blank, the default directory C:\ProgramData\Tableau is used for the configuration and data files.</p>
<p>--installerLog <file path></p>	<p>Optional. The existing directory where the installer's log files are written. If blank, the log files will be written to the</p>

Option	Description
	user's TEMP directory.

Note: The node configuration file is automatically saved after installing the first node using `SilentInstaller.py`. You can find it under the working directory of the script.

Update cluster topology

The `SilentInstaller.py` script runs the proper commands to update the cluster topology as desired for Tableau Services Manager (TSM). Run `SilentInstaller.py updateTopology -h` to see the full list of options and their default values.

To update cluster topology:

On the initial node, at a Python prompt, type:

```
SilentInstaller.py updateTopology --secretsFile secrets.json --configFile myconfig.json
```

Option	Description
<code>--secretsFile <file path></code>	Required. The relative or absolute path to the Secrets File that describes the credentials of the Windows account to authenticate to Tableau Services Manager (TSM), and the username/password of the initial administrator user for Tableau Server. The secrets file also includes the product key you want to use to activate Tableau Server. By default, the secrets file template contains a trial license.

Option	Description
	<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note: Providing the password in the secrets file is optional. However, if passwords are not found in the secrets file, you will be prompted to provide them during installation.</p> </div> <p>The automated installer package includes the template for the secrets file.</p>
<p><code>--con-figFile <file path></code></p>	<p>Required. The relative or absolute path to the Server Topology file describing the Tableau Server topology to update. Only the topologyVersion part of the file will be applied, other configurations will be ignored.</p>

Configuration, registration, and secrets file templates

You can use the following example templates to pass data to the `SilentInstaller.py` script.

Secrets file template example

```
{
  "local_admin_user": "",
  "local_admin_pass": "",
  "content_admin_user": "",
  "content_admin_pass": "",
  "product_keys": ["trial"]
}
```

The `local_admin_user` is the Windows account to authenticate to the Tableau Services Manager.

The `content_admin_user` is the initial administrative user, who acts as a superuser for all of Tableau Server with respect to creating and managing users, sites, etc.

When installing additional nodes or updating the cluster topology, these credentials are ignored because the initial admin user was already created when the initial node was installed.

The `product_keys` is the key used to activate Tableau Services Manager. If multiple keys are specified, they will be activated one by one. In the case of non-install mode, these keys are ignored because the licenses have already been activated.

Server Configuration file template example

```
{
"configEntities":{
  "runAsUser":{
    "_type":"runAsUserType",
    "name":"NT AUTHORITY\\NetworkService"
  },
  "gatewaySettings":{
    "_type":"gatewaySettingsType",
    "port":80,
    "firewallOpeningEnabled":true,
    "sslRedirectEnabled":true,
    "publicHost":"****replace me****",
    "publicPort":80,
    "sslEnabled":false,
    "sslPort":443
  },
  "identityStore":{
    "_type":"identityStoreType",
    "type":"local",
    "domain":"****Domain Name Here****",
```

Tableau Server on Windows Help

```
        "nickname": "****Domain Nickname Here****"
    }
},
"topologyVersion": {
    "nodes": {
        "****insert nodeId (lowercase) here****": {
            "services": {
                "filestore": {
                    "instances": [
                        {
                            "instanceId": "0"
                        }
                    ]
                },
                "tabadmincontroller": {
                    "instances": [
                        {
                            "instanceId": "0"
                        }
                    ]
                },
                "clientfileservice": {
                    "instances": [
                        {
                            "instanceId": "0"
                        }
                    ]
                },
                "dataserver": {
                    "instances": [
                        {
```

```
        "instanceId":"0"
      },
      {
        "instanceId":"1"
      }
    ]
  },
  "cacheserver": {
    "instances":[
      {
        "instanceId":"0"
      },
      {
        "instanceId":"1"
      }
    ]
  },
  "vizqlserver": {
    "instances":[
      {
        "instanceId":"0"
      },
      {
        "instanceId":"1"
      }
    ]
  },
  "backgrounder": {
    "instances":[
      {
        "instanceId":"0"
```

Tableau Server on Windows Help

```
    },  
    {  
      "instanceId":"1"  
    }  
  ]  
},  
"appzookeeper": {

"industry" : "Finance",  
"phone" : "311-555-2368",  
"city" : "Kirkland",  
"state" : "WA",  
"zip" : "98034",  
"country" : "United States"  
}
```

Install Tableau Server in a Disconnected (Air-Gapped) Environment

You can install Tableau Server in a disconnected environment that has no outside network access of any kind. Such disconnected environments, commonly referred to as air-gapped, are used when high security is needed to prevent data breaches or to guard against hacking. Air-gapped environments have no internet access, no outside network access, no outside wireless access, etc. The only means of getting software and data into or out of an air-gapped environment is by using removable media such as USB sticks or writable optical CDs or DVDs.

Installing Tableau Server in an air-gapped environment is an advanced task for IT administrators who are familiar with the security considerations, best practices, and pitfalls of installing software in air-gapped environments.

The following Tableau Server features will be unavailable or will have reduced functionality in an air-gapped environment:

Tableau Server on Windows Help

- **Maps** – Tableau Server uses externally hosted map data by default. Beginning with version 2020.4.0, you can configure Tableau Server to use offline maps. With earlier versions of Tableau, maps are unavailable in an air-gapped environment unless you also install a map server in your air-gapped environment. For more details, see [Displaying Maps in an Air-Gapped Environment](#).
- **Licensing** – Tableau Server needs to connect to the internet in order to activate product keys. However, you can [manually activate](#) the product keys.
- **External data** – Any data located outside your air-gapped environment is unavailable.

Prerequisites

In order to install Tableau Server in an air-gapped environment, you'll need the following:

- Trusted computer with limited access to the internet that you can use to download the installation packages and resources required by Tableau Server. A trusted computer has been scanned and cleared of any viruses and malware.
- Trusted removable media that you can use to transfer the downloaded software to your air-gapped environment. Trusted removable media is removable media that is new and previously unused and comes from a reputable or known source. Trusted removable media has been scanned and verified that it does not contain any viruses or malware.
- Air-gapped environment with computers and storage that meet the [requirements](#) for installing Tableau Server.

Installing Tableau Server on an Air-Gapped Computer Running Windows

The easiest way to install Tableau Server on a computer in an air-gapped environment is to do so before the computer is placed into the air-gapped environment. If that is not possible

you'll need to download the required packages to a trusted computer outside the air gap and transfer them to the air-gapped computer:

1. On a trusted computer outside the air gap with internet access, download the Tableau Server installation package.
2. Transfer the package to your removable media.
3. On your air-gapped computer, insert the removable media containing the Tableau Server installation package, and then **run the installer**.
4. After installation is complete, you can activate the Tableau Server product keys. For more information, see [Activating Tableau Server in an Air-Gapped Environment](#).

Activating Tableau Server in an Air-Gapped Environment

Because an air-gapped computer is not connected to the internet, you'll need to perform the Tableau Server activation process manually.

Step 1. Log in to Tableau Services Manager

- To log in to Tableau Services Manager (TSM), run the following command:

```
tsm login -u <username>
```

What if I can't log in?

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Step 2. Transcribe data from your air-gapped system into an activation request template.

1. On your Tableau Server in the air-gapped environment, use TSM to obtain the offline activation file. At a command prompt:

Tableau Server on Windows Help

```
tsm licenses get-offline-activation-file -k <product-key> -  
o <target-directory>
```

The `<target-directory>` must exist. You can obtain your product key in the [Tableau Customer Portal](#).

2. If you can copy the offline request file (Tableau-OfflineActivationRequest.tlq) from the target directory to a computer that has Internet access, skip to step 5.

Otherwise, if you cannot copy the file to another computer due to security reasons, continue with step 3.

3. Download and open the `server_secondpass_windows.tlq` file in an XML text editor such as Notepad++ on a trusted computer that has Internet access.

You'll need to write down the values listed in step 4 from the air-gapped computer in order to copy them to the offline template (`server_secondpass_windows.tlq`).

4. Update the following XML elements in the appropriate `server_secondpass_windows.tlq` file with the values for the same elements listed below from the air-gapped computer.

All the Machine / Hash values in the .tlq files are Hex values. The only valid characters are 0 - 9 and A - F. Use all caps for any letters.

Do not add any additional spaces or carriage controls and only modify the "X" characters found in the template. The format of the file must not change.

Line 2 - `<EntitlementId>`

Line 5 - `<ClientVersion>`

Line 5 - `<RevisionType>` (This value is present in the `server_secondpass_windows.tlq` file.)

Line 5 - `<MachineIdentifier>` (This value is present in the `server_secondpass_windows.tlq` file.)

Line 11 - `<Value>` (If the value is not present, remove the "X" place holder, leaving `<Value></Value>`.)

Line 12 - `<Value>` (If the value is not present, remove the "X" place holder, leaving `<Value></Value>`.)

Line 14 - `<SequenceNumber>`

Line 60 - `<Hash>`

5. Upload the offline request file (`TableauOfflineActivationRequest.tlq`) to the [Tableau Offline Activation](#) website.
6. The website should say The activation was successful. Please [click here](#) to download your activation file.

Download the `activation.tlf` file from Tableau.

Step 3. Initialize or activate your license

1. Move the activation file (`activation.tlf`) to your air-gapped computer using trusted removable media.
2. Run the following command:

```
tsm licenses activate -f <path-and-activation-file>
```

You should see the message "Activation successful.", which indicates that Tableau Server is activated.

Displaying Maps in an Air-Gapped Environment

In an air-gapped environment, maps in Tableau Server will be unavailable by default due to the lack of internet access. If you have Tableau Server 2020.4.0 or later, you can configure

Tableau Server on Windows Help

Tableau to use local maps. If you have an earlier version, you can use one of several workarounds to display maps in an offline environment.

Configuring Tableau Server to use offline maps (version 2020.4.0 and later):

1. Open a command prompt as administrator.
2. Configure Tableau to use locally available offline maps:

```
tsm configuration set -k vizqlserver.force_maps_to_offline  
-v true
```

```
tsm pending-changes apply
```

Workarounds to display maps in Tableau Server in an offline environment (versions earlier than 2020.4.0):

- **Option 1** – Use the offline background maps

To use the offline background map select **Map > Background maps > Offline**. For more information, see [Select Background Maps](#).

Note: Due to size limitations with the offline map, zooming in too deep may result in errors as the images for the more close-up maps are not stored offline.

- **Option 2** – Use a map as a background image

Locate the desired map online and save it as an image file, or copy a map from another location. Set this map image as a static background image in Tableau Desktop. For more information, see [Use Background Images in Your Views](#).

Note: Zooming in and out will not work with background images.

- **Option 3** – Use a local GeoServer

For more information, see [Use Web Map Service \(WMS\) Servers](#).

Install Tableau Server in the Cloud

Even if you don't have your own infrastructure and server hardware, you can deploy an enterprise-level Tableau Server installation in the cloud. Building a cloud-based solution has many benefits over an on-premises installation. For example, the overall total cost of ownership for building a Tableau Server solution in the cloud is normally much less than a similar on-premises solution because you don't have to buy all of the expensive hardware. In addition, the cloud can provide better uptime, reliability, and fault-tolerance, especially if you deploy your solution across different regions and availability zones.

Looking for Tableau Server on Linux? See [Install Tableau Server in the Cloud](#).

You can build and scale your Tableau environment in the following cloud environments:

- **Tableau Online** - If you don't want to install software or purchase hardware, you can choose analytics as a service with Tableau Online, the Tableau-hosted environment in the cloud. For more information, see [Tableau Online](#).
- **Amazon Web Services** - You install and manage Tableau Server on Amazon Web Services (AWS). For more information, see [Install Tableau Server in the AWS Cloud](#).
- **Google Cloud Platform** - You install and manage Tableau Server on the Google Cloud Platform. For more information, see [Install Tableau Server on the Google Cloud Platform](#).
- **Microsoft Azure** - You install and manage Tableau Server on Microsoft Azure. For more information, see [Install Tableau Server on Microsoft Azure](#).
- **Alibaba Cloud** - You install and manage Tableau Server on Alibaba Cloud. For more information, see [Install Tableau Server in the Alibaba Cloud](#).

Post Installation Tasks

After you install Tableau Server, you can perform other configuration tasks, such as reviewing the security hardening checklist, configuring server event notifications, configuring the data cache for views, and configuring server crash reporting.

Security Hardening Checklist

The following list provides recommendations for improving the security ("hardening") of your Tableau Server installation.

Looking for Tableau Server on Linux? See [Security Hardening Checklist](#)

Installing security updates

Security updates are included in the latest versions and maintenance releases (MR) of Tableau Server. You cannot install security updates as patches. Rather, you must upgrade to a current version or MR to update Tableau Server with the latest security fixes.

Always reference the most current version of this topic after upgrading. The current version includes `/current/` in the topic URL.

For example, the US version URL is: https://help.tableau.com/current/server/en-us/security_harden.htm.

1. Update to the current version

We recommend that you always run the latest version of Tableau Server. Additionally, Tableau periodically publishes maintenance releases of Tableau Server that include fixes for known security vulnerabilities. (Information regarding known security vulnerabilities can be found on the Tableau [Security Bulletins](#) page and the [Salesforce Security Advisories](#) page.)

We recommend that you review maintenance release notifications to determine whether you should install them.

To get the latest version or maintenance release of Tableau Server, visit the [Customer Portal](#) page.

2. Configure SSL/TLS with a valid, trusted certificate

Secure Sockets Layer (SSL/TLS) is essential for helping to protect the security of communications with Tableau Server. Configure Tableau Server with a valid, trusted certificate (not a self-signed certificate) so that Tableau Desktop, mobile devices, and web clients can connect to the server over a secured connection. For more information, see [SSL](#).

3. Disable older versions of TLS

Tableau Server uses TLS to authenticate and encrypt many connections between components and with external clients. External clients, such as browsers, Tableau Desktop, Tableau Mobile connect to Tableau using TLS over HTTPS. Transport layer security (TLS) is an improved version of SSL. In fact, older versions of SSL (SSL v2 and SSL v3) are no longer considered to be adequately secure communication standards. As a result, Tableau Server does not allow external clients to use SSL v2 or SSL v3 protocols to connect.

We recommend that you allow external clients to connect to Tableau Server with TLS v1.3 and TLS v1.2.

TLS v1.2 is still regarded as a secure protocol and many clients (including Tableau Desktop) do not yet support TLS v1.3.

TLS v1.3 capable clients will negotiate TLS v1.3 even if TLS v1.2 is supported by the server.

The following tsm command enables TLS v1.2 and v1.3 (using the "all" parameter) and disables SSL v2, SSL v3, TLS v1, and TLS v1.1 (by prepending the minus [-] character to a given protocol). TLS v1.3 is not yet supported by all components of Tableau Server.

Tableau Server on Windows Help

```
tsm configuration set -k ssl.protocols -v "all -SSLv2 -SSLv3 -  
TLSv1 -TLSv1.1"
```

```
tsm pending-changes apply
```

You can also modify the default list of cipher suites that Tableau Server uses for SSL/TLS sessions. For more information see the *ssl.ciphersuite* section at `tsm configuration set Options`.

4. Configure SSL encryption for internal traffic

Configure Tableau Server to use SSL to encrypt all traffic between the Postgres repository and other server components. By default, SSL is disabled for communications between server components and the repository. We recommend enabling internal SSL for all instances of Tableau Server, even single-server installations. Enabling internal SSL is especially important for multi-node deployments. See [Configure SSL for Internal Postgres Communication](#).

5. Enable firewall protection

Tableau Server was designed to operate inside a protected internal network.

Important: Do not run Tableau Server, or any components of Tableau Server on the internet or in a DMZ. Tableau Server must be run within the corporate network protected by an internet firewall. We recommend configuring a reverse proxy solution for internet clients that need to connect to Tableau Server. See [Configuring Proxies for Tableau Server](#).

A local firewall should be enabled on the operating system to protect Tableau Server in single and multi-node deployments. In a distributed (multi-node) installation of Tableau Server, communication between nodes does not use secure communication. Therefore, you should enable firewalls on the computers that host Tableau Server.

To prevent a passive attacker from observing communications between nodes, configure a segregated virtual LAN or other network layer security solution.

See [Tableau Services Manager Ports](#) to understand which ports and services Tableau Server requires.

6. Restrict access to the server computer and to important directories

Tableau Server configuration files and log files can contain information that is valuable to an attacker. Therefore, restrict physical access to the machine that is running Tableau Server. In addition, make sure that only authorized and trusted users have access to the Tableau Server files in the `C:\ProgramData\Tableaudoirectory`.

7. Update the Tableau Server Run As User account

By default, Tableau Server runs under the predefined Network Services (NT Authority\Network Service) Windows account. Using the default account is acceptable in scenarios where Tableau Server does not need to connect to external data sources that require Windows authentication. However, if your users require access to data sources that are authenticated by Active Directory, update the Run As User to a domain account. It's important to minimize the rights of the account that you use for the Run As User. For more information, see [Run As Service Account](#).

8. Generate fresh secrets and tokens

Any Tableau Server service that communicates with repository or the cache server must first authenticate with a secret token. The secret token is generated during Tableau Server setup. The encryption key that internal SSL uses to encrypt traffic to Postgres repository is also generated at during setup.

We recommend that after you install Tableau Server, you generate new encryption keys for your deployment.

These security assets can be regenerated with the `tsm security regenerate-internal-tokens` command.

Tableau Server on Windows Help

Run the following commands:

```
tsm security regenerate-internal-tokens
```

```
tsm pending-changes apply
```

9. Disable services that you're not using

To minimize the attack surface of the Tableau Server, disable any connection points that are not needed.

JMX Service

JMX is disabled by default. If it's enabled but you're not using it, you should disable it by using the following:

```
tsm configuration set -k service.jmx_enabled -v false
```

```
tsm pending-changes apply
```

10. Verify session lifetime configuration

By default, Tableau Server does not have an absolute session timeout. This means that browser-based client (Web authoring) sessions can remain open indefinitely if the Tableau Server inactivity timeout is not exceeded. The default inactivity timeout is 240 minutes.

If your security policy requires it, you can set an absolute session timeout. Be sure to set your absolute session timeout in a range that allows the longest-running extract uploads or workbook publishing operations in your organization. Setting the session timeout too low may result in extract and publishing failures for long-running operations.

To set the session timeout run the following commands:

```
tsm configuration set -k wgserversession.apply_lifetime_limit -v true
```

```
tsm configuration set -k wgsession.lifetime_limit -v  
value, where value is the number of minutes. The default is 1440, which is 24 hours.
```

```
tsm configuration set -k wgsession.idle_limit -v value,  
where value is the number of minutes. The default is 240.
```

```
tsm pending-changes apply
```

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, Bridge, and personal access tokens) use OAuth tokens to keep users logged in by re-establishing a session. You can disable this behavior if you want all Tableau client sessions to be solely governed by the browser-based session limits controlled by the commands above. See [Disable Automatic Client Authentication](#).

11. Configure a server allowlist for file-based data sources

By default, Tableau Server allows authorized Tableau Server users to build workbooks that use files on the server as file-based data sources (such as spreadsheets). In this scenario, files are accessed by the Run As Service Account.

To prevent unwanted access to files, we recommend that you configure allowlist functionality. This lets you limit the Run As service account to just the directory paths where you host data files.

1. On the computer running Tableau Server, identify the directories where you will host data source files.

Important Make sure the file paths you specify in this procedure exist on the server. If the paths do not exist when the computer starts, Tableau Server will not start.

2. Run the following commands:

Tableau Server on Windows Help

```
tsm configuration set -k native_api.allowed_paths -v "path"  
, where path is the directory to add to the allowlist. All subdirectories of the specified  
path will be added to the allowlist. If you want to specify multiple paths, separate them  
with a semicolon, as in this example:
```

```
tsm configuration set -k native_api.allowed_paths -v  
"c:\datasources;c:\HR\data"  
  
tsm pending-changes apply
```

12. Enable HTTP Strict Transport Security for web browser clients

HTTP Strict Transport Security (HSTS) is a policy configured on web application services, such as Tableau Server. When a conforming browser encounters a web application running HSTS, then all communications with the service must be over a secured (HTTPS) connection. HSTS is supported by major browsers.

For more information about how HSTS works and the browsers that support it, see [The Open Web Application Security Project web page, HTTP Strict Transport Security Cheat Sheet](#).

To enable HSTS, run the following commands on Tableau Server:

```
tsm configuration set -k gateway.http.hsts -v true
```

By default, HSTS policy is set for one year (31536000 seconds). This time period specifies the amount of time in which the browser will access the server over HTTPS. You should consider setting a short max-age during initial roll-out of HSTS. To change this time period, run `tsm configuration set -k gateway.http.hsts_options -v max-age-e=<seconds>`. For example, to set HSTS policy time period to 30 days, enter `tsm configuration set -k gateway.http.hsts_options -v max-age=2592000`.

```
tsm pending-changes apply
```

13. Disable Guest access

Core-based licenses of Tableau Server include a Guest user option, which allows any user in your organization to see and interact with Tableau views embedded in web pages.

Guest user access is enabled by default on Tableau Servers deployed with core-based licensing.

Guest access allows users to see embedded views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on.

If your organization has deployed Tableau Server with core licensing and Guest access is not required, then disable Guest access.

You can disable Guest access at the server or site level.

You must be a server administrator to disable the Guest account at either the server or the site level.

To disable Guest access at the server level:

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.
2. For **Guest Access**, clear the **Enable Guest account** check box.
3. Click **Save**.

To disable Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the Settings page, clear the **Enable Guest account** check box.

For more information, see Guest User.

14. Set referrer-policy HTTP header to 'same-origin'

Beginning in 2019.2, Tableau Server includes the ability to configure Referrer-Policy HTTP header behavior. This policy is enabled with a default behavior that will include the origin URL for all "secure as" connections (`no-referrer-when-downgrade`), which sends origin referrer information only to like connections (HTTP to HTTP) or those that are more secure (HTTP to HTTPS).

However, we recommend setting this value to `same-origin`, which only sends referrer information to same-site origins. Requests from outside the site will not receive referrer information.

To update the referrer-policy to `same-origin`, run the following commands:

```
tsm configuration set -k gateway.http.referrer_policy -v same-origin  
  
tsm pending-changes apply
```

For more information about configuring additional headers to improve security, see [HTTP Response Headers](#).

15. Configure TLS for SMTP connection

Beginning in 2019.4, Tableau Server includes the ability to configure TLS for the SMTP connection. Tableau Server only supports STARTTLS (Opportunistic or Explicit TLS).

Tableau Server can be optionally configured to connect to a mail server. After configuring SMTP, Tableau Server can be configured to email server administrators about system failures, and email server users about subscribed views and data-driven alerts.

To configure TLS for SMTP:

1. Upload a compatible certificate to Tableau Server. See `tsm security custom-cert add`.
2. Configure TLS connection using TSM CLI.

Run the following TSM commands to enable and force TLS connections to the SMTP server and to enable certificate verification.

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_
enabled -v true
```

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_
required -v true
```

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_
check_server_identity -v true
```

By default, Tableau Server will support TLS versions 1, 1.1, and 1.2, but we recommend that you specify the highest TLS version that the SMTP server supports.

Run the following command to set the version. Valid values are `SSLv2Hello`, `SSLv3`, `TLSv1`, `TLSv1.1`, and `TLSv1.2`. The following example sets the TLS version to version 1.2.:

```
tsm configuration set -k svcmonitor.notification.smtp.ssl_
versions -v "TLSv1.2"
```

For more information about other TLS configuration options, see [Configure SMTP Setup](#).

3. Restart Tableau Server to apply changes. Run the following command:

```
tsm pending-changes apply
```

16. Configure SSL for LDAP

If your Tableau Server deployment is configured to use a generic LDAP external identity store, we recommend configuring SSL to protect authentication between Tableau Server and your LDAP server. See [Configure Encrypted Channel to LDAP External Identity Store](#).

If your Tableau Server deployment is configured to use Active Directory, we recommend enabling Kerberos to protect authentication traffic. See Kerberos.

17. Scope permissions for non-default installation locations

If you install Tableau Server on Windows to a non-default location then we recommend manually scoping the permissions on the custom installation directory to reduce access.

By default, Tableau Server will install on the system drive. The drive where Windows is installed is the system drive. In most cases, the system drive is the C:\ drive. In this default case, Tableau Server will install into the following directories:

- C:\Program Files\Tableau\Tableau Server\packages
- C:\ProgramData\Tableau\Tableau Server

However, many customers install onto a non-system drive or into a different directory. If you selected a different installation drive or directory location during Setup, then the data directory for Tableau Server will install into the same path.

To scope permissions on the custom installation directory, only the following accounts should have the corresponding permissions on the installation folder and all subfolders:

Set permissions for this account:	Permissions required
The user account that is used to install and upgrade Tableau Server	Full control
The user account that is used to run TSM commands	Full control
System account	Full control
Run As service account, Network Service, and Local Service	Read & execute

A procedure for setting these permissions can be found at [Installing in a non-default location](#).

Change List

Date	Change
May 2018	Added clarification: Do not disable REST API in organizations that are running Tableau Prep.
May 2019	Added recommendation for referrer-policy HTTP header.
June 2019	Removed recommendation to disable Triple-DES. As of version 2019.3, Triple-DES is no longer a default supported cipher for SSL. See What's Changed - Things to Know Before You Upgrade .
January 2020	Added recommendation to configure TLS for SMTP.
February 2020	Added recommendation to configure SSL for LDAP server.
May 2020	Added TLS v1.3 to the disabled list of TLS ciphers. Added clarification to introduction about topic versioning.
August 2020	Added scoped permissions for non-default installations on Windows
October 2020	Added TLS v1.3 as a default supported cipher.
January 2021	Added clarification: All products enabled by the Data Management license require REST API.
February 2021	Removed recommendation to disable REST API. The API is now used internally by Tableau Server and disabling it may limit functionality.

Configure SMTP Setup

Tableau Server can email server administrators about system failures, and email server users about subscribed views and data-driven alerts. First, however, you need to configure the SMTP server that Tableau Server uses to send email. After configuring SMTP, complete the steps to configure notifications (Configure Server Event Notification), then when

Tableau Server on Windows Help

you start or restart the server, it will trigger an email notification, which confirms that you have set up notifications correctly.

Configuring SMTP requires that you restart Tableau Server services.

Secure SMTP

To enable and configure TLS for SMTP, you must use the TSM CLI as described in this topic. Tableau Server only supports STARTTLS (Opportunistic or Explicit TLS).

If your organization does not use public certificates for verifying TLS connections, then you can upload a private certificate to Tableau Server to verify trusted connections. For more information, see the `tsm security custom-cert add` command.

You may also configure SMTP TLS for encryption-only by disabling the certificate validation process. For more information, see the section, *Configuration file reference*, in the *Use the TSM CLI* tab below.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **Notifications** on the **Configuration** tab and click **Email Server**.
3. Enter the SMTP configuration information for your organization:

The screenshot shows the 'CONFIGURATION' tab in the Tableau Server interface. Under the 'Notifications' section, the 'Email Server' sub-tab is active. The 'Configure email server' section contains the following fields and instructions:

- SMTP server address:** smtp.example.lan
- Username:** tableau-notify@example.lan
- Password:** [Redacted]
- Port Number:** 25 (Default)
- Send all emails from:** no-reply@example.lan (Instruction: Type an email address that all emails will be sent from (example: no-reply@example.com))
- Send server health email to:** tableau-health@example.lan (Instruction: Type email addresses, separated by a comma, that will receive Tableau Server health emails. Tableau Server health emails are typically sent to server administrators or other IT admins.)
- Tableau Server URL:** https://tableau.example.lan (Instruction: Choose a footer link to embed in all email alerts and subscriptions. This link is typically the sign-in page of Tableau Server.)

At the bottom of the configuration form, there are two buttons: 'Cancel' and 'Save Pending Changes'.

4. Click **Save Pending Changes** after you've entered your configuration information.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.
7. Run the `tsm email test-smtp-connection` to view and verify the connection configuration. See `tsm email test-smtp-connection`.

Use the TSM CLI

For the initial configuration of SMTP, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in `tsm configuration set`.

Tableau Server on Windows Help

1. Copy the following json template to a file.

Important: The template below includes common options for most deployments. After you copy the template to a text file, you must edit the option values for your SMTP server requirements. You may need to remove or add options. See the reference section that follows for more information about all supported SMTP key options.

```
{
  "configKeys": {
    "svcmonitor.notification.smtp.server": "SMTP server host
name",
    "svcmonitor.notification.smtp.send_account": "SMTP user
name",
    "svcmonitor.notification.smtp.port": 443,
    "svcmonitor.notification.smtp.password": "SMTP user
account password",
    "svcmonitor.notification.smtp.ssl_enabled": true,
    "svcmonitor.notification.smtp.from_address": "From email
address",
    "svcmonitor.notification.smtp.target_addresses": "To email
address1,address2",
    "svcmonitor.notification.smtp.canonical_url": "Tableau
Server URL"
  }
}
```

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server for SMTP. Tableau Services Manager will validate the entity values.
3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm`

pending-changes apply.

4. Run the `tsm email test-smtp-connection` to view and verify the connection configuration. See `tsm email test-smtp-connection`.

SMTP CLI configuration reference

This table lists all of the options that can be used to configure SMTP with TSM CLI.

Option	Description
<code>svc-mon-itor.notification.smtp.server</code>	Address of SMTP server. Example: "svc-mon-itor.notification.smtp.server": "mail.example.com"
<code>svc-mon-itor.notification.smtp.send_account</code>	User name for SMTP account.
<code>svc-mon-itor.notification.smtp.port</code>	Port number for SMTP server. The default is 25.
<code>svc-mon-itor.notification.smtp.password</code>	Password for SMTP server account. Example: "svc-

Tableau Server on Windows Help

Option	Description
	<pre>monitor.notification.smtp.password": "password"</pre>
<pre>svc-monitor.notification.smtp.ssl_enabled</pre>	<p>Specifies whether the connection to the SMTP server is encrypted. The default is false.</p>
<pre>svc-monitor.notification.smtp.ssl_required</pre>	<p>If enabled, Tableau Server will refuse to connect to SMTP servers without using TLS. The <code>svc-monitor.notification.smtp.ssl_enabled</code> option must also be set to true.</p> <p>The default is false.</p>
<pre>svc-monitor.notification.smtp.ssl_check_server_identity</pre>	<p>If set to true, Tableau Server will check the SMTP server identity as specified by RFC 2595. These additional checks based on the content of the server's certificate are intended to prevent man-in-the-middle attacks.</p> <p>The default is false.</p>
<pre>svc-monitor.notification.smtp.ssl_trust_all_hosts</pre>	<p>When using TLS, trust certificates from all mail servers, ignoring the validity of the certificate's chain of trust. By setting this key to true, TLS will be used only to encrypt the traffic to the SMTP host.</p> <p>The default is false.</p>

Option	Description
<pre>svc- mon- itor.no- tification.smtp.ssl_ ciphers</pre>	<p>The default and supported sets of cipher suites is defined by the version of JDK that is installed with Tableau Server. See the section below, TLS ciphers, for a list of supported and default ciphers.</p> <p>To update the cipher suites used by Tableau Server for SMTP TLS connections, enter a white space-separated list of cipher suites for this value. For example, "TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256 TLS_DHE_DSS_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384".</p>
<pre>svc- mon- itor.no- tification.smtp.ssl_ versions</pre>	<p>The default TLS versions enabled on this version of Tableau Server are TLSv1, TLSv1.1, TLSv1.2 and TLSv1.3.</p> <p>TLS version support is defined by the version of JDK that is installed with Tableau Server.</p> <p>Supported versions of TLS are SSLv2Hello, SSLv3, TLSv1, TLSv1.1, TLSv1.2, TLSv1.3.</p> <p>To update the versions used by Tableau Server for SMTP TLS connections, enter a white space-separated list of versions for this value. For example, "TLSv1.2 TLSv1.3".</p>
<pre>svc-</pre>	<p>Email address that will send an notification if</p>

Option	Description
<code>monitor.notification.smtp.from_address</code>	<p>there's a system failure. The email address must have valid syntax (for example, ITalerts@bigco.com or noreply@mycompany), but it does not have to be an actual email account on Tableau Server. (Some SMTP servers may require an actual email account, however.)</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <p>Note: You can override the system-wide email address on a per-site basis. For more information, see What is a site.</p> </div> <p>Example:</p> <pre>"svc-monitor.notification.smtp.from_address": "donot-reply@example.com"</pre>
<code>svc-monitor.notification.smtp.target_addresses</code>	<p>Email address to receive notifications. If email notifications are enabled, you need to include at least one address. Separate multiple addresses with commas.</p> <p>Example:</p> <pre>"svc-monitor.notification.smtp.target_addresses": "iluvdata@example.com"</pre>
<code>svc-monitor</code>	<p>URL of the Tableau Server. Enter <code>http://</code> or <code>https://</code>, followed by the name or IP address</p>

Option	Description
<code>itor.notification.smtp.canonical_url</code>	<p>of the Tableau server. Used in the footer of subscription email.</p> <p>Example:</p> <pre>"svc-monitor.notification.smtp.canonical_url": "http://myserver.example.com"</pre>

TLS ciphers

The following is a list of TLS ciphers that are supported by the JDK that is included with Tableau Server. In this version of Tableau Server, all of these ciphers are enabled by default. You can specify a custom list of ciphers for your SMTP configuration by entering a white-space separated list with the option, `svcmonitor.notification.smtp.ssl_ciphers`, as described in the table above.

<code>TLS_RSA_WITH_AES_128_CBC_SHA256</code>	<code>TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384</code>
<code>TLS_DHE_DSS_WITH_AES_256_GCM_SHA384</code>	<code>TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256</code>
<code>TLS_ECDH_RSA_WITH_AES_256_CBC_SHA384</code>	<code>TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA</code>
<code>TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA</code>	<code>TLS_RSA_WITH_AES_256_CBC_SHA256</code>
<code>TLS_RSA_WITH_AES_128_GCM_SHA256</code>	<code>TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384</code>

Tableau Server on Windows Help

TLS_ECDH_RSA_WITH_AES_128_CBC_SHA256	TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
TLS_DHE_DSS_WITH_AES_128_CBC_SHA256	TLS_DHE_DSS_WITH_AES_256_CBC_SHA
TLS_DHE_RSA_WITH_AES_128_CBC_SHA256	TLS_DHE_RSA_WITH_AES_256_CBC_SHA256

TLS_RSA_WITH_AES_128_CBC_SHA	TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384	TLS_AES_256_GCM_SHA384
TLS_AES_128_GCM_SHA256	

Configure Server Event Notification

A Tableau Services Manager (TSM) administrator can configure Tableau Server to allow notifications for the following events:

- Content updates
 - Extract failures (enabled by default)
 - Subscription views for users (disabled by default)
- Server health monitoring
 - Server status changes (disabled by default)
 - Desktop License reporting (disabled by default)
- Drive space
 - Email alerts when disk space crosses or remains below pre-configured thresholds (disabled by default)
 - Recording usage history (enabled by default)

Note: You need to configure SMTP before you can configure subscriptions or notifications. For more information, see [Configure SMTP Setup](#).

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850.`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click **Notifications** on the **Configuration** tab and click **Events**.
3. Configure notification settings for your organization:

- Content updates

- **Send emails for extract refresh failures**

When this option is enabled (the default), a server administrator can configure email notifications to be sent when extract refreshes fail. These messages are configured at the site level, so even if this option is enabled, messages are not sent unless the **Send email to data source and workbook owners when scheduled refreshes fail** option is enabled for a site (this is enabled by default). For details, see [Enable Extract Refresh Scheduling and Failure Notification](#).

- **Allow users to receive email for views that they have subscribed to**

When this option is enabled (by default is it disabled), a server administrator can configure a site to send subscription email. These email messages are configured at the site level and can only be configured when this option is enabled. For details, see [Set Up a Site for Subscriptions](#).

When users subscribe to a workbook or view, a snapshot of the view is emailed to them on a scheduled basis, so they can see the latest updates without having to sign into Tableau Server.

To allow users to attach PDF renderings on subscription emails, select **Let users add attachments to subscribed views**.

- Server health monitoring
 - **Send emails for Tableau Server process events (up, down, and failover)**

Tableau Server sends an email message when the data engine, repository, or gateway server processes stop or restart, or when the initial Tableau Server node stops or restarts.

If you are running a single-server installation (all processes on the same computer), health alerts are only sent when Tableau Server is up. No "down" alerts are sent. If you are running a distributed installation that's configured for failover, a DOWN alert means that the active repository or a data engine instance has failed and the subsequent UP alert means that the passive instance (repository) or second instance (data engine) of that process has taken over.

Note: Tableau Server is designed to be self-correcting. If a service or process stops responding or goes down, Tableau Server attempts to restart it. This can take 15 to 30 minutes to complete. Because of this, reacting immediately to service or process alerts can be counter-productive, especially in an installation with redundant services that can handle requests while one restarts.

- **Enable Tableau Desktop License reporting**

License reporting data originates in Tableau Desktop and is sent to Tableau Server. When this option is enabled, Tableau Server will gen-

erate and display the administrative report for Desktop License reporting. For information on the report, see Desktop License Usage.

- Drive space

Enable notifications (alerts) for remaining disk space on your Tableau Server.

- **Send emails when unused drive space drops below thresholds**

You can configure Tableau Server to send email notifications when disk space usage on any node crosses a threshold, or remains below the threshold. And you can configure how often threshold notifications are sent.

There are two thresholds you must set, **Warning threshold** and **Critical threshold**. Thresholds are expressed in percentage of disk space remaining. The critical threshold must be less than the warning threshold.

You also specify the **Send threshold alert every** option. This determines how often, in minutes, warning and critical notifications should be sent. The default value is 60 minutes.

- **Record disk space usage information and threshold violations for use in custom administrative views**

When you configure Tableau Server to record disk space usage, information about free disk space is saved in the repository and you can view the usage history using the Administrative Views.

4. Click **Save Pending Changes** after you've entered your configuration information.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.

Use the TSM CLI

The various notification values described above can be set individually with the `tsm configuration set` command. Alternatively, you can construct a json file and pass all configuration values in one operation. Both methods are described in this section.

Set notification values individually

The following table shows the key/value pairs that map to the notification events described earlier in this topic. Use the `tsm configuration set` command with the following syntax to set a single key/value pair:

```
tsm configuration set -k <config.key> -v <config_value>
```

For example, to enable job failure notifications, run the following command:

```
tsm configuration set -k backgrounder.notifications_enabled -v true
```

Notification option	Key	Value
Extract failures or Flow run failures	<code>backgrounder.notifications_enabled</code>	<code>true false</code>
Enable subscription views for user	<code>subscriptions.enabled</code>	<code>true false</code>
Enable PDF attachments	<code>subscriptions.attachments_enabled</code>	<code>true false</code>

Tableau Server on Windows Help

for sub- scriptions		
Maximum attachment size (MB) for subscription notifications	<code>subscriptions.max_attachment_size_megabytes</code>	integer value, default is 150
Server status changes	<code>svcmonitor.notification.smtp.enabled</code>	true false
License reporting	<code>features.DesktopReporting</code>	true false
Remaining space thresholds: enable email notifications	<code>storage.monitoring.email_enabled</code>	true false
Remaining space thresholds: warning percentage	<code>storage.monitoring.warning_percent</code>	integer value, for example, 20
Remaining space thresholds: critical percentage	<code>storage.monitoring.critical_percent</code>	integer value, for example, 15
Set email interval	<code>storage.monitoring.email_interval_min</code>	integer value, in minutes, for example, 25
Record usage	<code>storage.monitoring.record_history_</code>	true false

history	enabled	
---------	---------	--

After you are done setting values, you must run the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Set all notification values with a single json file

To make all notifications settings with a single configuration, you can pass a json file.

Copy and edit the following template to create a file for your configuration.

```
{
  "configKeys": {
    "backgrounder.notifications_enabled": true,
    "subscriptions.enabled": true,
    "subscriptions.attachments_enabled": true,
    "subscriptions.max_attachment_size_megabytes": 150,
    "svcmonitor.notification.smtp.enabled": true,
    "features.DesktopReporting": true,
    "storage.monitoring.email_enabled": true,
    "storage.monitoring.warning_percent": 20,
    "storage.monitoring.critical_percent": 15,
    "storage.monitoring.email_interval_min": 25,
    "storage.monitoring.record_history_enabled": true
  }
}
```

After you have saved the file, pass it with the following command:

Tableau Server on Windows Help

```
tsm settings import -f <path-to-file.json>
```

To apply changes, run the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Configure Data Cache

Views published to Tableau Server are interactive and sometimes have a live connection to a database. As users interact with the views in a web browser, the data that is queried gets stored in a cache. Subsequent visits will pull the data from this cache if it is available. By default, Tableau Server will cache and reuse data for as long as possible. You can change this behavior by configuring the caching option using the `tsm data-access caching set` command.

1. Run this command:

```
tsm data-access caching set -r <value>
```

Where `<value>` is one of these options:

- **low or empty string ("").** This is the default value and indicates that Tableau Server should configure cache and always use cached data when available.
- `<value>`. "`<value>`" specifies the maximum number of minutes data should be cached.

- **always** or **0** (zero). These values indicates that Tableau Server should always get the latest data and that the cache should be refreshed each time a page is reloaded.
2. Apply changes with the `tsm pending-changes apply` command. This will restart Tableau Server.

Database Drivers

Tableau connectors require a driver to talk to the database. Before you can connect to data sources from Tableau Server, you must install drivers for the data sources you want to connect to. You can find driver links and installation instructions for all the supported connectors on the [Driver Download page](#).

Install drivers in a cluster

You need to install the drivers for your data sources on the initial node in a Tableau Server cluster. If you install Tableau Server on multiple nodes, you must also install drivers on any node that runs any of the following processes:

- Application Server (Vizportal)
- Backgrounder
- Data Server
- VizQL Server

Tableau Server Pre-Flight Check

Introduced in version 2020.3.0 of Tableau Server on Windows, the pre-flight check (PFC) does basic checks of key system configurations to help avoid common installation and upgrade problems.

- **Install**—During installation of Tableau Server on Windows, a check of permissions on the installation directory and the data directory are done. If this check determines that permissions aren't adequate for Tableau Server to run successfully, the installation will not fail, but any errors are logged to the Administration Controller log.
- **Upgrade**—During upgrade of Tableau Server on Windows, when you run the `upgrade-tsm.cmd` script, checks of permissions on the installation and data

Tableau Server on Windows Help

directories are done, along with verification that the ports necessary for specific services are available. Any permissions issues are logged to the `app-upgrade.log` but do not block the upgrade. Port conflicts stop the upgrade process before initialization starts, allowing you to correct the problem. Because this happens *before* initialization of the new version, you can continue to use your existing version while you investigate the issue, then rerun the `upgrade-tsm` script.

tsm pre-flight check commands

Two `tsm` commands gives you the ability to check permissions and ports before running an upgrade, and fix any issues:

```
tsm maintenance preflight-check permissions
```

```
tsm maintenance preflight-check ports
```

Server Crash Reporter

The Tableau Server administrator can enable an option to allow logs and related files to be sent to Tableau when the server has an issue that results in a crash. These files are used by Tableau to identify and address issues that cause crashes. By default this option is disabled, and it should only be enabled in organizations that are not subject to regulations related to data privacy.

Important: Do not enable crash reporting if your data is subject to privacy regulations.

If Tableau Server has a problem that results in a crash, log files and dump files are generated. If the crash data upload feature is enabled, these files are automatically gathered and zipped into an encrypted package that is sent in the background, at the scheduled time. The encrypted package is sent in small pieces to limit impact to network performance. Only one crash report is packaged and uploaded at a time (a new crash report is not packaged until

the previous package has been uploaded) and is sent in a "first in, first out" order. You can schedule the sending for a low-use window to further reduce any impact to your users.

The encrypted package is made up crash dump files and logs that include the following:

- Crash/core dump files
- Error log files related to the crash
- Manifest files related to the crash

The files can contain data that includes:

- Machine-specific information (for example: hardware, operating system, domain).
- A snapshot of the contents of memory at the time of the crash, including application activity details like information about data connections, actions taken by the user in Tableau, and data being worked on in Tableau.
- Tableau information including customer-identifiable information.

Configure Server Crash Reporter

Server crash reporting is disabled by default. This topic describes how to enable and configure server crash reporting. Crash reports are encrypted and sent to Tableau. See [Server Crash Reporter](#) for more information.

If your organization uses a proxy server to connect to the internet then you must configure server crash reporter to use the proxy. Even if you have already configured Tableau Server to use a proxy, you must also configure server crash reporter separately. To configure proxy for server crash reporter you must use TSM CLI procedure as described in this topic.

Important: Do not enable crash reporting if your data is subject to privacy regulations.

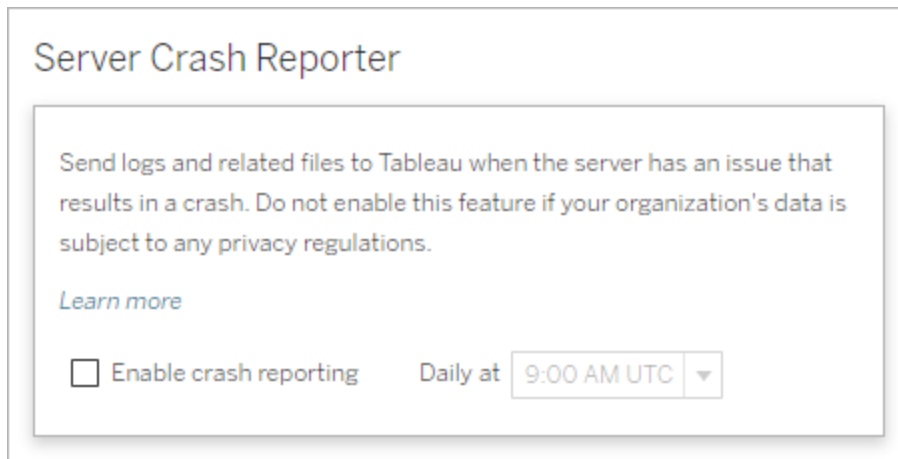

Use the TSM web interface

Tableau Server on Windows Help

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Maintenance** tab.
3. Under Other Maintenance Tasks, in Server Crash Reporter, select **Enable crash reporting**:

4. Specify the scheduled time of day to upload the crash reports to Tableau.
5. When you are finished, click **Pending Changes**, and then click **Apply Changes and Restart**.

Use the TSM CLI

Use the configuration file template below to create a json file. After you have filled in the options with the appropriate values, pass the json file and apply settings with the following commands:

```
tsm settings import -f path-to-file.json
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Because the configuration file is using `configKey` class, the values that you pass are not validated by TSM as they are when you use `configEntities` class. You can verify and set individual options by using the `tsm configuration` commands.

Crash reporter settings

The crash reporter settings in the template below specify a range of options for configuring Tableau Server to send crash reports to Tableau.

Configuration template

Use this template to configure the gateway settings.

For more explanation about configuration files, entities, and keys see [Configuration File Example](#).

```
{
  "configKeys": {
    "servercrashupload.enabled": "true",
    "servercrashupload.scheduled_time": "1:00:00 UTC",
    "servercrashupload.proxy_server_host": "",
    "servercrashupload.proxy_server_port": "",
    "servercrashupload.proxy_server_username": "",
    "servercrashupload.proxy_server_password": "",
    "servercrashupload.preserve_upload_packages": "false",
    "servercrashupload.delete_completed_dumps": "false"
  }
}
```

Tableau Server on Windows Help

Configuration file reference

This table includes keys that you can set to configure crash reporting.

`servercrashupload.enabled`

Default: `false`.

Set to `true` to enable crash reporting.

`servercrashupload.scheduled_time`

Default: `1:00:00 UTC`

Specifies the scheduled time that crash uploads will begin. Enter time of day in 24 hour format.

`servercrashupload.proxy_server_host`

If your organization uses a proxy server to communicate with the internet, specify the host name.

`servercrashupload.proxy_server_port`

If your organization uses a proxy server to communicate with the internet, specify the port number.

`servercrashupload.proxy_server_username`

If your proxy server requires authentication, specify the user name with this key.

`servercrashupload.proxy_server_password`

If your proxy server requires authentication, specify the password with this key.

`servercrashupload.preserve_upload_packages`

Default: `false`.

To save all packages that are created for a crash reporting, set this key to `true`.

By default, packages are saved to `C:\ProgramData\Tableau\Tableau Server-\data\tabsvc\clustercontroller\tabcrashreporter`.

`servercrashupload.delete_completed_dumps`

Default: `false`.

To delete all dumps after they are sent, set this key to `true`.

Navigate the Admin Areas of the Tableau Web Environment

As an administrator on Tableau Server or Tableau Online, you can access admin settings that aren't available to other users to configure sites, users, projects, and to do other content-related tasks.

The settings in this article refer to the Tableau web environment. Tableau Server administrators with appropriate credentials can also change server settings such as processor, caching, authentication, distributed deployment, and related configurations using the TSM web environment. For information, see [Sign in to Tableau Services Manager Web UI](#).

Access based on site role and number of sites

The menus you get when you sign in to Tableau Server or Tableau Online depend on the following conditions:

- Whether you're a site or server administrator.

Site administrator access is available on Tableau Online and Tableau Server. Server administrator access is only on Tableau Server.

- Whether you have access to only one site or to multiple sites.

Tableau Server on Windows Help

Server administrator

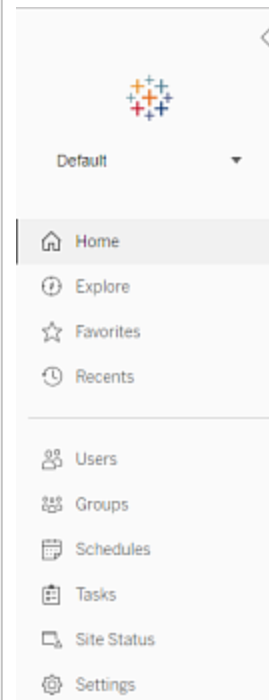

On a **single-site** server, the site selector does not appear, and all other menus are the same.

In a **multi-site** environment, menus along the left enable you to modify a specific site or all sites, and to configure users, groups, schedules, tasks, and server settings.

To access server administrator settings that affect all sites, open the site menu by clicking the arrow next to the current site name, and then select **Manage all sites**.

The **Content** and **Group** tabs go away, and the site menu text changes to **All Sites** to let you know you are managing server-wide settings, and options like **Server Status** reflect the server-wide view.

To return to the site administration menus, select **All Sites**, and then select the site you want to manage.

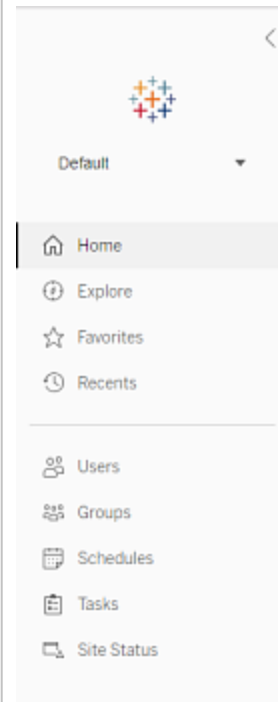

Tableau Server on Windows Help

Site administrator

If you are a site administrator for Tableau Online or Tableau Server, and you have access to multiple sites, you'll get menus for selecting which site to manage, and for managing that site's content, users, groups, schedules, and tasks, and for monitoring its status.

The site selector displays the name of the current site. To go to another site, select the site menu, and then select the site name.

If you have access to only one site, the site selector does not appear, but all other menus are the same.

Server administrator tasks

Server administrators (available with Tableau Server Enterprise only) can do the following:

- Monitor server status and activity.
- Generate log files.
- Add sites and edit site settings. Only server administrators can add sites to the server.
- Add users to the server, and assign users to sites.
- Add and manage site groups.

To manage settings only for a specific site, you must first navigate to the site. Within each site, you can do the following:

- Administer content: Create projects, move content from one project to another, assign permissions, change ownership of a content resource, and so on.
- Manage schedules for extract refreshes and subscriptions.
- Monitor site activity and record workbook performance metrics.
- Manage storage space limits for content published by users.
- Allow web authoring.
- Enable revision history.
- Allow site administrators to add and remove users.
- Set the maximum number of licenses that site can consume for each license type (Creator, Explorer, Viewer).
- Allow users to subscribe to workbooks and views, and allow content owners to subscribe others to workbooks and views.
- Enable offline snapshots for favorites (iOS only).

Site administrator tasks

A site administrator on Tableau Online or Tableau Server can do the following tasks:

- Administer content: Create projects, move content from one project to another, assign permissions, change ownership of a content resource, and so on.
- View, manage, and manually run schedules for extract refreshes and subscriptions.
- Add and manage site users (if allowed by the server administrator; see Site Settings Reference).
- Add and manage site groups.
- Monitor site activity.

Move Tableau Server to Another Drive

By default Tableau Server on Windows is installed to the system drive (usually C:\). This means that all program and data files are installed to that drive. If you need to move Tableau Server to a different drive (if a new policy requires you to not have application data on your system drive, for example, or you are running out of space on the original drive), you can do this by following the procedure below. The steps are intended as an example for moving Tableau Server from one drive to another drive on the same computer, and may not exactly reflect your installation and configuration. For instructions on moving Tableau Server to a new computer, see [Migrate to New Hardware](#).

Before you start

Before starting, make sure you:

- Have a current backup of your data and assets from your existing installation. You'll need these to restore your installation of Tableau Server on the new drive. For details on creating a backup, see [Perform a Full Backup and Restore of Tableau Server](#).

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

- Have administrative credentials to the Tableau Server computer. This is where you will be working and you need to be logged on to the computer as an administrator.
- Have a copy of the installation program for the version of Tableau Server you are moving. You need this to install Tableau Server to the new drive.
- Know what authentication methods your current installation is using. For example, if Tableau Server is configured for SSL, SAML, or Kerberos, you will need to back up

the related certificate or keytab files separately, and then copy them to the new drive after you reinstall Tableau Server.

When you are ready to move Tableau Server to another drive and have fully backed up your data and all assets and saved those files in a safe location on a different computer:

1. Open a command prompt as an administrator on the initial Tableau Server computer.
2. Change to the scripts directory (By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`) and run the obliterate script to completely remove Tableau Server from the computer:

```
tableau-server-obliterate.cmd -y -y -y
```

3. Restart the computer.
4. Install Tableau Server to the new drive. For details, see Install TSM.

At the end of the install process a browser window will open and you will be prompted to create an initial administrative user. Close this without creating the user.

5. Copy your backup file `.tsbak` to the folder location specified by the `base-filepath.backuprestore` variable. By default this is: `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\files\backups`.

Note: You can change the location for the backup file. For more information, see [tsm File Paths](#).

6. Open a command prompt as an administrator.
7. Stop Tableau Server:

```
tsm stop
```

8. Restore your Tableau Server data backup and assets you saved earlier. This

Tableau Server on Windows Help

includes restoring your database, and any assets that need to be restored manually.

For details, see Restoring core Tableau Server functionality.

9. Start Tableau Server:

```
tsm start
```

Tableau Server product key activation

You can activate the same Tableau Server product key up to three times. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer or VM to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you use role-based licensing, be sure to activate a Creator or Explorer key or you may lose administrator access to Tableau. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled. For example, if you are moving Tableau from one drive on a computer to a different drive on the same computer. For information on how to deactivate a product key, see `tsm licenses deactivate`.

When you remove Tableau Server using the `obliterate` script, you have the option to have the script deactivate and delete the Tableau product key information by using a `"-1"` switch. This will deactivate and remove all Tableau license information, including Tableau Desktop if you have that installed. If you know you want to deactivate the key, we recommend you deactivate the key *before* running the script. For more information, see [Remove Tableau Server from Your Computer](#).

Distributed and High Availability Tableau Server Installations

The most basic way to run Tableau Server is to install a single node. With this type of installation you have a fully functional Tableau Server, with all Tableau Services Manager (TSM) and Tableau Server processes running on that single node, but this may not be the optimal way to use Tableau Server. You can decide how to install Tableau based on your organization's needs, and your resources, adding additional nodes and configuring Tableau for high availability. Your installation options include:

- **Single-node installation**—This type of installation is reasonable for testing, running trials, and for environments that can handle occasional downtime and system availability due to lack of redundancy. All server processes are running on a single machine. There is less redundancy and fewer safeguards in the event of a problem with one of the server processes. You also need to make sure the computer you install Tableau Server on has adequate resources to handle the processes and the demands of users and data.
- **Distributed installation**—This type of installation is also called a multi-node installation and requires multiple computers so you can install and run server processes on those distributed nodes. Spreading the server processes out over multiple nodes can extend the reliability and efficiency of Tableau Server by providing redundancy and additional computing power. With the right configuration, a distributed installation can also provide you with automatic repository failover. For more information on failover, see [Repository Failover](#).
- **Highly available (HA) installation**—An HA installation of Tableau Server is a special type of multi-node installation with a minimum of three nodes and multiple instances of key processes (the Repository, File Store/Data Engine (Hyper), Coordination Service, and Client File Service) on different computers. With an HA installation, there is built-in redundancy of those key processes, including multiple File Stores, and automatic Repository failover. The goal is to minimize system downtime

Tableau Server on Windows Help

by eliminating single points of failure, and enabling detection of failures with failover where possible.

Downtime is still possible in the event of an initial node failure, or when a node running Application Server (VizPortal) is recovering from a failure. Dashboards and views may load more slowly than expected, and timeouts are possible, depending on how your system is configured and being used. For more information about initial node failure, see [If an initial node fails](#) below.

The first computer you install Tableau on, the "initial node," has some unique characteristics. Three processes run only on the initial node and cannot be moved to any other node except in a failure situation, the License Service (License Manager), Activation Service, and TSM Controller (Administration Controller). Tableau Server includes a script that automates moving these processes to one of your other existing nodes so you can get complete access back to TSM and keep Tableau Server running.

Two other processes are initially included on the initial node but can be added or moved to additional nodes, the CFS (Client File Service) and the Coordination Service. Depending on how your installation was configured with CFS and Coordination Service, you may also need to take steps to redeploy these.

For information about moving the License service and TSM Controller from the initial node to another node, see [Recover from an initial node failure](#) below.

Prerequisite

These instructions assume that your cluster meets the [Distributed Requirements](#).

Note: All nodes in a multi-node cluster must have the same type of operating system. You cannot install a multi-node instance of Tableau Server on a combination of Linux and Windows nodes.

Licensing

You must have a valid Tableau Server product key. The type of license you have may determine how many nodes you can install Tableau on. You cannot use a trial license key for a distributed Tableau Server installation. For more information on licensing, see [Licensing Overview](#).

Creating a distributed Tableau Server installation

These are the general steps you follow to create a distributed installation of Tableau Server:

1. Begin by installing Tableau Server on your initial node.

For details, see [Install and Configure Tableau Server](#).

2. Generate a node configuration (bootstrap) file on the initial node.

For details, see [Generate the node bootstrap file](#).

3. Install Tableau Server on an additional node using the node bootstrap file.

4. Configure your additional node with the processes you want to run on it.

5. Repeat Steps 3 and 4 for any additional nodes you want to install.

6. Deploy a new Coordination Service ensemble.

For more information, see [Deploy a Coordination Service Ensemble](#).

7. Add Client File Service to every node that is running the Coordination Service.

For more information, see [Configure Client File Service](#).

Creating a highly available (HA) Tableau Server installation

A high availability Tableau Server installation is a special type of distributed installation, designed to accommodate failure in key server components without loss of complete server

Tableau Server on Windows Help

functionality. To create an HA installation, follow the same steps you take to create a distributed deployment but include additional steps to make the deployment highly available. These additional steps include adding at least two additional nodes (for a minimum of three nodes in the cluster), adding a second instance of the repository, and second instances of the data engine/file store, adding additional gateway processes, and deploying a Coordination Service ensemble. You can also add a load balancer to distribute requests among the gateways.

At a high level, these are the steps you follow to create a highly available installation of Tableau Server:

1. Begin by installing Tableau Server on your initial node.

For details, see [Install and Configure Tableau Server](#).

2. Generate a node configuration (bootstrap) file on the initial node.

For details, see [Generate the node bootstrap file](#).

3. Install Tableau Server on at least two additional nodes using the node bootstrap file.

For more information, see [Install and initialize an additional node](#).

4. Configure each additional node with the processes you want to run on it. These must include a second copy of the Tableau Server repository, and a second copy of the data engine and file store, as well as additional instances of the gateway.

For more information, see [Configure the additional node](#).

5. Deploy a Coordination Service ensemble.

For more information, see [Deploy a Coordination Service Ensemble](#).

6. Add Client File Service to every node that is running the Coordination Service.

For more information, see [Configure Client File Service](#).

7. (Optional) Configure a load balancer.

For more information, see [Add a Load Balancer](#).

For details on how to create a three-node HA installation, see [Example: Install and Configure a Three-Node HA Cluster](#).

If an initial node fails

If there is a problem with the initial node and you have redundant processes on your other nodes, there is no guarantee that Tableau Server will continue to run. Tableau Server can continue to run for up to 72 hours after an initial node failure, before the lack of the licensing service impacts other processes. If so, your users may be able to continue to sign in and see and use their content after the initial node fails, but you will not be able to reconfigure Tableau Server because you won't have access to the Administration Controller.

Even when configured with redundant processes, *it is possible that Tableau Server may not continue to function after the initial node fails*. This is true even when an installation is configured for high availability. This means you should make a point of moving the two unique processes to another of your running nodes as soon as possible. If your initial node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Recover from an initial node failure

With a Tableau Server installation, the initial node includes two services that are only installed on that node, the License service, and the TSM Controller. If there is a problem with the initial node, Tableau Server may not continue to function, even when configured for high availability. To recover from a situation where the initial node fails, you can move the TSM Controller and the License service to one of your already configured nodes. This allows you to recover from the failure while using resources you already have in the cluster. You do not have to configure a standby initial node in case the initial node fails.

For details on how to recover from a failure on the initial node, see [Recover from an Initial Node Failure](#).

Configure Coordination Service ensemble on additional nodes

Configuring a Coordination Service on multiple nodes provides additional duplication of processes and so reduces the possibility of server downtime due to an issue with one of the Coordination Service nodes. For details on how to deploy a Coordination Service ensemble on your cluster, see [Deploy a Coordination Service Ensemble](#).

Add Client File Service (CFS) to additional nodes

Tableau Server requires at least one instance of Client File Service (CFS). Adding additional instances of CFS to other nodes provides additional duplication of processes and so reduces the possibility of server downtime due to an issue with one of the CFS nodes. We recommend that you configure an instance of CFS on each of the nodes where you deploy the Coordination Service. For details on how to configure CFS on other nodes, see [Configure Client File Service](#).

Tableau Server service license check

A number of processes are installed when you install Tableau Server. Some of these processes are dependent on the existence of a valid Tableau Server license while other installed processes are not. The subset of Tableau Server that require a valid Tableau Server license are considered "licensed processes."

When a licensed process starts or restarts, the process checks with the Tableau Server License Manager service on the primary node to verify there is a valid license. When the License Manager validates the license, the process is fully functional and able to respond to requests from other Tableau Server processes. Once a licensed process has received confirmation from the License Manager, the process does not need to reconfirm the license for

72 hours, or until the process restarts. If the process is not able to verify that it is licensed (if the primary node is unavailable, for example) it cannot run, but it continues to check for a valid license until it confirms the license. To see when the last licensing check occurred, look at the log files in the `ProgramData\Tableau\Tableau Server-\data\tabsvc\logs\licenseservice` folder. For more information about licensed processes, see [Licensed processes](#).

Distributed Requirements

Before you start to configure a Tableau Server cluster, make sure you meet the following requirements.

Hardware

While the computers you use in your cluster must meet the requirements described in [Before you install...](#), they do not need to be identical.

Hardware Guidelines for High Availability

Here are some guidelines for the systems you use for [failover and high availability](#):

- **Failover—three computers:** To configure a cluster that provides failover support for the file store and repository processes, you need at least three computers or VMs: one for the initial Tableau Server node and two for additional nodes.
- **Multiple gateways—three computers and a load balancer:** Adding multiple Gateway processes to your Tableau Server installation and using a load balancer to automatically distribute requests to those gateways enhances the reliability of Tableau further. To configure a cluster that provides failover support and multiple gateways, you need to add a load balancer to front your three-node cluster.
- **Failover & multiple gateway support—three computers and a load balancer:**

Tableau Server on Windows Help

To configure a cluster that provides the above plus support for multiple gateways, you need at least three computers or VMs, and a load balancer to front the cluster.

- **High availability—three computers and a load balancer:** To configure for high availability, you need the resources described above.
- **Initial computers:** If you configure for high availability, the initial Tableau Server node may be running few or no Tableau Server processes. Therefore, the computer that serves as the initial node does not need as many cores as the ones running your additional nodes. You will, however, need adequate disk space for backups because the initial computer is used during the backup and restore processes. In addition to the amount of space needed for the backup file, you need temporary disk space. For details on disk space requirements, see [Disk Space Usage for Backup and Restore](#).

Software

All nodes in a distributed installation must be running the same version of Tableau Server.

Installation location

The installation location for Tableau Server must be the same on all nodes in a cluster. This is true whether you install to the default location or to a non-default location.

Networking and Ports

- **Ports:** As with any distributed system, the computers or VMs you use need to be able to communicate with one another. For information on how Tableau Services Manager handles port mapping, see [Tableau Services Manager Ports](#).
- **Same domain:** If Tableau Server is installed in a Windows Active Directory environment, then all computers in a cluster must be members of the same domain.
- **Latency:** Network latency between server nodes can impact Tableau Server performance. Be aware of possible latency issues, especially if you run into performance

problems. To reduce network latency, you can take steps such as locating your gateways and data sources in proximity to Tableau Server.

- **Service account:** The server's Run As Service Account account, which is specified on the initial Tableau Server, must be the same on each computer in the cluster.

If you are running in an Active Directory environment, then we recommend running a domain user account as the Run As service account. While you can leave the default NetworkServices account on each node in the cluster, we do not recommend this as a best security practice.

If you are running a distributed deployment in a Windows workgroup, then you must use the same user account and password on each node in the cluster. In this scenario, specify the Run As service account using a period (.) instead of a computer name in TSM. For example, if the workgroup Run As service account is `tableau-sa`, then specify `.\tableau-sa` in TSM. Windows interprets the `.\` syntax as equivalent to "local host computer name."

- **Static IP addresses:** Any computer running Tableau Server, whether it's a single server installation or part of a cluster, must have a static IP address.
- **Discoverable:** Each node in the cluster must be discoverable from other node computers using DNS or a local host file.
- **Time zone and time:** Each node in the cluster must be in the same timezone, with their system clocks synchronized. This may happen automatically. For example, if your nodes are all in the Active Directory domain, the domain controller usually handles this. If you are not sure your cluster meets this requirement, consult with your internal IT experts.

Best Practices

Here are some things to keep in mind before you start to install and configure:

Tableau Server on Windows Help

- **IP addresses or computer names:** As mentioned above, each computer in the cluster must use a static IP address.
- **CNAME record:** If you are using a load balancer, it's the load balancer's name that users will be using as the Tableau Server URL, regardless of the gateway that's actually handling the request.
- **User account credentials:** For each computer, you need credentials for a user account with local admin permissions.
- **Backup:** It's a best practice to create a backup prior to making significant system changes. See [Back up Tableau Server data](#) for steps.
- **Distributed deployment across data centers:** We do not recommend installing Tableau Server nodes across distributed data centers. The following examples describe some issues that are common when nodes are distributed between multiple data centers:
 - Disruption in network connectivity between nodes can cause many tasks to fail or for Tableau Server components to become unlicensed.
 - Proxies and firewalls between data centers may impede the ability of the Tableau Server nodes to communicate with each other.
 - Routing traffic between geographically dispersed data centers, can cause latency or bottleneck data transmission, resulting in poor performance and connection timeouts.

SSL

If you are planning to configure SSL for a highly available Tableau Server cluster with multiple gateways and a load balancer ([learn more](#)), make sure that the SSL certificate you use was issued for the load balancer's host name. See [Configure SSL for External HTTP Traffic to and from Tableau Server](#) for other details.

Distributed Installation Recommendations

When you add nodes to a Tableau Server installation, you must decide how many processes to run on each computer. This page provides some general recommendations that are intended only as a starting point.

In addition to these general recommendations, you should also:

- Understand how your organization uses Tableau Server and tune your configuration for your use case—for example, whether you want to optimize for user response or for extract refreshes.
- Perform thorough performance testing to identify the best places to adjust process configuration.

For more information on tailoring a Tableau Server installation to your organization's needs, see [Performance Tuning](#).

For more information on the requirements for a distributed installation and for information on configuring additional nodes, see [Distributed and High Availability Tableau Server Installations](#).

Recommendations for all installations

Although the computers that make up a Tableau Server cluster do not need to have identical hardware, they must all meet the same minimum system requirements. The recommendations on this page assume that the computers where you install Tableau Server have eight cores or more.

The following recommendations apply to all server configurations:

- Run Backgrounder processes on a dedicated computer if you plan on refreshing extracts frequently. Backgrounder processes are generally the most CPU intensive and can slow down other processes on the same computer.

Note: In versions earlier than 10.5, the backgrounder process spun up temporary instances of Data Engine when refreshing extracts. In 10.5, a single instance of Data Engine is installed with the backgrounder during setup. The backgrounder uses this running instance of Data Engine when refreshing extracts.

- If you plan to refresh extracts frequently or if you plan to refresh large extracts, increase the number of processes for Backgrounder processes.
- Run VizQL processes on a different computer than Backgrounder processes. Having them on the same machine means that extract refreshes can affect user views.
- The instance of Data Engine installed on the node where File Store is installed is used for querying data for view requests. Consider separating the File Store process from the backgrounder processes to help minimize the backgrounder tasks from affecting user views.
- **Optimizing with topology configurations:**
 - Co-locating File Store on the same node as the Administration Controller can reduce the length of time it takes to back up Tableau Server by reducing or eliminating the need to transfer data between nodes during the backup process. This is especially true if your organization uses many extracts.
 - Co-locating the repository (pgsql) with the Administration Controller node can also help to reduce back up time, but the time savings is less significant than that of the File Store.

The Administration Controller is usually on the initial node, unless you have had an initial node failure and moved the controller to another node.

Note: In a distributed installation with three or more nodes, you can have a maximum of two repository instances (active and passive). You can also run Tableau Server with one repository, but doing this means there is no failover available for the repository. For more information, see [Tableau Server Repository](#).

Install and Configure Additional Nodes

After you install Tableau Server on one computer (or node), the server is functional and ready for use, but it has no redundancy. If there is a problem with a process or a problem with the computer itself, Tableau Server may be unavailable. In addition, all processes are running on a single computer, so there can be contention for resources on that computer.

You can extend your Tableau Server installation by adding Tableau to additional nodes, creating a distributed installation. This article describes the general steps for installing Tableau Server on additional nodes and assumes you have already installed Tableau on an initial node. For more information on installing Tableau on the initial node, see [Install TSM](#).

If you are installing Tableau Server on multiple nodes, you should install and configure one node at a time. This makes it easier to troubleshoot any issues you might run into.

Important: You should add and configure additional nodes when you can fully complete the process by applying pending changes. Adding a node without finishing by applying pending changes can result in users being unable to log into Tableau Server.

Installation location

The installation location for Tableau Server must be the same on all nodes in a cluster. This is true whether you install to the default location or to a non-default location.

Use the TSM web interface

Generate the node bootstrap file

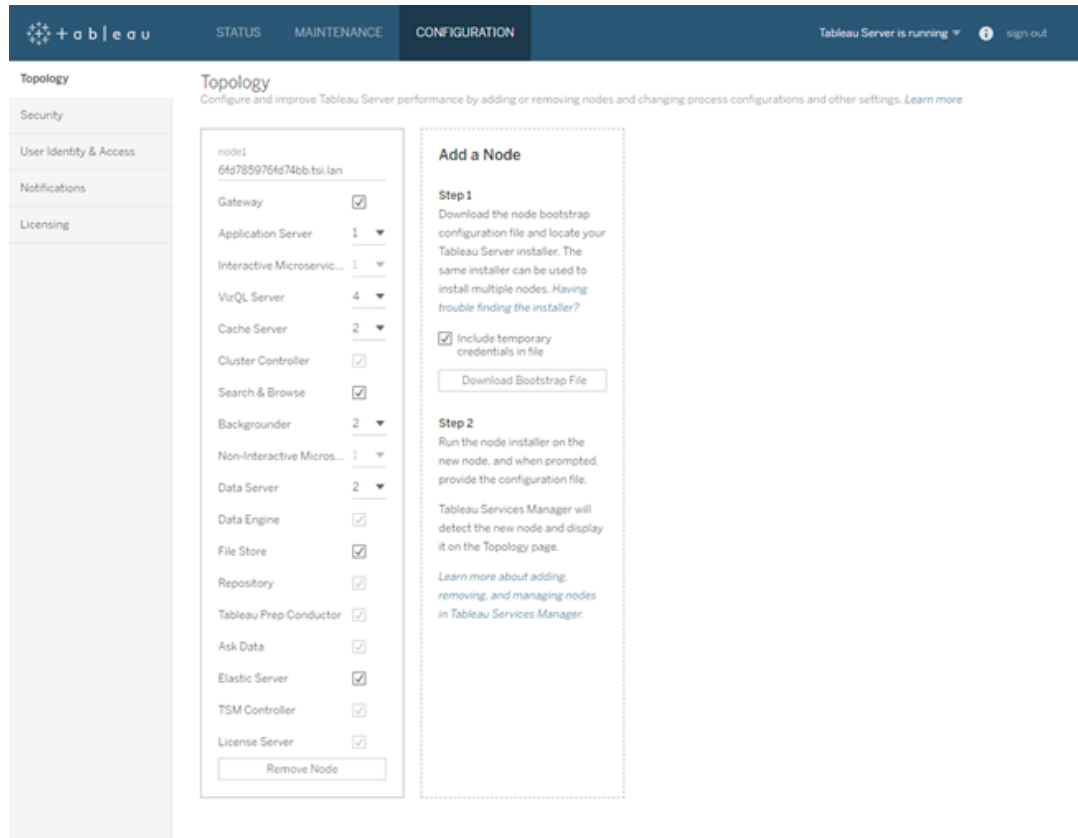

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab, and in the Add a Node box, click **Download Bootstrap**

File.

The bootstrap file is created and copied to your local computer.

Beginning with version 2019.3, embedded credentials are included in the bootstrap file by default. If you don't want credentials embedded in the bootstrap file, clear the **Include temporary credentials in file** option. See What's New and Changed in Tableau Server in What's New for more information. If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See features.PasswordlessBootstrapInit for more details.

Install and initialize an additional node

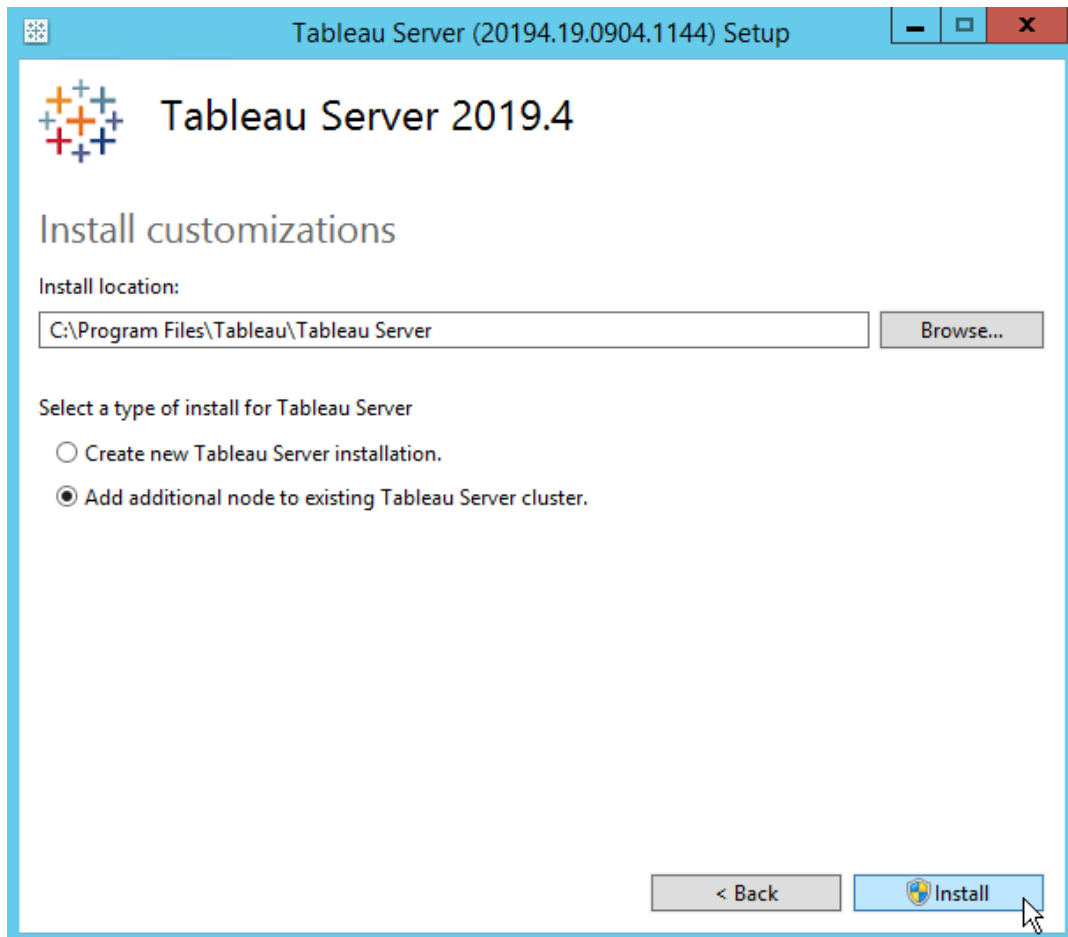

Before you begin, verify that your node bootstrap file is recent. For example, if you have run `tsm security regenerate-internal-tokens` after you generated a bootstrap file,

then initialization will fail.

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server. Accept the terms of the license agreement and click **Next**.

The **Install location** must be the same on every node in the cluster.

During installation you will be asked to select an installation type. Select **Add additional node to existing Tableau Server cluster**:

4. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

5. In the installer, after the Tableau Server files are copied, you will be prompted to provide the bootstrap file and the name and password of the TSM administrator:

The bootstrap file can be generated by running the "tsm topology nodes get-bootstrap-file" command on the initial node.

Bootstrap File

Tableau Services Manager (TSM) Username:

Tableau Services Manager (TSM) Password:

Click **Next** to continue.

6. Enter the location of the bootstrap file, or click **Browse** to navigate to the location. If the bootstrap file does not include embedded credentials, or those credentials have expired, enter the TSM administrator username and password. These credentials must be the credentials of the user that you used during the installation process on the initial node.
7. A browser window opens and you are prompted to sign in to TSM. Enter the TSM administrator user name and password.

If no browser window opens automatically, open a window and navigate to TSM:

`https://<tsm-computer-name>:8850`

Tableau Server on Windows Help

8. In TSM, click **Configuration**.

A message displays, telling you the node was added:

9. Click **Continue**.

Configure the additional node with Cluster Controller

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab. A message should tell you that the new node was added.

Click **Continue** to dismiss the message.

3. Cluster Controller is part of the minimum topology and is already selected. Each node must run Cluster Controller.

If you only want to set the minimum topology for the node, go to Step 4 below. You might do this if you will be adding additional nodes and are not ready to configure this node beyond the minimum.

If you want to add additional processes to the minimum topology, specify the processes that should run on the node. Do this by selecting the processes you want, or specifying the number of processes that should run on the node.

For example, to add a Gateway and two instances of the Backgrounder on the node:

- a. Select **Gateway**.
- b. Set the **Backgrounder** count to 2.

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when

Tableau Server on Windows Help

you add another process. For more information, see [Configure Nodes and Tableau Server Processes](#).

Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see `tsm topology set-process`.

4. Click **Pending Changes** at the top of the page:

If you are configuring a cluster with three or more nodes, a Coordination Service ensemble warning displays. You can continue. You will deploy a Coordination Service ensemble in a separate step.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

After Tableau Server restarts, the node is included with the minimum topology necessary and any additional processes you configured.

Use the TSM CLI

Note: This method of installation from the command line requires you to set Windows environment variables on each additional node for the username and password of an administrator on the initial node. For an alternate method of automating Tableau Server installation without including unencrypted credentials, see [Automated Installation of Tableau Server](#).

Generate the node bootstrap file

To install Tableau Server on additional computers you use the same installer you did for the initial node, along with a "bootstrap" file you generate on the initial node.

Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. The file can also embedded credentials which are valid for a pre-determined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie. We strongly recommend that you take additional measures to secure the bootstrap file.

1. After installing Tableau Server on the initial node, generate the node bootstrap file.
2. On the initial node, open a command prompt as administrator.
3. Type this command to generate the bootstrap file:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json
```

Beginning with version 2019.3, embedded credentials are included in the bootstrap file by default. If you don't want the bootstrap file to include credentials, use the `-nocredentials` or `--no-embedded-credentials` option:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json --no-embedded-credentials.
```

See [What's New and Changed in Tableau Server](#) in [What's New](#) for more information. If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See [features.PasswordlessBootstrapInit](#) for more details.

Install and initialize an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are

Tableau Server on Windows Help

adding Tableau Server to. This could be a mounted network share, or directly on the new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server.

```
TableauServer-64bit-<version>.exe /silent /accepteula  
/embeddedcredential /bootstrapfile="path\bootstrapfile"
```

For more information about switches you can use with the Setup program, see [Install Switches and Properties for Tableau Server](#).

Configure the additional node

Note: This basic example illustrates how to set the topology on a node. For a more detailed, working multi-node example, see [Example: Install and Configure a Three-Node HA Cluster](#).

On the initial (original) node, set the topology for the newly added node. The topology specifies which processes should run on the node, and how many instances of each process should run. The topology for the node will depend on your environment and organizational needs. The below are just examples of setting the topology.

1. On the initial (original) node, open a command prompt.
2. Get the node-id for the new node:

```
tsm topology list-nodes -v
```

The `-v` option lists the nodes and the processes they are currently running. You can identify the newly added node because it will not have any processes on it.

3. Specify the individual processes that should run on this node.

Do this with the following command:

```
tsm topology set-process -n <nodeID> -pr <processname> -c
<n>
```

You must add an instance of the Cluster Controller to each node.

For example, to add the Cluster Controller, two instances of the Backgrounder, and a Gateway to node2:

```
tsm topology set-process -n node2 -pr clustercontroller -c
1
tsm topology set-process -n node2 -pr backgrounder -c 2
tsm topology set-process -n node2 -pr gateway -c 1
```

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see [Configure Nodes and Tableau Server Processes](#).

4. Apply the node configuration. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

A warning about deploying a Coordination Service ensemble displays if you have deployed a three- or five-node cluster. If this is the only warning, you can safely override it using the `--ignore-warnings` option to apply the configuration changes in spite of the warning.

Tableau Server on Windows Help

```
tsm pending-changes apply --ignore-warnings
```

Install drivers

You need to install drivers so that Tableau Server can connect to data and run extracts.

Install these drivers on nodes that are running any of the following processes:

- VizQL Server (vizqlserver)
- Application Server (vizportal)
- Data Server (dataserver)
- Backgrounder (backgrounder)

Drivers and administrative views

If you want to use the built-in administrative views in Tableau Server, you also need to install the PostgreSQL driver on any nodes running any of the above processes.

For more information, see [Database Drivers](#).

Install Tableau Resource Monitoring Tool Agent

If you are using Resource Monitoring Tool to monitor Tableau Server Performance, when you add a new node, you must also install the Resource Monitoring Tool. For more information, see [Tableau Server Topology Changes](#).

Database Drivers

Tableau connectors require a driver to talk to the database. Before you can connect to data sources from Tableau Server, you must install drivers for the data sources you want to connect to. You can find driver links and installation instructions for all the supported connectors on the [Driver Download page](#).

Install drivers in a cluster

You need to install the drivers for your data sources on the initial node in a Tableau Server cluster. If you install Tableau Server on multiple nodes, you must also install drivers on any node that runs any of the following processes:

- Application Server (Vizportal)
- Backgrounder
- Data Server
- VizQL Server

Example: Install and Configure a Three-Node HA Cluster

A multi-node high availability installation of Tableau Server can help to maximize the efficiency and availability of Tableau Server. When configuring a multi-node Tableau Server deployment, the steps you perform are designed to build in redundancy, helping to reduce your potential downtime. In addition to simply improving efficiency by moving or adding server processes to additional nodes, you can create a highly available (HA) installation of Tableau Server by satisfying these requirements:

- Add additional nodes for a total of at least three nodes
- Deploy a Coordination Service ensemble on at least three nodes
- Add an instance of Client File Service (CFS) on at least one additional node (we recommend adding an instance on each node running the Coordination Service)
- Add a second instance of the File Store on one of the additional nodes (Data Engine will be installed automatically, if it is not already on the node)
- Add a second instance of the Repository (pgsql) on one of the additional nodes

A Tableau Server installation that includes these additions will have built-in redundancy and can support failover in the event of a problem with the repository. This example shows how to do this, and more.

A Single Server System

After installing Tableau Server on an initial node, you have a system that is running everything it needs to function. It has at least one instance of all server processes and is the most basic configuration of Tableau Server. It has no redundancy. The server topology looks like this (some TSM-specific processes are not shown):

A Three-Node System

To build in redundancy, you need to add additional nodes to host instances of the repository and the data engine and file store processes. You can add instances of other processes, including multiple instances of a process on a node. In addition, to reduce the system's vulnerability, you can run multiple gateways and additional instances of some of the server processes. The fewest number of computers required to achieve this configuration is three.

In the diagram below, the file store process has been added to both additional nodes. A second, passive instance of the repository has also been added to one of the other new nodes. Finally, the server processes (shown in blue) have been added to the additional nodes to provide redundancy.

Configuration steps

This procedure describes how to configure a three-node HA Tableau Server cluster with two repository instances and two file store/data engine instances on the additional nodes as pictured above.

Before you begin

Before you install Tableau Server on any additional nodes, ensure that each additional node meets the distributed requirements. See [Distributed Requirements](#) for details.

Use the TSM web interface

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Step 1: Install the initial node

See [Install and Configure Tableau Server](#).

Step 2: Generate a bootstrap file for the additional nodes

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab, and in the Add a Node box, click **Download Bootstrap File**.

The bootstrap file is created and copied to your local computer.

Beginning with version 2019.3, embedded credentials are included in the bootstrap file by default. If you don't want credentials embedded in the bootstrap file, clear the **Include temporary credentials in file** option. See *What's New and Changed in Tableau Server* in *What's New* for more information. If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See `features.PasswordlessBootstrapInit` for more details.

Step 3: Install and initialize an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the

new computer.

2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server. Accept the terms of the license agreement and click **Next**.

The **Install location** must be the same on every node in the cluster.

During installation you will be asked to select an installation type. Select **Add additional node to existing Tableau Server cluster**:

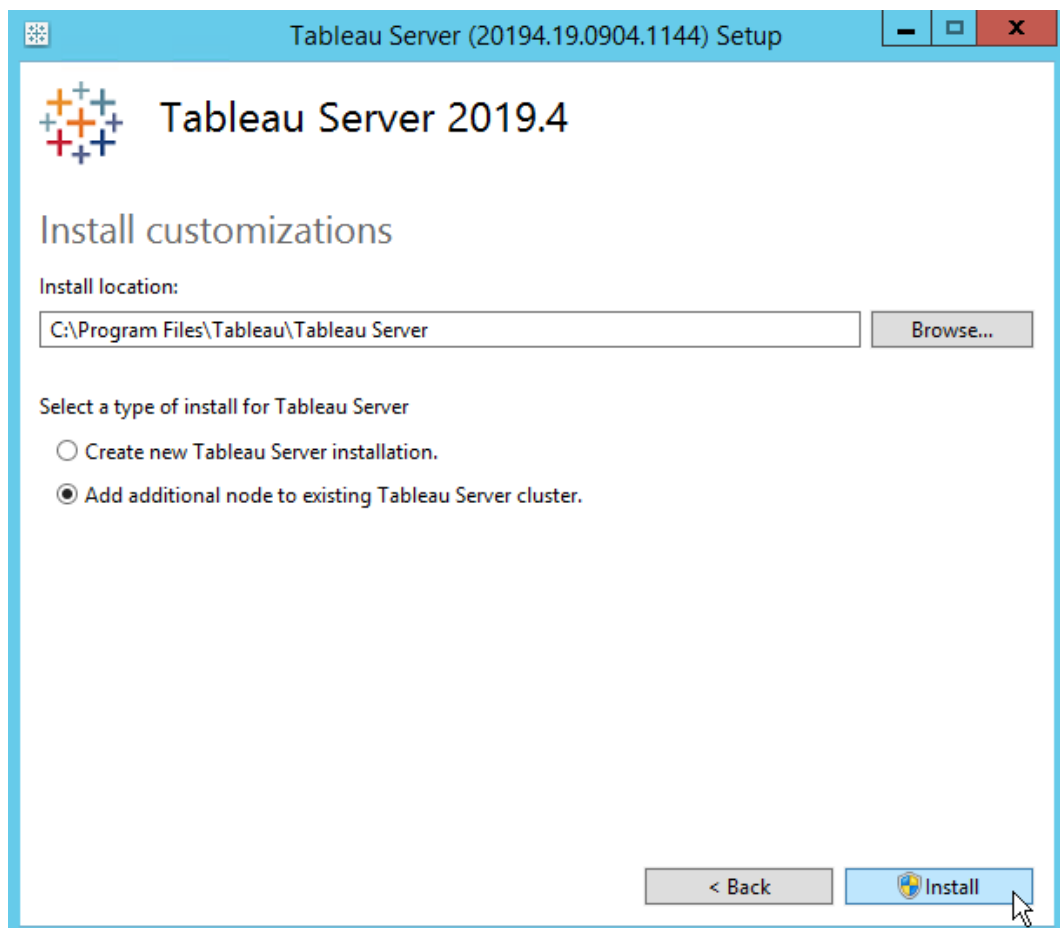

Tableau Server on Windows Help

4. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

5. In the installer, after the Tableau Server files are copied, you will be prompted to provide the bootstrap file and the name and password of the TSM administrator:

The bootstrap file can be generated by running the "tsm topology nodes get-bootstrap-file" command on the initial node.

Bootstrap File

Tableau Services Manager (TSM) Username:

Tableau Services Manager (TSM) Password:

Click **Next** to continue.

6. Enter the location of the bootstrap file, or click **Browse** to navigate to the location. If the bootstrap file does not include embedded credentials, or those credentials have expired, enter the TSM administrator username and password. These credentials must be the credentials of the user that you used during the installation process on the

initial node.

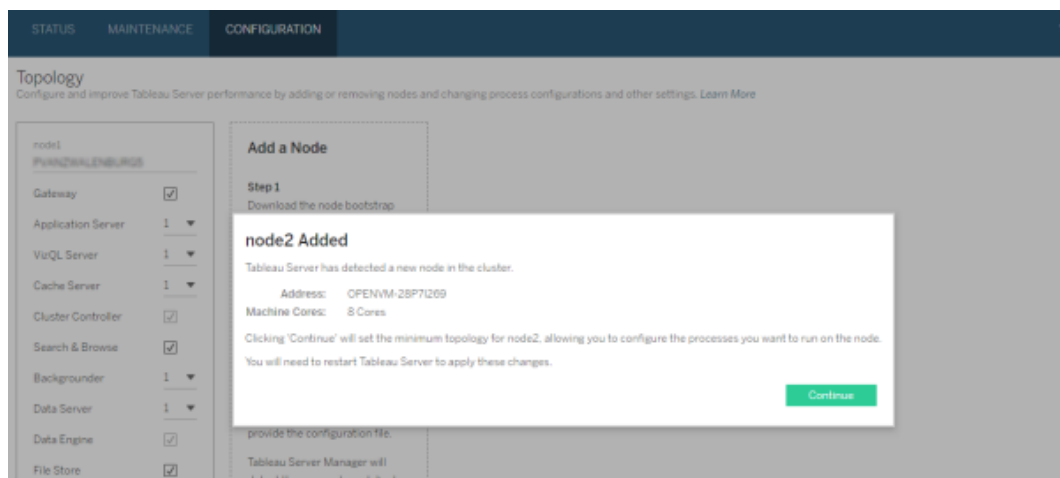

7. A browser window opens and you are prompted to sign in to TSM. Enter the TSM administrator user name and password.

If no browser window opens automatically, open a window and navigate to TSM:

`https://<tsm-computer-name>:8850`

8. In TSM, click **Configuration**.

A message displays, telling you the node was added:

9. Click **Continue**.

Step 4: Install and initialize a second additional node

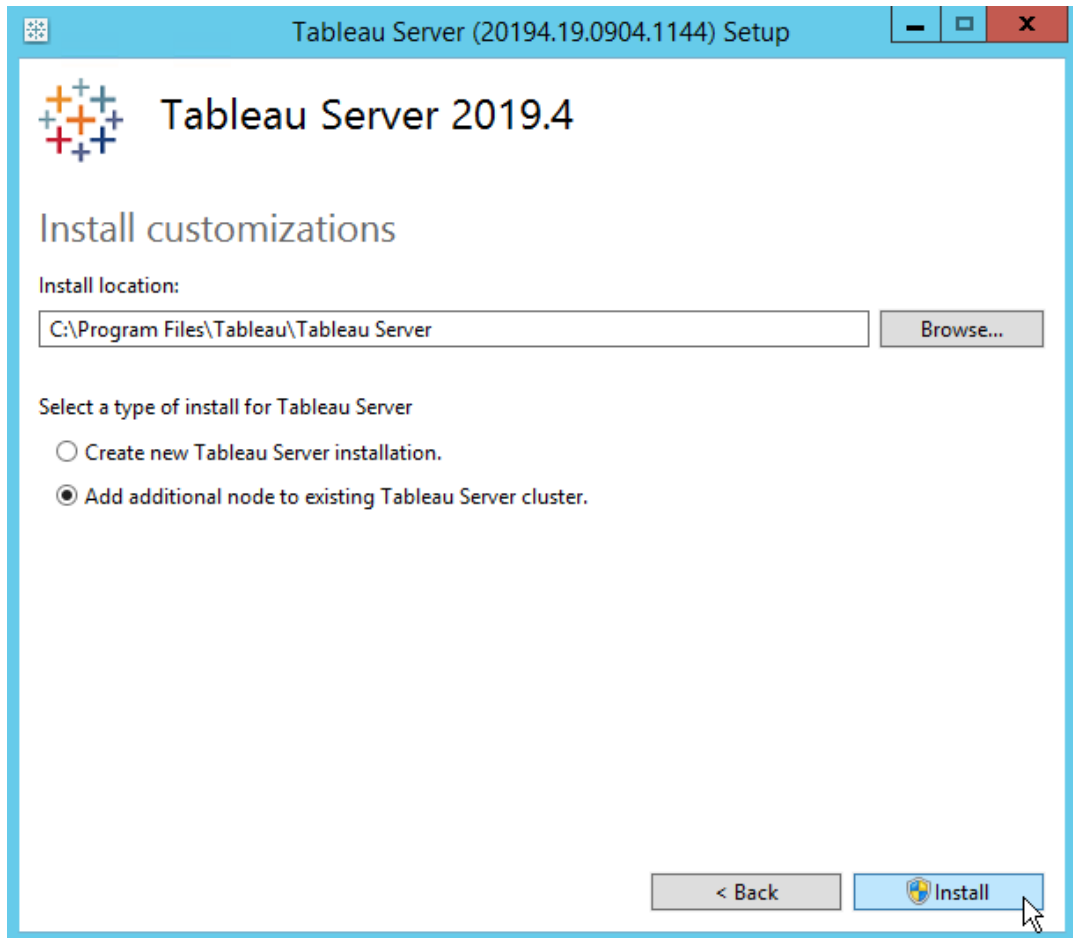

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same

Tableau Server on Windows Help

installer program you ran on the initial node to install Tableau Server. Accept the terms of the license agreement and click **Next**.

The **Install location** must be the same on every node in the cluster.

During installation you will be asked to select an installation type. Select **Add additional node to existing Tableau Server cluster**:

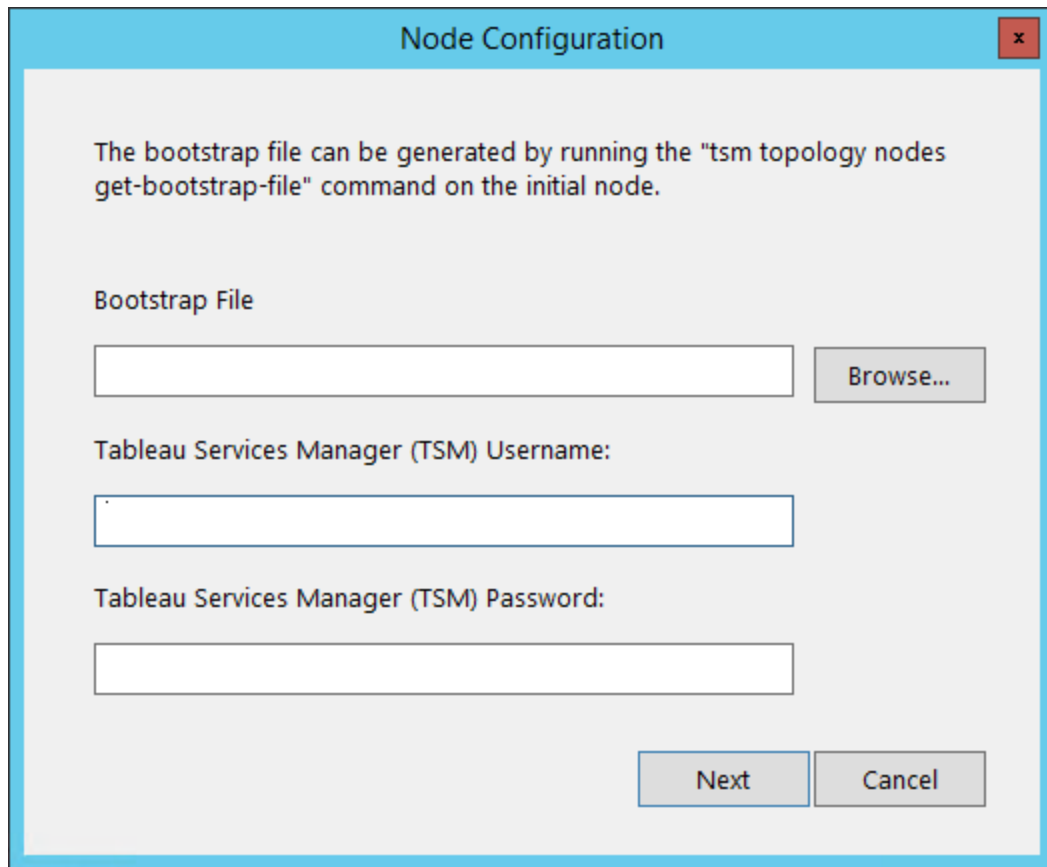

4. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

5. In the installer, after the Tableau Server files are copied, you will be prompted to

provide the bootstrap file and the name and password of the TSM administrator:

The dialog box is titled "Node Configuration" and has a close button (X) in the top right corner. The main content area contains the following text and fields:

The bootstrap file can be generated by running the "tsm topology nodes get-bootstrap-file" command on the initial node.

Bootstrap File

Tableau Services Manager (TSM) Username:

Tableau Services Manager (TSM) Password:

Click **Next** to continue.

6. Enter the location of the bootstrap file, or click **Browse** to navigate to the location. If the bootstrap file does not include embedded credentials, or those credentials have expired, enter the TSM administrator username and password. These credentials must be the credentials of the user that you used during the installation process on the initial node.
7. A browser window opens and you are prompted to sign in to TSM. Enter the TSM administrator user name and password.

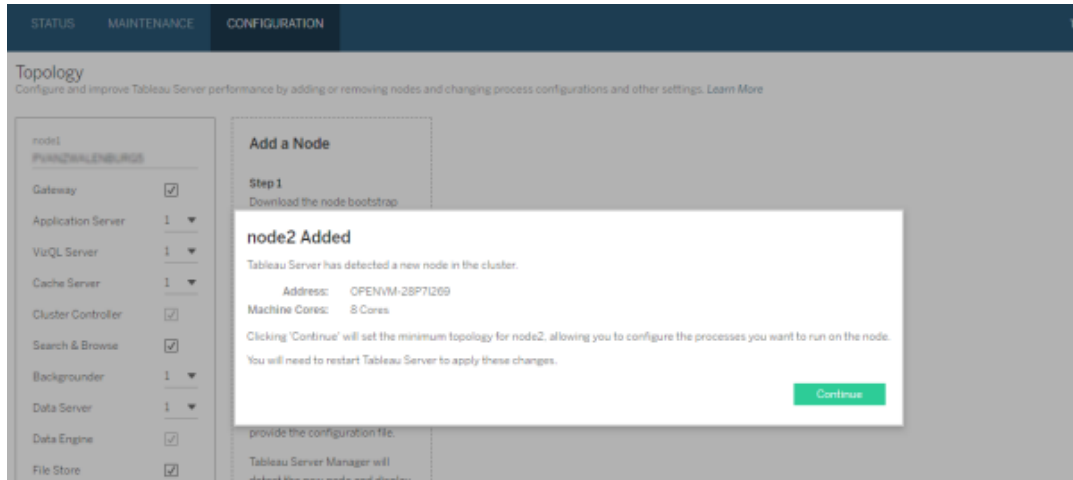

If no browser window opens automatically, open a window and navigate to TSM:

Tableau Server on Windows Help

<https://<tsm-computer-name>:8850>

8. In TSM, click **Configuration**.

A message displays, telling you the node was added:

9. Click **Continue**.

Step 5: Configure the new node with a minimum topology

To complete the process of adding new nodes to your cluster, you need to configure them with a minimum topology. With a minimum topology, the only pending change will be the addition of Cluster Controller, which is required on each node. If you want other processes on the nodes you can add most of them at the same time. This example only configures the nodes with Cluster Controller.

1. Open TSM in a browser:

<https://<tsm-computer-name>:8850>

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab. A message should tell you that new nodes were added.

Click **Continue** to dismiss the message.

3. Click **Pending Changes** at the top of the page:

If you are configuring a cluster with three or more nodes, a Coordination Service ensemble warning displays. You can continue. You will deploy a Coordination Service ensemble in a separate step.

4. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

When Tableau Server restarts, the nodes are included with the minimum topology necessary.

Step 6: Deploy a Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

Tableau Server on Windows Help

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

Do not attempt to deploy a Coordination Service ensemble if there are other changes pending. Discard or apply any pending changes before deploying a new Coordination Service ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a command prompt as administrator.
2. Stop Tableau Server:

```
tsm stop
```

If prompted, sign in as a TSM administrator.

Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

3. Confirm there are no pending changes:

```
tsm pending-changes list
```

If there are pending changes, you need to either discard the changes or apply them.

Applying pending changes will take some time:

- Discard the changes

```
tsm pending-changes discard
```

or

- Apply the changes:

```
tsm pending-changes apply
```

Wait until the command completes and you are returned to the system prompt.

4. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble, unless the deployment fails. If this happens, see step 6 below.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```
tsm topology deploy-coordination-service -n  
node1,node2,node3
```

Wait until the command completes and you are returned to the system prompt.

6. (Optional) If the deployment fails, you need to run the `tsm topology cleanup-`

Tableau Server on Windows Help

`coordination-service` command to remove the unsuccessfully deployed ensemble. For details on running the command, see `tsm topology cleanup-coordination-service`.

7. Start Tableau Server:

```
tsm start
```

For more information and details on deploying a new Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

Step 7: Configure Client File Services (CFS) on additional nodes

Add CFS to additional nodes. We recommend you add CFS to every node running the Coordination Service.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are adding CFS to:

```
tsm topology list-nodes -v
```

3. Add CFS on the node by specifying the node, the process, and a single instance.

For example, this command adds an instance of CFS to node2:

```
tsm topology set-process -n node2 -pr clientfileservice -c  
1
```

If you attempt to add an instance of CFS to a node that already is configured with CFS, an error message will let you know there is already an instance on the node.

To add CFS to additional nodes, repeat this step for each node.

4. Apply the changes:

```
tsm pending-changes apply
```

Step 7: Configure processes for the second node

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see Sign in to Tableau Services Manager Web UI.

2. Click the **Configuration** tab.
3. Specify the processes and number of instances that should run on the first additional node.

In this example:

- a. Select **Gateway**.
- b. Set the **Application Server** (vizportal) count to 2.
- c. Set the **VizQL Server** count to 2.
- d. Set the **Cache Server** count to 2.
- e. Select **Search & Browse**.
- f. Set the **Backgrounder** count to 2.

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

Tableau Server on Windows Help

- g. Set the **Data Server** count to 2.
- h. Select **File Store**.
- i. Select **Repository** (pgsql).

The specific processes and process counts you set will depend on your organizational environment and needs. Some processes are added automatically when you add another process. For more information, see [Configure Nodes and Tableau Server Processes](#).

Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see [tsm topology set-process](#).

Step 8: Configure processes for third node

1. In TSM, on the **Configuration** tab, specify the processes and number of instances that should run on the second additional node.

In this example:

- a. Select **Gateway**.
- b. Set the **Application Server** (vizportal) count to 2.
- c. Set the **VizQL Server** count to 2.
- d. Set the **Cache Server** count to 2.
- e. Select **Search & Browse**.
- f. Set the **Backgrounder** count to 2.

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

- g. Set the **Data Server** count to 2.
 - h. Select **File Store**.
2. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

3. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

Note: This method of installation from the command line requires you to set Windows environment variables on each additional node for the username and password of an administrator on the initial node. For an alternate method of automating Tableau Server installation without including unencrypted credentials, see Automated Installation of Tableau Server.

Step 1: Install the initial node

See [Install and Configure Tableau Server](#).

Step 2: Generate a bootstrap file for the additional nodes

To install Tableau Server on additional computers you use the same installer you did for the initial node, along with a "bootstrap" file you generate on the initial node.

Important: The bootstrap file contains a copy of the master keystore file used for encrypting the configuration secrets. The file can also embedded credentials which are valid for a

Tableau Server on Windows Help

predetermined amount of time (see `tabadmincontroller.auth.expiration.minutes`) and serve as a session cookie. We strongly recommend that you take additional measures to secure the bootstrap file.

1. After installing Tableau Server on the initial node, generate the node bootstrap file.
2. On the initial node, open a command prompt as administrator.
3. Type this command to generate the bootstrap file:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json
```

Beginning with version 2019.3, embedded credentials are included in the bootstrap file by default. If you don't want the bootstrap file to include credentials, use the `-noc` or `--no-embedded-credentials` option:

```
tsm topology nodes get-bootstrap-file --file <path\file>.json --no-embedded-credentials.
```

See [What's New and Changed in Tableau Server](#) in [What's New](#) for more information. If you want to completely disable the ability to include embedded credentials in node bootstrap files, you can set a configuration option for the server. See [features.PasswordlessBootstrapInit](#) for more details.

Step 3: Install an additional node

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same

installer program you ran on the initial node to install Tableau Server.

```
TableauServer-64bit-<version>.exe /silent /accepteula
/embeddedcredential /bootstrapfile="path\bootstrapfile"
```

For more information about switches you can use with the Setup program, see [Install Switches and Properties for Tableau Server](#).

Step 4: Install a second additional node

Install Tableau Server on the second additional node:

1. Copy the original installer you used on the first computer along with the bootstrap file you generated and put them in a location accessible from the new computer you are adding Tableau Server to. This could be a mounted network share, or directly on the new computer.
2. If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).
3. On the new node, run the Tableau Server Setup program. This should be the same installer program you ran on the initial node to install Tableau Server.

```
TableauServer-64bit-<version>.exe /silent /accepteula
/embeddedcredential /bootstrapfile="path\bootstrapfile"
```

For more information about switches you can use with the Setup program, see [Install Switches and Properties for Tableau Server](#).

Step 5: Add a process to the additional nodes

1. On the initial node, configure a cluster controller instance on each additional node:

```
tsm topology set-process -n <nodeID_second-node> -pr
clustercontroller -c 1
```

```
tsm topology set-process -n <nodeID_third-node> -pr
clustercontroller -c 1
```

2. Apply the node configuration changes:

```
tsm pending-changes apply --ignore-warnings
```

A warning about deploying a Coordination Service ensemble displays because you have deployed a three-node cluster. Use the `--ignore-warnings` option to apply the configuration changes in spite of the warning. You will deploy a new Coordination Service ensemble in the next step.

Step 6: Deploy a Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

Do not attempt to deploy a Coordination Service ensemble if there are other changes pending. Discard or apply any pending changes before deploying a new Coordination Service ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a command prompt as administrator.
2. Stop Tableau Server:

```
tsm stop
```

If prompted, sign in as a TSM administrator.

Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

3. Confirm there are no pending changes:

```
tsm pending-changes list
```

If there are pending changes, you need to either discard the changes or apply them.

Applying pending changes will take some time:

- Discard the changes

```
tsm pending-changes discard
```

or

- Apply the changes:

```
tsm pending-changes apply
```

Wait until the command completes and you are returned to the system prompt.

4. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to

Tableau Server on Windows Help

specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble, unless the deployment fails. If this happens, see step 6 below.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are node1, node2, and node3:

```
tsm topology deploy-coordination-service -n  
node1,node2,node3
```

Wait until the command completes and you are returned to the system prompt.

6. (Optional) If the deployment fails, you need to run the `tsm topology cleanup-coordination-service` command to remove the unsuccessfully deployed ensemble. For details on running the command, see `tsm topology cleanup-coordination-service`.

7. Start Tableau Server:

```
tsm start
```

For more information and details on deploying a new Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#) .

Step 7: Configure Client File Services (CFS) on additional nodes

Add CFS to additional nodes. We recommend you add CFS to every node running the Coordination Service.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on

one of the nodes in your installation and TSM administrator credentials to run TSM commands.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are adding CFS to:

```
tsm topology list-nodes -v
```

3. Add CFS on the node by specifying the node, the process, and a single instance.

For example, this command adds an instance of CFS to node2:

```
tsm topology set-process -n node2 -pr clientfileservice -c
1
```

If you attempt to add an instance of CFS to a node that already is configured with CFS, an error message will let you know there is already an instance on the node.

To add CFS to additional nodes, repeat this step for each node.

4. Apply the changes:

```
tsm pending-changes apply
```

Step 7: Configure processes for the second node

1. On the initial node, set the topology for the second node. The topology specifies which processes should run on the node, and how many instances of each process should run. For details about configuring nodes, see [Configure Nodes](#). Data engine will be added automatically when you add other processes. For details on when data engine is added, see [Tableau Server Processes](#).
 - a. Get the node-id for the new node: `tsm topology list-nodes -v`
 - b. Specify individual processes that will run on the new node:

Tableau Server on Windows Help

```
tsm topology set-process -n <node-id> -pr gateway -c 1

tsm topology set-process -n <node-id> -pr vizqlserver -
c 2

tsm topology set-process -n <node-id> -pr vizportal -c
2

tsm topology set-process -n <node-id> -pr backgrounder
-c 2

tsm topology set-process -n <node-id> -pr cacheserver -
c 2

tsm topology set-process -n <node-id> -pr searchserver
-c 1

tsm topology set-process -n <node-id> -pr dataserver -c
2

tsm topology set-process -n <node-id> -pr filestore -c
1

tsm topology set-process -n <node-id> -pr pgsq1 -c 1
```

2. Apply the node configuration changes. You will be prompted with a message that Tableau Server will restart.

```
tsm pending-changes apply
```

Step 8: Configure processes for third node

On the initial node, set the topology for the new node. The topology specifies which processes should run on the node, and how many instances of each process should run. Data engine will be added automatically when you add other processes. For details on when data engine is added, see [Tableau Server Processes](#).

1. Get the node-id for the new node:

```
tsm topology list-nodes -v
```

2. Specify individual processes that will run on the new node:

```
tsm topology set-process -n <node-id> -pr gateway -c 1
```

```
tsm topology set-process -n <node-id> -pr vizqlserver -c 2
```

```
tsm topology set-process -n <node-id> -pr vizportal -c 2
```

```
tsm topology set-process -n <node-id> -pr backgrounder -c  
2
```

```
tsm topology set-process -n <node-id> -pr cacheserver -c 2
```

```
tsm topology set-process -n <node-id> -pr searchserver -c  
1
```

```
tsm topology set-process -n <node-id> -pr dataserver -c 2
```

```
tsm topology set-process -n <node-id> -pr filestore -c 1
```

3. Apply the node configuration. You will be prompted with a message that Tableau Server will restart.

```
tsm pending-changes apply
```

4. Start the server:

```
tsm start
```

Step 9: Configure firewall rules (optional)

If you are running a local firewall, then you need to configure firewall rules for all the nodes in the cluster. For more information, see [Local firewall configuration](#).

Add a Load Balancer

At this point, all three nodes have gateways, which are used to route requests to available server processes. All gateways are active, but to further reduce the potential for downtime in the cluster, you can configure a load balancer. For more information, see [Add a Load Balancer](#).

Add a Load Balancer

You can enhance the reliability of Tableau Server by running gateways on multiple nodes, and configuring a load balancer to distribute requests across the gateways. Unlike the repository process, which can be active or passive, all gateway processes are active. If one gateway in a cluster becomes unavailable, the load balancer stops sending requests to it. The load balancer algorithm you choose determines how the gateways will route client requests.

Notes: If you will be using Kerberos authentication, you need to configure Tableau Server for your load balancer before you configure Tableau Server for Kerberos. For more information, see [Configure Kerberos](#).

Windows SSPI authentication is not supported with a load balancer.

Note the following as you configure your load balancer to work with Tableau Server:

- **Tested load balancers:** Tableau Server clusters with multiple gateways have been tested with Apache and F5 load balancers.

If you are using an Apache load balancer and creating custom administrative views, you need to connect directly to the Tableau Server repository. You cannot connect through the load balancer.

- **Tableau Server URL:** When a load balancer is in front of a Tableau Server cluster, the URL that's accessed by Tableau Server users belongs to the load balancer, not

the initial Tableau Server node.

- **Single load balancer endpoint:** You must configure your load balancers for a single URL endpoint. You cannot configure different endpoint hosts to redirect to the same Tableau Server deployment. The single external URL is defined in `gateway.public.host` when you configure Tableau Server, as described in the procedure below.
- **Trusted host settings:** The computer running the load balancer must be identified to Tableau Server as a trusted host. See the procedure below for how to configure Tableau Server.
- **Proxy server configurations:** The settings used to identify a load balancer to Tableau Server are the same ones that are used to identify a proxy server. If your Tableau Server cluster requires both a proxy server and a load balancer, both must use a single external URL defined in `gateway.public.host` and all proxy servers and load balancers must be specified in `gateway.trusted` and `gateway.trusted_hosts`. For more information, see [Configuring Proxies for Tableau Server](#).

Configure Tableau Server to work with a load balancer

Use the following key-value pairs to configure Tableau Server for a load balancer. You can set the values individually with the `tsm configuration set` command.

Or, use the configuration file template example at the end of this topic to create a `configKey.json` file. After you have filled in the options with the appropriate values, pass the `json` file and apply settings with `tsm` commands.

Load balancer configuration key-value pairs

The key-value pairs described in this section can be set with the `tsm configuration set` command. After you have set all values, run the following command:

```
tsm pending-changes apply
```

Tableau Server on Windows Help

gateway.public.host

Value: name

The value, `name` is the URL that will be used to reach Tableau Server through the load balancer.

For example, if Tableau Server is reached by entering `tableau.example.com` in a browser address bar, enter this command:

```
tsm configuration set -k gateway.public.host -v "tableau-  
.example.com"
```

gateway.public.port

Value: port_number

By default, Tableau assumes that the load balancer is listening on port 80 for external communications. Use this key to specify a different port.

For example, if your load balancer is configured for SSL and listening on port 443, enter the following command:

```
tsm configuration set -k gateway.public.port -v "443"
```

gateway.trusted

Value: server

Specify the load balancer(s) IPv4 address or host name. If you are using an internal load balancer, you must use IP addresses, not host names.

The value for `server` can be a comma-separated list, for example:

```
tsm configuration set -k gateway.trusted -v "10.32.139.45,  
10.32.139.46, 10.32.139.47"
```

or

```
tsm configuration set -k gateway.trusted -v "proxy1, proxy2,  
proxy3"
```

gateway.trusted_hosts

Value:

Specify alternate names for the load balancer(s), such as its fully-qualified domain name, any non-fully-qualified domain names, and any aliases. These are the names a user might type in a browser. Separate each name with a comma:

```
tsm configuration set -k gateway.trusted_hosts -v "name1, name2,
name3"
```

For example:

```
tsm configuration set -k gateway.trusted_hosts -v "lb.example.com,
lb, ftp.example.com, www.example.com"
```

In most cases, if there are no alternate names for the load balancer, you may enter the same value for this key as you entered for the `gateway.public.host` key.

Configuration template example

You can configure all of the settings in one operation by customizing the following configuration template example and creating a `configKey.json` file.

Refer to the key-value pair descriptions above to customize the values for your organization.

```
{
  "configKeys": {
    "gateway.public.host": "tableau.example.com",
    "gateway.public.port": "443",
    "gateway.trusted": "proxy1, proxy2, proxy3",
    "gateway.trusted_hosts": "lb.example.com, lb, ftp.example.com,
www.example.com"
  }
}
```

When you are finished, save the json file.

Tableau Server on Windows Help

Pass the json file with tsm to set the configuration, and then apply settings by running the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

For more information about using configKey schemes, see [Configuration File Example](#).

Deploy a Coordination Service Ensemble

The Coordination Service is built on [Apache ZooKeeper](#), an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

Important: The process to deploy a Coordination Service ensemble changed as of version 2020.1.0. If you are running an earlier version of Tableau Server, see the documentation for that version. You can find documentation for all supported versions here: [Tableau Help](#)

- Hardware requirements
- The Coordination Service Quorum
- Deploy a new Coordination Service ensemble

Hardware requirements

The hardware you use for Tableau Server can have an effect on how well the Coordination Service runs. In particular:

- **Memory.** The Coordination Service maintains state information in memory. By design, the memory footprint is small, and is typically not a factor in overall server performance.
- **Disk speed.** Because the service stores state information on disk, it benefits from fast disk speed on the individual node computers.
- **Connection speed** between nodes. The service communicates continuously between cluster nodes; a fast connection speeds between nodes helps with efficient synchronization.

Because the Coordination Service is I/O intensive, if you are running Tableau Server on computers that meet or just exceed the minimum hardware requirements, you may want to configure a Coordination Service ensemble that puts the service on nodes that are not being used for other server processes. This reduces the chance of delays due to I/O contention between server processes. For information on how to deploy an ensemble on dedicated Coordination Service-only nodes, see [Configure Tableau Server for High Availability with Coordination Service-Only Nodes](#).

The Coordination Service Quorum

To ensure that the Coordination Service can work properly, the service requires a *quorum*—a minimum number of instances of the service. This means that the number of nodes in your installation impacts how many instances of the Coordination Service you want to configure in your ensemble.

Number of Coordination Service instances to use

The maximum number of Coordination Service instances you can have in an ensemble on Tableau Server depends on how many Tableau Server nodes you have in your deployment. Configure a Coordination Service ensemble based on these guidelines:

Total number of server nodes	Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5)	Notes
1-2 nodes	1 node	This is the default and requires no changes unless you want to move the Coordination Service off your initial node and onto your additional node.
3-4 nodes	3 nodes	
5 or more nodes	3 nodes or 5 nodes	<p>Five is the maximum number of Coordination Service instances you can install. A 3-node Coordination Service ensemble allows for one of the ensemble nodes to fail without causing Tableau Server to fail. A 5-node ensemble allows for two of the ensemble nodes to fail without causing Tableau Server to fail.</p> <p>For most installations, three Coordination Service nodes are adequate, and because of the I/O-intensive nature of the Coordination Service, this is the most performant configuration.</p> <p>If high availability is your absolute priority, you may want to consider deploying a 5-node Coordination Service ensemble. This provides the most redundancy in the event that one or more nodes fail but will require more system resources. A maximum of two of the ensemble nodes can fail without impacting Tableau Server (as long as any other services on the node also exist on still-functioning nodes).</p> <p>To reduce performance impact, locate the Coordination Service on nodes that are running fewer other</p>

Total number of server nodes	Recommended number of Coordination Service nodes in ensemble (must be 1, 3, or 5)	Notes
		services or consider using Coordination Service-only nodes. For details, see Configure Tableau Server for High Availability with Coordination Service-Only Nodes .

Deploy a new Coordination Service ensemble

If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

Do not attempt to deploy a Coordination Service ensemble if there are other changes pending. Discard or apply any pending changes before deploying a new Coordination Service ensemble.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

The following steps illustrate how to deploy a new Coordination Service ensemble on an existing three-node Tableau Server cluster and clean up the old ensemble.

1. On the initial node, open a command prompt as administrator.
2. Stop Tableau Server:

```
tsm stop
```

If prompted, sign in as a TSM administrator.

Some TSM processes will continue to run, including the Administration Controller and Administration Agent.

3. Confirm there are no pending changes:

```
tsm pending-changes list
```

If there are pending changes, you need to either discard the changes or apply them. Applying pending changes will take some time:

- Discard the changes

```
tsm pending-changes discard
```

or

- Apply the changes:

```
tsm pending-changes apply
```

Wait until the command completes and you are returned to the system prompt.

4. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

5. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble, unless the deployment fails. If this happens, see step 6 below.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to all three nodes of a three-node cluster, where the nodes are `node1`, `node2`, and `node3`:

```
tsm topology deploy-coordination-service -n  
node1,node2,node3
```

Wait until the command completes and you are returned to the system prompt.

6. (Optional) If the deployment fails, you need to run the `tsm topology cleanup-coordination-service` command to remove the unsuccessfully deployed ensemble. For details on running the command, see `tsm topology cleanup-coordination-service`.
7. Start Tableau Server:

```
tsm start
```

Configure Client File Service

The Client File Service (CFS) manages most shared files in a multinode cluster. For example, authentication related certificates, keys, and files (OpenID, mutual SSL, SAML, and Kerberos), and customization files are managed by CFS.

Tableau Server on Windows Help

A single instance of CFS is configured on the initial node when you first install Tableau Services Manager (TSM) and Tableau Server. You can and should configure additional instances on other nodes.

In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes. For a list of files managed by CFS, see [Tableau Server Client File Service](#).

Keep in mind these limitations and recommendations:

- There must be at least one instance of CFS for any Tableau Server installation. You cannot remove all instances of CFS.
- We recommend you do not configure more than one instance on any one node. Additional instances would not provide any benefit and would be a waste of resources.
- We recommend you configure a CFS instance on each node where you deploy the Coordination Service. This provides redundancy and helps safeguard Tableau Server from unexpected errors in case a node fails.

This article explains how to add or remove an instance of CFS. You cannot configure CFS from the Web UI. You must use the CLI to add or remove CFS. The procedure is the same one you use for adding a process to a node.

Configure CFS on additional nodes

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are adding CFS to:

```
tsm topology list-nodes -v
```

3. Add CFS on the node by specifying the node, the process, and a single instance.

For example, this command adds an instance of CFS to node2:

```
tsm topology set-process -n node2 -pr clientfileservice -c  
1
```

If you attempt to add an instance of CFS to a node that already is configured with CFS, an error message will let you know there is already an instance on the node.

To add CFS to additional nodes, repeat this step for each node.

4. Apply the changes:

```
tsm pending-changes apply
```

Repository Failover

In a Tableau Server installation, the repository (pgsql) database is one of the key required processes. The Tableau Server repository stores information about Tableau Server users, groups and group assignments, permissions, projects, data sources, and extract metadata and refresh information. Because it is critical to the server functioning, Tableau Server has a built-in automatic "failover" for the repository when server is installed in a distributed environment that meets certain requirements.

Automatic repository failover

Automatic repository failover means that if there is a problem with the active Tableau Server repository, the server will automatically switch to using the passive repository. This does not happen immediately, to protect against momentary issues with the repository that don't justify a switch, but if the repository is unavailable for more than five minutes, failover occurs.

For automatic repository failover to work, your Tableau Server installation needs:

- A minimum of three nodes
- Two instances of the repository installed

Optional but highly recommended:

- A multi-node Coordination Service ensemble deployed

Tableau Server on Windows Help

With these conditions satisfied, repository failover will occur if the active repository becomes unavailable, either due to a problem with the process, or a problem with the node the process is running on. If the original repository becomes available again (if, for example, the node is restarted and all processes come up properly), it is made the passive repository, available for failover if necessary.

Manual repository failover

There may be reasons you want to shift back to the original repository after failover occurs. One reason would be if that instance of the repository is installed on a computer with more resources. To do this, use the `tsm topology failover-repository` command to manually switch back to the original repository. For more information, see `tsm topology failover-repository`.

Preferred active repository

When you configure Tableau Server you have the option to specify a node as the preferred active repository. When Tableau Server is configured for repository failover, the preferred active repository node is the one used for the active repository. This is an optional step, and if you do not specify a preferred active repository node, Tableau Server will select the active repository node on startup.

To configure the preferred active repository, use the `tsm configuration set` command to configure the `pgsql.preferred_host` option:

```
tsm configuration set -k pgsql.preferred_host -v "<host_name>"
```

Note: The `host_name` is case-sensitive and must match the node name shown in the output of `tsm status -v`.

Configure a preferred active repository node if you want Tableau Server to select a specific node on startup. You might want to do this if you have a particular server you want to use for your active repository (a computer with more disk space or memory for example), or if you

are using custom administrative views. Custom administrative views have embedded connection information that refers to the repository for which you created the views. For more information on connecting to the Tableau Server repository, see [Collect Data with the Tableau Server Repository](#)

Recover from an Initial Node Failure

The first computer you install Tableau on, the "initial node," has some unique characteristics. Three processes run only on the initial node and cannot be moved to any other node except in a failure situation, the License Service (License Manager), Activation Service, and TSM Controller (Administration Controller). Tableau Server includes a script that automates moving these processes to one of your other existing nodes so you can get complete access back to TSM and keep Tableau Server running.

Two other processes are initially included on the initial node but can be added or moved to additional nodes, the CFS (Client File Service) and the Coordination Service. Depending on how your installation was configured with CFS and Coordination Service, you may also need to take steps to redeploy these.

If an initial node fails

If there is a problem with the initial node and you have redundant processes on your other nodes, there is no guarantee that Tableau Server will continue to run. Tableau Server can continue to run for up to 72 hours after an initial node failure, before the lack of the licensing service impacts other processes. If so, your users may be able to continue to sign in and see and use their content after the initial node fails, but you will not be able to reconfigure Tableau Server because you won't have access to the Administration Controller.

Even when configured with redundant processes, *it is possible that Tableau Server may not continue to function after the initial node fails*. This is true even when an installation is configured for high availability. This means you should make a point of moving the two unique processes to another of your running nodes as soon as possible. If your initial node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware

failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Note: The steps in this article require server downtime and can be disruptive, and should only be used in the event of a catastrophic failure of the initial node. If you are unable to get your initial node running again, use the following steps to move key TSM processes to another node in your cluster.

General requirements

The 2021.1 version of Tableau Server has been updated with improved recovery functionality. The procedure in this topic has been written for Tableau Server 2021.1.

If you are attempting to recover a failed node from an earlier version of Tableau Server, you must follow the procedure for that version. To view archived versions of Tableau online help, see [Tableau Help](#).

- As part of the process for setting up a multi-node Tableau Server installation you should have deployed a Coordination Service ensemble. The process below assumes there was a Coordination Ensemble deployed before there was a problem with the initial node. For more information about deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).
- This process assumes that you have configured instances of Client File Service (CFS) on every node that is running the Coordination Service. If you did not add additional instances of CFS, your only instance was on the initial node, and you will need to add at least one instance of CFS to another node. You will also need to repopulate CFS. Tableau Server requires at least one instance of the CFS. For more information, see [Configure Client File Service](#) and [Tableau Server Client File Service](#).

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Move the TSM Controller, License Service, and Activation Service to another node

If there is a problem with the initial node, the TSM Controller, the Licensing Service, and Activation Service need to be started on another node. Follow these steps to use the provided `move-tsm-controller` script and get the TSM Controller, Licensing Service, and Activation Service working on another node.

1. On a node that is still working, run the Controller recovery script. To do this, open a command prompt, navigate to the Tableau Server script directory (By default: `C:\Program Files\Tableau\Tableau Server-\packages\scripts.<version_code>\`), and type the following command:

```
move-tsm-controller -n <nodeID>
```

where "nodeID" is the ID for the node you want the TSM Controller to run on. For example:

```
move-tsm-controller -n node2
```

2. Close and reopen the command window and verify the Administration Controller is running on the node by typing this command:

```
tsm status -v
```

3. Stop Tableau Server.

The remainder of this procedure includes some commands with the `--ignore-node-status` option. When a command is run with the `--ignore-node-status` option, the command will run without consideration of the status of the specified node. To use `--ignore-node-status`, specify the failed node:

```
tsm stop --ignore-node-status <nodeID>
```

For example, if node1 has failed, run the command as follows:

Tableau Server on Windows Help

```
tsm stop --ignore-node-status node1
```

4. Add the License Service to the node:

```
tsm topology set-process -pr licenseservice -n <nodeID> -c  
1
```

5. Remove the old License Service from the original node, where "nodeID" is the initial node that has failed:

```
tsm topology set-process -pr licenseservice -n <nodeID> -c  
0
```

6. If you're using Server ATR, add the Activation Service to the node:

```
tsm topology set-process -pr activationservice -n  
<nodeID> -c 1
```

7. If you're using Server ATR, remove the old Activation Service from the original node, where "nodeID" is the initial node that has failed:

```
tsm topology set-process -pr activationservice -n  
<nodeID> -c 0
```

Important: In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes. For a list of files managed by CFS, see [Tableau Server Client File Service](#).

8. If the initial node had been running the Messaging Service, add the Messaging Service to this node:

```
tsm topology set-process -pr activemqserver -n node2 -c 1
```

- (Optional) You can also add other processes that had been running on the initial node but are not running on this node. For example, to add an cache server:

```
tsm topology set-process -pr cacheserver -n node2 -c 1
```

- Apply the changes:

```
tsm pending-changes apply --ignore-node-status <nodeID>
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

- Restart the TSM Administration Controller:

```
net stop tabadmincontroller_0
```

```
net start tabadmincontroller_0
```

Note: You must run these commands as an administrator from a command prompt. Depending on how your computer is configured, you may need to run them in the `C:\Windows\System32` folder.

Note: It may take a few minutes for `tabadmincontroller` to restart. If you attempt to apply pending changes in the next step before the controller has fully restarted, TSM will not be able to connect to the controller. You can verify that the controller is running by using the `tsm status -v` command. Tableau Server Administration Controller should be listed as "is running".

- Apply pending changes (there may not appear to be any, but this step is required):

Tableau Server on Windows Help

```
tsm pending-changes apply --ignore-node-status <nodeID>
```

13. Activate the Tableau Server license on the new Controller node:

```
tsm licenses activate -k <product-key>
```

14. Verify the license is properly activated:

```
tsm licenses list
```

15. If the initial node was running the Coordination Service, you need to deploy a new Coordination Service ensemble that does not include that node. If you have a three node cluster and the initial node was running the Coordination Service, you must deploy a new, single-instance Coordination Service ensemble on a different node and clean up the old ensemble. In this example, a single instance of the Coordination Service is being deployed to the second node:

```
tsm topology deploy-coordination-service -n node2 --ignore-node-status node1
```

16. If the initial node was running a File Store instance, you need to remove that instance:

```
tsm topology filestore decommission -n <nodeID> --delete-filestore
```

Where `nodeID` is the initial node that has failed.

17. Apply pending changes, using the `--ignore-warnings` flag if the new Coordination Service ensemble you deployed above is a single node ensemble:

```
tsm pending-changes apply --ignore-node-status node1 --ignore-warnings
```

18. Remove the initial node, where `nodeID` is the initial node that has failed:

```
tsm topology remove-nodes -n <nodeID>
```

19. Apply pending changes, using the `--ignore-warnings` flag if the new

Coordination Service ensemble you deployed above is a single node ensemble:

```
tsm pending-changes apply --ignore-warnings
```

20. Start Tableau Server:

```
tsm start
```

At this point your server should start, and you will be able to use TSM to configure it. The next step is to replace your initial node so your cluster has the original number of nodes. How you do this depends on whether or not you want to reuse the node that failed. We recommend that you only reuse that node if you are able to identify the reason it failed, and take steps to keep the failure from recurring.

21. If you plan to reuse the original node, you first need to completely remove Tableau from it. Do this by running the `tableau-server-obliterate` script. For details on doing this, see [Remove Tableau Server from Your Computer](#).

22. On a fresh computer, or on your original computer after completely removing Tableau, install Tableau using your original Setup program and a bootstrap file generated from the node that is now running the Administration Controller and Licensing Service. This creates an additional node you can configure as part of your cluster. For details on how to add the node, see [Install and Configure Additional Nodes](#).

A best practice is to configure any processes you lost when the original node failed, to make sure your cluster is fully redundant. You may want to move processes from your new initial node to the newly added additional node to duplicate your original configuration. For example, if your initial node was only running gateway and File Store, you may want to configure the new initial node the same way.

23. You should also redeploy a new Coordination Service ensemble, once you have your nodes up and running the way you want. For details, see [Deploy a Coordination Service Ensemble](#).

24. Finally, if you have not already done this, add an instance of CFS to every node that is

running the Coordination Service. For more information, see [Configure Client File Service](#)

In a cluster, if a node that is running your only instance of CFS fails, any files being managed by CFS will be lost, and you will need to repopulate CFS those files by reimporting certs and custom images, and making any related configuration changes. For a list of files managed by CFS, see [Tableau Server Client File Service](#).

Recover from a Node Failure

If there is a problem with one of your server nodes, and you have redundant processes on your other nodes, Tableau Server can continue to run. Your users can continue to sign in and see and use their content after the node fails, but they may experience performance degradation as a result of the failed node. In addition, your server will be at greater risk of catastrophic failure if the bad node was running processes that are no longer redundant. This means you should make a point of removing the bad node and replacing it as soon as you can. If your node fails for reasons that are recoverable in a relatively short amount of time (for example, a hardware failure you can correct), you should first attempt to bring the node back up without using the procedure below.

Note: If the failed node is your *initial* node, there are larger implications for your Tableau Server installations. For details on how to recover from the failure of an initial node, see [Recover from an Initial Node Failure](#).

General requirements

The 2020.1 version of Tableau Server has been updated with improved recovery functionality. The procedure in this topic has been written for Tableau Server 2020.1.

If you are attempting to recover a failed node from an earlier version of Tableau Server, you must follow the procedure for that version. To view archived versions of Tableau online help, see [Tableau Help](#).

- There is at least one functioning node with an instance of the File Store on it.
- There is at least one functioning node with a Repository on it.
- There is at least one functioning node with the Client File Service (CFS) on it.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Removing a Failed Node

To remove a failed node from a Tableau Server cluster:

1. Identify the failed node:

```
tsm status -v
```

The failed node will have a status of "ERROR" and processes will show as unavailable. The node ID is listed as "node<n>" with the machine name following it. For example, node3:

```
node3: WIN-00915SFASVH
```

```
                Status: ERROR
'Tableau Server Gateway 0' status
```

2. Stop Tableau Server.

The remainder of this procedure includes some commands with the `--ignore-node-status` option. When a command is run with the `--ignore-node-`

Tableau Server on Windows Help

`status` option, the command will run without consideration of the status of the specified node. To use `--ignore-node-status`, specify the failed node:

```
tsm stop --ignore-node-status <nodeID>
```

For example, if node3 has failed, run the command as follows:

```
tsm stop --ignore-node-status node3
```

3. Determine any key processes that were running on the node:

- If the failed node was running the Messaging Service, you need to remove the service from the failed node and add it to a new node.

Remove it from the failed node:

```
tsm topology set-process -pr activemqserver -n <nodeID>  
-c 0
```

Add it to a new node:

```
tsm topology set-process -pr activemqserver -n <nodeID>  
-c 1
```

- If the failed node was running the Coordination Service, you need to deploy a new ensemble before you can remove the node:

```
tsm topology deploy-coordination-service -n <good_nodeID> --ignore-node-status <failed_nodeID>
```
- If the failed node was running the only instance of Client File Service (CFS), you need to configure a new instance of CFS on a working node. We recommend that you configure CFS on every node that is running the Coordination Service. For detail steps, see [Configure Client File Service](#).
- If the failed node was running File Store, you need to force-decommission File

Store and remove it before you can remove the node.

```
tsm topology filestore decommission -n <nodeID> --
delete-filestore
```

Apply pending changes (use `--ignore-warnings` option if you had a three node cluster and a single Coordination Service instance):

```
tsm pending-changes apply --ignore-warnings --ignore-
node-status <nodeID>
```

4. If the cluster was a three-node cluster and there are repositories on the remaining working nodes, you need to either remove one repository, or add a new node. This is because you are limited to a single instance of the repository when you have fewer than three nodes.

To remove one repository:

```
tsm topology set-process -n <nodeID> -pr pgsql -c 0
```

5. Run the command to remove the failed node. This adds the change to the pending changes list:

```
tsm topology remove-nodes -n <nodeID>
```

6. Verify the node removal is pending:

```
tsm pending-changes list
```

7. Apply pending changes to remove the node:

```
tsm pending-changes apply
```

8. Start Tableau Server:

```
tsm start
```

9. Install Tableau Server on a new node and configure the node with the processes that the old, failed node had been running.

Tableau Server on Windows Help

10. On a fresh computer, or on your original computer after completely removing Tableau, install Tableau using your original Setup program and a bootstrap file generated from the initial node. For details on how to do this, see [Install and Configure Additional Nodes](#).

A best practice is to configure any processes you lost when the original node failed, to make sure your cluster is fully redundant.

11. You should also redeploy a new Coordination Service ensemble, once you have your nodes up and running the way you want. For details, see [Deploy a Coordination Service Ensemble](#).
12. Finally, if you have not already done this, add an instance of CFS to every node that is running the Coordination Service. For more information, see [Configure Client File Service](#).

Configure Nodes

Use the Tableau Services Manager (TSM) Web UI or CLI commands to configure the topology of a node. The initial node is configured with a default that includes all the processes used by TSM and Tableau Server. When you add additional nodes you need to specify which processes will run on those nodes, and how many instances of those processes will run. You may also want to change the topology of the initial node, either adding instances of existing processes, or moving some of those processes to your additional nodes (this is common when setting up a distributed installation of Tableau Server).

Note: You cannot remove the File Store or Repository (pgsql) if this is the only instance of that process in your cluster. You must have at least one instance of each of the processes in your Tableau Server installation, and you must add the second instance and allow it to synchronize with the first before you remove the process on the original node.

For more information see [Move the Repository Process](#) and [Move the File Store Process](#).

Note: If you have Tableau Resource Monitoring Tool Agent installed on this node, you will need to update the Resource Monitoring Tool Master Server to reflect the changes you make to a Tableau Server node. Changes include adding or removing processes, or changing the number of processes on a node. For more information, see [Tableau Server Topology Changes](#).

Use the TSM web interface

In most cases, you can make multiple changes to your server configuration. Exceptions are if you are moving or removing a File Store instance or the Repository.

To configure your Tableau Server nodes using the TSM web interface, do the following:

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab.

Your next steps depend on the configuration changes you want to make.

- **Add processes**—Add processes to a node by specifying the number of instances you want on the node, or selecting the box for the process.

For example, to add four instances of the Backgrounder and a Gateway to a node:

Tableau Server on Windows Help

- a. Select the **Gateway** box:

- b. Set the **Backgrounder** count to 4:

Adding Backgrounder to a node will also add an instance of Data Engine if one is not already on the node.

Note: The TSM Web UI limits you to a maximum of 8 instances of processes that allow you to select the number of instances. To configure more instances than this, use the command line and the `TSM topology set-process` command. For more information, see `tsm topology set-process`.

- **Change process count**—Change the number of processes on a node by specifying the new number, or selecting the box for the process.
- **Remove a process completely**—Remove all instances of a process from a

node by clearing the box for the process, or setting the count to 0 (zero).

In most cases you move a process from one node to another by setting the process instance count on the first node to 0 (zero), and setting the count to a non-zero value on the second node.

If you are attempting to make a configuration that is not allowed (if, for example, you try to remove a File Store that has not been decommissioned), a message displays to let you know this.

3. Click **Pending Changes** at the top right, and **Apply Changes and Restart** to commit the changes and restart Tableau Server.

Use the TSM CLI

- Adding processes to a node
- Changing the number of processes on a node
- Removing all instances of a process from a node
- Moving all instances of a process from one node to another node

To configure nodes, run commands from the initial node and use the node ID to specify which node you are configuring. To determine the node ID, use the `tsm topology list-nodes` command. Use the `tsm topology set-process` command to add, update or remove a process on a node. You need to specify the node you are configuring, the process you are adding, updating, or removing, and the number of instances of the process. After setting the topology for a node you need to apply the changes to Tableau Server.

Apply changes using the `tsm pending-changes apply` command. After the changes are applied, Tableau Server is returned to the state it was in before the command was run. This means that if it was running, it will be restarted, and if it was stopped it will remain stopped after pending changes have been applied. In most cases, if Tableau Server is

Tableau Server on Windows Help

running when you apply pending changes, the server is stopped so that changes can be applied, and then restarted. The exception is if you are changing the number of instances of Backgrounder, or VizQL Server on an existing node. With changes to those processes on an existing node, Tableau Server does not have to be stopped if it is running.

You need the node ID for a node in order to configure the node. To determine the node ID, use this command:

```
tsm topology list-nodes -v
```

Note: Examples here show some process names. For a complete list, see [Tableau Server Processes](#).

Adding processes to a node

Use the `tsm topology set-process` command to add a process to a node. You need to specify the node you are configuring, the process you are adding, and the number of instances of the process.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Add processes on the node by specifying the process and the number of instances.

For example, this command adds two instances of backgrounder to node1:

```
tsm topology set-process -n node1 -pr backgrounder -c 2
```

4. Apply the changes:

```
tsm pending-changes apply
```

Changing the number of processes on a node

Change the number of processes on a node by specifying an already configured process and providing a new value for the number of instances.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Change the number of processes on the node by specifying an already configured process and providing a new value for the number of instances.

For example, on a node (node1) that is already running backgrounder, this command changes the number of instances to four:

```
tsm topology set-process -n node1 -pr backgrounder -c 4
```

4. Apply the changes:

```
tsm pending-changes apply
```

Removing all instances of a process from a node

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Remove a process from a node by specifying a count of 0 instances for that process on the node.

For example, this command removes the backgrounder process from node1:

```
tsm topology set-process -n node1 -pr backgrounder -c 0
```

Tableau Server on Windows Help

4. Apply the changes:

```
tsm pending-changes apply
```

Moving all instances of a process from one node to another node

In most cases you move a process from one node to another by setting the process instance count on the first node to zero, and setting the count to a non-zero value on the second node.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Move a process from one node to another node by specifying a count of 0 instances for that process on the first node and specifying a count of 1 or greater to the second node.

For example, these commands remove Backgrounder from node0 and add two instances of it to node1:

```
tsm topology set-process -n node0 -pr backgrounder -c 0
```

```
tsm topology set-process -n node1 -pr backgrounder -c 2
```

4. Apply the changes:

```
tsm pending-changes apply
```

Workload Management through Node Roles

Using node roles, you can configure where certain types of workloads are processed on your Tableau Server installation. The node roles features allows you to dedicate and scale resources to specific workloads. You can configure node roles for Backgrounder and File Store.

The Backgrounder node role specifies the type of background tasks that should run on a node, whereas the File Store node role specifies the type extract workload that should run on a node. Both node roles are specified at a node level. Although these node roles can work independently to optimize selected workload, the two node roles in combination can be used to specialize server nodes to preferentially execute selected workloads to optimize performance extract heavy workloads. This combination is discussed in more detail later in the File Store node roles section.

Backgrounder node roles

The Backgrounder process runs Tableau Server tasks, including extract refreshes, subscriptions, flow tasks, 'Run Now' tasks, and tasks initiated from *tabcmd*. Running all these tasks can use a lot of machine resources. If you have more than one Backgrounder node in your cluster, you can manage your Backgrounder workload by specifying the type of tasks a Backgrounder can run on a node using the Backgrounder node role feature.

This configuration option is currently available only through TSM CLI commands and is only useful on multi-node clusters. If you have only one node, the Backgrounder is set to run all tasks by default and that cannot be changed.

Using Backgrounder node roles

The Backgrounder node role feature is intended to give you more control and governance over where certain type of Backgrounder workloads are processed in your Tableau Server installation and allows you to dedicate and scale resources to specific workloads.

For example, if your deployment is heavy on extract and users are running a lot of extract refreshes or encryption jobs, it could be beneficial to dedicate a node to extract refreshes. Similarly, in the case of subscriptions, if your Tableau Server installation processes a lot of subscriptions and you want to ensure that other jobs do not take resources from subscriptions, then you can dedicate a node to subscriptions. In these cases, you would also want to dedicate other backgrounder nodes to workloads other than extract refreshes or subscriptions.

Tableau Server on Windows Help

To support high availability, Tableau recommends having multiple nodes that are dedicated towards a specific workload. For example, if you dedicate a node to extract refreshes, you should also configure a second node to process extract refresh workload. This way if a node dedicated to extract refreshes becomes unavailable, extract refreshes can still be processed by the other node.

Configuration options

Configuration	Jobs
all-jobs (default)	All Tableau Server jobs
flows	Flow run jobs.
no-flows	All jobs except flows.
extract-refreshes	Jobs that are created for: Incremental refreshes, full refreshes, encryption and decryption of all extracts including extracts that flow outputs create.
subscriptions	Subscription jobs
extract-refreshes-and-subscriptions	Extract-refreshes, encryption and decryption of all extracts including extracts that flow outputs generate, and subscription jobs.
no-extract-refreshes	All jobs except extract-refreshes, extract encryption and decryption of all extracts including extracts created from flow outputs.
no-subscriptions	All jobs except subscriptions.
no-extract-refreshes-and-subscriptions	All jobs except extract-refreshes, encryption and decryption of all extracts including extracts created from flow outputs, and subscriptions.

For more information on how to use the tsm commands to set the node role, see tsm topology.

Note: Making configurations to node roles require a restart of the server and will require some downtime. For more information, see [tsm pending-changes](#).

License requirements

Configuring a node to do only a specific type of tasks, like, flows, extract refreshes, and subscriptions, you must have one of the following licenses activated on your Tableau Server:

- To configure a node to run flows, you must have a valid Data Management Add-on license activated on your server, and have Tableau Prep Conductor running on that node. To learn more about Tableau Prep Conductor, see [Tableau Prep Conductor](#).
- To configure a node to run extract refreshes, subscriptions, and any combination related to extract refreshes and subscriptions you must have a valid Advanced Management license activated on your Tableau Server. If the license expires or is deactivated, you will see an error any time you make a change to the Server configuration. For more information on Advanced Management. see [About Tableau Advanced Management](#).

Important!

While flows, extract refreshes, and subscriptions can be expensive and resource heavy, they are not the only jobs that may require dedicated resources. In the **all jobs** group, there are a variety of System jobs that the Backgrounder executes, such as thumbnail generation for workbooks. Make sure that the nodes that run jobs other than extract refreshes, subscriptions, or flows have enough machine resources.

For more information on configuring node roles using TSM commands, see [tsm topology set-node-role](#).

Considerations

There are some rules you must consider when configuring Backgrounder node roles, which are listed below:

Tableau Server on Windows Help

- Only one node role configuration can be set for a node at a time. You cannot configure multiple node roles on a node.
- To configure a node role, there must be at least one Backgrounder process on that node.
- If you have only one Backgrounder node, you must configure this node to run all jobs. This is the default configuration and does not require additional licensing.
- If you have more than one Backgrounder node, combined, they must be configured to handle all jobs. This can be achieved in the following ways:
 - Configure one of the nodes to run all jobs using the all jobs option. This is the easiest and most straightforward way.
 - Using one of the exception configurations on one of the nodes:
 - no-flows
 - no-subscriptions
 - no-extract-refreshes
 - no-extract-refreshes-and-subscriptions

For example, in a cluster where there are three backgrounders, you could have one node configured to run flows, one to run subscriptions and extract refreshes, and one to run all jobs except flows, subscription and extract refreshes.

Note: The ability to specify node roles to run flows, or run all jobs except flows, or run all jobs was introduced in 2019.1.

File Store node roles

The Tableau Server File Store controls the storage of extracts. There are three broad categories of workloads that are extract dependent.

Extract Workload	Execution Service
Refresh	Backgrounder
Query	Data Engine
Backup/Restore	Backup/Restore

File Store node role management in combination with Backgrounder node role management gives server admins the ability to specialize server nodes to preferentially execute selected workloads to optimize performance of all categories of extract heavy workloads.

It is possible to specialize a node to execute extract query workloads through a topology that has only stand-alone Data Engine nodes. For more information, see [Optimize for Extract Query Heavy Environments](#). However, this is at the expense of extract refresh workloads, which are executed by Backgrounder nodes. With the topology-based isolation approach, extract refresh heavy Backgrounder workloads can get slower as none of the Backgrounder nodes have a File Store and thus all extract refresh traffic goes over the network.

With the File Store Node Role configuration option, it is possible to designate certain server nodes that process extract queries to be preferentially selected from the list of server nodes that can do so. This helps speed up workloads such as backup and extract refreshes by allowing server admins to enable File Store on Backgrounder server nodes, which prevents extract queries from running on these nodes. This feature is useful if you have an extract-heavy query workload and an extract-heavy refresh workload and want to achieve optimal extract query and refresh performance.

Guidelines to optimize for extract refresh and backup or restore workloads.

Start from a topology with specialized Data Engine nodes (see [Optimize for Extract Query Heavy Environments](#)).

Tableau Server on Windows Help

Process	Initial Node	Additional Node 1	Additional Node 2	Additional Node 3
Cluster Controller	✓	✓	✓	✓
Gateway	✓	✓		
Application Server	✓	✓		
VizQL Server	✓ ✓	✓ ✓		
Cache Server	✓ ✓	✓ ✓		
Search & Browse	✓	✓		
Backgrounder	✓ ✓ ✓ ✓	✓ ✓ ✓ ✓		
Data Server	✓ ✓	✓ ✓		
Data Engine	✓	✓	✓	✓
File Store			✓	✓
Repository	✓	✗		

Topology 1 - Dedicated Data Engine Nodes

1. Add File Store to Node 0.

```
tsm topology set-process -n node0 -pr filestore -c 1
```

2. Designate Node 2 and Node 3 to preferentially execute extract-query workloads

```
tsm topology set-node-role -n node2, node3 -r extract-queries
```

3. Designate Node 0 to preferentially execute extract-refresh workloads.

```
tsm topology set-node-role -n node0 -r extract-refreshes
```

4. Designate Node 1 to preferentially execute non-extract-refresh workloads.

```
tsm topology set-node-role -n node1 -r no-extract-refreshes
```

5. Apply pending changes.

```
tsm pending-changes apply
```

Process	Initial Node	Additional Node 1	Additional Node 2	Additional Node 3
Cluster Controller	✓	✓	✓	✓
Gateway	✓	✓		
Application Server	✓	✓		
VizQL Server	✓ ✓	✓ ✓		
Cache Server	✓ ✓	✓ ✓		
Search & Browse	✓	✓		
Backgrounder	✓ ✓ ✓ ✓	✓ ✓ ✓ ✓		
Data Server	✓ ✓	✓ ✓		
Data Engine	✓	✓	✓	✓
File Store	✓		✓	✓
Repository	✓	✗		

Topology 2 - Extra File Store Node

Note: In your Tableau Server deployment, adding File Store roles to existing nodes will temporarily increase network I/O between all File Store nodes while the new File Store is being synchronized. The duration of this operation is dependent on the volume of data on the File Store and the network bandwidth capacity. The status of synchronization can be monitored using the TSM Web GUI. If you are adding more than one File Store to your deployment, it is recommended to add them consecutively and wait for the initial synchronization to complete in between each File Store addition.

Fine tune extract query workload management

When extract queries for email subscriptions and metric alerts are running at the same time that users are interactively viewing extract-based visualizations, users may experience slower than normal viz load times. Use the following node roles to fine tune how these workloads are prioritized.

Node role to use	Type of extract query workload	Example
<code>extract-queries</code>	scheduled	email subscriptions and metric alerts

Tableau Server on Windows Help

<code>extract-queries-interactive</code>	<code>interactive</code>	users viewing an extract-based visualization
--	--------------------------	--

If your server deployment is seeing growth in email subscriptions and metric alerts, you can add nodes and assign the `extract-queries` node role, which makes them more available to handle subscriptions and alerts.

If your server deployment is seeing growth in users viewing extract-based visualizations, you can add nodes and assign the `extract-queries-interactive` node role, which makes them prioritize interactive extract queries to reduce extract-based viz load times. The `extract-queries-interactive` node role is a preference and not strict isolation. This means that queries will be routed to nodes that have the `extract-queries-interactive` node role assigned. If you have multiple nodes with the `extract-queries-interactive` role, queries will be routed based on node health.

For example, add a node and designate it to preferentially execute `extract-queries-interactive` workloads.

- `tsm topology set-node-role -n node4 -r extract-queries-interactive`

Configuration options

Configuration	Jobs
<code>all-jobs</code> (default)	All Tableau Server jobs
<code>extract-queries</code>	Jobs that are created for extract queries. The nodes selected will run as <code>all-jobs</code> and will prioritize the processing of extract queries.
<code>extract-queries-interactive</code>	Jobs that are created for extract queries. The nodes selected will run as <code>all-jobs</code> and will prioritize the processing of interactive extract queries, such as those that run when a user is looking at their screen and waiting for an extract-based dashboard to load. This is an advanced setting and it should only be used if the cluster has a heavy subscription and

alert job workload that causes users to experience degraded performance on viz load times that run around the same time as scheduled loads.

For more information on configuring node roles using TSM commands, see `tsm topology set-node-role`.

License requirements

To configure a node to run extract queries you must have a valid Advanced Management license activated on your Tableau Server.

How to see node roles

Use the following command to see what node roles are currently configured on Tableau Server:

```
tsm topology list-nodes -v
```

Who can do this

Tableau Server Administrators can configure node roles and activate any required product keys.

Install Tableau Server on a Two-Node Cluster

When you install Tableau Server on a two-node cluster, you can install server processes on one or both nodes. A two-node cluster can improve the performance of Tableau Server, because the work is spread across multiple machines.

Note the following about two-node clusters:

- A two-node cluster does not provide failover or support for high availability.
- You can't install more than one instance of the repository on a two-node cluster, and the repository must be on the initial node.

Tableau Server on Windows Help

If you need failover or high availability, or want a second instance of the repository, you must install Tableau Server on a cluster of at least three computers. In a cluster that includes at least three nodes, you can configure two instances of the repository, which gives your cluster failover capability.

Restart Multi-Node Tableau Server Computers

Restarting the computers running a multi-node installation of Tableau Server requires that you follow a few specific steps.

To start computers running a multi-node installation of Tableau Server:

1. Stop Tableau Server. To do this:
 - a. On the initial node, open a command prompt as administrator.
 - b. Run this tsm command:

```
tsm stop
```
 - c. Wait until Tableau Server is stopped.
2. Restart the additional node computers. These are all the other computers *except* for the one running TSM.
3. Wait until each of the additional node computers has completely restarted, including the Tableau Server software installed there.
4. Restart the initial node computer (the computer running TSM). When it has completely restarted and Tableau Server is running, connections to each additional node should be restored.

Maintain a Distributed Environment

After you set up an initial node and one or more additional nodes for a distributed installation,

you can perform all subsequent configuration and updates from the initial node, using the TSM CLI, or from any computer using a browser and the TSM Web interface.

When you install additional nodes, they are added by computer name. If the computer name of a node changes, you will need to remove and reinstall the node. For details on removing a node, see [Remove a Node](#).

You can monitor the status of the Tableau Server cluster on the TSM Status page. See [View Server Process Status](#) for details.

Additional actions you may need to maintain your distributed environment include:

Move the Repository Process

Tableau Server relies on the PostgreSQL repository to store server data. There must always be at least one active instance of the repository in any Tableau Server installation, and you can have a maximum of two instances (one active, one passive) if you have at least three nodes in your installation. You cannot remove a repository instance if it is the only instance.

This means that if you want to move the only instance of your repository from one node to another node, you need to add a second instance and synchronize the new repository with the old one before you remove the old one. Synchronize repository instances by starting server. If you've added a new repository, it will automatically synchronize with the existing instance.

If you are deleting a node from your server cluster and that node is hosting the only instance of the repository, you must add a second instance of the repository and synchronize the instances before removing the node.

If you are also moving the file store, you can move the repository at the same time. See [Move the File Store Process](#).

Before making a change to the repository, create a full backup of Tableau Server. For more information, see [tsm maintenance backup](#).

Important: You cannot add a second repository instance and remove the first one in the same step. You must have both running so the contents of the first is synchronized with the second, before you remove the original instance.

The steps for moving the repository are:

1. Add a new instance of the repository to another node, start server, and wait for it to synchronize with the first repository.
2. Remove the instance of the repository from the original node.

Use the TSM web interface

To move a repository you need to first add a second instance on a second node, and then after the two instances have synchronized all the data in the original repository, remove the original instance. These steps must be done separately to allow for the synchronization of content between the two instances.

Add a new instance of the repository.

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab.
3. For the node you are adding the repository to:

Select **Repository** (pgsql).

4. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

If you are configuring a three- or five-node cluster and have not deployed a Coordination Service ensemble, a warning will display. You can continue, and deploy a Coordination Service ensemble in a separate step. For details on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#) .

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.
6. After Tableau Server has restarted, on the **Status** tab, verify that all processes are active.

Remove an instance of the repository.

1. In TSM, on the **Status** tab, verify that all processes are active. When both repositories show as Active, you can remove the first one.
2. Click the **Configuration** tab.
3. For the node you're removing the repository from, clear the **Repository** box.
4. Click **Pending Changes** at the top of the page.

If you are configuring a three- or five-node cluster and have not deployed a Coordination Service ensemble, a warning will display. You can continue, and deploy a Coordination Service ensemble in a separate step. For details on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#) .

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

To move a repository you need to first add a second instance on a second node, and then after the two instances have synchronized all the data in the original repository, remove the

Tableau Server on Windows Help

original instance. These steps must be done separately to allow for the synchronization of content between the two instances.

Add a new instance of the repository.

1. Add the repository (pgsql) to another node:

```
tsm topology set-process -n <nodeID> -pr pgsql -c 1
```

2. Apply the changes. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

3. Wait for the new repository on the second node to synchronize with the repository on the first node.

```
tsm status -v
```

Wait until the new repository status shows as "passive".

Remove an instance of the repository.

Once the new instance of the repository is fully synchronized and shows as "passive" you can remove the original instance:

1. Remove the repository from the first node by setting the process count to 0 (zero):

```
tsm topology set-process -n <nodeID> -pr pgsql -c 0
```

2. Apply the change. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not

change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

Move the File Store Process

This topic describes File Store process when configured to run locally on Tableau Server. However, File Store can be run locally as well as external to Tableau Server. For more information on Tableau Server External File Store, see [Tableau Server External File Store](#).

You cannot remove an instance of File Store if it is the only instance on the server. You cannot run Tableau Server without at least one instance of File Store. This means if you need to move the File Store, or if you are deleting a server node that is hosting the only instance of the File Store, you must first move File Store to another node.

Moving the File Store is a two-part process:

- Adding a second instance of File Store (if there is not an existing second instance).
- Decommissioning and removing the original instance of File Store.

This article assumes you have installed Tableau Server on an initial node and at least one additional node. For more information on adding nodes to Tableau Server, see [Install and Configure Additional Nodes](#).

Use the TSM web interface

Adding a second instance of File Store

This procedure assumes you have added an additional node. For more information on adding nodes to Tableau Server, see [Install and Configure Additional Nodes](#).

1. Open TSM in a browser:

```
https://<tsm-computer-name>:8850
```

For more information, see [Sign in to Tableau Services Manager Web UI](#).

Tableau Server on Windows Help

2. Click the **Configuration** tab.
3. For the node you want to add an instance of File Store on, select **File Store**.

Adding File Store to a node will also add an instance of Data Engine if one is not already on the node.

4. Click **Pending Changes** at the top of the page:

The Pending Changes list displays.

A Coordination Service ensemble warning displays because you are configuring a three-node cluster. You can continue. You will deploy a Coordination Service ensemble in an upcoming step.

5. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Decommissioning and removing an instance of file store

1. In TSM, on the **Status** tab, verify that all processes are active.
2. Click the **Configuration** tab.
3. For the node you're removing File Store from, clear the **File Store** box.

This will generate a warning about decommissioning the File Store before removing it. You cannot remove an instance of File Store unless it has been decommissioned. Click **OK** to decommission and remove the file store. Data Engine will also be removed unless an instance of one of these processes is installed on the node: VizQL Server, Application Server (Vizportal), Data Server, or Backgrounder.

4. If you are removing File Store from a node that also has the TSM Administrative Controller (usually the initial node), a warning will caution you about impact to server

backup performance.

Click **Continue** to decommission File Store.

5. Click the **Status** tab to see the status of the decommission. When the instance of File Store is marked "Ready for removal" you can continue.

6. Click **Pending Changes** at the top of the page.

Note: If you are configuring a three- or five-node cluster, a Coordination Service ensemble warning will display. You can continue to apply pending changes and deploy a Coordination Service ensemble in a separate step. For information on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

7. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

Adding a second instance of file store

1. Create a full backup of Tableau Server. For more information, see [Back up Tableau Server data](#).
2. Add the File Store to a second node.

```
tsm topology set-process -n <nodeID> -pr filestore -c 1
```

The File Store is automatically added. Data engine is also added if it is not already on the node.

Apply the configuration changes:

Tableau Server on Windows Help

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

3. Check the status of the new file store instance.

```
tsm status -v
```

Wait for the new File Store to synchronize with the File Store on the first node. When synchronization is complete the new File Store has a status of "running" instead of "synchronizing".

Decommissioning and removing an instance of File Store

Once you have a second instance of File Store installed and synchronized you can decommission and remove the original instance. You must decommission the original instance before you remove it. Doing this guarantees that any unique files on the File Store node are duplicated to another file store node.

1. Decommission the original File Store:

```
tsm topology filestore decommission -n <nodeID> --override
```

2. When the decommission command completes, remove the File Store from the node by applying the pending configuration changes. The File Store is automatically removed. Data Engine is also removed unless an instance of one of these processes is installed on the node: VizQL Server, Application Server (Vizportal), Data Server, or Backgrounder.

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Move the Messaging Service Process

This article assumes you have installed Tableau Server on an initial node and at least one additional node. For more information on adding nodes to Tableau Server, see [Install and Configure Additional Nodes](#).

You cannot remove an instance of the Messaging Service if it is the only instance on the server. You cannot run Tableau Server without one instance of the Messaging Service. This means if you need to move the Messaging Service, or if you are deleting a server node that is hosting the Messaging Service, you must first move the service to another node.

Moving the Messaging Service is straightforward process of three steps:

- Remove the original instance of the Messaging Service.
- Add a new instance of the Messaging Service.
- Apply the pending changes.

Use the TSM web interface

Moving the Messaging Service

1. In TSM, on the **Status** tab, verify that all processes are active.
2. Click the **Configuration** tab.
3. For the node you're removing the Messaging Service from, clear the **Messaging Service** box.

Tableau Server on Windows Help

This will activate the **Pending Changes** button, but in Pending Changes an error will tell you that the Messaging Service (activemqserver) is not on any node. Until you add it to another node, you cannot apply pending changes.

4. For the node you are adding the Messaging Service to, select the **Messaging Service** box.
5. Click **Pending Changes** at the top of the page.
6. Click **Apply Changes and Restart** and **Confirm** to confirm a restart of Tableau Server.

Use the TSM CLI

Moving the Messaging Service

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the nodes you are changing:

```
tsm topology list-nodes -v
```

3. Remove the Messaging Service from one node:

```
tsm topology set-process -n <nodeID> -pr activemqserver -c  
0
```

4. Add the Messaging Service to another node:

```
tsm topology set-process -n <nodeID> -pr activemqserver -c  
1
```

5. Apply the configuration changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt

displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Remove a Node

If your Tableau Server installation includes a node you no longer need, you can remove it to simplify your installation, and to free up the hardware resources on that node.

Note: If you have Tableau Resource Monitoring Tool Agent installed on this node, you must remove it from the Resource Monitoring Tool Master Server Environment. For more information, see [Tableau Server Topology Changes](#).

Prerequisites for removing a node

There are prerequisites you must satisfy before you can remove a node from your Tableau Server cluster. If your node has one of a number of limitations, you need to address these before you can remove the node. The limitations include confirm that the node has been added with at least one process, and that the node does not include any process that is not also installed on another node.

If one of the following configuration limitations applies, you must take action before you can remove the node:

- If the node was just added using the Web UI, you need to apply pending changes before you can remove it. If you added it using the command line, you need to configure it with at least one process before you can remove it.
- If the node includes the only Repository instance, you need to move the Repository to another node. See [Move the Repository Process](#).
- If the node is running the only instance of the File Store, you need to move the File

Tableau Server on Windows Help

Store to another node. See [Move the File Store Process](#).

- If the node is running an instance of the Coordination Service, you must deploy a new Coordination Service ensemble that does not include the node. See [Deploy a Coordination Service Ensemble](#).
- If the node is running the Messaging Service, you need to move the Messaging Service to another node. See [Move the Messaging Service Process](#).

Important: Do not use the `tableau-server-obliterate` script to remove a node. First remove the node using the TSM UI or the `tsm topology remove-nodes` command. This leaves the rest of the cluster in a good state. Later, if you want to re-add the node to the cluster, run the `tableau-server-obliterate` script on the node to completely remove Tableau. After removing Tableau from the node, restart the computer and then re-add the node using the normal steps for adding and configuring a node. For details on running the script, see [Remove Tableau Server from Your Computer](#).

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`

For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click the **Configuration** tab and, under the node you want to remove, click **Remove Node**:

If a configuration limitation does not allow you to remove the node (if, for example, it includes a File Store that must first be decommissioned), a message will display letting you know this. See **Prerequisites** above for more information.

Note: If you just added the node, and have not configured it, you must first apply pending changes before you can remove the node.

3. Click **Pending Changes** at the top right, and **Apply Changes and Restart**.

Use the TSM CLI

Use the `tsm topology remove-nodes` command to remove a node from a cluster.

To remove a node from a cluster it must have been configured with a process at some point in the past. If you added a node using the CLI and want to remove it but have not configured any processes, you must add a process on it, run the `tsm pending-changes apply` command, and then remove the node. For example, you might add one instance of Cluster Controller to the node: `tsm topology set-process -n <nodeID> -pr clustercontroller -c 1`.

If you are removing a node you added using the Web UI, the Cluster Controller process is automatically added so you do not need to add it before removing the node.

1. On the initial node, open a command prompt as administrator.
2. Find the node ID for the node you are changing:

```
tsm topology list-nodes -v
```

3. Remove a node using the `remove-nodes` command.

For example, to remove `node2` from an existing cluster:

```
tsm topology remove-nodes --node-names "node2"
```

If a configuration limitation does not allow you to remove the node (if, for example, it includes a File Store that must first be decommissioned), a message will display letting you know this. See **Prerequisites** above for more information.

4. Apply the changes:

```
tsm pending-changes apply
```

Configure Tableau Server for High Availability with Coordination Service-Only Nodes

The Coordination Service is built on [Apache ZooKeeper](#), an open-source project, and coordinates activities on the server, guaranteeing a quorum in the event of a failure, and serving as the source of "truth" regarding the server topology, configuration, and state. The service is installed automatically on the initial Tableau Server node, but no additional instances are installed as you add additional nodes. Because the successful functioning of Tableau Server depends on a properly functioning Coordination Service, we recommend that for server installations of three or more nodes, you add additional instances of the Coordination Service by deploying a new Coordination Service ensemble. This provides redundancy and improved availability in the event that one instance of the Coordination Service has problems.

The Coordination Service can generate a large amount of I/O as it communicates with other components of the server, so if you are running Tableau Server on computers that meet or just exceed the minimum hardware requirements, you may want to install Tableau Server in a configuration that uses Coordination Service-only nodes. This means installing Coordination Service on nodes that run no other server processes, and removing Coordination Service from any nodes that are running other server processes. This procedure explains how to do this. You can also run the Coordination Service ensemble on the same nodes running other Tableau Server processes. For details on how to do that, see [Deploy a Coordination Service Ensemble](#) .

Important: The process to deploy a Coordination Service ensemble changed as of version 2020.1.0. If you are running an earlier version of Tableau Server, see the documentation for that version. You can find documentation for all supported versions here: [Tableau Help](#)

Prerequisite

Before proceeding with the procedures in this topic, complete the following prerequisites:

- Install and Configure Tableau Server - Install Tableau on your initial node.
- Install and Configure Additional Nodes - Install Tableau on at least two additional nodes.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Deploy an ensemble on Coordination Service-only nodes

One way to accommodate the high I/O impact of the Coordination Service is to deploy an ensemble on nodes that only run the Coordination Service and the Cluster Controller. The following steps illustrate how to deploy a Coordination Service ensemble on an existing multi-node Tableau Server cluster.

Note: For a core-based Tableau Server license, Coordination Service-only nodes do not count against the total count of licensed cores.

1. Add additional nodes to your cluster.

See [Install and Configure Additional Nodes](#).

2. If you added the new nodes using the TSM CLI, you need to configure the nodes with Cluster Controller (this step is not necessary if you added the nodes using the TSM Web UI because Cluster Controller is automatically added when you add a node with the Web UI).

Tableau Server on Windows Help

On the initial node, open a command prompt as administrator.

3. From the initial node of the cluster, configure the new nodes with an instance of the Cluster Controller:

```
tsm topology set-process -pr clustercontroller -n <node4> -  
c 1
```

```
tsm topology set-process -pr clustercontroller -n <node5> -  
c 1
```

```
tsm topology set-process -pr clustercontroller -n <node6> -  
c 1
```

If prompted, sign in as a TSM administrator.

4. Apply the configuration changes. If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

```
tsm pending-changes apply
```

A warning about deploying a Coordination Service ensemble displays because you have deployed a multi-node cluster. If this is the only warning, you can safely override it using the `--ignore-warnings` option to apply the configuration changes in spite of the warning.

```
tsm pending-changes apply --ignore-warnings
```

5. Confirm that all nodes are up and running:

```
tsm status -v
```

6. On the initial node of the cluster, open a terminal session and type this command to stop Tableau Server:

```
tsm stop
```

7. Get the node IDs for each node in the cluster:

```
tsm topology list-nodes -v
```

8. Use the `tsm topology deploy-coordination-service` command to add a new Coordination Service ensemble by adding the Coordination Service to specified nodes. You must specify the node(s) that the Coordination Service should be added to. The command also makes the new ensemble the "production" ensemble (the ensemble in use) and removes the old ensemble.

Note: A "y/n" prompt displays confirming that a server restart will take place. To run the command without input, include the `--ignore-prompt` option.

For example, deploy the Coordination Service to three nodes of a six-node cluster:

```
tsm topology deploy-coordination-service -n  
<node4,node5,node6>
```

Wait until the command completes and you are returned to the system prompt.

9. Start Tableau Server:

```
tsm start
```

Add a Load Balancer

You can enhance the reliability of Tableau Server by running gateways on multiple nodes, and configuring a load balancer to distribute requests across the gateways. Unlike the repository process, which can be active or passive, all gateway processes are active. If one gateway in a cluster becomes unavailable, the load balancer stops sending requests to it. The load balancer algorithm you choose determines how the gateways will route client requests.

Notes: If you will be using Kerberos authentication, you need to configure Tableau Server for your load balancer before you configure Tableau Server for Kerberos. For more information, see [Configure Kerberos](#).

Windows SSPI authentication is not supported with a load balancer.

Note the following as you configure your load balancer to work with Tableau Server:

- **Tested load balancers:** Tableau Server clusters with multiple gateways have been tested with Apache and F5 load balancers.

If you are using an Apache load balancer and creating custom administrative views, you need to connect directly to the Tableau Server repository. You cannot connect through the load balancer.

- **Tableau Server URL:** When a load balancer is in front of a Tableau Server cluster, the URL that's accessed by Tableau Server users belongs to the load balancer, not the initial Tableau Server node.
- **Single load balancer endpoint:** You must configure your load balancers for a single URL endpoint. You cannot configure different endpoint hosts to redirect to the same Tableau Server deployment. The single external URL is defined in `gateway.public.host` when you configure Tableau Server, as described in the procedure below.
- **Trusted host settings:** The computer running the load balancer must be identified to Tableau Server as a trusted host. See the procedure below for how to configure Tableau Server.
- **Proxy server configurations:** The settings used to identify a load balancer to Tableau Server are the same ones that are used to identify a proxy server. If your Tableau Server cluster requires both a proxy server and a load balancer, both must use a single external URL defined in `gateway.public.host` and all proxy servers

and load balancers must be specified in `gateway.trusted` and `gateway.trusted_hosts`. For more information, see [Configuring Proxies for Tableau Server](#).

Configure Tableau Server to work with a load balancer

Use the following key-value pairs to configure Tableau Server for a load balancer. You can set the values individually with the `tsm configuration set` command.

Or, use the configuration file template example at the end of this topic to create a `configKey.json` file. After you have filled in the options with the appropriate values, pass the `json` file and apply settings with `tsm` commands.

Load balancer configuration key-value pairs

The key-value pairs described in this section can be set with the `tsm configuration set` command. After you have set all values, run the following command:

```
tsm pending-changes apply
```

```
gateway.public.host
```

Value: `name`

The value, `name` is the URL that will be used to reach Tableau Server through the load balancer.

For example, if Tableau Server is reached by entering `tableau.example.com` in a browser address bar, enter this command:

```
tsm configuration set -k gateway.public.host -v "tableau-  
.example.com"
```

```
gateway.public.port
```

Value: `port_number`

Tableau Server on Windows Help

By default, Tableau assumes that the load balancer is listening on port 80 for external communications. Use this key to specify a different port.

For example, if your load balancer is configured for SSL and listening on port 443, enter the following command:

```
tsm configuration set -k gateway.public.port -v "443"
```

gateway.trusted

Value: server

Specify the load balancer(s) IPv4 address or host name. If you are using an internal load balancer, you must use IP addresses, not host names.

The value for `server` can be a comma-separated list, for example:

```
tsm configuration set -k gateway.trusted -v "10.32.139.45,  
10.32.139.46, 10.32.139.47"
```

or

```
tsm configuration set -k gateway.trusted -v "proxy1, proxy2,  
proxy3"
```

gateway.trusted_hosts

Value:

Specify alternate names for the load balancer(s), such as its fully-qualified domain name, any non-fully-qualified domain names, and any aliases. These are the names a user might type in a browser. Separate each name with a comma:

```
tsm configuration set -k gateway.trusted_hosts -v "name1, name2,  
name3"
```

For example:

```
tsm configuration set -k gateway.trusted_hosts -v "lb.example.com,  
lb, ftp.example.com, www.example.com"
```

In most cases, if there are no alternate names for the load balancer, you may enter the same value for this key as you entered for the `gateway.public.host` key.

Configuration template example

You can configure all of the settings in one operation by customizing the following configuration template example and creating a `configKey.json` file.

Refer to the key-value pair descriptions above to customize the values for your organization.

```
{
  "configKeys": {
    "gateway.public.host": "tableau.example.com",
    "gateway.public.port": "443",
    "gateway.trusted": "proxy1, proxy2, proxy3",
    "gateway.trusted_hosts": "lb.example.com, lb, ftp.example.com,
www.example.com"
  }
}
```

When you are finished, save the json file.

Pass the json file with `tsm` to set the configuration, and then apply settings by running the following commands:

```
tsm settings import -f /path/to/file.json
```

```
tsm pending-changes apply
```

For more information about using `configKey` schemes, see [Configuration File Example](#).

Migrate

The topics in this section provide information on migrating between hardware and cloud platforms for Tableau Server on Windows.

Looking for Tableau Server on Linux? See [Migrate](#).

Looking for the Tableau Configuration Utility? As of version 2018.2, the Configuration Utility has been replaced by Tableau Services Manager (TSM). For more information about TSM, see [Comparing Functionality of tabadmin and TSM](#).

To migrate a site from one Tableau Server to another, see [Export or Import a Site](#).

To copy or migrate content between Tableau Server projects using the Tableau Content Migration Tool, see [About Tableau Content Migration Tool](#).

Changing the Identity Store

Infrastructure or business changes may require you to change the identity store on Tableau Server. There are two kinds of identity stores: local and external. When you installed Tableau Server you configured either a local identity store or an external identity store.

When you configure Tableau Server with a local identity store, all user and group information is stored and managed in the Tableau Server repository. In the local identity store scenario, there is no external source for users and groups.

When you configure Tableau Server with an external store, all user and group information is stored and managed by an external directory service. Tableau Server must synchronize with the external identity store so that local copies of the users and groups exist in the Tableau Server repository, but the external identity store is the authoritative source for all user and group data. Examples of external identity stores are OpenLDAP and Active Directory.

For more information about the Tableau identity store, see [Identity Store](#).

You can change from local store to an external store, or you can change from an external store to a local store. In either case, to change the identity store type, you complete these steps:

1. Uninstall (including manual deletion of directories) and then reinstall of Tableau Server. The procedure for full uninstall and clean install are at the end of this topic.
2. Restore content and permissions.

In these steps the term "restore" does not refer to using the `TSM maintenance restore` command to restore the backup you are making. You cannot restore a backup (`.tsbak`) created on a Tableau Server instance that uses a different identity store than the target Tableau Server. The backup is a best practice safeguard, in case you need to go back to your original Tableau Server configuration.

Warning

Changing the installation type on Tableau Server can be a complicated and time-consuming process. To avoid data loss or orphaning of content or users, you'll need to plan this process carefully. In all cases, user filters applied to workbooks and data sources will need to be updated manually after the change.

Most importantly, determine how you will transition content and permissions to the new identity store after you reinstall Tableau Server.

Methods for restoring content and permissions

The following list describes two methods for restoring content and permissions after you reinstall Tableau Server. Select the method that best fits with your environmental requirements.

- **Method 1: Use site export and import**—In this method, you start by exporting each site in your existing deployment. Then, you install the new server and configure it for the new identity store type. You then create new users in the default site on the new server. Finally, you import all the original sites. During the import stage, you can map the original identities to the new users that you created in the default site.

Tableau Server on Windows Help

You must use the same version of Tableau Server for the export and import operations. Importing a site to a version of Tableau Server that is different from the exported site version is not supported.

Because this method exports all content and permissions at each site, it is the best method for organizations that require a high fidelity replica of the content and permissions after the identity store change is complete. Some organizations require an identity store change as the result of an authentication change. In these cases, a different user name syntax is often a requirement in the new model. This method, which includes a process of mapping original user names to new names, provides flexibility for such scenarios.

- **Method 2: Fresh installation; users republish content**—In this method, you install a new version of Tableau Server and select the new identity store type during setup. You also create new sites. You then create users and give them access, and they republish their workbooks and data sources. Unlike the other method, in this one, you do not reuse any of your existing Tableau Server infrastructure.

This method is most appropriate for smaller deployments with fairly autonomous and data savvy users. From an administrative perspective, this method is the simplest, since you're not actively porting over content. However, because you rely entirely on users to republish content, this method may not be successful for large organizations or for those where centralized oversight of content is required.

User filters

User filters are domain-specific. Therefore, when the domain of Tableau Server changes or authentication type changes, filters no longer function as expected. Although the user filters are generated by Tableau Server, after they are set by the user, the filters are stored in the workbooks and data sources. Neither of these methods for changing the identity store modifies the contents of the workbooks or data sources.

As you plan the identity store change, you must also include a final task to correct user filtering in all workbooks and data sources with Tableau Desktop.

User names and the Tableau Identity store

If you are using Method 1, it's helpful to understand how Tableau Server stores user names in the Tableau identity store. Tableau stores all user identities in the repository, which coordinates content permissions and site membership with various services in Tableau Server. Generally, an identity store configured for Active Directory store user names in the format, `domain\username`. Some organizations use a UPN (`jsmith@domain.lan`).

On the other hand, organizations that configure Tableau Server with local identity store usually create standard, truncated user names, such as `jsmith`.

In all cases, these user names are literal strings that must be unique in the Tableau identity store. If you are changing from one identity store type to another, then your target authentication, SSO, or user provisioning solution may require a specific user name format.

Therefore, to maintain all permissions, content, and user viability, one of the following must be true after you change the identity store type:

- The new user names must match the original user names, or
- The original user names must be updated to match a new format.

If an authentication change is driving the identity store change, then the target authentication scheme will likely impose a user name syntax that is different than your original user names. Method 1 includes a process where you can map original user names to new user names.

It's possible that the original user name format will work with the new authentication type. For example, if you used UPN names in a local identity store deployment, you might be able to use the same user names in an Active Directory deployment. You could also use the `domain\username` format for local identity store, as long as users continue to use that format to sign in to Tableau Server.

If you are changing from local identity store to an external Active Directory store, review the topic, [User Management in Deployments with External Identity Stores](#), as part of your planning process.

Method 1: Use site export and import

You must use the same version of Tableau Server for the export and import operations.

1. Export all sites on your server. See [Export or Import a Site](#).
2. Back up, remove, and then reinstall .
3. Create new users on Tableau Server. You should have a new user that corresponds to each user on the original server.
4. Import the sites that you exported in Step 1. See [Export or Import a Site](#). During import, you will be prompted to map the new users to the original users.

Method 2: Fresh installation—users republish content

Even if you do not plan to port content as part of your identity store change, we recommend that you back up the server.

1. Back up, remove, and then reinstall .
2. Create users, sites, and groups.
3. Inform your users of the new Tableau Server, provide them with credentials, and allow them to republish their content.

Back up, remove, and then reinstall

Both methods include the following steps:

1. Back up Tableau Server
2. Remove Tableau Server.
3. Reinstall Tableau Server with the new identity store type.

Step 1: Back up Tableau Server

As a best practice, you should back up the server before proceeding.

Follow the procedure, [Create a backup using the TSM command line interface \(CLI\)](#). Run the `backup` command with the `-d` option. The `-d` option adds the datestamp.

When you are finished, copy the backup file (`.tsbak`) to a safe location that is not a part of your Tableau Server installation.

Step 2: Remove Tableau Server

You must completely remove Tableau Server from the computer. See [Remove Tableau Server from Your Computer](#).

Step 3: Reinstall Tableau Server with new authentication type

1. Go to the Tableau Customer Portal, sign in with your Tableau user name and password, and then download Tableau Server.
2. Install Tableau Server. See [Install and Configure Tableau Server](#) more information. During installation, you will select the new identity store type. See [Configure Initial Node Settings](#).

Migrate to New Hardware

Use the following procedure to migrate Tableau Server from one computer to another. You might do this if you are upgrading the computer hardware that Tableau is running on.

Specifically, these steps describe how to move Tableau Server data from your in-production computer to a new computer where Tableau Server is installed. Before you start, make sure you have followed the steps in [Preparing for Upgrade](#), including creating a backup and gathering any assets that require manual actions. For details, see [Perform a Full Backup and Restore of Tableau Server](#). You'll need these to restore your Tableau Server data and configuration.

You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Tableau Server on Windows Help

1. Deactivate your product key on your original installation of Tableau Server. You need to do this so you can activate it on the new computer. For more information, see "Tableau Server product key activation" below.
2. Install Tableau Server on the new computer, activate your license, configure initial settings, and create your admin user. For details, see [Install and Configure Tableau Server](#).
3. Copy your backup file `.tsbak` to the folder location specified by the `base-filepath.backuprestore` variable. By default this is: `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\files\backups`.

Note: You can change the location for the backup file. For more information, see [tsm File Paths](#).

4. Next, stop Tableau Server:

```
tsm stop
```

5. Restore your in-production data to your new Tableau Server installation using the `tsm maintenance restore` command:

```
tsm maintenance restore -f <filename>
```

where `<filename>` is the name of the `.tsbak` file you copied in step 3.

For more information about restoring Tableau Server data, see [Restore from a backup](#).

6. Start the server:

```
tsm start
```

7. **Distributed installations only:** Install Tableau Server on the new computers you

want to add to your new Tableau Server cluster. See [Install and Configure Additional Nodes](#) for steps.

8. If you have not deactivated your product key on the old computer, do that after you test your new Tableau Server installation and confirm that it's ready for production. For details, see ["Tableau Server product key activation"](#) below.

Note: If you do not have an internet connection, you are prompted to create an offline activation file to complete the deactivation process. See [Activate Tableau Server Offline - Adding a License](#) for steps.

Tableau Server product key activation

You can activate the same Tableau Server product key up to three times. This allows you to test Tableau Server (in a sandbox or QA environments, for example), as well as use Tableau in production. To maximize your activations, you should deactivate your product key when you remove Tableau Server from a computer, unless you will be reinstalling Tableau on the same computer. Doing this gives you the opportunity to use the activation on a different computer. For example, if you move Tableau Server from one computer or VM to another, deactivate the product key, then remove Tableau from the original computer. When you install Tableau on the new computer, you can activate the key there without any conflict. If you use role-based licensing, be sure to activate a Creator or Explorer key or you may lose administrator access to Tableau. If you are removing Tableau Server to reinstall it on the same computer, you don't need to deactivate the key. Tableau will use the key when reinstalled. For example, if you are moving Tableau from one drive on a computer to a different drive on the same computer. For information on how to deactivate a product key, see [tsm licenses deactivate](#).

Migrate Tableau Server from an On-Premises Computer to a VM in the Cloud

You can migrate Tableau Server from a computer in your data center to a virtual machine (VM) in the cloud. As a part of this migration, you'll need to move various Tableau Server data and configuration settings from your on-premises computer to a VM in the cloud where Tableau Server is installed.

Note: This operation includes steps that you may need to perform using the TSM command line. To use the TSM CLI you need administrator access to the command line on one of the nodes in your installation and TSM administrator credentials to run TSM commands.

Prerequisites

Before you migrate Tableau Server from an on-premises computer to a VM in the cloud, be sure to review the following prerequisites:

- Have an account and an environment set up on your cloud provider. For more information, see:
 - [Install Tableau Server on Amazon Web Services](#)
 - [Install Tableau Server on the Google Cloud Platform](#)
 - [Install Tableau Server on Microsoft Azure](#)
 - [Install Tableau Server in the Alibaba Cloud](#)
- Read [Preparing for Upgrade and Back up Tableau Server data](#) to prepare for the migration.

To migrate Tableau Server to a VM in the cloud

1. Ensure that there are no background tasks running, such as, extract refreshes, workbook publishing, etc. When Tableau Server is idle, note any data source connection

types in use so that you can install the appropriate drivers on the new Tableau Server on the VM in the cloud.

2. Stop Tableau Server. At a command prompt, type:

```
tsm stop
```

3. After Tableau Server is stopped, make a complete backup, following the steps in [Preparing for Upgrade and Back up Tableau Server data](#). The backup is what you will use to restore your Tableau Server data. You'll use this backup to restore your Tableau Server data on the VM in the cloud.
4. Move the backup off the server and store the backup securely. For example, you can store your backup on cloud storage such as Amazon S3, Google Drive, etc.
5. If you are using SSL on the on-premises server, make a copy of the SSL folder. Be sure to note any security rules, for example, firewall rules, ports, etc. to avoid communication issues between different elements of your infrastructure and your new Tableau Server on the VM in the cloud.
6. Remove any DNS entries using the IP address of the on-premises Tableau Server, so you can reassign them to the Tableau Server on the VM in the cloud.
7. Launch a VM into the cloud that meets the Tableau Server recommendations.
8. Install Tableau Server on the VM in the cloud. For more information, see:
 - [Install Tableau Server on Amazon Web Services](#)
 - [Install Tableau Server on the Google Cloud Platform](#)
 - [Install Tableau Server on Microsoft Azure](#)
 - [Install Tableau Server in the Alibaba Cloud](#)
9. After installation is complete, copy any SSL files to Tableau Server on the VM in the cloud, and restore the backup on your new server.
10. Configure Tableau Server on the VM in the cloud and install all SSH and port related stuff.

Note: If you change the IP address/port of the database, you might need to update all connection information.

Tableau Server on Windows Help

11. Copy your backup file `.tsbak` to the folder location specified by the `base-filepath.backuprestore` variable. By default this is: `C:\ProgramData\Tableau\Tableau Server\data\tabsvc\files\backups`.

Note: You can change the location for the backup file. For more information, see [tsm File Paths](#).

12. Next, stop Tableau Server. At a command prompt, type:

```
tsm stop
```

13. Restore your in-production data without configuration information to your new Tableau Server installation. At a command prompt, type:

```
tsm maintenance restore -f <filename>
```

where `<filename>` is the name of the `.tsbak` file you copied in step 11.

For more information about restoring Tableau Server data, see [Restore from a backup](#).

14. Start the server. At a command prompt, type:

```
tsm start
```

15. **Distributed installations only:** Install Tableau Server on the new VMs you want to add to your new Tableau Server cluster in the cloud. For more information, see:

- [Install and Configure Additional Nodes](#)
- [Self-Deploy Tableau Server on AWS in a Distributed Environment](#)
- [Self-Deploy Tableau Server on the Google Cloud Platform in a Distributed Environment](#)
- [Self-Deploy Tableau Server on Microsoft Azure in a Distributed Environment](#)
- [Self-Deploy Tableau Server on Alibaba Cloud in a Distributed Environment](#)

16. Test your Tableau Server on your VM in the cloud to ensure that it works as expected. If your Tableau Server is working fine in the cloud, you can deactivate your on-premises Tableau Server product key and use this same product key to activate your Tableau Server on the VM in the cloud.

Note: If you do not have an internet connection, you are prompted to create an offline activation file to complete the deactivation process. For more information, see [Deactivate Tableau Server Offline](#).

17. The same Tableau Server product key can be activated three times: once for a production environment, once for a test environment, and once for a QA environment. After you have tested your new Tableau Server installation and confirmed that it's ready for production, you must deactivate your earlier production version of Tableau Server, and then you must uninstall it. To deactivate the earlier version, see [tsm licenses deactivate](#).

Note: If you do not have an internet connection, you are prompted to create an offline activation file to complete the deactivation process. See [Deactivate Tableau Server Offline](#) for steps.

Upgrade Tableau Server Overview

The articles in this section help you upgrade an existing installation of Tableau Server on Windows. They describe the recommended steps of planning and testing *before* actually performing the upgrade. There's information about best practices, and when you're ready to actually perform your upgrade, steps for upgrading a single node server and a multi-node installation. Where possible, we call out possible pitfalls and help you to avoid these.

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

Looking for Tableau Server on Linux? See [Upgrade Tableau Server on Linux](#).

Unsupported Versions

- This topic may refer to Tableau Server versions that have gone out of support. The information here is no longer being maintained and may be out of date, but is being left in place for customers who are still running these older versions. For details on which versions are supported, see the bottom of this [Technical Support Programs](#) page: <https://www.tableau.com/support/services>.
- This topic refers to versions of Tableau Server that are no longer available. Downloads of versions prior to 2020.4 have been removed due to the security issues currently identified in [CVE-2021-44228](#) and [CVE-2021-45046](#). In order to address these security issues, you must update to the newest version of your desired Tableau product. For more information please see the [Knowledge Article, Apache Log4j2 vulnerability \(Log4shell\)](#).

Choose your upgrade path

Blue/Green upgrades

Blue/green upgrades are a special type of upgrade approach that provide minimal downtime, but require a knowledgeable IT team and resources to implement. These are not for every organization, but for those who are equipped to handle them, they can be the right upgrade solution. For more information, see [Using a Blue/Green approach for upgrading Tableau Server](#).

Upgrading in place

Your upgrade steps depend on the version of Tableau Server on Windows you are upgrading from, the version you are upgrading to, and the install location of your existing version. Use the table below to find a link to the steps that apply to your upgrade situation.

Upgrade Type

Note: Special steps are required if you have a pre-TSM version installed in a non-default location and are upgrading to version 2019.4.0 through 2019.4.4 or 2020.1.0 through 2020.1.1.

Current version	Upgrading to version	Install location	Upgrade procedure
<i>What version are you upgrading from?</i>	<i>If you aren't sure how to find your version, see Determine your Tableau Server version below.</i>	<i>If you do not know where Tableau Server is installed, see Determine your Tableau Server install location below.</i>	<i>Upgrade steps to use</i>
pre-TSM to TSM			
10.0 through 2018.1.x	2018.2.0 through 2019.3.x	default location or non-default location	Upgrade from Tableau Server 2018.1.x or Earlier to 2019.3.x (Windows) (opens 2019.3 Server Help)
	2019.4.0 or later	default location	Upgrade from Tableau Server 2018.1.x or Earlier (Windows)
	2019.4.0	non-default location	Upgrade from Tableau Server 2018.1.x or Earlier in a Non-

Current version	Upgrading to version	Install location	Upgrade procedure
	through 2019.4.4 or 2020.1.0 through 2020.1.1		Default Location (Windows)
	2019.4.5 or later or 2020.1.2 or later	default <i>or</i> non-default location	Upgrade from Tableau Server 2018.1.x or Earlier (Windows)
TSM to TSM			
2018.2.x or later	2018.2.x or later	default <i>or</i> non-default location	Upgrading from 2018.2 and Later (Windows)
TSM to TSM			
2018.2.x or later	2018.2.x or later	default <i>or</i> non-default location	Upgrading from 2018.2 and Later (Windows)

Determine your Tableau Server version

To see what version of Tableau Server you are running, sign in to Tableau Server and click the information icon ( or ) at the upper right of the Tableau Server window, then click **About Tableau Server**. Your server version is listed in the About Tableau Server dialog.

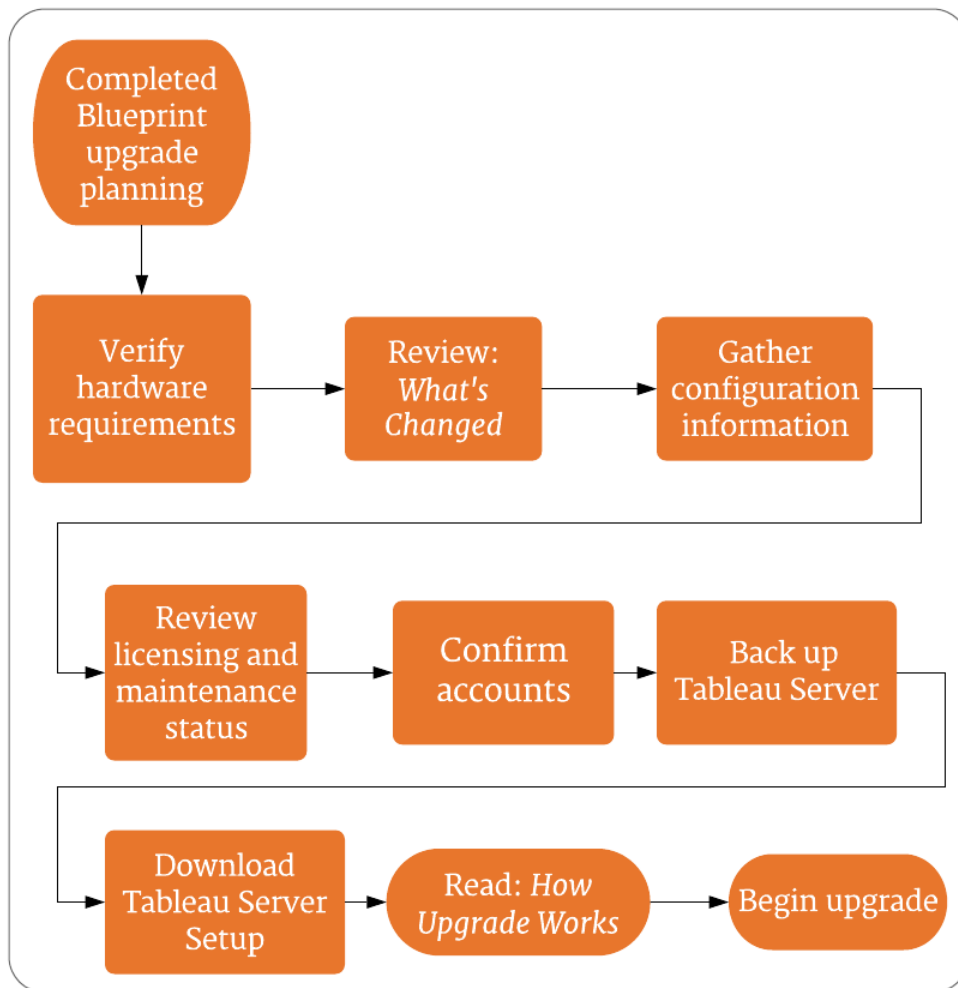

Determine your Tableau Server install location

Knowing where your current version of Tableau Server is installed is a key aspect of choosing the right upgrade path. By default Tableau Server versions 2018.1.x or earlier install to `C:\Program Files\Tableau\Tableau Server\<version>`. When you uninstall

version 2018.1.x or earlier, a backup is automatically created and saved in the data directory. Non-default location installs of Tableau Server version 2018.1.x or earlier use the same location for both the install directory and the data directory. Locate the backup and you have identified both the data directory and the install directory.

Preparing for Upgrade

Follow the flow chart and the linked topics to prepare your environment for Tableau Server upgrade.

Release Navigator

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

Server Upgrade - Minimum Hardware Recommendations

For production use, the computer on which you upgrade Tableau Server should meet or exceed the minimum hardware recommendations. These recommendations are general. Actual system needs for Tableau Server installations can vary based on many factors, including number of users and the number and size of extracts. If the Setup program determines that your computer does not meet the following recommendations, you will get a warning, but you can continue with the setup process. The minimum recommendations listed here are intended as general guidance. However the recommendations for your environment may vary. For more information, see the [Hardware recommendations section](#) of the [Recommended Baseline Configurations](#) topic.

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
Single node	<ul style="list-style-type: none"> 64-bit (x64 chipsets) Must support SSE4.2 and POPCNT instruction sets ARM-based processors are not sup- 	8-core, 2.0 GHz or higher	<ul style="list-style-type: none"> 64 GB (version 2021.4.0 and later) 32 GB (versions prior to 2021.4.0) 	50 GB

<i>Install Type</i>	<i>Processor</i>	<i>CPU</i>	<i>RAM</i>	<i>Free Disk Space</i>
---------------------	------------------	------------	------------	------------------------

ported

If you are adding Tableau Prep Conductor to your Tableau Server installation, we recommend you add a second node and dedicate this to running Tableau Server Prep Conductor. This node should have a minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Multi-node
and enter-
prise deploy-
ments

Contact Tableau for technical guidance.

Nodes must meet or exceed the minimum hardware recommendations, except:

- Nodes running backgrounder, where 4 cores may be acceptable.
- Dedicated node for Tableau Prep Conductor: Minimum of 4 cores (8 vCPUs), and 16 GB of RAM.

Important: The disk space requirement cannot be checked until you initialize TSM.

- Free disk space is calculated after the Tableau Server Setup program is unzipped. The Setup program uses about 1 GB of space. You may need to allocate additional disk space depending on various factors like whether you will be using extracts.
- **Network attached storage space requirements for External File Store:** If you are planning to configure [Tableau Server with External File Store](#), you will need to estimate the amount of storage space to dedicate on your network attached storage.

Estimating the storage size: You must take into account the amount of storage needed for publishing and refreshing extracts. In addition, you must also take into account the repository backup size unless you specifically choose the option to do your repository backup separately as described in the [Option 2: Backup Repository Separately](#) topic.

Tableau Server on Windows Help

- Extracts:
 - Consider the number of extracts that will be published to Tableau Server and the size of each extract. Test your needs by publishing several extracts to Tableau Server, and then checking the disk space used. You can use this amount of disk space to help you figure out how many extracts will be published to Tableau Server over time as well as how each existing extract will increase in size.
 - Consider the space needed by the temp directory during an extract refresh. The temp directory, which is where an extract is stored to during a refresh, may require up to three times the final file size of the extract.
- Repository Backup:
 - To obtain an estimate of the repository data, check the size of `<data directory>/pgsql/data/base` directory.
 - To obtain the exact size of the repository data, open the backup file and use the size of the `workgroup.pg_dump` file.
- Core count is based on "physical" cores. Physical cores can represent actual server hardware or cores on a virtual machine (VM). Hyper-threading is ignored for the purposes of counting cores.
- RAM shown is the minimum recommended for a single-node installation. Your installation may function better with more RAM, depending on activity, number of users, and background jobs, for example.

For hardware recommendations for Tableau Server in the cloud, see the following:

- Selecting an AWS Instance Type and Size in the [Tableau Server on Windows in the AWS Cloud Administrator Guide](#)
- Selecting a Google Compute Engine Virtual Machine Type and Size in the [Tableau Server on Windows in the Google Cloud Platform Administrator Guide](#)

- Selecting a Microsoft Azure Virtual Machine Type and Size in the [Tableau Server on Windows in Microsoft Azure Administrator Guide](#)

Determining Computer Hardware

To determine how many physical cores a computer has, the Tableau Server setup program queries the operating system. To view hardware information that the setup program detected on your computer, open the `tabadmin.log` file in the following folder on the computer where you are installing Tableau Server:

```
<install directory>\ProgramData\Tableau\Tableau Server-  
\logs\tabadmin.log
```

In the `tabadmin.log` file, look for lines similar to the following. These lines provide information about the physical and logical cores that the setup program detected and that it used to determine the core count that is being used for licensing.

```
2015-04-09 14:22:29.533 -0700_DEBUG_10.36.2.32:<machine  
name>_:pid=21488_0x2cd83560__user=__request=__ Running hard-  
ware check
```

```
2015-04-09 14:22:29.713 -0700_DEBUG_10.36.2.32:<machine  
name>_:pid=21488_0x2cd83560__user=__request=__ Detected 12  
cores and 34281857024 bytes of memory
```

```
2015-04-09 14:22:29.716 -0700_DEBUG_10.36.2.32:<machine  
name>_:pid=21488_0x2cd83560__user=__request=__ Hardware meets  
recommended specifications. Default values will be used.
```

Manually determining the number of cores on your computer

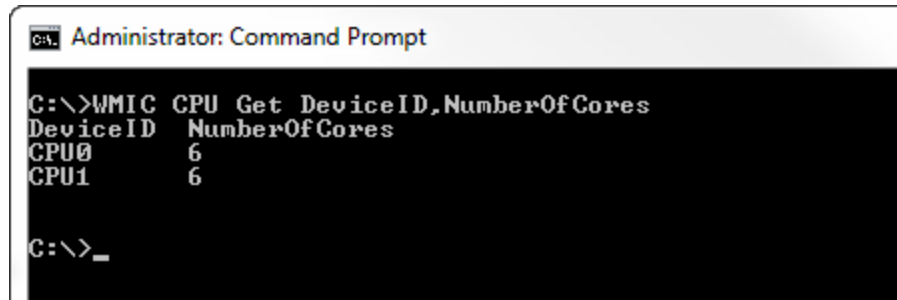

To determine manually how many physical cores your server has, you can use the Windows Management Instrumentation Command-line tool (WMIC). This is useful if you do not know whether your computer will meet the minimum hardware requirements for installing Tableau Server.

Tableau Server on Windows Help

1. Open a command prompt.
2. Enter the following command:

```
WMIC CPU Get DeviceID,NumberOfCores
```

The output will display the device ID or IDs and the number of physical cores the computer has.

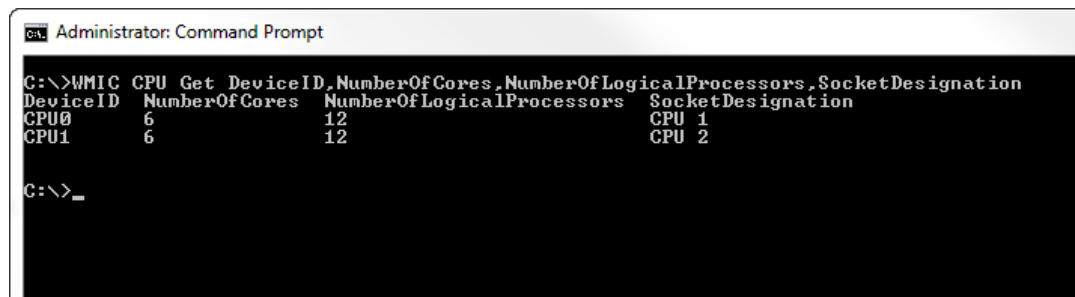

```
Administrator: Command Prompt
C:\>WMIC CPU Get DeviceID,NumberOfCores
DeviceID  NumberOfCores
CPU0      6
CPU1      6
C:\>_
```

In this example, there are two CPUs, each with six cores, for a total of twelve physical cores. This computer would satisfy the minimum hardware requirements for installing Tableau Server.

The following command shows a longer version that lists the logical processors as well as the physical cores.

```
WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
```

```
Administrator: Command Prompt
C:\>WMIC CPU Get DeviceID,NumberOfCores,NumberOfLogicalProcessors,SocketDesignation
DeviceID  NumberOfCores  NumberOfLogicalProcessors  SocketDesignation
CPU0      6              12                         CPU 1
CPU1      6              12                         CPU 2
C:\>_
```

In the above example, the server has a total of twelve physical cores, resulting in 24 logical cores.

Continue to Server Upgrade - Review What's Changed.

Server Upgrade - Review What's Changed

This topic includes a list of important product changes in Tableau Server, beginning with version 2018.3 . The changes described in this topic may impact the upgrade process itself, or they may impact functionality after you have upgraded. Read these changes carefully and make note of the changes and remediation steps that you'll need to take. Include these remediation steps as part of your upgrade process or post-upgrade configuration plan.

This list is cumulative, so if you are upgrading from an early version (for example, 2018.3), read the list of changes for every version between your version and the version you are upgrading to.

This topic does not include all of the new features that have been added in each release. To develop a more robust verification and testing plan, we recommend that you also review new features before you upgrade.

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

[Tableau Server Release Notes | Known Issues](#)

Changed in 2021.4

Version 2021.4 includes the following changes you should know about before upgrading.

Tableau Server on Windows Help

Increase in memory recommendations for production installations of Tableau Server

Beginning with Tableau Server 2021.4, the minimum amount of memory for a production installation of Tableau Server increases from 32 GB to 64 GB. This increase helps ensure a satisfactory experience with Tableau Server, and accounts for increased memory needs of newer features.

For customers wanting to do proof of concept testing, we recommend using a Tableau Online account, which will guarantee you a system running on adequate hardware. Tableau Online is also a good option for organizations that would otherwise be running Tableau Server on a single node (a one-computer installation).

For more information about Tableau Server system requirements, see [Before you install....](#)

Search using attributes, operators, and special characters is no longer supported

Beginning with Tableau Server 2021.4, search attributes, operators, and special characters cannot be used to limit search on Tableau Server and Tableau Online. You can limit the search results using filters. To learn more about searching on Tableau, see [Search Your Tableau Site](#).

IdP-initiated SLO support for server-wide and site-specific SAML

In addition to supporting service provider (SP)-initiated single log out (SLO) for both server-wide SAML and site-specific SAML, Tableau Server supports identity provider (IdP)-initiated SLO beginning with Tableau Server 2021.4. For more information about SAML configuration and requirements, see [SAML Requirements](#).

Offline activation process is simpler

Beginning with Tableau Server version 2021.4, offline activation has been made simpler, with fewer steps required to activate Tableau Server. In addition, the offline activation request file (`offline.tlq`) has been renamed `TableauOfflineActivationRequest.tlq`. The offline deactivation request file (`deactivate.tlq`) has been renamed `TableauOfflineDeactivationRequest.tlq`. For more information about offline activation, see [Offline](#)

Activation When Installing Tableau Server . For more information about offline deactivation, see [Deactivate Tableau Server Offline](#).

Changed in 2021.3

Version 2021.3 includes the following changes you should know about before upgrading.

Python package is installed with Tableau Server

Beginning with Tableau Server 2021.3, The Tableau Server Setup program installs a Python package. Python will be used by future advanced analytics features. If you cannot or choose not to install Python with Tableau Server, you will not have access to any future features that require Python. For more information on how to opt out of installing the Python package, see the `/skippythoninstall` switch in [Install Switches and Properties for Tableau Server](#).

Backup behavior changed

Beginning with Tableau Server 2021.3, when you run a backup of Tableau, the backup job skips any files that are newer than the start time of the backup job. This change impacts extract refreshes that run after the backup has begun. These will be skipped during the current backup. Other impacts to customers should be minimal except a reduction of the size of some backup files.

Tableau Server no longer supports Windows Server 12 or Windows Server 12 R2

Beginning with version 2021.3, in keeping with Microsoft's Windows Server support policy, Windows Server 12 and Window Server 12 R2 are no longer supported operating systems for Tableau Server. This change was originally scheduled to begin with version 2021.1 but was delayed until version 2021.3. For details of the announcement, see the [Tableau Blog](#).

For more information about supported versions of Windows, see [Operating system requirements](#).

Tableau Server on Windows Help

Tableau Server no longer supports Internet Explorer 11

Beginning with version 2021.3, we are ending our support for Internet Explorer (IE) for accessing Tableau Server. Tableau Server is fully compliant with Chrome, Firefox, Safari, and Edge. For details of the announcement, see the [Tableau Blog](#).

For more information about supported web browsers supported by Tableau Server, see [Tableau Tech Specs](#).

SP-initiated SLO support for site-specific SAML

In addition to supporting service provider (SP)-initiated single log out (SLO) for server-wide SAML, Tableau Server supports SP-initiated SLO for site-specific SAML beginning with Tableau Server 2021.3. For more information about SAML configuration and requirements, see [SAML Requirements](#).

Changed in 2021.2

Version 2021.2 includes the following changes you should know about before upgrading.

Encrypted communication channel with Active Directory is required

Beginning with Tableau version 2021.2, Tableau Server no longer allows insecure connections with Active Directory. If your current instance of Tableau Server is communicating with Active Directory over a non-encrypted channel, upgrade will fail.

Run the following command to allow an insecure connection on your current version of Tableau Server before you upgrade:

```
tsm configuration set -k wgservers.domain.allow_insecure_connection -v true --force-key
```

After upgrade completes, we recommend securing the channel and then setting this option to `false`.

Note: By default (when `wgserver.domain.allow_insecure_connection` is set to `true`), Active Directory group synchronization will fail if the communication channel with Active Directory is not encrypted.

Secure SAML configuration is enforced

Beginning with version 2021.2, Tableau Server enforces secure SAML configuration for Server-wide and Site SAML.

Signature algorithm The certificate that you configure for SAML must use a secure signature algorithm, for example SHA-256. If you attempt to upgrade Tableau Server with a SAML certificate that uses SHA-1 signature hash, upgrade will fail.

We recommend that you upload a new certificate with SHA-256. See [Update SAML Certificate](#).

Alternatively, you can configure Tableau Server to accept the less-secure SHA-1 hash by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.

RSA key and ECDSA curve sizes The certificate used for SAML must either have an RSA key strength of 2048, or ECDSA curve size of 256. If you attempt to upgrade Tableau Server with a SAML certificate that uses less-secure key or curve sizes, upgrade will fail.

We recommend that you upload a new certificate with more secure key or curve size. See [Update SAML Certificate](#).

Alternatively you can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys, `wgserver.saml.min_allowed.rsa_key_size` and `wgserver.saml.min_allowed.elliptic_curve_size`.

Site SAML secure configuration verification

This release includes an updated `tabcmd` utility with the `validateidpmetadata` command. The `validateidpmetadata` command will scan your existing SAML sites and identify the signature algorithms and key sizes that are configured for each site. See `validateidpmetadata`.

Tableau Server on Windows installer logging changes

Beginning with Tableau Server 2021.2, due to internal changes to the installer, the logging behavior by the Tableau Server installer program has changed if you use the `/log` switch on the command line.

Prior to version 2021.2 you could use the `/log` switch to specify a log file name without a path, and the file was written to the current working directory. Starting in 2021.2, if you do not also specify a path, the file will be written to a temporary location that is deleted when the installation is done. If you use the `/log` switch, you must also specify both the path and the log file name in `<name>.<ext>` format if you want to preserve the log. If you do not include a file name, the installer will ignore the switch and save the log to `%TEMP%`.

The behavior is unchanged if you do not use the `/log` switch: the installer log is created in the logged in user's temp directory, `%TEMP%` using a naming convention of `Tableau_Server_<version_code>.log`.

For more information on command line switches for the installer, see [Install Switches and Properties for Tableau Server](#)

Tableau Prep Flow Service has been renamed to Tableau Prep Minerva Service

Beginning with version 2021.2, the Tableau Prep Flow Service (`flowqueryservice`) has been renamed to the Tableau Prep Minerva Service (`flowminerva`). This process appears on the TSM Status page and in the output of the TSM command `tsm status -v`. For more information, see [Tableau Server Processes](#).

New configuration key for setting maximum time for single subscription job

Beginning in version 2021.2, you now set the maximum time to complete a single subscription job using the new `backgrounder.timeout.single_subscription_notify` configuration key. This key replaces use of the `backgrounder.timeout_tasks` key for configuring timeouts on single subscription jobs. As of version 2021.2 the `backgrounder.timeout_tasks` key no longer uses the `single_subscription_notify` option. For more information, see `backgrounder.timeout.single_subscription_notify`.

Changed in 2021.1

Version 2021.1 includes the following changes you should know about before upgrading.

Change in default behavior for snapshot backups

Note: If you have both External File Store and External Repository enabled and use scripts to do backups, this can potentially result in not having a backup of the repository.

Beginning with Tableau Sever 2021.1, if you have both External File Store and External Repository enabled, Tableau Server backup process no longer includes creating a backup file of the repository by default. If you are upgrading from a version earlier than 2021.1, and you have scripts to run or schedule your backups, and want to continue to include the repository backup, see Option 1: Include Repository in the Backup .

SHA-256 hash algorithm enforced for SAML assertions with IdP

Beginning with Tableau Sever 2021.1, Tableau Server will hash message signatures and digests with SHA-256 in SAML assertions to the IdP. To change this behavior, see `wgserv-er.saml.sha256`.

New SAML configuration keys

Beginning with Tableau Server 2021.1, Tableau Server includes three new SAML configuration keys:

- `wgserver.saml.blocklisted_digest_algorithms`: Specifies the digest algorithms that are not allowed as part of certificates used in SAML configuration or for signing SAML assertions. When set, assertions that are signed with a blocklisted algorithm will fail and certificates containing a blocklisted digest algorithm will fail. We recommend blocking the SHA-1(SHA1) algorithm. Before blocking SHA-1, confirm that your SAML certificates digest algorithms are not SHA-1, and that your SAML idP does not sign messages with SHA-1.
- `wgserver.saml.min.allowed.elliptic_curve_size`: Specifies the minimum elliptic curve size required for ECDSA certificates that uploaded and configured for Tableau Server. If Tableau Server is configured with an ECDSA certificate that does not satisfy this minimum curve size, Tableau Server may go into a degraded state. If you attempt to upload a certificate that does not meet the minimum curve size, Tableau Server will reject the certificate. We recommend a minimum curve size of 256.
- `wgserver.saml.min.allowed.rsa_key_size`: Specifies the minimum key size that required for RSA certificates that are uploaded and configured for Tableau Server. If Tableau Server is configured with an RSA certificate that does not satisfy this minimum key size, Tableau Server may go into a degraded state. If you attempt to upload a certificate that does not meet the minimum key size, Tableau Server will reject the certificate. . We recommend a minimum key size of 2048.

In future releases of Tableau Server, these keys will be configured with secure minimum defaults, as specified in the recommendations above. In future releases, if your SAML configuration is not configured with the minimum requirements, SAML functionality or upgrade may fail. In the meantime, we recommend that you update your SAML configuration to be in compliance with the recommendations above.

Client and CA certificates used for mutual SSL must meet minimum security requirements

Beginning with Tableau Server 2021.1, Tableau Server configured for mutual SSL authentication will enforce secure certificate requirements.

Client and certificate authority (CA) certificates used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

Tableau Server will fail mutual authentication requests from client certificates that do not meet these requirements.

Additionally, upgrade of Tableau Server will fail if the certificate authority (CA) certificate that is configured for mutual SSL does not meet these requirements.

- To update the CA certificate file for Tableau Server mutual SSL, upload the certificate as described in [Configure Mutual SSL Authentication](#).
- To disable the certificate security enforcement, see the Tableau KB topic, [Tableau Server Using Mutual SSL Authentication Fails to Start or Rejects Login After Upgrade to Tableau Server 2021.1 because Certificates Use Insecure Key Attribute](#).

Improvements to JVM maximum heap size scaling for Tableau Catalog ingestion and elastic server

Beginning with Tableau Sever 2021.1, JVM maximum heap size scales automatically for Catalog ingestion and elastic server. For more information, see `non-interactivecontainer.vmopts` and `elasticserver.vmopts`.

Old notifications do not appear in new notifications center

When you upgrade to Tableau Server 2021.1, old notifications will not appear in the new notifications center. All existing email notifications will continue. To continue tracking older notifications, make sure the server setting for Notifications for Extract Jobs and Flow Runs is enabled before upgrading. For more information, see [What's New and Changed in Tableau Server](#).

Changed in 2020.4

Tableau Server on Windows Help

Version 2020.4 includes the following changes you should know about before upgrading.

SHA1 certificates disabled for SSL mutual authentication

Beginning with Tableau Server 2020.4, Tableau Server configured for mutual SSL authentication will block authentication of users with client certificates that use the SHA-1 signing algorithm.

Users who attempt to log in with SHA-1 client certificates encounter an "Unable to sign in" error, and the following error will be visible in the VizPortal logs:

```
Unsupported client certificate signature detected: [certificate  
Signature Algorithm name]
```

If the clients in your organization are connecting to Tableau Server using SSL mutual authentication and the clients are using certificates with the SHA-1 signing algorithm, then you must perform one of the following actions before upgrading:

- Update the certificates used by your clients. The certificates must use the SHA-256 (or stronger) signing algorithm, or
- Disable the SHA-1 blocklist before upgrading to Tableau Server 2020.4. To disable the blocking functionality, run the following TSM commands before you upgrade:

```
tsm configuration set -k "ssl.client_certificate_login.b-  
locklisted_signature_algorithms" -v ""
```

Note that the value (-v) includes an empty set of quotes to specify a null value.

For more information about how to reset this value after you have updated client certificates, see the Knowledge Base article, [Mutual SSL Fails After Upgrading if Certificates Signed with SHA-1](#).

For more information about why this change has been implemented, see the Tableau Community post, [Retiring Default Support for SHA-1 Signed Certificates Used During Mutual SSL Authentication in Customer-Managed Tableau Server 2020.4](#), and the National Institute of Standards and Technology policy statement, [NIST Policy on Hash Functions](#).

`wgserver.domain.whitelist` config key has been deprecated

Beginning with version 2020.4, the `wgserver.domain.whitelist` configuration key has been deprecated. Use the new key, `wgserver.domain.accept_list` to specify allowed domains.

All functionality of the older key has been transferred to the new key. As of 2020.4.0, existing installations configured with the old key will not be impacted, and the key can still be used, but you must include the `--force-keys` option when setting the key, and the key will be permanently removed in a future release. For all new configurations, use `wgserver.domain.accept_list` instead. For more information about the new configuration key, see `wgserver.domain.accept_list`.

CPU requirement update

Beginning with version 2020.4, Tableau Server requires all nodes to have CPUs that support SSE4.2 and POPCNT instruction sets. These CPUs have been common for more than 10 years and are installed on most newer computers. If you attempt to install or upgrade Tableau on a computer that does not support these instruction sets, the installer will not allow you to continue.

Checkpoint Upgrade for Tableau Server

Version 2020.4 of Tableau Server includes updates to the `upgrade-tsm` script that give you the ability to rerun the script when an upgrade fails. The script keeps track of successful progress, and when you rerun the script after an upgrade failure, restarts at the latest successful "checkpoint." This saves time because successful steps do not need to be repeated on rerunning the script. As a first troubleshooting step, rerun the `upgrade-tsm` script. Doing this can result in a successful upgrade if a momentary environmental problem or timing issue caused the initial failure.

Checkpoint upgrades also give experienced IT professionals the option to further troubleshoot the failure, and make corrections (for example, if there is a problem with disk space, or a permissions issue on a particular file or directory) before rerunning the upgrade script. For troubleshooting details, see [Upgrade fails on 2020.4.0 or later](#).

Tableau Server on Windows Help

PostgreSQL upgrade

Version 2020.4 of Tableau Server includes a major-version update of the PostgreSQL database used for the Tableau repository. During the upgrade a temporary pgsq-`only` backup is created and this increases the length of time the upgrade takes as well as the amount of temporary disk space used.

If you have External Repository configured, before upgrading your Tableau Server to 2020.4, you must make sure you are using PostgreSQL version 12 or later. For more information, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#)

Visual improvements to user, group, and site dialogs

The 2020.4 release adds visual updates to administrator menus and dialogs to make managing users, groups, and sites easier in Tableau Server.

Changes to default JVM heap size for Tableau Catalog ingestion

Beginning with Tableau Server 2020.4, the default JVM heap size for Catalog ingestion is determined by and then scales based on system memory. To review the default values for Catalog ingestion, see `noninteractivecontainer.vmopts`.

Changed in 2020.3

Version 2020.3 includes the following changes you should know about before upgrading.

Data Acceleration for Workbooks that use the Object Model Framework

Administrators can now also enable data acceleration for workbooks that use the Object Model framework. See [Data Acceleration](#).

Changed in 2020.2

Version 2020.2 includes the following changes you should know about before upgrading.

Analytics extensions (external service) connections must be reconfigured

Tableau supports a set of functions that your users can use to pass expressions to analytics extensions for integration with R and Python. Previously, this feature was referred to "external services."

In previous versions of Tableau Server, the analytics extensions configuration applied to the Tableau Server global configuration and was administered with TSM.

Beginning with version 2020.2, you can configure a different analytics extensions connection for each site. Administration of the analytics extensions connection has moved out of TSM and to Tableau Server administrator. Additionally, configuring an analytics extensions connection no longer requires a restart of Tableau Server.

However, if you have configured Tableau Server with an analytics extensions connection, then you must reconfigure that connection after you upgrade Tableau Server to version 2020.2.

Before upgrading, document the existing analytics extensions configuration. On previous versions (2019.1-2020.1) you can run the `tsm security vizql-extsvc-ssl list` command to list the existing connection details. To retrieve the password that is stored for the analytics extensions connection (if any), run the following tsm command:

```
tsm configuration get -k vizqlserver.rserve.password
```

After you have upgraded, configure the analytics extension connection. See [Configure Connections with Analytics Extensions](#).

Oracle data source connections require updated driver

Beginning with version 2020.2, Oracle data sources use a new JDBC driver. You must download and install this driver on Tableau Server to enable existing content relying on Oracle connections to properly display. Until this driver is downloaded and installed on Tableau Server, existing content will not display or refresh. Follow the instructions on the [Driver Download](#) page to get and install the new driver. For details on the changes and how they impact Tableau authors, see [Oracle](#) in the Tableau Desktop and Web Authoring Help.

Tableau Server on Windows Help

WDC behavior change if Run As service account has admin group privileges

Beginning with version 2020.2, because of changes to the QTWebEngine component used by Tableau Server, if you use Web Data Connectors (WDCs) and Tableau is configured with a Run As service account in a local administrators or domain administrators group, you may run into problems using WDCs. Our recommendation has been and continues to be to use a domain User account for the Run As service account. This is a good security practice.

For more information on possible issues, see the [Tableau Knowledge Base](#). For details on suggested best practices when creating a Run As service account, see [Creating the Run As service account](#).

Tableau Resource Monitoring Tool Updates

- **Installers:** Starting in 2020.2, the Master Server installer installs both the prerequisites and the Master Server. You no longer need to install the prerequisites separately. For more information, see:
 - [Install the RMT Server Using Web Interface](#)
 - [Upgrading Resource Monitoring Tool](#)
- **Installation Experience:** The steps to create an environment after installing the Master Server, and the steps to install and register Resource Monitoring Tool Agent on Tableau Server nodes have changed. For more information, see :
 - [Install the RMT Server Using Web Interface](#)
 - [Install the Agent Using the Web Interface](#)
- **OS Requirements:** Starting in 2020.2, Windows Server 2012 is no longer supported. The minimum supported operating system is now Windows Server 2012 R2.

The Startup Values of some TSM services have changed

Beginning in maintenance versions, the startup values of several TSM services have been changed from "Automatic" to "Automatic (Delayed Start)" to help address some occasional issues in timing. This change should not have a significant impact. Services affected: Tableau Server Administration Agent, Tableau Server Administration Controller, Tableau Server Client File Service, Tableau Server Coordination Service, Tableau Server License Manager, and Tableau Server Service Manager.

If you are running an older version of Tableau Server you can leave the startup values as they were originally configured ("Automatic"), but updating them to the new values ("Automatic (Delayed Start)") will not negatively impact Tableau Server. For more information about service startup values, including the specific maintenance releases where this change took place, see [Verify Tableau Service Settings](#) in our current documentation.

Changed in 2020.1

Version 2020.1 includes the following changes you should know about before upgrading.

- Tableau Server no longer supports Windows 7 or Windows 2008
- `tableau-server-obliterate` script now preserves backup and log files
- Improvements to the `tsm topology deploy-coordination-service` command
- Large statistical file extracts consume system resources

Tableau Server no longer supports Windows 7 or Windows 2008

Beginning with version 2020.1, in keeping with Microsoft's Windows Server support policy, Windows 7 and Windows 2008 are no longer supported operating systems for Tableau Server.

For more information about supported versions of Windows, see [Operating system requirements](#).

`tableau-server-obliterate` script now preserves backup and log files

In previous versions of Tableau Server, running the `tableau-server-obliterate` script deleted all content from the Data directory. Beginning with version 2020.1, the default behavior of the `tableau-server-obliterate` script has changed: the script copies and saves Tableau Server backup and log files to the `logs-temp` directory. The default location for the `logs-temp` directory is at `\ProgramData\Tableau\logs-temp`. You can set options on the script to disable this new functionality.

See [Remove Tableau Server from Your Computer](#).

Tableau Server on Windows Help

Improvements to the `tsm topology deploy-coordination-service` command

Beginning with version 2020.1, the command to deploy a new coordination service ensemble waits for the ensemble to be properly deployed and removes the old ensemble before returning control to the command prompt. This simplifies the process for deploying a new coordination service ensemble and eliminates the chances of continuing on with other commands or actions before Tableau Server is properly configured for the new ensemble. You no longer need to run the `tsm topology cleanup-coordination-service` command after deploying a new ensemble in version 2020.1.0 and later.

Note: With this change, all coordination service ensemble commands require input for a "y/n" prompt confirming that a server restart will take place. To run these commands without input, include the `--ignore-prompt` option.

For more information about deploying a coordination service ensemble, see [Deploy a Coordination Service Ensemble](#).

Large statistical file extracts consume system resources

Beginning with Tableau Server 2020.1, a change to the Statistical File (SAS) library may cause large SAS-based extract refreshes to fail. The following connection error will be visible in the backgrounder logs, along with spikes in system memory consumption.

"exceeded per-process memory threshold"

To work around the issue, run the following TSM commands after upgrading Tableau Server:

```
tsm configuration set -k features.ReadStat -v false
tsm pending-changes apply
```

For more information and steps to work around the issue in Tableau Desktop, see the Knowledge Base article, [Large Sas File Extract Refresh Failed And Huge Memory Consumption Observed After Upgraded Tableau Server To 2020.3.1](#).

Changed in 2019.4

Version 2019.4 includes the following changes you should know about before upgrading.

- Tableau Server installer has been rewritten
- New tabcmd installer for Windows
- Updates to Tableau Server Job management
- Updates to tsm maintenance cleanup command
- Changed behavior for Copy Link when sharing a view

Tableau Server installer has been rewritten

The 2019.4 release of Tableau Server features a newly rewritten Setup program for Tableau Server.

This update changes some of the command line switches and options available for the installer. If you have automated the installing or upgrading of Tableau Server, be sure to review the current command line options for the Server Setup program. See [Changes to Command Line Install Options for Tableau Server Setup](#) for more information.

New tabcmd installer for Windows

The 2019.4 release of Tableau Server features a newly rewritten Setup program for installing tabcmd on Windows.

This update changes some of the command line options. If you have automated the installation of tabcmd, be sure to review the current command line options for the tabcmd Setup program. For more information, see [tabcmd and Install Switches and Properties for tabcmd \(Windows\)](#)

Updates to Tableau Server Job management

The Job management page has several updates and new options including the following:

- The **Jobs** page now includes **Average Run** and **Average Queue** time information for each job.
- Improved job cancellation experience. Server and Site admins can now enter customized notes as well as pick recipients of the e-mail when cancelling a job.

Tableau Server on Windows Help

- More information is provided in the job detail dialog box, such as: the last time the job was run successfully, and the name of the job creator.
- Canceling flow run jobs is now supported. Previously, in Tableau Server version 2019.3, only extract refreshes and subscriptions were supported.
- New **Task Type** has been added: Encryption jobs.
- Failed jobs now includes jobs that have been suspended. Suspended jobs are a sub-status of the failed jobs and have their own icon to distinguish them from other failed jobs.

For more information, see [Managing Background Jobs in Tableau Server](#).

Updates to tsm maintenance cleanup command

The `tsm maintenance cleanup` command now includes an option to clear the image cache.

In addition, the `--verbose` option has been removed from the command. Running the command with the `--verbose` option will result in an error. If your organization has automated task using the `tsm maintenance cleanup` command with the `--verbose` option, update your automation scripts.

Changed behavior for Copy Link when sharing a view

Beginning with version 2019.4, the behavior of the **Copy Link** option of the **Share** button in a view no longer includes the "embed=y" parameter by default. To include this parameter you need to edit the copied URL before adding it to your web page code. For more information sharing views by embedding them in web pages, see [Embed Views into Webpages](#) in the Tableau Desktop and Web Authoring Help. For details about the parameter, see [URL parameters for iframe tags](#) in the Tableau Desktop and Web Authoring Help.

Changed in 2019.3

Version 2019.3 includes the following changes you should know about before upgrading.

- Default cipher suite no longer includes default support for old ciphers
- Server Upgrade - Review What's Changed
- Upgrade without needing to provide a password
- Some tsm command options are no longer configurable

Default cipher suite no longer includes default support for old ciphers

The 2019.3 version of Tableau Server no longer includes default support for Triple-DES, IDEA, and CAMELIA ciphers for SSL connections. These ciphers are no longer considered adequately secure. In the previous versions of the Security Hardening Checklist, we included a recommendation to disable the Triple-DES cipher, which was enabled by default.

Depending on your environment, you may need to make additional configurations before our after upgrading:

- If you disabled the Triple-DES cipher as documented in the Checklist, then we recommend running the following commands before you upgrade to 2019.3:

```
tsm configuration set -k ssl.ciphersuite -d
tsm pending-changes apply
```

This command reverts Tableau Server to the 2019.2 (and older) default cipher suite configuration. After you have upgraded to 2019.3, Triple-DES, IDEA, and CAMELIA will be removed from the default supported ciphers.

Do not run the command if you made other changes to the `ssl_ciphersuite` key.

- If you did not change the `ssl_ciphersuite` key, then Setup will update the key value to the new default as part of the upgrade process. The new default value for the `ssl_ciphersuite` key is
`HIGH:MEDIUM:!aNULL:!MD5:!RC4:!3DES:!CAMELLIA:!IDEA:!SEED.`
- If your users still require support for Triple-DES, then we recommend upgrading to more recent browsers that support more secure ciphers. If that is not an option, then

Tableau Server on Windows Help

you can run the following commands after you have upgraded. The first command sets the `ssl_ciphersuite` key to the pre-2019.3 configuration, which supports Triple-DES:

```
tsm configuration set -k ssl.ciphersuite -v  
"HIGH:MEDIUM:!aNULL:!MD5:!RC4"  
  
tsm pending-changes apply
```

Usage data is sent to Tableau

Beginning with Tableau Server 2019.3, server usage data is sent to Tableau by default. This is the case for new installs and upgrades. You have the ability to opt out during installation, upgrade, or at any time after Tableau Server has been installed. For more information about usage data, see [Server Usage Data](#).

To disable the sending of server usage data:

- If you are installing Tableau Server for the first time, you can disable this feature during the configuration of initial node settings. For details, see [Configure Initial Node Settings](#).
- If you are upgrading Tableau Server, the `upgrade-tsm` script will let you know about the option and how to disable it.
- If you want to have installed or upgraded Tableau Server and want to disable the sending of server usage data, you can do this from the TSM Maintenance page, or from the command line. For details, see [Server Usage Data](#).

Upgrade without needing to provide a password

Beginning with Tableau Server 2019.3, when you upgrade from version 2019.2 or later, the `upgrade-tsm` script no longer requires you to specify a user and password. Version 2019.3 and later take advantage of the What's New and Changed in Tableau Server feature and uses the account you have logged in as to authenticate the upgrade. You can override this behavior with the `--user` option, to specify an administrative user. When you do this,

you can also provide a password using the `--password` option, or enter a password when prompted. Upgrades from versions earlier than 2019.2.0 will still prompt you for a password.

Some tsm command options are no longer configurable

Beginning with Tableau Server 2019.3, the following options are enabled on install and are no longer configurable:

- `backgrounder.enable_sort_jobs_by_job_rank`
- `backgrounder.enable_task_run_time_and_job_rank`

Changed in 2019.2

Version 2019.2 includes the following changes you should know about before upgrading.

- Minimum hardware requirements have changed
- Upgrade requires at least 15% free disk space on each node
- "Referrer-Policy" HTTP header added
- Map-related internet addresses have changed

Minimum hardware requirements have changed

Beginning with version 2019.2, Tableau Server requires a minimum of 4 cores and 16 GB of RAM in order to install. The installation program will check that the computer you are installing on satisfies these minimums before you can install. If the computer does not meet these hardware minimums, Tableau cannot be installed. For details, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#). For more information about this change, see this Tableau blog post: [Updated machine requirements for Tableau Server trials](#).

Upgrade requires at least 15% free disk space on each node

Upgrading to version 2019.2 includes a version update to the PostGRES database that Tableau uses internally. This update means that a backup of the database is done before

Tableau Server on Windows Help

upgrading, and that requires a minimum of 15% free space on each node.

"Referrer-Policy" HTTP header added

Beginning in 2019.2, Tableau Server includes the ability to configure Referrer-Policy HTTP header behavior. This policy is enabled with a default behavior that will include the origin URL for all "secure as" connections (policy no-referrer-when-downgrade). In previous versions, the Referrer-Policy header was not included in responses sent by Tableau Server. This change is not likely to impact user scenarios for most browsers. However, we recommend testing browser-based user scenarios after you upgrade to 2019.2. In the event a user scenario is effected, you can disable or change this header behavior. See HTTP Response Headers.

Map-related internet addresses have changed

Beginning in 2019.2, Tableau Server needs access using port 443 to two new map locations:

- mapsconfig.tableau.com
- api.mapbox.com

These replace the address used by previous versions: maps.tableau.com. For details on configuring Tableau Server for proper internet access, see [Configuring Proxies for Tableau Server](#).

Changed in 2019.1

Version 2019.1 includes the following changes you should know about before upgrading.

- High-resolution thumbnails
- Project card images

High-resolution thumbnails

In version 2019.1 and later, workbooks and views use higher resolution thumbnails. When you upgrade to Tableau Server version 2019.1 or later, the Backgrounder runs the Enqueue Thumbnails Upgrade job and the Upgrade Thumbnails job, which refreshes thumbnails for

any views that have not been edited or published since Tableau version 2018.2 and converts them from low resolution thumbnail images (192 x192 pixels) to high resolution thumbnail images (300 x 300 pixels), as shown in the figure below.

When the Upgrade Thumbnails job refreshes the thumbnail images, the modified date of the view is changed to match the thumbnail update date. The Upgrade Thumbnails job does not change the modified date of workbooks when it updates the contained view's thumbnails.

Thumbnails may appear blurry until the Upgrade Thumbnails job is complete. Depending on the number of workbooks you have, this could a few minutes to a few hours. You may also notice that thumbnail images may appear in low resolution for up to a week after upgrading to Tableau Server 2019.1. For more information, see [Upgrade Thumbnails Job](#).

Project card images

In version 2019.1 and later, project card images will not appear on the project card unless they are added as the last item in the project description and encapsulated with ! (exclamation marks). For more information, see [Add a Project Image](#).

Changed in 2018.3

Version 2018.3 includes some changes you should know about before upgrading.

Tableau Server on Windows Help

- Connecting to secondary trusted Active Directory domains may result in error
- Floating worksheet captions become transparent
- Changes to some Data Engine tsm configuration set options
- SSL Off-loading and SAML

Connecting to secondary trusted Active Directory domains may result in error

A secondary domain is one that Tableau Server connects to for user synchronization, but is a domain where Tableau Server is not installed. Tableau Server will attempt to connect to secondary domains for user and group synchronization. But in some cases, Tableau Server will be unable to connect to the secondary domain, which will result in the error, "Domain not in whitelist (errorCode=101015)."

Setting the `wgserver.domain.whitelist` option in TSM is required by a fix for the security vulnerability, [\[Important\] ADV-2020-003: Tableau Server Forced Authentication](#). As of February 2020, the fix for this vulnerability is included in all latest versions and maintenance releases of Tableau Server. See `wgserver.domain.whitelist`.

Floating worksheet captions become transparent

To make a floating caption visible again, content authors will need to change the caption background to a color.

Changes to some Data Engine tsm configuration set options

Two new configuration tsm set configuration options have been added: `hyper.hard_concurrent_query_thread_limit` and `hyper.soft_concurrent_query_thread_limit`

The new options replace the `hyper.num_job_worker_threads` and `hyper.num_task_worker_threads` options available in Tableau Server versions 2018.3 and earlier. The `hyper.num_job_worker_threads` and `hyper.num_task_worker_threads` have been deprecated and will no longer work in 2019.1 and later.

SSL Off-loading and SAML

Beginning with version 2018.3, Tableau Server validates SAML response message returned from the IdP. If your organization terminates SSL connections from the IdP at a proxy server before sending the authentication request to Tableau Server, then users may be unable to login with SAML after you upgrade from 2018.2.

In this scenario, SSL is "off-loaded" at the proxy server, which means the https request is terminated at the proxy server and then forwarded to Tableau Server over http. Since SSL is off-loaded at the proxy, Tableau Server will validate with the protocol that it receives (http), but the IdP response is formatted with https, so validation will fail unless your proxy server includes the X-Forwarded-Proto header set to `https`. See [Configure Tableau Server to work with a reverse proxy server](#).

Continue to Server Upgrade - Gather Configuration Details.

Server Upgrade - Gather Configuration Details

If you are running an in-place upgrade (you're not updating hardware as part of your upgrade), then nearly all the configuration data is preserved. Strictly-speaking, you do not need to gather all of the configuration information in this case. However, we recommend gathering the information as detailed in this topic. In the worse case scenario, should upgrade fail, then you will have a record of all configuration information should you need to restore. In any case, you can use the configuration details you collect to verify the upgrade when it's complete.

Take screen shots

A relatively quick way to capture the basics of your configuration is to take screen shots of the TSM web interface pages and the Tableau Server admin area.

Click through all visible pages and take screen shots:

- Sign in to Tableau Services Manager Web UI
- Sign in to the Tableau Server Admin Area

Tableau Server on Windows Help

Record object counts

When you are in Tableau Server admin area, count and record the following in each site:

- Projects, workbooks, views, data sources
- Users and groups

Gather asset files

Many of the supporting files (certificates, IdP metadata, logos, etc) that you upload to Tableau Server are not accessible with TSM after you upload them. Specifically, files that are uploaded and managed by the Client File Service are renamed and obfuscated before they are distributed across the deployment. This process also parametrizes the file attributes that are required by Tableau services. As a result, files are not mapped to a single file location on the file system for the following files. If you have uploaded any of the following files, be sure to have copies of them saved off of the computer that is running Tableau Server:

- SAML certificate file
- SAML key file
- SAML IdP metadata file
- The custom certificate installed by `tsm security custom-cert add`
- `OpenID.static.file`
- `Kerberos.keytab` file
- LDAP Kerberos keytab file
- LDAP Kerberos conf file
- Mutual SSL certificate file
- Mutual SSL revocation file
- Customization header logo file
- Customization sign-in logo file
- Customization compact logo file

Gather custom configuration information

Some configuration information is not displayed in the TSM or Tableau Server web pages. This section includes configuration details that you may need to gather depending on how you've customized your Tableau deployment.

Secure SMTP

If you have configured TLS for Tableau Server, then you will need to record the TLS-related configurations, which are not included in the **Email Server** configuration of the TSM Web UI.

To gather the TLS-related configurations, you must run `tsm configuration get` with the following key values:

- `svcmonitor.notification.smtp.ssl_enabled`
- `svcmonitor.notification.smtp.ssl_required`
- `svcmonitor.notification.smtp.ssl_check_server_identity`
- `svcmonitor.notification.smtp.ssl_trust_all_hosts`
- `svcmonitor.notification.smtp.ssl_ciphers`
- `svcmonitor.notification.smtp.ssl_versions`

For example, to retrieve the list of ciphers that are configured for SMTP TLS, run the following command:

```
tsm configuration get -k svcmonitor.notification.smtp.ssl_ciphers
```

You can find more information about each of the keys above in the TSM CLI section of [Configure SMTP Setup](#).

Analytics extensions

If you have configured analytics extensions (formerly referred to as "external services"), you will need to record your configuration information. Upgrading to Tableau Server 2020.2 or later will remove all configuration for this feature.

To retrieve the analytics extensions configuration from Tableau Server versions 2019.1 through 2020.1, run the following command:

```
tsm security vizql-extsvc-ssl list
```

To retrieve the password that is stored for the analytics extensions connection (if any), run the following `tsm` command:

Tableau Server on Windows Help

```
tsm configuration get -k vizqlserver.rserve.password
```

You should also have a copy of the certificate for analytics extensions if you've configured SSL.

External Repository

This applies only if you are using the External Repository configuration with Tableau Server. If you are not sure if this applies to you, see [Tableau Server External Repository](#).

Tableau Server 2021.4.x requires a major version change in PostgreSQL version for the repository, PostgreSQL version 12 or later. If your repository is local and installed on Tableau Server, the Tableau Server upgrade process will automatically upgrade the PostgreSQL database and there are no specific steps that you need to take. If however, you have configured the repository external to Tableau Server, there are some steps you must take prior to the upgrade as described below:

1. Create a new instance of PostgreSQL DB. For more information, see:
 1. [Create a PostgreSQL DB Instance on AWS Relational Database Service \(RDS\)](#)
 2. [Create a Azure Database PostgreSQL Instance on Azure](#)
2. Create a configuration file and download the SSL certificate file for the new instance that you created in Step 1. For more information, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

During upgrade, you will need to point Tableau Server to the new instance using the configuration file. The upgrade process will migrate the content from your current external repository to your new instance. For more details, see [Upgrade Tableau Server with External Repository for a New Major Version of PostgreSQL](#).

Port customization

If you have changed the dynamic port range or have configured ports manually for Tableau Server, record the changes you have made.

Run the following command:

```
tsm topology list-ports
```

For more information see Tableau Services Manager Ports.

Continue to .Server Upgrade - Verify Licensing Status

Server Upgrade - Verify Licensing Status

Prior to upgrading Tableau Server, review the product keys that are currently installed and compare them to the product keys, maintenance expiration, and license expiration end dates that are listed in the Tableau Customer Portal.

It is important that all expiration and end dates associate with product keys are up-to-date before you upgrade.

Step 1: View license expiration information.

Run the following command to view all licenses that are installed on your Tableau Server installation:

```
tsm licenses list
```

The `tsm licenses list` command returns all licenses, each with a number of fields. For upgrade, you need to make note of two fields:

- For each subscription license, make note of the date in the LIC EXP field. LIC EXP displays the date that the license expires and Tableau Server will stop working.
- For each legacy perpetual key, make note of the MAINT EXP field. MAINT EXP displays the date that the maintenance contract for the Tableau Server deployment expires.

Step 2: Compare license expiration dates from TSM to your licenses in [Tableau Customer Portal](#).

Step 3: If required, update licenses.

If your TSM maintenance date is not current or the expiration date will occur soon or is not the same as the date listed in the Tableau Customer Portal, refresh the license.

Tableau Server on Windows Help

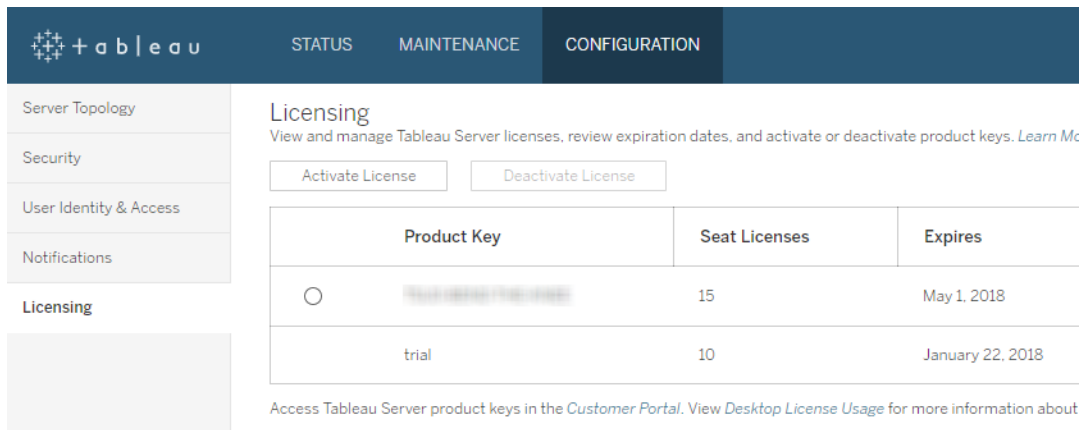

To refresh the license:

1. If the computer where you are running Tableau Server has been configured to connect to the internet through a forward proxy, follow the procedure in the topic, [Configure Product Key Operations with Forward Proxy](#), before continuing.

2. Open TSM in a browser:

`http://<tsm-computer-name>:8850`

3. Click **Configuration** and **Licensing** and click **Refresh All**:

The screenshot shows the Tableau Server Configuration interface. The top navigation bar includes 'STATUS', 'MAINTENANCE', and 'CONFIGURATION'. The 'CONFIGURATION' section is active, and the 'Licensing' sub-section is selected in the left-hand menu. The main content area displays the 'Licensing' page, which includes buttons for 'Activate License' and 'Deactivate License'. Below these buttons is a table with columns for 'Product Key', 'Seat Licenses', and 'Expires'. The table contains two rows: one for a product key with 15 seat licenses expiring on May 1, 2018, and another for a 'trial' key with 10 seat licenses expiring on January 22, 2018. At the bottom of the page, there is a note: 'Access Tableau Server product keys in the Customer Portal. View Desktop License Usage for more information about'.

Product Key	Seat Licenses	Expires
[Redacted]	15	May 1, 2018
trial	10	January 22, 2018

If this does not update the maintenance or expiration end date but the Tableau Customer Portal does show more current end dates, please contact [Tableau Technical Support](#).

Reactivating the product key will be part of the upgrade process.

Continue to Server Upgrade - Verify Accounts.

Server Upgrade - Verify Accounts

Before you upgrade Tableau Server, verify that you have passwords for two accounts:

- An account that is a member of the local administrators group: The account that you use to install Tableau Server must be a member of the local administrators group.
- Run As service account: If your organization uses Active Directory as the identity store and/or if you have configured Tableau Server to connect to data sources in Active

Directory, then it's a best practice to keep the Run As service account credentials at hand as you run upgrade.

Tableau Server Setup will not modify existing directory permissions during the upgrade process. But it's a best practice to verify any non-default permission configurations before you run Setup:

- If you have installed Tableau Server on to a non-default drive (default is typically `C:\Program Files`), then verify that permissions for the Run As service account are compliant with the required permissions specified in Installing in a non-default location.
- In addition, if you have scoped permissions on the computer running Tableau Server, verify that those permissions are compliant with the required directory permissions specified in Windows Accounts and Permissions.

Continue to Server Upgrade - Back Up Tableau Server.

Server Upgrade - Back Up Tableau Server

We recommend that you make a backup of your installation of Tableau Server before beginning the upgrade process. This provides data that you'll need to set up a test version of the upgraded environment. It also lets you recover if the upgrade process fails.

Notes:

- We recommend you disable subscriptions and scheduling in your production environment immediately before taking the backup, and reenabling them after the backup is complete. Doing this will help avoid having your users receive duplicate subscriptions and email messages when you restore your backup in your test environment.
- The full backup can take a while if you have a large installation or a lot of extracts.
- Any changes made between the time you took the backup and the time you do the upgrade are lost because they aren't included in the backup.
- Remove Unneeded Files.

Tableau Server on Windows Help

To back up server configuration data, use the `tsm settings` command. When you use the `tsm maintenance backup` command, the current date is appended to the backup file:

```
tsm maintenance backup -f <backup_file> -d
```

For more information, see `tsm maintenance backup`.

Continue to Server Upgrade - Download Setup.

Server Upgrade - Download Setup

You must download and copy the Tableau Server Setup program to the computer running Tableau Server. If you are running a multi-node deployment of Tableau Server, copy the Setup program to each node in the cluster.

To get the latest version of Tableau Server software, go to the [Customer Portal](#). When you purchase Tableau, you get a user name and password to sign in to the Customer Portal.

Important: Always download and install the latest maintenance release for the version you are upgrading to.

Continue to How Tableau Server Upgrade Works.

How Tableau Server Upgrade Works

When upgrading from Tableau Server 2018.2 or later, you do not uninstall the previous version. The upgrade process is designed to install a new version side-by-side with your existing version, and then switch from the earlier version to the later one.

When doing a TSM-to-TSM upgrade (version 2018.2.x to later version), you must leave your existing version in place and running until just before you upgrade using the upgrade script. If you uninstall your existing version before upgrading, you will not be able to upgrade. For your end-users, this has the impact of reducing downtime because you install your new version

while the existing version is running. The only time the server is not running is during the period the upgrade script is actually upgrading to the new version.

After installing the new version and upgrading, you can uninstall the previous version when you choose to do so. You can leave the older version installed indefinitely, though one reason you might choose to uninstall it is to free up disk space used by files specific to the older version. To understand the difference between uninstalling Tableau Server and completely removing all aspects of Tableau Server, see [Uninstall Tableau Server](#).

Upgrading Tableau Server requires a stop and start the server as part of the upgrade process. During this stop/restart Tableau Server is unavailable.

What's Changed - Things to Know Before You Upgrade

Beginning with version 2020.2, this topic has been merged with [What's New in Tableau Server](#), to provide a single location for new and changed features and behavior in Tableau Server. See [What's New and Changed in Tableau Server](#) for both new features and for changes introduced in this and earlier versions.

Note: Use [Tableau Release Navigator](#) to search for features in Tableau Desktop, Server, and Prep, or to see a full list of features when comparing your current version of Tableau to a later one.

Upgrading from 2018.2 and Later (Windows)

Follow the flow chart below and the linked topics to perform an in-place upgrade of Tableau Server.

Before you start the upgrade, make sure you have completed the Upgrade Preparation, For more details, see [Preparing for Upgrade](#).

If you are migrating Tableau Server to new hardware as part of your upgrade, see [Migrate to New Hardware](#).

Upgrading Tableau Server on Windows from version 2018.1 or older requires special steps

Tableau Server on Windows Help

that are documented separately. For instructions for how to upgrade from a pre-2018.2 version, see [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#).

This topic is part of the Tableau Server in-place upgrade scenario for upgrading from Tableau Server on Windows 2018.2 or later.

Support and services to help with Tableau Server upgrades

Tableau Server upgrades require planning and testing. Upgrades are generally done during times when users are not on Tableau Server. If you plan an upgrade over a weekend and anticipate needing Tableau Technical Support, see the [Technical Support Programs](#) information on the Tableau web site. Availability depends on the level of support you have. If you would like Tableau to assist with the planning and upgrading of your Tableau Server installation, see our [Tableau Global Services Server Upgrade](#) page for details.

Server Upgrade - Disable Scheduled Tasks

Though not strictly required, we recommend disabling scheduled tasks before you perform the upgrade.

Run the following procedure to disable all scheduled extract refreshes, flows, and subscriptions.

1. Sign in to the Tableau Server Admin Area as the Tableau Server administrator.
2. Go to the server-wide Schedules page:
 - On a Tableau Server where only a single (Default) site exists, click **Schedules** in the left pane.
 - On a Tableau Server with more than one site, click **Manage all sites** in the drop-down menu on the top of the left pane, and then click **Schedules**.
3. On the Schedules page, click **Select All**.
4. On the **Actions** menu, select **Disable**, and then click **Disable** in the resulting prompt.

Continue to: [Single-Server Upgrade -- Run Setup](#), or [Multi-node Upgrade -- Run Setup](#)

Single-Server Upgrade -- Run Setup

Upgrading Tableau Server on Windows from version 2018.1 or older requires special steps that are documented separately. For instructions for how to upgrade from a pre-2018.2 version, see [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#).

This topic is part of the Tableau Server in-place upgrade scenario for upgrading from Tableau Server on Windows 2018.2 or later.

Run Setup

Follow these steps to upgrade a single-node installation of Tableau Server version 2018.2 or later.

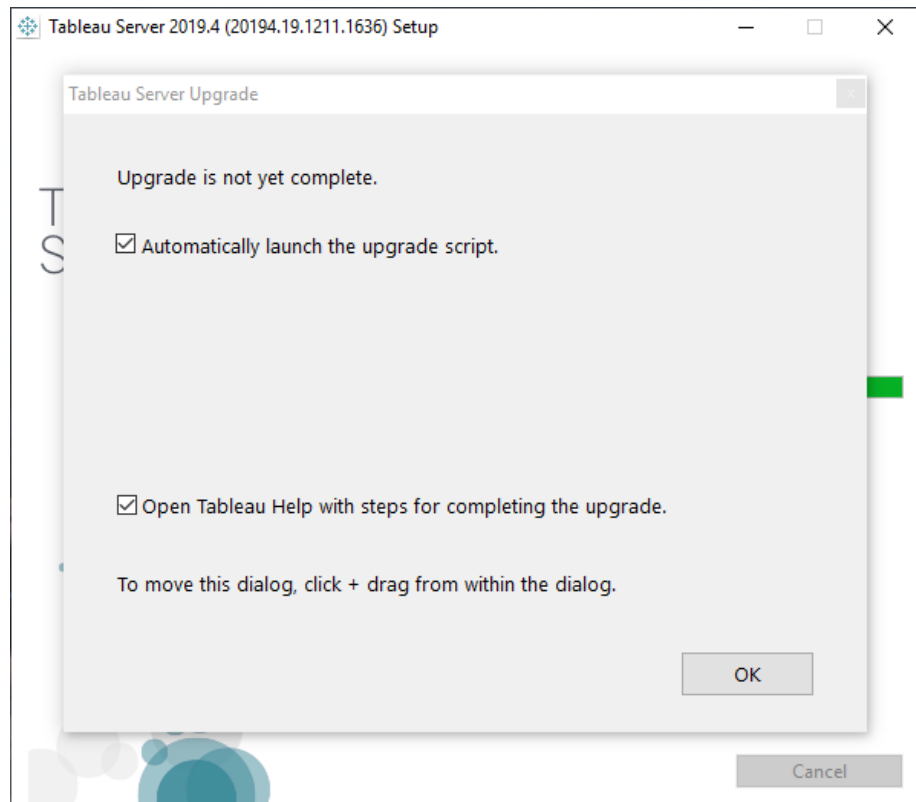

1. Log onto the computer with an account that is a member of the local administrators group.
2. Navigate to the folder where you copied the Tableau Server Setup program and run it.
3. The Setup program checks system resources to confirm that the computer satisfies the minimum requirements and recommendations.
4. The Setup program displays the location of your existing version and will install the new version side-by-side in the same location. You cannot change the location.
5. When the installation is done, the last page of the Setup program tells you that the upgrade is not yet complete. You need to run an upgrade script, `upgrade-tsm`, to complete the upgrade. If Tableau Server is running, the script will let you know, and will offer to stop it. Tableau Server must be stopped to complete the upgrade.

Note: Beginning in version 2020.4.0, if the upgrade script fails, details about the failure display in the command window and you can rerun the script to try the upgrade again. The script restarts at the point it failed. This saves time and is a good first step if your upgrade fails. For more information, see [Upgrade fails on 2020.4.0 or later](#).

Run the upgrade script in one of two ways.

Tableau Server on Windows Help

- From the Setup program:
 - a. Select **Automatically launch the upgrade script**, and click **OK**:

- b. A command window will open for the script. Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password.

Clicking **OK** will close the Setup program dialog. If you cleared the option to automatically launch the upgrade script, you will need to run the script manually, from the command line.

- On the command line:

- a. On the initial node, open a command prompt as administrator.

You must open a new command window because the Setup program updates the path for the new installation.

- b. Navigate to the scripts folder for your new installation.

By default:

```
C:\Program Files\Tableau\Tableau Server-
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password when you run the script using `--username` and `--password` options.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

6. Start Tableau Server. You can do this from the TSM web UI or from a command prompt:

- In TSM, click **Tableau Server is stopped**, and **Start Tableau Server**:

Tableau Server on Windows Help

- From a command prompt:
 - a. Open a new command prompt as administrator.
 - b. Enter this command:

```
tsm start
```

If you get an error that the command is not recognized, close all command windows and then open a command prompt as administrator.

7. The upgrade process leaves your existing folders in place. You can identify these by the version code. For example:

```
C:\Program Files\Tableau\Tableau Server\packages\
```

Continue to Verify Tableau Server Upgrade.

Multi-node Upgrade -- Run Setup

Upgrading Tableau Server on Windows from version 2018.1 or older requires special steps that are documented separately. For instructions for how to upgrade from a pre-2018.2 version, see [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#).

This topic is part of the Tableau Server in-place upgrade scenario for upgrading from Tableau Server on Windows 2018.2 or later.

Run Setup

1. Log onto the initial node with an account that is a member of the local administrators group.
2. Navigate to the folder where you copied the Tableau Server Setup program and run it. This will install the new version of Tableau Server side-by-side with your existing, running version.
3. The Setup program checks system resources to confirm that the computer satisfies

the minimum requirements and recommendations.

4. The Setup program displays the location of your existing version and will install the new version side-by-side in the same location. You cannot change the install location.
5. When the installation is done on the initial node, the last page of the Setup program tells you that the upgrade is not yet finished. You need to run an upgrade script to complete the upgrade. Leave the Setup window open on the initial node and continue with your installation on all other nodes in the cluster.

Important: You *must* install the new version on every node before you run the upgrade script. *Do not run the upgrade script* until after you have installed the new version on all nodes in your cluster.

Continue to Multi-node Upgrade -- Run Setup on Each Node.

Multi-node Upgrade -- Run Setup on Each Node

Upgrading Tableau Server on Windows from version 2018.1 or older requires special steps that are documented separately. For instructions for how to upgrade from a pre-2018.2 version, see [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#).

This topic is part of the Tableau Server in-place upgrade scenario for upgrading from Tableau Server on Windows 2018.2 or later.

Run Setup

On each additional node, navigate to the folder where you copied the Tableau Server Setup program and run the Setup program as you did on the initial node. This will install the new version of Tableau Server on each node, side-by-side with your existing, running version.

When the installation is done on each additional node, the last page of the Setup program tells you that the upgrade is not yet finished. Make sure **Automatically launch the**

upgrade script is *not* selected, and click **OK** to close the Setup window. You will run the upgrade script after the new version is installed on all nodes.

Continue to Multi-node Upgrade -- Run Upgrade Script.

Multi-node Upgrade -- Run Upgrade Script

Upgrading Tableau Server on Windows from version 2018.1 or older requires special steps that are documented separately. For instructions for how to upgrade from a pre-2018.2 version, see [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#).

This topic is part of the Tableau Server in-place upgrade scenario for upgrading from Tableau Server on Windows 2018.2 or later.

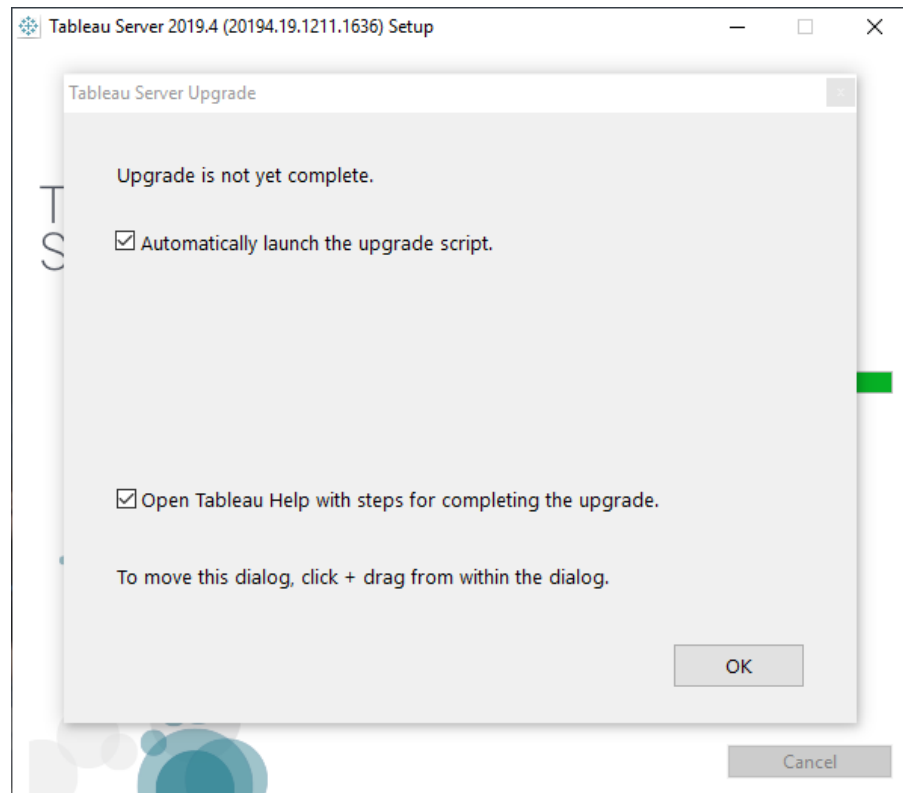

Run Upgrade script

1. After you have installed the new version on *every node in the cluster*, run the upgrade script on the initial node. If Tableau Server is running, the script will let you know, and offer to stop it. Tableau Server must be stopped to run the upgrade script.

If the final Setup screen is still open, you can select **Automatically launch the upgrade script** and a command window will open to run the script. Alternately, you can run the script directly from a command prompt.

Note: Beginning in version 2020.4.0, if the upgrade script fails, details about the failure display in the command window and you can rerun the script to try the upgrade again. The script restarts at the point it failed. This saves time and is a good first step if your upgrade fails. For more information, see [Upgrade fails on 2020.4.0 or later](#).

- To run the upgrade script from the Setup program:
 - a. Select **Automatically launch the upgrade script** and click **OK**:

- b. A command window will open for the script. Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password.

Clicking **OK** will close the Setup program dialog. If you cleared the option to automatically launch the upgrade script, you will need to run the script manually, from the command line.

- To run the upgrade script from a command prompt:

Tableau Server on Windows Help

- a. Open a command prompt as administrator.

You must open a new command window because the Setup program updates the path for the new installation.

- b. Navigate to the scripts directory for the new version you just installed.

By default:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password using the `--user-name` and `--password` options.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

The upgrade script will take some time to complete.

2. When the upgrade script completes, start Tableau Server. You can do this from the TSM web UI or from a command prompt:

- In TSM, click **Tableau Server is stopped**, and **Start Tableau Server**:

- From a command prompt:
 - a. Open a new command prompt as administrator.
 - b. Enter this command:

```
tsm start
```

Continue to Verify Tableau Server Upgrade.

Verify Tableau Server Upgrade

Work through the sections of this topic to verify if server upgrade was successful.

Verify Tableau Service processes

Start your verification process by signing into TSM with the command line and verifying the status of Tableau Server processes.

1. Open a new command prompt as a user with administrator access.

For more information on using the tsm command line, see Using the tsm CLI.

2. Run the following command to view the status of all the Tableau Server processes:

```
tsm status -v.
```

What if I get an access denied error when I attempt to run TSM commands?

Tableau Server on Windows Help

Verify that the account you are using is a member of the Local Administrators group on the Windows computer where you are installing Tableau Server.

Verify TSM global settings

As part of the preparation for upgrade, you should have taken screen shots of the TSM web UI settings. Sign in to Tableau Services Manager Web UI and compare the settings with the screen shots.

Enable subscriptions and scheduling

1. Sign in to the Tableau Server Admin Area as the Tableau Server administrator.
2. Go to the server-wide Schedules page:
 - On a Tableau Server where only a single (Default) site exists, click **Schedules** in the left pane.
 - On a Tableau Server with more than one site, click **Manage all sites** in the drop-down menu on the top of the left pane, and then click **Schedules**.
3. On the Schedules page, click **Select All**.
4. On the **Actions** menu, select **Enable**, and then click **Enable** in the resulting prompt.

Verify user access

With a user account, sign in to Tableau Server with Tableau Desktop and a browser.

If Tableau Server is available from outside your organization, verify connectivity from the internet.

If your organization supports mobile connectivity to Tableau Server, sign in to server with a mobile device.

View published workbooks

With a user account, sign in to Tableau Server and browse published workbooks. Open workbooks to view them in a browser

Verify publishing workbooks and data sources

Using an account with a Creator license, verify web authoring functionality to connect to data, and to create and publish workbooks and data sources:

- [Connect to Data on the Web](#)
- [Publish a Data Source on the Web](#)
- [Upload Workbooks to a Tableau Site](#)

Verify Tableau Prep Builder

If your organization is running Tableau Prep Builder, verify that you can connect to data, open a flow, and other Prep tasks. See [Tableau Prep: Connect to Data](#).

Verify count of Tableau objects

As part of upgrade preparation, you should have noted how many projects, workbooks, views, data sources, users, and groups are in your deployment. Verify that all objects still appear.

Sign in to the Tableau Server Admin Area as the Tableau Server administrator.

- Verify count of projects, workbooks, views, data sources
- Verify count of users and groups

Verify API functionality

If your organization has deployed or developed content with Tableau APIs, verify that these are operational.

REST API

Verify REST API access and authentication by running the sample cURL from [Get Started Tutorial: Introduction and Set Up](#):

```
curl "https://MY-SERVER/api/3.8/auth/signin" -X POST -d
@signin.xml
```

Content of signin.xml:

Tableau Server on Windows Help

```
<tsRequest>
  <personalAccessTokenName="MY_PAT_NAME"
    <credentials name="username" password="password" >
      <site contentUrl="MarketingSite" />
    </credentials>
  </tsRequest>
```

Example response:

```
<tsResponse version-and-namespace-settings>
  <credentials token="12ab34cd56ef78ab90cd12ef34ab56cd">
    <site id="9a8b7c6d-5e4f-3a2b-1c0d-9e8f7a6b5c4d"
      contentUrl="MarketingSite"/>
  </credentials>
</tsResponse>
```

Compatibility testing

For other developed features, perform compatibility testing to verify that the upgraded version of Tableau Server operates as expected with your existing solutions:

- Dashboard Extensions
- JavaScript API for embedded Tableau
- Connectors (Web Data Connector, Tacos)

Go to [Post Upgrade Cleanup](#).

Post Upgrade Cleanup

As discussed in [How Tableau Server Upgrade Works](#), the Tableau Server upgrade process installs a new version side-by-side with your existing version. Now that upgrade is complete and verified, you can remove the older version of Tableau Server to free up disk space. This is an optional step.

Uninstall previous version

To uninstall a version of Tableau Server:

1. Open Control Panel, click **Uninstall a program**, and locate the version you want to uninstall.

Be sure you select the correct version to uninstall:

- Uninstalling previous versions of Tableau Server does not impact the running version and simply removes unnecessary files from those previous versions.
- **Do not** uninstall the current, running version. Uninstalling the current, running version of Tableau Server stops server and removes server-specific files and folders, but may leave some elements behind. Uninstalling does not create a backup of your repository data.

2. With the Tableau Server version selected, click **Uninstall**.

Delete 'Tableau Server' folders from `\packages` directory

After an upgrade, you will see multiple versions of Tableau Server folders in the `\packages` folder. When the upgrade is completed successfully, you can delete the folders related to the older version you upgraded from. You can identify these by the version code in the folder name. For example, `scripts.<version_code>`. For more information about version codes, see [View Server Version](#).

Perform the Upgrade

Unsupported Versions

- This topic may refer to Tableau Server versions that have gone out of support. The information here is no longer being maintained and may be out of date, but is being left in place for customers who are still running these older versions. For details on which versions are supported, see the bottom of this [Technical Support Programs](#) page: <https://www.tableau.com/support/services>.
- This topic refers to versions of Tableau Server that are no longer available. Downloads of versions prior to 2020.4 have been removed due to the security issues

currently identified in [CVE-2021-44228](#) and [CVE-2021-45046](#). In order to address these security issues, you must update to the newest version of your desired Tableau product. For more information please see the [Knowledge Article, Apache Log4j2 vulnerability \(Log4shell\)](#).

Performing the upgrade

After you've completed the tasks in Prepare for the Upgrade - Pre-tsm (Windows), you're ready to upgrade your existing Tableau Server installation to version 2018.2 or later.

The steps you follow depend on the install location of your existing pre-TSM Tableau Server on Windows installation:

- Default install location

If you are upgrading from Tableau Server on Windows version 2018.1 or earlier installed in the default location, see Upgrade from Tableau Server 2018.1.x or Earlier (Windows). Upgrading from a pre-TSM version of Tableau Server requires special steps that are explained in that topic.

- Non-default install location

When you are upgrading from 2018.1.x or earlier in a non-default location, you need to specify the location during the upgrade. How you do this depends on the version you are upgrading to:

- Version 2018.2.0 through 2019.3.x—If you are upgrading to version between 2018.2.x and 2019.3.x in a *non-default* location, you need to navigate to the location during the upgrade. This way, data and configuration settings from your earlier version can be automatically imported. For detailed steps, see the [2019.3 Server Administrator Help for upgrades](#). (Opens the 2019.3 Help in a new window.)
- Version 2019.4.0 or later—If you are upgrading to version 2019.4.0 or later in a *non-default* location you need to take special steps to specify the location. For

detailed instructions, see Upgrade from Tableau Server 2018.1.x or Earlier in a Non-Default Location (Windows).

- If you are migrating to new hardware as part of your upgrade, refer to Migrate to New Hardware instead.

Note: When upgrading from a pre-TSM version of Tableau Server (a version earlier than 2018.2.0), the uninstall of Tableau creates a server backup file in the data directory. This backup file has a `.tsbak` extension and is required for the upgrade. *After* you upgrade successfully, you can safely delete this file to free up space (make a copy on a computer that is not part of your Tableau Server installation in case you need the file for any reason). Do not delete this file until you have completed the upgrade and know it is working.

As a best practice, you should *always* make a backup of your Tableau Server data before upgrading, and save this backup in a safe place that is not part of your Tableau installation. Do this even though the process of uninstalling your pre-TSM version will create a backup. This guarantees you have access to your Tableau data if something unexpected happens during the upgrade, or if you need to go back to your previous version of Tableau Server.

Prepare for the Upgrade - Pre-tsm (Windows)

To properly prepare to upgrade from Tableau Server on Windows 2018.1 or earlier to version 2018.2 or later, gather the following information about your existing installation, key files related to your installation and the upgrade, and complete the pre-upgrade tasks.

Unsupported Versions

- This topic may refer to Tableau Server versions that have gone out of support. The information here is no longer being maintained and may be out of date, but is being left in place for customers who are still running these older versions. For details on which versions are supported, see the bottom of this Technical Support Programs

Tableau Server on Windows Help

page: <https://www.tableau.com/support/services>.

- This topic refers to versions of Tableau Server that are no longer available. Downloads of versions prior to 2020.4 have been removed due to the security issues currently identified in [CVE-2021-44228](#) and [CVE-2021-45046](#). In order to address these security issues, you must update to the newest version of your desired Tableau product. For more information please see the [Knowledge Article, Apache Log4j2 vulnerability \(Log4shell\)](#).

Gather custom configuration information

If you are upgrading on the existing hardware your configuration will be preserved, but it's a good practice to collect this configuration information about your existing installation for several reasons: you need this information when you configure a test environment, you need this information if you are migrating to new hardware migration as part of the upgrade, and you can use the information to confirm that the upgraded Tableau Server is configured as expected if you notice something unexpected after upgrading.

Collect this information and any associated files and save them to a location that is not on any of the Tableau Server computers.

The following list includes examples of the type of information you should gather:

- **Customizations** This includes non-default ports, timeout values, custom logo images, and fonts.

Also make a note of Windows path environment variables that affect Tableau Server.

- **SMTP** configuration.

For pre-TSM versions of Tableau Server (versions 2018.1 or earlier), you can see your current SMTP configuration on the **SMTP Setup** tab of the Configuration utility.

- **SSL** configuration and certificates.

For pre-TSM versions of Tableau Server (versions 2018.1 or earlier), you can see your SSL configuration on the **SSL** tab of the Configuration utility. This tab also lists the location of the certificate and certificate key files. You should copy and save these files in a safe location.

- **SAML** configuration, certificates and any IdP metadata files.

For pre-TSM versions of Tableau Server (versions 2018.1 or earlier), you can view your current SAML configuration on the **SAML** tab of the Configuration utility, including the certificate, key, and metadata files. Save copies of these files to a safe location.

- **Kerberos** configuration.

For pre-TSM versions of Tableau Server (versions 2018.1 or earlier), you can see your current Kerberos configuration on the **Kerberos** tab of the Configuration utility, including the location of the keytab file you should copy and save.

- **OpenID** configuration.

For pre-TSM versions of Tableau Server (versions 2018.1 or earlier), you can find your current OpenID configuration details on the **OpenID** tab of the Configuration utility.

- **Additional node** configurations. Collect the configurations of any additional Tableau Server nodes, including any certificates or other supporting files that you copied to these nodes.

For pre-TSM versions of Tableau Server (versions 2018.1 or earlier), you can find detailed information about the number of processes configured on each node on the **Servers** tab of the Configuration utility.

- **Other** values. Note the number of projects, groups, workbooks, views, data sources, and users you have in your production environment. Having this information makes it easy to do a quick check after the upgrade to make sure everything was restored as

expected.

Gather the environment configuration

The steps you need to take during the upgrade process depend on whether you're installing the upgrade on the same hardware or you're migrating to new hardware. Upgrading on the same hardware is straightforward and requires a minimum of manual steps (the steps you need to take depend on what version you are upgrading from, what version you are migrating to, and whether or not your existing installation is in the default location). Migrating to new hardware requires you to manually restore your Tableau Server data and reconfigure your settings after you install the new version.

Copy the setup files to a local file share

You will need the following setup files before you upgrade Tableau Server:

- The Setup program for your existing version of Tableau Server.

You might not need the Setup program. However, we recommend that you have it available in case there's a problem during the upgrade. That way you can use the setup program and your server backup to restore your installation to its pre-upgrade state.

Note: If you do not have the Setup program for your existing version, you can download it from the [Alternate Downloads Site](#). Save the Setup program in a safe location that is not part of your production or test version of Tableau Server. You will need the Setup program if you need to go back to your existing version after upgrading.

- The setup program for the new version of Tableau Server.

Update tabcmd

A new version of tabcmd is released with every release of Tableau Server. If you install tabcmd on computers that are not part of your Tableau Server installation, you need to update tabcmd on those computers as part of your upgrade process. For more information, see tabcmd.

Back up Tableau Server data

Make a backup of your installation of Tableau Server before beginning the upgrade process, and save the backup file to a safe location (a network share for example). Do not save it on any computer that is part of the Tableau Server installation. This backup provides data that you'll need to set up a test version of the upgraded environment. It also lets you recover if the upgrade process fails.

Notes:

- We recommend you disable subscriptions and scheduling in your production environment immediately before taking the backup, and reenabling them after the backup is complete. Doing this will help avoid having your users receive duplicate subscriptions and email messages when you restore your backup in your test environment.
- The full backup can take a while if you have a large installation or a lot of extracts.
- Any changes made between the time you took the backup and the time you do the upgrade are lost because they aren't included in the backup.
- You can only restore from a backup that has the same type of identity store as the running server. For example, a backup from a server using local authentication can be restored to a Tableau Server initialized with local authentication, but a backup from a server using Active Directory authentication cannot be restored to a server initialized with local authentication.

Tableau Server on Windows Help

Save your asset keys file before uninstalling Tableau Server for Windows 2018.1.x or earlier

If you are upgrading from Tableau Server on Windows version 2018.1.x or earlier, and you generated a custom asset key, save a copy of the `asset_keys.yml` file before you uninstall your earlier version. Store this file in a safe place that is not part of your Tableau Server installation (a network share for example).

In most cases you will not need this file. The upgrade process updates asset keys automatically when an upgrade is successful. You only need this file if the upgrade fails and you need to install a new version of Tableau Server and manually restore your backup file. In this case, you also need to specify the asset keys file when doing the restore.

Locating an existing asset keys file

If you generated a custom asset key file, you will have an `asset_keys.yml` file in the data directory. By default this is:

```
\ProgramData\Tableau\Tableau Server\data\tabsvc\config
```

If you do not see an `asset_keys.yml` file, you can skip this.

Restoring a pre-2018.2 Tableau Server for Windows backup and specifying an asset keys file

To manually restore a backup from Tableau Server 2018.1.x on Windows or earlier to Tableau Server 2018.2 or later, and include asset keys, use `tsm`, for example:

```
tsm maintenance restore --file <backup> --ak <asset_key_file>
```

For more information, see `tsm maintenance restore`.

Check your product maintenance status

If you attempt to upgrade a Tableau Server installation that has a product key with expired maintenance, your upgraded Tableau Server will be unlicensed and the upgrade may fail. Before upgrading, make sure that the server's maintenance hasn't expired.

If your maintenance has expired, select the product key and then click **Refresh**. If this does not update the maintenance date, check the Tableau Customer Portal for a replacement

Tableau Server product key with a later maintenance date. For any questions or concerns, please contact [Tableau Technical Support](#). Reactivating the product key will be part of the upgrade process.

For more information, see [Activate and Register Tableau Server](#). If your server doesn't have internet access, see [Activate Tableau Server Offline - Adding a License](#).

Important: If you are upgrading from Tableau Server version 2018.1 or earlier, make sure the Manage Product Keys application is closed before you uninstall Tableau. Leaving it open may result in a failed upgrade.

Disable your extract refreshes

Beginning in 10.5, extracts use .hyper format instead of .tde. Once the file format has been upgraded to .hyper, it cannot be reverted back to .tde format and cannot be opened in Tableau Desktop version earlier than 10.5. For more information, see [Extract Upgrade to .hyper Format](#).

The following tasks on Tableau Server will upgrade a .tde extract to a .hyper extract:

- Manual refresh
- A scheduled full or incremental extract refresh
- Automated refresh tasks that are performed through tabcmd, Extract API 2.0, or through Extract Command Line Utility
- Automated append data to an extract using tabcmd or using the Extract Command Line Utility

Note: We recommend that you disable any automated tasks and schedules that result in an extract upgrade. If you have desktop versions that have not yet been upgraded to

10.5, your desktop users will not be able to open the upgraded .hyper extracts. You may also want to first test a few extracts manually after doing the server upgrade, and then reenable any schedules or automated refresh tasks.

For more information about extract refresh scheduling, see [Enable Extract Refresh Scheduling and Failure Notification](#).

Ensure that your license has enough user capacity

When upgrading from a Tableau 2018.1 or earlier license with legacy site roles, all users are automatically mapped to their current equivalent site role. Before upgrading, it's important to make sure that your new license supports the number of users you have. Otherwise, some users may become unlicensed after the upgrade.

The following table shows the mapping of the legacy site roles to the current site roles.

2018.1 legacy site role	2018.1 user-based site role	2018.2 and later site role
Server Administrator	Server Administrator	Server Administrator
Site Administrator	Site Administrator Explorer	Site Administrator Explorer
Publisher	Explorer (can publish)	Explorer (can publish)
Interactor	Explorer	Explorer
Viewer	Read Only	Viewer

Users always use the highest level role they have on any site, which is called the Maximum Site Role. You can view the Maximum Site Role is for users before you convert your license. For more information, see [Permissions](#).

If you have more users than licenses for your current roles, you should reallocate or balance users to the available roles by changing their role, unlicensing users, or moving users. You

can use the following steps to synchronize groups of new users after upgrading to 2018.2 or later:

1. Unlicense all users.
2. Create five Active Directory (AD) groups (one for each site role).
3. Import users into the correct AD group for the appropriate site role, and then sync those groups with Tableau Server. For more information, see [Create Groups via Active Directory](#).
4. Restart Tableau Server. Users are automatically migrated into their new site roles. Content permissions are not affected.

Plan your strategy if you use virtual machines (VMs)

If you run Tableau Server on VMs, either locally, or in the cloud, be aware of the potential for complications related to licensing. If you are simply upgrading Tableau Server on the VM, you do not need to take any extra action related to licensing. If you plan to clone the VM to create either a new production or test environment to upgrade, you need to deactivate any Tableau Server licenses before cloning. If you do not do this, the new VM environment can end up with an untrusted license, and any attempts to upgrade will fail. You may also end up hitting the maximum number of activations for the licenses.

To avoid issues with licensing on VMs, deactivate all Tableau licenses before cloning a VM or allowing it to be permanently shut down.

To clone a VM, make sure Tableau is unlicensed (all licenses are deactivated) before cloning. After cloning the VM, activate a Tableau license there and proceed with the upgrade. If you have role-based licensing, be sure that the first license you activate is a Creator or Explorer license, or you may lose administrator access to your new Tableau installation.

Upgrade from Tableau Server 2018.1.x or Earlier (Windows)

This topic applies to upgrades of Tableau Server on Windows with these specific characteristics:

Tableau Server on Windows Help

- You are currently running Tableau Server 2018.1.x or earlier
- You are upgrading to version 2019.4.0 or later
- Tableau Server is installed to the default location

Or

- You are currently running Tableau Server 2018.1.x or earlier
- You are upgrading to version 2019.4.5 or later
- Tableau Server is installed to the default location or to a non-default location

If your deployment does not meet these criteria, see [Upgrade Tableau Server Overview](#) to determine the correct instructions for your upgrade.

Beginning with version 2018.2, Tableau Server on Windows is available with Tableau Services Manager (TSM). TSM is the web-based server configuration and management utility that replaces the Server Configuration utility and the `tabadmin` command line utility. The Tableau Server upgrade process has changed with the introduction of TSM. For information on how upgrade has changed, see [Upgrade process changes](#).

When you upgrade from a pre-TSM version of Tableau Server (2018.1 or earlier) to a version running with TSM, you need to go through some special upgrade steps. *These are required only for the pre-TSM to TSM upgrade.* Pre-TSM versions of Tableau Server on Windows are versions older than 2018.2. Examples of pre-TSM versions are 9.3, 10.5, and 2018.1. For instructions on how to determine your version of Tableau Server, see [View Server Version](#).

Unsupported Versions

- This topic may refer to Tableau Server versions that have gone out of support. The information here is no longer being maintained and may be out of date, but is being left in place for customers who are still running these older versions. For details on which versions are supported, see the bottom of this [Technical Support Programs](#) page: <https://www.tableau.com/support/services>.
- This topic refers to versions of Tableau Server that are no longer available. Downloads of versions prior to 2020.4 have been removed due to the security issues

currently identified in [CVE-2021-44228](#) and [CVE-2021-45046](#). In order to address these security issues, you must update to the newest version of your desired Tableau product. For more information please see the [Knowledge Article, Apache Log4j2 vulnerability \(Log4shell\)](#).

Upgrading to Server with Tableau Services Manager (TSM)

Beginning with version 2018.2, Tableau Server on Windows now uses Tableau Services Manager (TSM). TSM is the web-based server configuration and management utility that replaces the Server Configuration utility and the tabadmin command line utility. The Tableau Server upgrade process has changed with the introduction of TSM. For details about how upgrade has changed, see Upgrade process changes.

When you upgrade from a pre-TSM version of Tableau Server (2018.1 or earlier) to a version running with TSM, you need to go through some special upgrade steps. *These are required only for the pre-TSM to TSM upgrade.* Pre-TSM versions of Tableau Server on Windows are versions older than 2018.2. Examples of pre-TSM versions are 10.5 and 2018.1. For instructions on how to determine your version of Tableau Server, see View Server Version.

Watch a video:

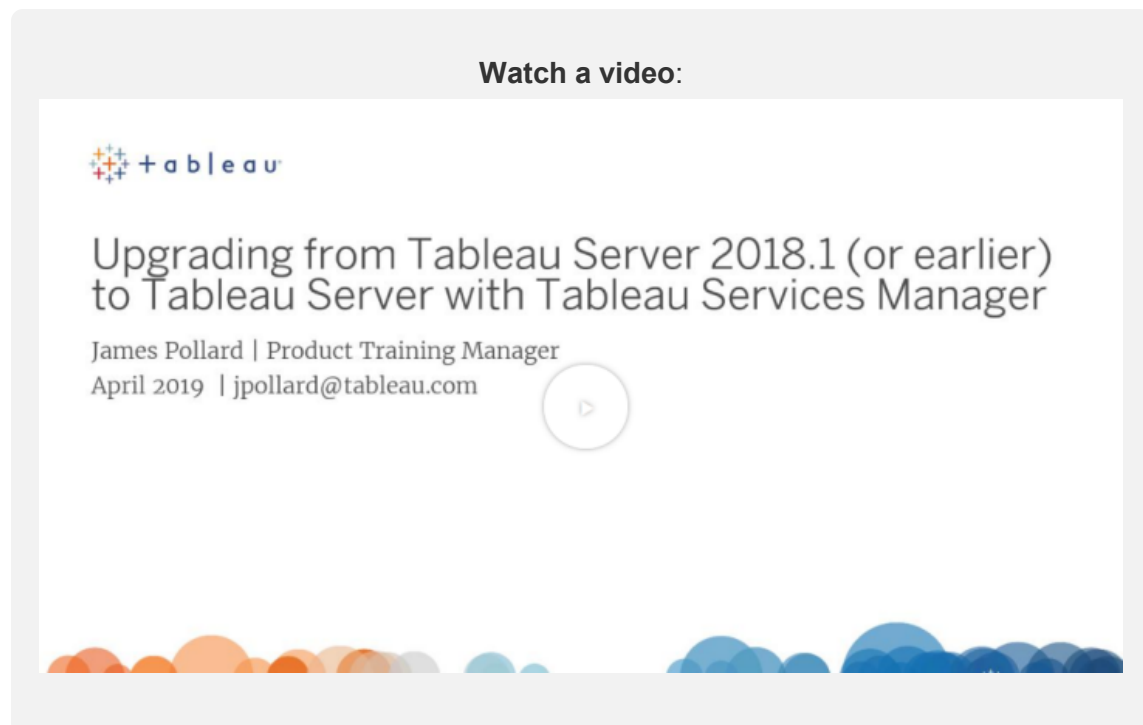

Tableau Server on Windows Help

Before you upgrade

Upgrading a server-based product requires planning and preparation. Upgrading Tableau Server from version 2018.1 or earlier to version 2018.2 or later is no different. Before you upgrade your production environment, make sure you have read through and completed the following sections: [Upgrades \(Tableau Blueprint\)](#) , Preparing for Upgrade, and Verify Tableau Server Upgrade.

As a best practice, you should *always* make a backup of your Tableau Server data before upgrading, and save this backup in a safe place that is not part of your Tableau installation. This backup preserves your Tableau data if something unexpected happens during the upgrade, or if you need to go back to your previous version of Tableau Server. For more information, see [Back up Tableau Server data](#).

Key Upgrade Aspects

Understand the key aspects of upgrading to TSM

Below are key aspects of upgrading Tableau Server from version 2018.1 or earlier to version 2018.2 or later that you need to be aware of.

All upgrades:

- **Local administrator**—Sign in as a local administrator. You need to be signed into the Tableau Server computer as a "local admin" to run the Tableau Server Setup program, and to run scripts related to upgrading. A "local admin" is a user who's a member of the Administrators group in the Local Users and Groups management console in Windows.
- **Local security policy**—Verify that your local security policy will allow "log on as a service" and "log on locally" permissions for the Run As service account. For details, see [Verify the Local Security Policy](#).
- **Run As**—Read and understand these Run As service account requirements:

Required Run As Service Account Settings.

- **Windows Accounts and Permissions**—Read and understand these Windows account requirements: Windows Accounts and Permissions.
- **Ports**—Before upgrading, read and understand the requirements for ports: Tableau Services Manager Ports.
- **Licenses**—
 - **Trial product keys**—You cannot directly upgrade a server that is running a trial product key from one major version to another (for example, from version 10.5.x to version 2018.x). To upgrade from one major version to another with a trial product key, install the new version of Tableau Server on a separate machine, activate a trial key there, and restore a backup from your existing version. For more information, see Server Upgrade - Verify Licensing Status.
 - **Expired maintenance**—You cannot upgrade a server with a product key whose maintenance has expired or expires on a date earlier than the release date of the version you are upgrading to. If you attempt to upgrade a server in this state, your server will be unlicensed and the upgrade may fail. If your maintenance has expired or is too old, use the **Manage Product Keys** application to refresh your product key *before* you uninstall your original version. If refreshing the key does not update maintenance to a valid date, check in the Tableau Customer Portal for a Tableau Server key with current maintenance.
- **Uninstall**—Use Windows Control Panel to uninstall your existing pre-TSM version of Tableau Server before upgrading. This special-case upgrade is unlike upgrades in earlier versions, which automatically uninstalled the previous version of Tableau Server. When you upgrade from version 2018.1 or earlier to version 2018.2 or later, you *must uninstall* your earlier version yourself. If you have not uninstalled your earlier version, you will be prompted to do so when you attempt to install your new version. This is specific to upgrades from 2018.1 or earlier to 2018.2 or later.
- **Backup**—Save a backup of your earlier version to a safe place on a different

computer. Uninstalling your previous version of Tableau Server will create a backup in the Tableau data directory (by default: `C:\ProgramData\Tableau\Tableau Server`). We **strongly** recommend you copy this backup to a computer that is not part of your Tableau Server installation before upgrading. This provides you with an up-to-date version of your data you can use if you need to go back to your earlier version of Tableau Server. For more information on properly preparing for an upgrade, see [Preparing for Upgrade](#).

Backups from versions of Tableau Server older than version 9.x cannot be used with version 2018.2.x or later. If you are running an older version of Server, you may need to do an intermediate upgrade to version 9.x through 10.x before upgrading to version 2018.2 or later.

- **Firewall management**—Firewall management is manual. Unlike earlier versions of Tableau Server, you must manage the local firewall on any computers where you run Tableau Server. For more information, see [Local firewall configuration](#).
- **Upgrade script**—After installing the new version, complete the upgrade and switch to the new version by running the `upgrade-tsm.cmd` script. The script is installed in the `\scripts.<version_code>` folder of the new version you just installed. By default: `C:\Program Files\Tableau\Tableau Server-\packages\scripts.<version_code>`

Tableau Server must be stopped to complete the upgrade. If Tableau Server is not stopped when you run the script, the script will let you know, and will offer to stop the server. You can also choose to stop the server before running the script using the `t-sm stop` command.

- **Antivirus software**—Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Multi-node upgrades:

- **Multi-node terminology**—With TSM, we've changed the language we use to describe the Tableau Server nodes in a distributed installation. Prior to the release of TSM we referred to the first node as the "primary" node, and any additional nodes as "worker" nodes. With TSM the nodes are more closely peers, so we refer to the first node as the "initial" node, and other nodes as "additional" nodes.
- **Uninstall**—Use Windows Control Panel to uninstall your existing pre-TSM version of Tableau Server from all nodes before upgrading. If you have not uninstalled your earlier version, you will be prompted to do so when you attempt to install your new version.
- **Node installation**—Run the Setup program on all nodes in a cluster. Unlike some distributed installation upgrades in versions prior to 2018.2.0, there is no automatic upgrade of any additional nodes.
- **Single installer**—Use the same Setup program on all nodes. Starting with 2018.2.0 you use the same installer on all nodes, and specify when prompted whether you are upgrading the initial (primary) node, or an additional (worker) node. There is no separate installer for the additional nodes.
- **Upgrade script**—After installing the new version on all nodes in your cluster, complete the upgrade and switch to the new version by running the `upgrade-tsm.cmd` script on the initial node in the cluster.

Tableau Server must be stopped to complete the upgrade. If Tableau Server is not stopped when you run the script, the script will let you know, and will offer to stop the server. You can also choose to stop the server before running the script using the `tsm stop` command.

Run As User format

Confirm your Run As user format includes the domain

Tableau Server installations default to using the local Network Service account (NT

Tableau Server on Windows Help

Authority\Network Service) for the Run As user. If you are using this default account you can skip this section. If you changed the default account, or if you are not certain whether you are using a custom Run As user, follow the steps below.

Before upgrading to version 2018.2 or higher, make sure your Run As user is in the correct format. The format should include the domain, like this: <domain>\<runasuser>

1. Stop the server by selecting **All Programs > Tableau Server <version> > Stop Tableau Server** on the Windows Start menu.
2. Select **Configure Tableau Server** on the Windows Start menu.
3. If you are using an Active Directory account for the server's Run As User account, enter its password on the **General** tab.
4. Confirm the format of your Run As User account:
 - If the Run As user is "NT AUTHORITY\NetworkService" you are using the default and do not need to make any changes. Cancel out of the configuration utility.
 - If the user name include the domain, you do not need to make any changes. Cancel out of the configuration utility.
 - If the user name does not include the domain, add the domain at the beginning of the user name, and separate the domain from the name using a back slash (\).

For example, if the Server Run As User is "TableauServer" in the "MYCO" domain, update the **User** field to this: MYCO\TableauServer.

5. Click **OK**.
6. Restart the server.

Existing files

Gather existing files

You will need to gather the following files from your existing Tableau Server deployment. Later, at the end of the upgrade process, you will need to upload these files to complete the upgrade.

Some of these files contain secrets that must be protected. Use a secure process to copy, store, and transport these files.

- **Custom logos** If you have customized the Tableau Server portal with custom images, then you will need copies of these files for the upgrade.
- **SAML files.** You will need the SAML certificate, key, and IdP metadata file. The default location for these files is `C:\Program Files\Tableau\Tableau Server\SAML`.
- **Kerberos keytab file.** If you've enabled Kerberos SSO for Tableau Server, then you will need the keytab file that was generated as part of that configuration.
- **SSL**
 - **CA cert file.** If your existing Tableau Server is configured for mutual SSL, you will need to resubmit the CA cert file. The default location for these files is `C:\Program Files\Tableau\Tableau Server\SSL`.
 - **Certificate and key files.** *You do not need to do anything with these files.* These files are automatically upgraded.
- **Open ID file.** If your organization uses a static discovery file (instead of an online discovery file), you will need a copy of that file for upgrade.

Upgrade a single node Tableau Server

1. Confirm that your product key and maintenance are valid for the version you are upgrading to, and that you have refreshed the product key before upgrading. See the **Licenses** section above for details. If you do not have a valid product key with active maintenance, your upgrade will fail.
2. After confirming that the Manage Product Keys application is not open, use Windows Control Panel to uninstall Tableau Server. Unlike earlier versions of the Setup program, version 2018.2 and later will not uninstall the previous version.

Uninstalling will create a backup of your data and stop Tableau. Your data directories are left in place.

The backup file created by the uninstall is used later, for the upgrade, and is saved as "uninstall-<version>.tsbak" in the Tableau data directory, by default: `C:\ProgramData\Tableau\Tableau Server`.

Important: Save a copy of the backup on a different computer. This ensures you have the backup if something goes wrong on the Tableau Server computer. Creating and saving a backup to a non-Tableau location is a best practice step you should always take.

3. Run the Setup program for the new version of Tableau Server with TSM on your Tableau Server node.

If you have not uninstalled your previous version of Tableau, a message will display telling you that the current version cannot be upgraded automatically.

You are currently running a version of Tableau Server that cannot be upgraded automatically.

To upgrade, uninstall your current version of Tableau Server and then run this installer. Your data will be preserved during this process.

If you see this message, uninstall the previous version using Control Panel and then return to this step.

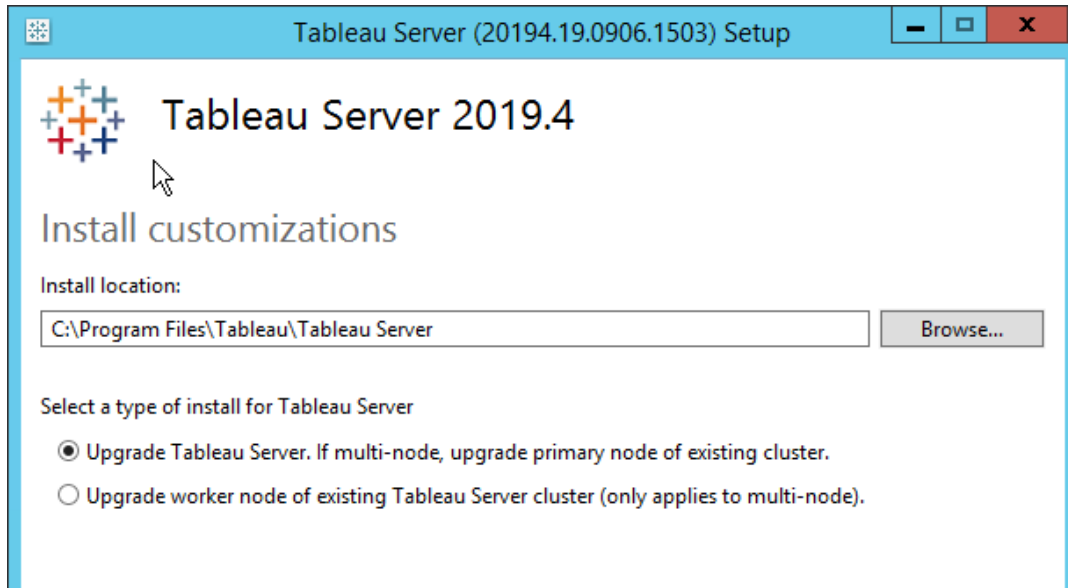

4. Select your install location:

- **Default location**—By default the install location shown is `C:\Program Files\Tableau\Tableau Server`. If your previous installation was to this default location, Tableau Server was installed in a version-specific folder under this path (for example: `C:\Program Files\Tableau\Tableau Server\10.5`). If this is the case, click **Next** to accept the default. The path should **not** include the version folder.
- **Non-default location**—If your previous installation was in a *non-default location*, you need to specify the correct location so that the Setup program will find your existing data and include it in the upgraded version.

If you do not select the correct location, the Setup program will treat this as a fresh installation and Tableau Server will not include your backup data.

Important: If you are upgrading a pre-TSM version that *was not installed to the default location* and you are upgrading to version 2019.4.0 through 2019.4.4, you should be following the steps in Upgrade from Tableau Server 2018.1.x or Earlier in a Non-Default Location (Windows).

5. When prompted to "Select a type of install", confirm that **Upgrade Tableau Server. If multi-node, upgrade primary node of existing cluster.** is selected (this is the default):

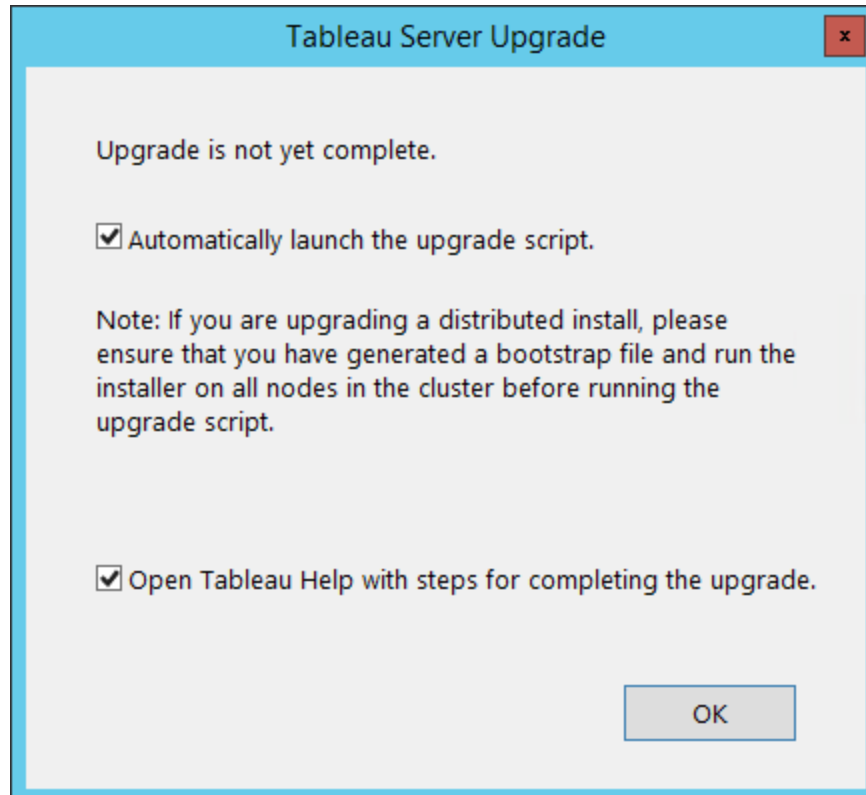

Important: If you are not prompted with an upgrade option but instead see an option to **Create a new Tableau Server installation**, you may not have navigated to the correct location of your previous installation. If you continue, the installation will not include your data or configuration information from the previous installation.

6. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

7. When the installation is done, the last page of the Setup program tells you that the upgrade is not yet finished. You need to run an upgrade script to complete the upgrade. You can run the script from the Setup program, or run it yourself from the command line.
8. Run the upgrade script in one of two ways.

- From the Setup program:
 - a. Select **Automatically launch the upgrade script**, and click **OK**:

- b. A command window will open for the script. Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. If your old installation of Tableau Server used a non-default Run As user, you will also be prompted for the Run As user password.

The upgrade script will look for the backup file created by the uninstall of the previous version in the Tableau data folder (`C:\ProgramData\Tableau\Tableau Server`). You can specify a backup file in a different location using a `--backup-path` option but to do this you need to run the script from the command line.

Note: Clicking **OK** will close the Setup program dialog. If you cleared the option to automatically launch the upgrade script, you will need to run the script manually, from the command line.

- On the command line:
 - a. On the initial node, open a command prompt as administrator.
 - b. Navigate to the scripts folder for your new installation.

By default:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

The script will assume a location for a backup file from your previous installation, and prompt you for passwords:

- By default the upgrade script will look for the backup file created by the uninstall of the previous version in the Tableau data folder (C:\ProgramData\Tableau\Tableau Server). You can specify a different location using a `--backup-path` option. For example:

```
upgrade-tsm --backup-path "C:\path\to\  
backup\file\uninstall-10.5.tsbak"
```

- Because you are logged in as a user with local administrator rights,

the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password when you run the script using `--username` and `--password` options.

- If your old installation of Tableau Server used a non-default Run As user, you will also be prompted for the Run As user password. You can provide this when you run the script using a `--service-runas-password` option.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

9. When the upgrade is complete, a browser window will open with the TSM sign in page. Sign in to TSM. You will be prompted to activate or register Tableau Server if these steps are needed.

If the window does not open automatically, open a browser window and go to:

```
https://<tsm-computer-name>:8850
```

10. Start Tableau Server.

- In the Web UI:
 - Click **Tableau Server is stopped**, and **Start Tableau Server**

- On the command line:

Tableau Server on Windows Help

- a. On the initial node, open a command prompt as administrator.
- b. Navigate to the bin directory for your new installation. By default this is:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\bin.<version_code>
```

- c. Start Tableau Server:

```
tsm start
```

11. Upload files. Use the following TSM commands to upload files from your previous Tableau Server. The files must be uploaded with TSM. Do not copy them to destinations in the Tableau Server folder hierarchy. Instead, copy them to a temporary directory (for example, `C:\temp`) and then run the TSM commands to copy them into the system.

- **Custom logo** files. If you have customized the Tableau Server portal with custom images, run the following command:

```
tsm customize --header-logo <file> --signin-logo <file>  
--logo <file>
```

- **SAML** files. Run the following command for SAML SSO:

```
tsm authentication saml configure --cert-file <file> --  
key-file <file> --idp-metadata <file>
```

If you are using SAML for datasource delegation, run the following command:

```
tsm data-access set-saml-delegation --cert-file <file>  
--key-file <file>
```

- **Kerberos**. Run the following commands:

```
tsm authentication kerberos configure --keytab-file  
<file>
```

```
tsm authentication kerberos enable
```

- **Mutual SSL** files. Follow the instructions here:

[Configure Mutual SSL Authentication](#)

- **Open ID** file. Run the following command:

```
tsm authentication openid configure --metadata-file  
<file>
```

If you run any of the above commands, you also need to apply pending changes:

```
tsm pending-changes apply
```

Upgrade multi-node Tableau Server (Windows)

Upgrade a multi-node Tableau Server

1. Confirm that your product key and maintenance are valid for the version you are updating to, and that you have refreshed the product key before upgrading. See the **Licenses** section above for details. If you do not have a valid product key with active maintenance, your upgrade will fail.
2. After confirming that the Manage Product Keys application is not open, use Windows Control Panel to uninstall Tableau Server. Unlike earlier versions of the Setup program, version 2018.2 and later will not uninstall the previous version.

Uninstalling will create a backup of your data and stop Tableau. Your data directories are left in place.

Tableau Server on Windows Help

The backup file created by the uninstall is used later, for the upgrade, and is saved as "uninstall-<version>.tsbak" in the Tableau data directory, by default: `C:\ProgramData\Tableau\Tableau Server`.

Important: Save a copy of the backup on a different computer. This ensures you have the backup if something goes wrong on the Tableau Server computer. Creating and saving a backup to a non-Tableau location is a best practice step you should always take.

3. When Tableau Server is uninstalled on the primary node, use Control Panel on all worker nodes to uninstall Tableau before continuing.
4. Run the Setup program for the new version of Tableau Server with TSM on your initial (old primary) node.

If you have not uninstalled your previous version of Tableau, a message will display telling you that the current version cannot be upgraded automatically.

You are currently running a version of Tableau Server that cannot be upgraded automatically.

To upgrade, uninstall your current version of Tableau Server and then run this installer. Your data will be preserved during this process.

If you see this message, uninstall the previous version using Control Panel and then return to this step.

5. Select your install location:
 - **Default location**—By default the install location shown is `C:\Program Files\Tableau\Tableau Server`. If your previous installation was to this default location, Tableau Server was installed in a version-specific folder under

this path (for example: `C:\Program Files\Tableau\Tableau Server\10.5`). If this is the case, click **Next** to accept the default. The path should **not** include the version folder.

- **Non-default location**—If your previous installation was in a *non-default location*, you need to specify the correct location so that the Setup program will find your existing data and include it in the upgraded version.

If you do not select the correct location, the Setup program will treat this as a fresh installation and Tableau Server will not include your backup data.

Important: If you are upgrading a pre-TSM version that *was not installed to the default location* and you are upgrading to version 2019.4.0 through 2019.4.4, you should be following the steps in Upgrade from Tableau Server 2018.1.x or Earlier in a Non-Default Location (Windows).

6. When prompted for "Installation type", confirm that **Upgrade Tableau Server. If multi-node, upgrade primary node of existing cluster.** is selected (this is the default).

Important: If you are not prompted with an upgrade option but instead see an option to **Create a new Tableau Server installation**, you may not have navigated to the correct location of your previous installation. If you continue, the installation will not include your data or configuration information from the previous installation.

7. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

When the installation is done, *do not run the upgrade script*. You need to generate a bootstrap file and install the other nodes before running the script.

8. Generate the bootstrap file on the initial node:

- a. On the initial node, open a command prompt as administrator.
- b. Navigate to the bin directory for your new installation. By default this is:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\bin.<version_code>
```

- c. Generate the bootstrap file:

```
tsm topology nodes get-bootstrap-file -f <path\  
file>.json
```

9. Copy the bootstrap file to each additional (worker) node, or to a network location accessible to the nodes.
10. On each additional node, run Setup to install the new version of Tableau Server. Unlike previous versions of Tableau Server, version 2018.2 and later has one Setup program you use on both the initial node and all additional nodes.

If you have not uninstalled your previous version of Tableau, a message will display telling you that the current version cannot be upgraded automatically. If you see this message, uninstall the previous version using Control Panel.

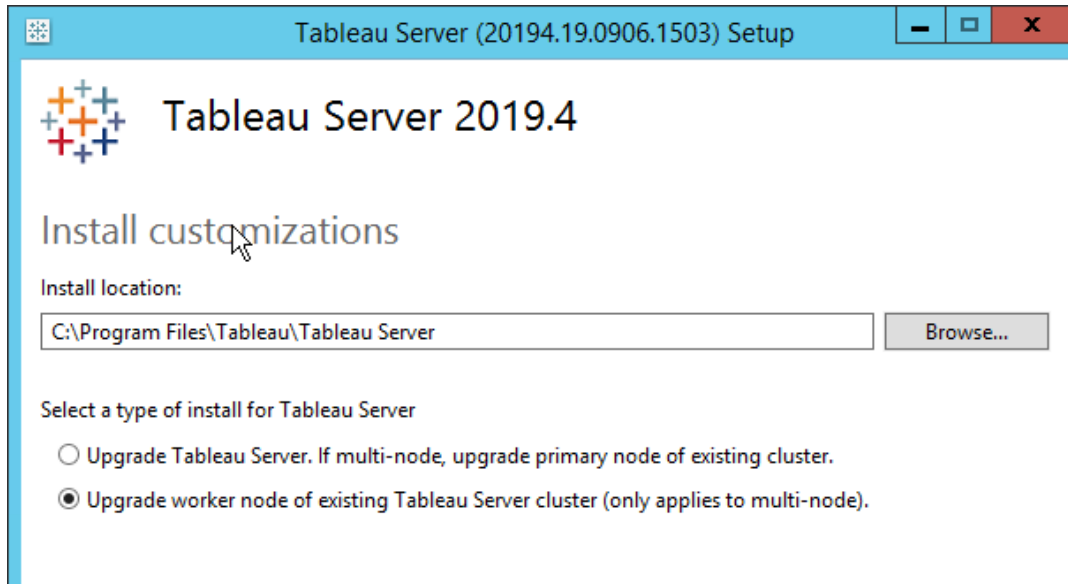

11. Confirm your install location:

- **Default location**—By default the install location shown is `C:\Program Files\Tableau\Tableau Server`. If your previous installation was to this default location, Tableau Server was installed in a version-specific folder under this path (for example: `C:\Program Files\Tableau\Tableau Server\10.5`). If this is the case, click **Next** to accept the default. The path should **not** include the version folder.

If your previous installation was not to the default location and you are upgrading to version 2019.4.0 or later, you should be following the steps in Upgrade from Tableau Server 2018.1.x or Earlier in a Non-Default Location (Windows).

If you do not select the correct location, the Setup program will treat this as a fresh installation and Tableau Server will not include your backup data.

12. When prompted to "Select a type of install", select the option to **Upgrade worker node of existing Tableau Server cluster (only applies to multi-node)**:

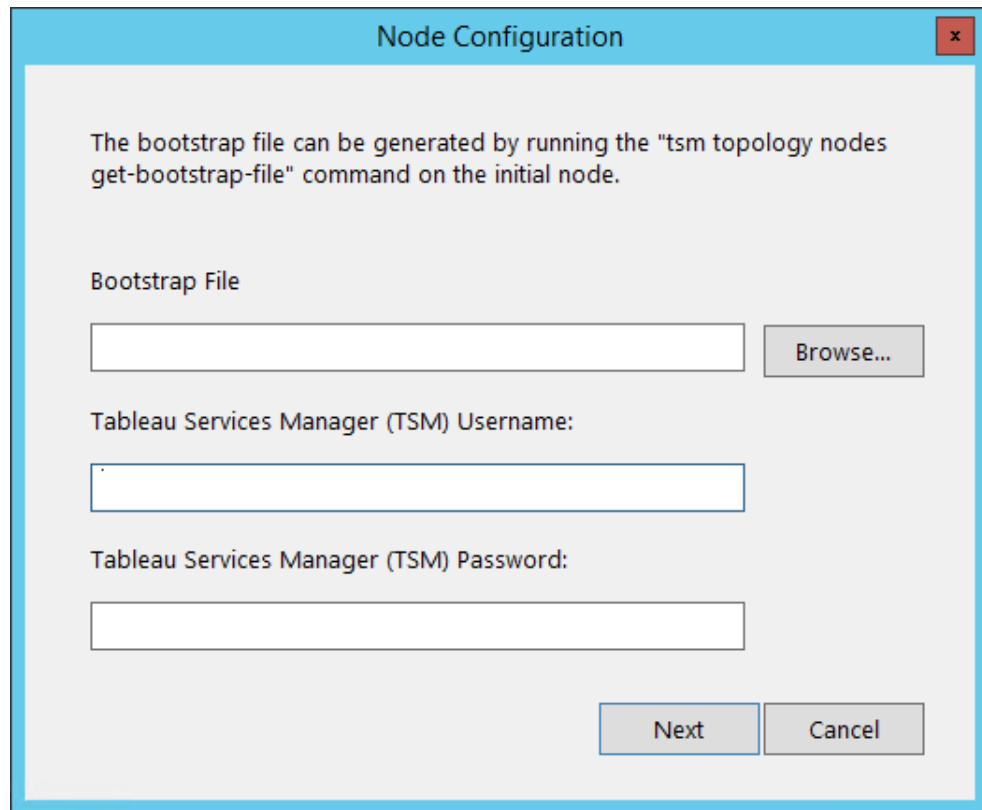

Important: If you are not prompted with an upgrade option but instead see an option to **Create a new Tableau Server installation**, you may not have navigated to the correct location of your previous installation. If you continue, the installation will not include your data or configuration information from the previous installation.

13. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

14. When prompted:
 - a. Navigate to the location of the bootstrap file you copied.
 - b. Enter the username and password for a user who has administrative rights on the computer where the bootstrap file was created (for example, the TSM administrator who created the bootstrap file).

- c. Click **Next** to continue.

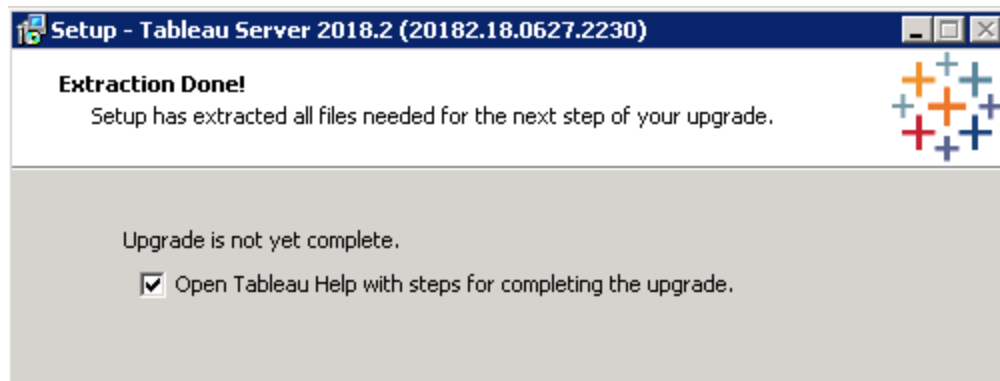

The bootstrap file can be generated by running the "tsm topology nodes get-bootstrap-file" command on the initial node.

Bootstrap File

Tableau Services Manager (TSM) Username:

Tableau Services Manager (TSM) Password:

15. When the node installation completes, a dialog tells you the upgrade is not yet complete:

Click **OK** to close the dialog.

16. After you *install the new version on all nodes*, run the upgrade script on the initial node:

- a. Navigate to the scripts directory for the new version.

By default:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\
```

- b. Run the upgrade script:

```
upgrade-tsm
```

Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password when you run the script using `--username` and `--password` options.

By default the upgrade script will look for the backup file created by the uninstall of the previous version in the Tableau data folder (`C:\ProgramData\Tableau\Tableau Server`).

Note: If your old installation of Tableau Server used a non-default Run As user, you will be prompted for the Run As user password. You can include the `--service-runas-password` option if you know this is the case.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

17. When the upgrade is complete, a browser window will open with the TSM sign in page. Sign in to TSM. You will be prompted to activate or register Tableau Server if these steps are needed.

Note: If the window does not open automatically, open a browser window and go to:

`https://<tsm-computer-name>:8850`

18. If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

For detailed instructions on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

19. Start Tableau Server:

In the Web UI

- Click **Tableau Server is stopped**, and **Start Tableau Server**:

- On the command line:

Tableau Server on Windows Help

- a. On the initial node, open a command prompt as administrator.
- b. Start Tableau Server:

```
tsm start
```

If you get an error that the command is not recognized, close all command windows and then open a command prompt as administrator.

20. Upload files. Use the following TSM commands to upload files from your previous Tableau Server. The files must be uploaded with TSM. Do not copy them to destinations in the Tableau Server folder hierarchy. Instead, copy them to a temporary directory (for example, `C:\temp`) and then run the TSM commands to copy them into the system.

After you have uploaded the files, the Client File Service process will distribute the files to the appropriate nodes in the installation.

- **Custom logo** files. If you have customized the Tableau Server portal with custom images, run the following command:

```
tsm customize --header-logo <file> --signin-logo <file>
--logo <file>
```

- **SAML** files. Run the following command for SAML SSO:

```
tsm authentication saml configure --cert-file <file> --
key-file <file> --idp-metadata <file>
```

If you are using SAML for datasource delegation, run the following command:

```
tsm data-access set-saml-delegation --cert-file <file>
--key-file <file>
```

- **Kerberos**. Run the following commands:

```
tsm authentication kerberos configure --keytab-file  
<file>
```

```
tsm authentication kerberos enable
```

- **Mutual SSL** files. Follow the instructions here:

[Configure Mutual SSL Authentication](#)

- **Open ID** file. Run the following command:

```
tsm authentication openid configure --metadata-file  
<file>
```

If you run any of the above commands, you also need to apply pending changes:

```
tsm pending-changes apply
```

Related topics

- [Common Tableau Server Upgrade Issues](#)

Upgrade from Tableau Server 2018.1.x or Earlier in a Non-Default Location (Windows)

Unsupported Versions

- This topic may refer to Tableau Server versions that have gone out of support. The information here is no longer being maintained and may be out of date, but is being left in place for customers who are still running these older versions. For details on which versions are supported, see the bottom of this [Technical Support Programs](#) page: <https://www.tableau.com/support/services>.
- This topic refers to versions of Tableau Server that are no longer available. Downloads of versions prior to 2020.4 have been removed due to the security issues

Tableau Server on Windows Help

currently identified in [CVE-2021-44228](#) and [CVE-2021-45046](#). In order to address these security issues, you must update to the newest version of your desired Tableau product. For more information please see the [Knowledge Article, Apache Log4j2 vulnerability \(Log4shell\)](#).

Using this topic to upgrade Tableau Server on Windows

This topic applies to upgrades of Tableau Server on Windows with these specific characteristics:

- You are currently running Tableau Server 2018.1.x or earlier
- Tableau Server is installed to a non-default location
- You are upgrading to version 2019.4.0 through 2019.4.4
or
You are upgrading to version 2020.1.0 through 2020.1.1

If your deployment does not meet these criteria, see [Upgrade Tableau Server Overview](#) to determine the correct instructions for your upgrade.

Upgrading to Server with Tableau Services Manager (TSM)

Beginning with version 2018.2, Tableau Server on Windows now uses Tableau Services Manager (TSM). TSM is the web-based server configuration and management utility that replaces the Server Configuration utility and the `tabadmin` command line utility. The Tableau Server upgrade process has changed with the introduction of TSM. For details about how upgrade has changed, see [Upgrade process changes](#).

When you upgrade from a pre-TSM version of Tableau Server (2018.1 or earlier) to a version running with TSM, you need to go through some special upgrade steps. *These are required only for the pre-TSM to TSM upgrade.* Pre-TSM versions of Tableau Server on Windows are versions older than 2018.2. Examples of pre-TSM versions are 10.5 and 2018.1. For instructions on how to determine your version of Tableau Server, see [View Server Version](#).

Before you upgrade

Upgrading a server-based product requires planning and preparation. Upgrading Tableau Server from version 2018.1 or earlier to version 2019.4 or later is no different. Before you upgrade your production environment, make sure you have read through and completed the following sections: [Upgrading \(Tableau Blueprint\)](#), [Preparing for Upgrade](#), and [Verify Tableau Server Upgrade](#).

As a best practice, you should *always* make a backup of your Tableau Server data before upgrading, and save this backup in a safe place that is not part of your Tableau installation. This backup preserves your Tableau data if something unexpected happens during the upgrade, or if you need to go back to your previous version of Tableau Server. For more information, see [Back up Tableau Server data](#).

Key Upgrade Aspects

Understand the key aspects of upgrading to TSM

Below are key aspects of upgrading Tableau Server from version 2018.1 or earlier to version 2018.2 or later that you need to be aware of.

All upgrades:

- **Local administrator**—Sign in as a local administrator. You need to be signed into the Tableau Server computer as a "local admin" to run the Tableau Server Setup program, and to run scripts related to upgrading. A "local admin" is a user who's a member of the Administrators group in the Local Users and Groups management console in Windows.
- **Local security policy**—Verify that your local security policy will allow "log on as a service" and "log on locally" permissions for the Run As service account. For details, see [Verify the Local Security Policy](#).
- **Run As**—Read and understand these Run As service account requirements:

Required Run As Service Account Settings.

- **Windows Accounts and Permissions**—Read and understand these Windows account requirements: Windows Accounts and Permissions.
- **Ports**—Before upgrading, read and understand the requirements for ports: Tableau Services Manager Ports.
- **Licenses**—
 - **Trial product keys**—You cannot directly upgrade a server that is running a trial product key from one major version to another (for example, from version 10.5.x to version 2018.x). To upgrade from one major version to another with a trial product key, install the new version of Tableau Server on a separate machine, activate a trial key there, and restore a backup from your existing version. For more information, see Server Upgrade - Verify Licensing Status.
 - **Expired maintenance**—You cannot upgrade a server with a product key whose maintenance has expired or expires on a date earlier than the release date of the version you are upgrading to. If you attempt to upgrade a server in this state, your server will be unlicensed and the upgrade may fail. If your maintenance has expired or is too old, use the **Manage Product Keys** application to refresh your product key *before* you uninstall your original version. If refreshing the key does not update maintenance to a valid date, check in the Tableau Customer Portal for a Tableau Server key with current maintenance.
- **Uninstall**—Use Windows Control Panel to uninstall your existing pre-TSM version of Tableau Server before upgrading. This special-case upgrade is unlike upgrades in earlier versions, which automatically uninstalled the previous version of Tableau Server. When you upgrade from version 2018.1 or earlier to version 2018.2 or later, you *must uninstall* your earlier version yourself. If you have not uninstalled your earlier version, you will be prompted to do so when you attempt to install your new version. This is specific to upgrades from 2018.1 or earlier to 2018.2 or later.
- **Backup**—Save a backup of your earlier version to a safe place on a different

computer. Uninstalling your previous version of Tableau Server will create a backup in the Tableau data directory (by default: `C:\ProgramData\Tableau\Tableau Server`). We **strongly** recommend you copy this backup to a computer that is not part of your Tableau Server installation before upgrading. This provides you with an up-to-date version of your data you can use if you need to go back to your earlier version of Tableau Server. For more information on properly preparing for an upgrade, see [Preparing for Upgrade](#).

Backups from versions of Tableau Server older than version 9.x cannot be used with version 2018.2.x or later. If you are running an older version of Server, you may need to do an intermediate upgrade to version 9.x through 10.x before upgrading to version 2018.2 or later.

- **Firewall management**—Firewall management is manual. Unlike earlier versions of Tableau Server, you must manage the local firewall on any computers where you run Tableau Server. For more information, see [Local firewall configuration](#).
- **Upgrade script**—After installing the new version, complete the upgrade and switch to the new version by running the `upgrade-tsm.cmd` script. The script is installed in the `\scripts.<version_code>` folder of the new version you just installed. By default: `C:\Program Files\Tableau\Tableau Server-\packages\scripts.<version_code>`

Tableau Server must be stopped to complete the upgrade. If Tableau Server is not stopped when you run the script, the script will let you know, and will offer to stop the server. You can also choose to stop the server before running the script using the `tsm stop` command.

- **Antivirus software**—Antivirus software that scans directories used by Tableau Server can interfere with installation and ongoing use of Tableau Server. In some cases, this can result in installation failures, problems starting Tableau Server, or impacts to performance. If you plan to run antivirus software on the computer running Tableau Server, follow the recommendations in the [Knowledge Base](#).

Multi-node upgrades:

Tableau Server on Windows Help

- **Multi-node terminology**—With TSM, we've changed the language we use to describe the Tableau Server nodes in a distributed installation. Prior to the release of TSM we referred to the first node as the "primary" node, and any additional nodes as "worker" nodes. With TSM the nodes are more closely peers, so we refer to the first node as the "initial" node, and other nodes as "additional" nodes.
- **Uninstall**—Use Windows Control Panel to uninstall your existing pre-TSM version of Tableau Server from all nodes before upgrading. If you have not uninstalled your earlier version, you will be prompted to do so when you attempt to install your new version.
- **Node installation**—Run the Setup program on all nodes in a cluster. Unlike some distributed installation upgrades in versions prior to 2018.2.0, there is no automatic upgrade of any additional nodes.
- **Single installer**—Use the same Setup program on all nodes. Starting with 2018.2.0 you use the same installer on all nodes, and specify when prompted whether you are upgrading the initial (primary) node, or an additional (worker) node. There is no separate installer for the additional nodes.
- **Upgrade script**—After installing the new version on all nodes in your cluster, complete the upgrade and switch to the new version by running the `upgrade-tsm.cmd` script on the initial node in the cluster.

Tableau Server must be stopped to complete the upgrade. If Tableau Server is not stopped when you run the script, the script will let you know, and will offer to stop the server. You can also choose to stop the server before running the script using the `t-sm stop` command.

Run As User Format

Confirm your Run As user format includes the domain

Tableau Server installations default to using the local Network Service account (NT Authority\Network Service) for the Run As user. If you are using this default account you can skip this section. If you changed the default account, or if you are not certain whether you are using a custom Run As user, follow the steps below.

Before upgrading to version 2018.2 or higher, make sure your Run As user is in the correct format. The format should include the domain, like this: `<domain>\<runasuser>`

1. Stop the server by selecting **All Programs > Tableau Server <version> > Stop Tableau Server** on the Windows Start menu.
2. Select **Configure Tableau Server** on the Windows Start menu.
3. If you are using an Active Directory account for the server's Run As User account, enter its password on the **General** tab.
4. Confirm the format of your Run As User account:
 - If the Run As user is "NT AUTHORITY\NetworkService" you are using the default and do not need to make any changes. Cancel out of the configuration utility.
 - If the user name include the domain, you do not need to make any changes. Cancel out of the configuration utility.
 - If the user name does not include the domain, add the domain at the beginning of the user name, and separate the domain from the name using a back slash (\).

For example, if the Server Run As User is "TableauServer" in the "MYCO" domain, update the **User** field to this: `MYCO\TableauServer`.
5. Click **OK**.
6. Restart the server.

Gather existing files

You will need to gather the following files from your existing Tableau Server deployment. Later, at the end of the upgrade process, you will need to upload these files to complete the upgrade.

Some of these files contain secrets that must be protected. Use a secure process to copy, store, and transport these files.

- **Custom logos** If you have customized the Tableau Server portal with custom images, then you will need copies of these files for the upgrade.
- **SAML** files. You will need the SAML certificate, key, and IdP metadata file. The default location for these files is `C:\Program Files\Tableau\Tableau Server\SAML`.
- **Kerberos keytab** file. If you've enabled Kerberos SSO for Tableau Server, then you will need the keytab file that was generated as part of that configuration.
- **SSL**
 - CA cert file. If your existing Tableau Server is configured for mutual SSL, you will need to resubmit the CA cert file. The default location for these files is `C:\Program Files\Tableau\Tableau Server\SSL`.
 - Certificate and key files. *You do not need to do anything with these files.* These files are automatically upgraded.
- **Open ID** file. If your organization uses a static discovery file (instead of an online discovery file), you will need a copy of that file for upgrade.

Upgrade steps

When you upgrade from a pre-TSM version of Tableau Server on Windows (version 2018.1.x or earlier) to version 2019.4, the steps you follow depend on which version you are upgrading to:

- Upgrading from 2018.1.x or earlier to 2019.4.0.
- Upgrading from 2018.1.x or earlier to 2019.4.1 through 2019.4.4 or 2020.1.0 through 2020.1.1

Choose the appropriate section below.

Upgrade single node Tableau Server from pre-TSM to 2019.4.0 (Windows, non-default location only)

Upgrade a single node Tableau Server from version 2018.1.x or earlier to version 2019.4.0 (non-default location only)

Upgrade to 2019.4.0 in stages - If you have Tableau Server version 2018.1.x or earlier installed to a non-default location and are upgrading to version 2019.4.0, you *must* upgrade in stages, first to a version of Tableau Server on Windows with TSM (version 2018.2.x through 2019.3.x) and then again to version 2019.4.0. We recommend you upgrade to version 2019.3.x, but upgrading to any TSM version prior to 2019.4 will allow you to then successfully upgrade to version 2019.4. In the steps below we assume you are upgrading to 2019.3.

1. Upgrade to version 2019.3. Follow the steps in the 2019.3 Tableau Server on Windows documentation for upgrading to version 2019.3. [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#) (this link opens an instance of the 2019.3 Help with instructions for upgrading to that version).

After you upgrade to 2019.3, proceed to the next step.

2. When you have confirmed that Tableau Server is running as expected, and your data is accessible, you can follow the instructions in [Upgrading from 2018.2 and Later \(Windows\)](#) in this Help.

Upgrade single node Tableau Server from pre-TSM to 2019.4.1 through 2019.4.4 or 2020.1.0 through 2020.1.1 (Windows, non-default location only)

Upgrade a single node Tableau Server from version 2018.1.x or earlier to version 2019.4.1 through 2019.4.4 or 2020.1.0 through 2020.1.1 (non-default location only)

If you have Tableau Server version 2018.1.x or earlier installed to a non-default location and are upgrading to version 2019.4.1 through 2019.4.4 or 2020.1.0 through 2020.1.1, you have two upgrade options:

- **Upgrade in stages**—You can first upgrade to a version of Tableau Server on Windows with TSM (version 2018.2.x through 2019.3.x) and then upgrade to version 2019.4.1 or later. We recommend you upgrade to version 2019.3.x, but upgrading to any TSM version prior to 2019.4 will allow you to then successfully upgrade to version 2019.4.1 or later. To do this, follow the steps above: [Upgrade single node Tableau Server from pre-TSM to 2019.4.0 \(Windows, non-default location only\)](#).
 - Upgrade to version 2019.3. Follow the steps in the [2019.3 Tableau Server on Windows documentation](#) for upgrading to version 2019.3. [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#) (this link opens an instance of the 2019.3 Help with instructions for upgrading to that version).

After you upgrade to 2019.3, proceed to the next step.
 - When you have confirmed that Tableau Server is running as expected, and your data is accessible, you can follow the instructions in [Upgrading from 2018.2 and Later \(Windows\)](#).
- **Upgrade on the command line**—You can upgrade directly to version 2019.4.1

through 2019.4.4 or 2020.1.0 through 2020.1.1, you run the Setup program from the command line. The steps below provide detailed instructions.

Upgrade to version 2019.4.1 through 2019.4.4 or 2020.1.0 through 2020.1.1 on the command line

1. Confirm that your product key and maintenance are valid for the version you are updating to, and that you have refreshed the product key before upgrading. See the **Licenses** section above for details. If you do not have a valid product key with active maintenance, your upgrade will fail.
2. Uninstall your existing version.

After confirming that the Manage Product Keys application is not open, use Windows Control Panel to uninstall Tableau Server. Unlike earlier versions of the Setup program, version 2018.2 and later will not uninstall the previous version.

Uninstalling will create a backup of your data and stop Tableau. Your data directories are left in place.

The backup file created by the uninstall is used later, for the upgrade, and is saved as "uninstall-`<version>`.tsbak" in the Tableau data directory, by default: `C:\ProgramData\Tableau\Tableau Server`.

Important: Save a copy of the backup on a different computer. This ensures you have the backup if something goes wrong on the Tableau Server computer. Creating and saving a backup to a non-Tableau location is a best practice step you should always take.

3. Run the Setup program for your new version 2019.4.1 or later from the command line:
 - a. Open a command prompt as an administrator and change to the folder where you downloaded the Setup program for your new version.

Tableau Server on Windows Help

- b. Run this command. The `DATADIR` and `INSTALLDIR` property names must be typed in uppercase. Do not include the version number in the path.

```
TableauServer-64bit-<version>.exe DATADIR=  
R="<drive:\path\to\data directory>" INSTALLDIR=  
R="<drive:\path\to\install\directory>"
```

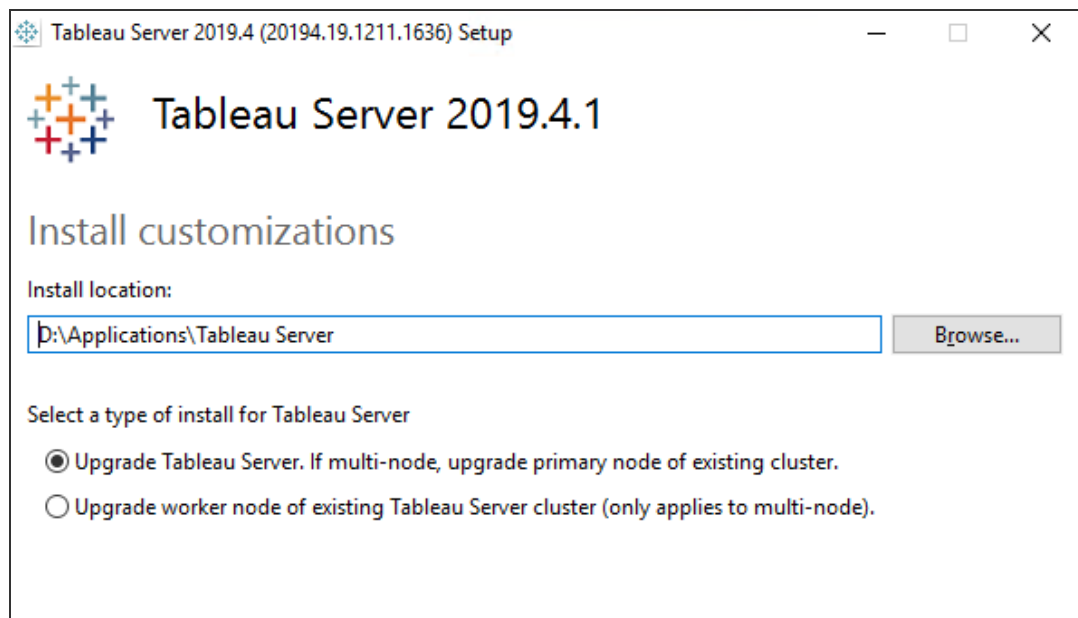

For example, if your existing installation was to `D:\Applications\Tableau Server\2018.1`:

```
c:\Users\bsmith\Downloads>TableauServer-64bit-2019-4-  
1.exe DATADIR="D:\Applications\Tableau Server"  
INSTALLDIR="D:\Applications\Tableau Server"
```

This will start the Setup program.

4. When prompted to "Select a type of install", your install directory should be shown (without the version folder).

Confirm that **Upgrade Tableau Server. If multi-node, upgrade primary node of existing cluster.** is selected (this is the default):

Important: If you do not see **Upgrade** options for install type, you may not have correctly specified the data and install directories for your previous version. Do not continue the install or your new version will not include your data. Cancel out of the Setup by clicking the "X" in the upper right corner, and locate your backup file created by uninstalling the earlier version. This file is saved in the data directory. Rerun the above command with the corrected paths.

5. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

6. When the installation is done, the last page of the Setup program tells you that the upgrade is not yet finished. You need to run an upgrade script to complete the upgrade. You can run the script from the Setup program, or run it yourself from the command line.
7. Run the upgrade script in one of two ways.

Tableau Server on Windows Help

- From the Setup program:
 - a. Select **Automatically launch the upgrade script**, and click **OK**:

- b. A command window will open for the script. Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. If your old installation of Tableau Server used a non-default Run As user, you will also be prompted for the Run As user password.

The upgrade script will look for the backup file created by the uninstall of the previous version in the Tableau data folder (C:\ProgramData\Tableau\Tableau Server). You can specify a backup file in a different location using a `--backup-path` option but to do this you need to run the script from the command line.

Note: Clicking **OK** will close the Setup program dialog. If you cleared the option to automatically launch the upgrade script, you will need to run the script manually, from the command line.

- On the command line:
 - a. On the initial node, open a command prompt as administrator.
 - b. Navigate to the scripts folder for your new installation.

By default:

```
C:\Program Files\Tableau\Tableau Server-
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

The script will assume a location for a backup file from your previous installation, and prompt you for passwords:

- By default the upgrade script will look for the backup file created by the uninstall of the previous version in the Tableau data folder (C:\ProgramData\Tableau\Tableau Server). You can specify a different location using a `--backup-path` option. For example:

```
upgrade-tsm --backup-path "C:\path\to\-
backup\file\uninstall-10.5.tsbak"
```

- Because you are logged in as a user with local administrator

Tableau Server on Windows Help

rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password when you run the script using `--username` and `--password` options.

- If your old installation of Tableau Server used a non-default Run As user, you will also be prompted for the Run As user password. You can provide this when you run the script using a `--service-runas-password` option.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

8. When the upgrade is complete, a browser window will open with the TSM sign in page. Sign in to TSM. You will be prompted to activate or register Tableau Server if these steps are needed.

If the window does not open automatically, open a browser window and go to:

```
https://<tsm-computer-name>:8850
```

9. Start Tableau Server.

- In the Web UI:
 - Click **Tableau Server is stopped**, and **Start Tableau Server**

- On the command line:

- a. On the initial node, open a command prompt as administrator.
- b. Navigate to the bin directory for your new installation. By default this is:

```
C:\Program Files\Tableau\Tableau Server-
\packages\bin.<version_code>
```

- c. Start Tableau Server:

```
tsm start
```

10. Upload files. Use the following TSM commands to upload files from your previous Tableau Server. The files must be uploaded with TSM. Do not copy them to destinations in the Tableau Server folder hierarchy. Instead, copy them to a temporary directory (for example, C:\temp) and then run the TSM commands to copy them into the system.

- **Custom logo files.** If you have customized the Tableau Server portal with custom images, run the following command:

```
tsm customize --header-logo <file> --signin-logo
<file> --logo <file>
```

- **SAML files.** Run the following command for SAML SSO:

```
tsm authentication saml configure --cert-file <file> -
-key-file <file> --idp-metadata <file>
```

If you are using SAML for datasource delegation, run the following command:

```
tsm data-access set-saml-delegation --cert-file <file>
--key-file <file>
```

- **Kerberos.** Run the following commands:

Tableau Server on Windows Help

```
tsm authentication kerberos configure --keytab-file  
<file>
```

```
tsm authentication kerberos enable
```

- **Mutual SSL** files. Follow the instructions here:

[Configure Mutual SSL Authentication](#)

- **Open ID** file. Run the following command:

```
tsm authentication openid configure --metadata-file  
<file>
```

If you run any of the above commands, you also need to apply pending changes:

```
tsm pending-changes apply
```

Upgrade a multi-node Tableau Server from pre-TSM to 2019.4.1 (Windows, non-default location only)

Upgrade a multi-node Tableau Server from version 2018.1.x or earlier to version 2019.4.1 through 2019.4.4 or 2020.1.0 through 2020.1.1

1. Confirm that your product key and maintenance are valid for the version you are upgrading to, and that you have refreshed the product key before upgrading. See the **Licenses** section above for details. If you do not have a valid product key with active maintenance, your upgrade will fail.
2. Uninstall your existing version.

After confirming that the Manage Product Keys application is not open, use Windows Control Panel to uninstall Tableau Server. Unlike earlier versions of the Setup program, version 2018.2 and later will not uninstall the previous version.

Uninstalling will create a backup of your data and stop Tableau. Your data directories are left in place.

The backup file created by the uninstall is used later, for the upgrade, and is saved as "uninstall-<version>.tsbak" in the Tableau data directory, by default: `C:\ProgramData\Tableau\Tableau Server`.

Important: Save a copy of the backup on a different computer. This ensures you have the backup if something goes wrong on the Tableau Server computer. Creating and saving a backup to a non-Tableau location is a best practice step you should always take.

3. When Tableau Server is uninstalled on the primary node, use Control Panel to uninstall Tableau on all worker nodes before continuing.
4. Run the Setup program for your new version 2019.4.1 or later from the command line on your initial (old primary) node:
 - a. Open a command prompt as an administrator and change to the folder where you downloaded the Setup program for your new version.
 - b. Run this command. The `DATADIR` and `INSTALLDIR` property names must be typed in uppercase. Do not include the version number in the path.

```
TableauServer-64bit-<version>.exe DATADIR-
R="<drive:\path\to\data directory>" INSTALLDIR-
R="<drive:\path\to\install\directory>"
```

For example, if your existing installation was to `D:\Applications\Tableau Server\2018.1:`

Tableau Server on Windows Help

```
c:\Users\bsmith\Downloads>TableauServer-64bit-2019-4-1.exe DATADIR="D:\Applications\Tableau Server"
INSTALLDIR="D:\Applications\Tableau Server"
```

This will start the Setup program.

5. When prompted to "Select a type of install", your install directory should be shown (without the version folder).

Confirm that **Upgrade Tableau Server. If multi-node, upgrade primary node of existing cluster.** is selected (this is the default):

Important: If you do not see **Upgrade** options for install type, you may not have correctly specified the data and install directories for your previous version. Do not continue the install or your new version will not include your data. Cancel out of the Setup by clicking the "X" in the upper right corner, and locate your backup file created by uninstalling the earlier version. This file is saved in the data directory. Rerun the above command with the corrected paths.

6. Click **Next** to continue.

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

When the installation is done, the last page of the Setup program tells you that the upgrade is not finished. You need to run an upgrade script to complete the upgrade. *Do not run the upgrade script yet.* You need to generate a bootstrap file and use this when you install the other nodes.

Only after you have installed your new version on all nodes will you run the script.

7. Generate a bootstrap file

Generate the bootstrap file on the initial node:

- a. On the initial node, open a command prompt as administrator.
- b. Navigate to the bin directory for your new installation. By default this is:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\bin.<version_code>
```

- c. Generate the bootstrap file:

```
tsm topology nodes get-bootstrap-file -f <path\  
file>.json
```

- d. Copy the bootstrap file to each additional (worker) node, or to a network location accessible to the nodes.
8. Copy the bootstrap file to each additional (worker) node, or to a network location accessible to the nodes.
 9. On every additional (worker) node, run Setup from the command line to install the new version of Tableau Server:
 - a. Open a command prompt as an administrator and change to the folder where you downloaded the Setup program for your new version.

Tableau Server on Windows Help

- b. Run this command. The `DATADIR` and `INSTALLDIR`, property names must be typed in uppercase. Do not include the version number in the path.

```
TableauServer-64bit-<version>.exe DATADIR-  
R="<drive:\path\to\data directory>" INSTALLDIR-  
R="<drive:\path\to\install\directory>"
```

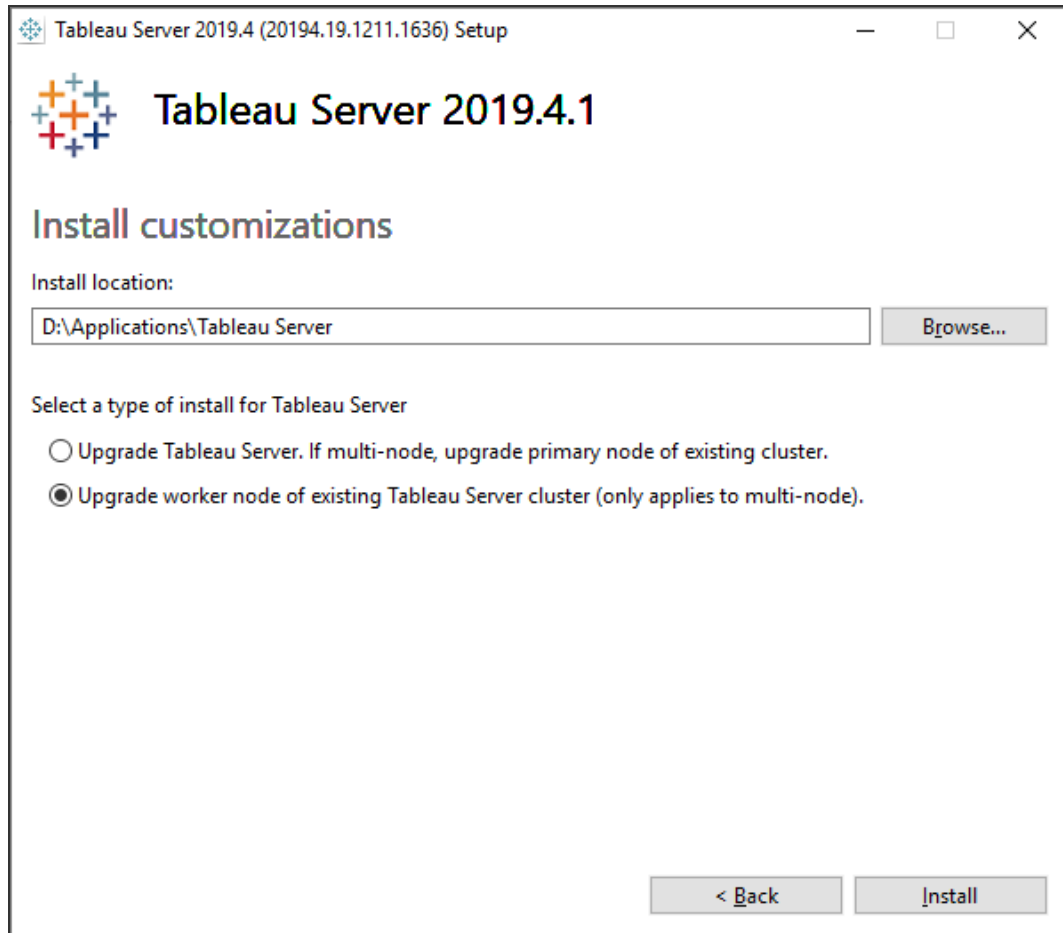

For example, if your existing installation was to `D:\Applications\Tableau Server\2018.1` and your bootstrap file is in your download directory:

```
TableauServer-64bit-2019-4-1.exe DATADIR-  
R="D:\Applications\Tableau Server" INSTALLDIR-  
R="D:\Applications\Tableau Server"
```

This will start the Setup program.

10. When prompted to "Select a type of install", your install directory should be shown (without the version folder).

Select **Upgrade worker node of existing Tableau Server cluster (only applies to multi-node)**:

Important: If you do not see **Upgrade** options for install type, you may not have correctly specified the data and install directories for your previous version. Do not continue the install or your new version will not include your data. Cancel out of the Setup by clicking the "X" in the upper right corner, and locate your backup file created by uninstalling the earlier version. This file is saved in the data directory. Rerun the above command with the corrected paths.

11. Click **Install** to continue.

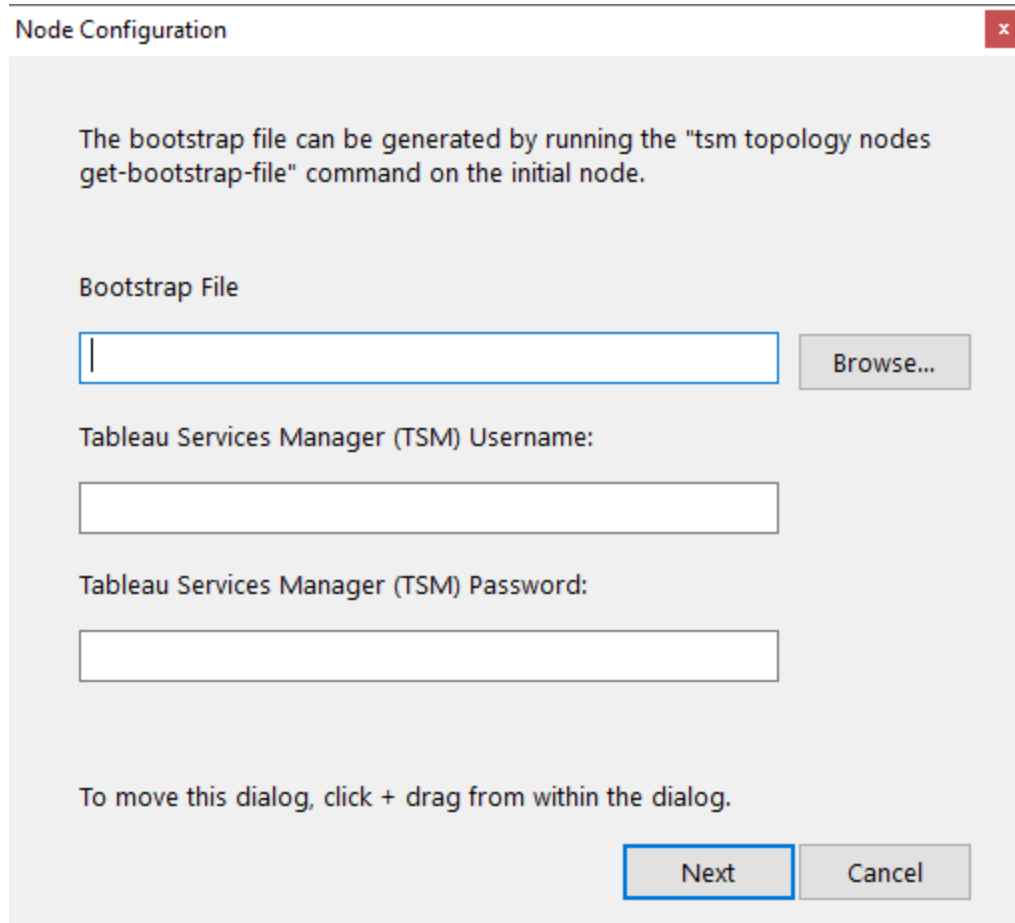

If you are prompted by Windows Defender Firewall, click **Allow access**. You may need to do this multiple times for the installation to complete.

12. When prompted:

Tableau Server on Windows Help

- a. Navigate to the location of the bootstrap file you copied.
- b. Enter the username and password for a user who has administrative rights on the computer where the bootstrap file was created (for example, the TSM administrator who created the bootstrap file).

Click **Next** to continue.

The dialog box is titled "Node Configuration" and contains the following elements:

- A text box with the instruction: "The bootstrap file can be generated by running the "tsm topology nodes get-bootstrap-file" command on the initial node."
- A section labeled "Bootstrap File" containing an empty text input field and a "Browse..." button.
- A section labeled "Tableau Services Manager (TSM) Username:" containing an empty text input field.
- A section labeled "Tableau Services Manager (TSM) Password:" containing an empty text input field.
- A note at the bottom: "To move this dialog, click + drag from within the dialog."
- Two buttons at the bottom right: "Next" (highlighted with a blue border) and "Cancel".

13. When the node installation completes, a dialog tells you the upgrade is not yet complete:

Click **OK** to close the dialog.

14. After you install the new version on all nodes, run the upgrade script on the initial node:

- a. On the initial node, open a command prompt as administrator.
- b. Navigate to the scripts folder for your new installation.

By default:

```
C:\Program Files\Tableau\Tableau Server-
\packages\scripts.<version_code>\
```

- c. Run the upgrade script:

```
upgrade-tsm
```

The script will assume a location for a backup file from your previous installation, and prompt you for passwords:

- By default the upgrade script will look for the backup file created by the uninstall of the previous version in the Tableau data folder (C:\ProgramData\Tableau\Tableau Server). You can specify a different location using a `--backup-path` option. For example:

```
upgrade-tsm --backup-path "C:\path\to\-
backup\file\uninstall-10.5.tsbak"
```

- Because you are logged in as a user with local administrator rights, the script will run using your credentials. If you are prompted, enter your password. You can specify a different user and password when you run the script using `--username` and `--password` options.
- If your old installation of Tableau Server used a non-default Run As user, you will also be prompted for the Run As user password. You can provide this when you run the script using a `--service-runas-password` option.

To see all options for the `upgrade-tsm` script, use the `-h` option:

```
upgrade-tsm -h
```

Tableau Server on Windows Help

15. When the upgrade is complete, a browser window will open with the TSM sign in page. Sign in to TSM. You will be prompted to activate or register Tableau Server if these steps are needed.

If the window does not open automatically, open a browser window and go to:

```
https://<tsm-computer-name>:8850
```

16. If you install a total of three or more nodes, you should also deploy a Coordination Service ensemble. If you do not, you will get a warning message every time you make changes to the server configuration or topology. You can ignore this message, but as a best practice you should deploy a multi-node Coordination Service ensemble.

When you install Tableau Server, a single instance of the Coordination Service is installed on the initial node. TSM and Tableau Server depend on the Coordination Service to function properly, so to provide redundancy and ensure availability on multi-node installations, configure additional instances of the Coordination Service by deploying a Coordination Service ensemble. Coordination Service ensembles are installed with one, three, or five instances of the Coordination Service. In a three-node installation of Tableau Server, the recommended number of Coordination Service instances is three, one on each node.

For detailed instructions on deploying a Coordination Service ensemble, see [Deploy a Coordination Service Ensemble](#).

17. Start Tableau Server.

- In the Web UI:
 - Click **Tableau Server is stopped**, and **Start Tableau Server**

- On the command line:
 - a. On the initial node, open a command prompt as administrator.
 - b. Navigate to the bin directory for your new installation. By default this is:

```
C:\Program Files\Tableau\Tableau Server-
\packages\bin.<version_code>
```

- c. Start Tableau Server:

```
tsm start
```

18. Upload files. Use the following TSM commands to upload files from your previous Tableau Server. The files must be uploaded with TSM. Do not copy them to destinations in the Tableau Server folder hierarchy. Instead, copy them to a temporary directory (for example, `C:\temp`) and then run the TSM commands to copy them into the system.

- **Custom logo files.** If you have customized the Tableau Server portal with custom images, run the following command:

```
tsm customize --header-logo <file> --signin-logo
<file> --logo <file>
```

Tableau Server on Windows Help

- **SAML files.** Run the following command for SAML SSO:

```
tsm authentication saml configure --cert-file <file> --  
key-file <file> --idp-metadata <file>
```

If you are using SAML for datasource delegation, run the following command:

```
tsm data-access set-saml-delegation --cert-file <file>  
--key-file <file>
```

- **Kerberos.** Run the following commands:

```
tsm authentication kerberos configure --keytab-file  
<file>
```

```
tsm authentication kerberos enable
```

- **Mutual SSL files.** Follow the instructions here:

[Configure Mutual SSL Authentication](#)

- **Open ID file.** Run the following command:

```
tsm authentication openid configure --metadata-file  
<file>
```

If you run any of the above commands, you also need to apply pending changes:

```
tsm pending-changes apply
```

Using a Blue/Green approach for upgrading Tableau Server

While many organizations are well-served by performing an in-place upgrade of Tableau Server, other organizations with mission-critical use of Tableau may want a more robust, enterprise-grade upgrade approach which uses investments of additional effort and resources to reduce risk and impact. In these cases Tableau recommends a “Blue/Green” upgrade approach to achieve that outcome, characterized by:

- Reliable deployment of applications into a freshly-configured host environment (versus an in-place upgrade)
- Performing pre-production testing of the new version to validate business-critical functionality, including testing content and use cases to detect changes in behavior that may impact the organization
- Testing in production-identical environments to validate integrations and resource requirements
- The ability to roll back to the previous version rapidly

This high-level guidance describes a Blue/Green approach to upgrades used successfully by many of our biggest customers to upgrade Tableau Server (and other mission-critical applications) with confidence. Blue/Green upgrades are a **long-established industry practice**; there are many variations and the specific steps below are one possible path. If you’re seeking specific guidance on customizing this approach for your organization’s next upgrade, talk to your Premium Support Technical Account Manager, or discuss a services engagement with your account executive or delivery partner.

The Blue/Green approach involves installing a new version of Tableau Server in a second environment (your “Green” installation) that mirrors your production environment (your “Blue” installation). By copying your content from the production installation to the Green installation, you can create an upgraded instance of Tableau Server with a minimum of downtime and with the safety net of having the original production installation to fall back to if necessary. Once you determine all your critical content in the Green environment is functional, switch your users over to the new environment (Green). Your Green environment becomes your production environment, and you can use your original installation (Blue environment) for your next upgrade.

Tableau Server on Windows Help

What follows is a high-level outline of the steps necessary to use Blue/Green as an approach to upgrade Tableau Server. These assume you have a load balancer or DNS that allows you to redirect user traffic from one installation to the other, and that you have downloaded the new version of Tableau you want to upgrade to.

Important: Your Blue/Green installations are production environments and should be treated as production environments. Do not use them for any other purposes and do not set them up in environments you need for other purposes. They should not serve as disaster recovery or general testing environments. For more details on Disaster Recovery please see [Disaster Recovery](#) in the Tableau Blueprint.

1. Create a second installation of servers that mirrors your production installation of Tableau Server as closely as possible. This second environment is your Green installation. It should have a similar capacity, resources, and configuration as your production cluster (“Blue”) because your Green cluster will become your production cluster after the upgrade.
2. Create an initial backup of your Tableau Server Blue installation. You’ll use this for initial user acceptance testing (UAT) in Green. Later, you’ll create a final, up-to-date backup to use before actually switching from Blue to Green. For details on creating backups, see [Back up Tableau Server data](#).
3. Install the new version of Tableau Server in Green. You should specify the same Identity Store type and Run As service account as you use in Blue.
4. Restore the initial backup from Blue into Green. This creates an upgraded, mirrored version of your Blue production cluster. See [Restoring core Tableau Server functionality](#).
5. Disable any scheduled tasks in Green to avoid sending duplicate messages while testing, and to avoid overloading database resources. For details, see [Server Upgrade - Disable Scheduled Tasks](#).

6. Test the Green installation to confirm it is functioning as expected. Perform User Acceptance Testing (UAT), and simulate any load testing if desired. If you have scripts or API integration with Tableau, you should test these as well. The more complete your testing, the better prepared you will be to address any discrepancies between your original Blue installation and your new Green installation.
7. Prepare the Blue installation so you can create a backup you'll use for production in Green. This might mean restricting access to Tableau, or sending a message instructing users not to make any changes to their content and warning them that any changes made after you create your backup will be lost.
8. Create a final backup of Blue. This is the backup you will use to bring Green up to the most recent production content. If you do regular backups, you can use your latest production backup, keeping in mind that any changes or updates done in Blue after the backup is created will be lost. We recommend a "change freeze" on your production environment after this backup is taken, so no new workbooks or data sources are added, and there are no changes to existing content.
9. Restore the final Blue backup to Green.
10. Perform UAT/sanity checks of Green content.
11. Reenable schedules for any jobs, subscriptions, and notifications you disabled in Step 5 above.
12. Switch your users to Green using a load balancer or DNS, and block access to Blue.
13. Verify that the Green server is functional as desired and monitor for production load issues. If you have the Tableau Server Management add-on, you can use the Resource Monitoring Tool to monitor performance.
14. Stop the Blue environment and prepare it for decommissioning.

Test the Upgrade

The best way to learn what impact a Tableau Server upgrade will have to your current environment is to test it. Knowing how an upgrade will affect your users and your server helps you plan and communicate before the actual upgrade, ensuring that your users will not be caught by surprise.

If you have a Tableau Server test environment this is a great place to test out the upgrade.

We recommend the following sequence for testing a Tableau Server upgrade:

1. [Prepare a test environment](#)
2. [Upgrade the test environment](#)
3. [Confirm that existing functionality works](#)
4. [Performance and user acceptance testing](#)
5. [Test new features](#)
6. [Communicate about the upgrade](#)

Prepare a test environment

To start, create a test environment that mirrors your production environment as closely as possible. The closer your test environment is to the actual environment you will be upgrading, the more accurate a representation you will have of how the upgrade will impact you. This includes identical or similar hardware and operating systems, as well as the same authentication options and network access.

When you've got a test computer or virtual machine ready, follow these steps for creating a test environment.

1. On the existing production environment, create a backup of Tableau Server using the `tsm maintenance backup` command.

For more information, see [Create a pre-upgrade backup](#).

2. On your test environment, install a copy of the same version of Tableau Server as you have in your production environment.

Note: You can download the setup program for your current version from the [Alternate Downloads Site](#).

3. Restore your existing database data using the `tsm maintenance restore` command.

For more information, see [Restore from a backup](#).

4. Manually replicate your existing Tableau Server configuration.

You need to manually configure certain aspects of your environment because when you restore the Tableau database it doesn't include configuration details and customizations.

Upgrade the test environment

Follow the appropriate steps for upgrading the test environment, based on your environment:

- [Upgrading from 2018.2 and Later \(Windows\)](#)
- [Upgrade from Tableau Server 2018.1.x or Earlier \(Windows\)](#)

Confirm that everything works as expected

After you have the new version of Tableau Server installed and configured in your test environment, you are ready to test. You should test basic functionality, along with any special aspects of server that your organization relies on. For example, if there are key subscriptions that your organization relies on, make sure that you test those.

These are some areas of testing to consider:

Tableau Server on Windows Help

- **Server processes.** Sign in to Tableau Server as a server administrator, and then open the Server Status page to confirm that all services and processes are running as expected (including on all additional nodes if this is a distributed installation).
- **User access.** Confirm that Tableau Server users can sign in. Test your normal user sign in process. Have some of your users participate in the testing to make sure they are able to sign in as expected, and that they can get to the same content that they have access to in your production environment.
- **Publishing workbooks and data sources.** Have users publish workbooks and data sources from Tableau Desktop to make sure this goes as you expect.
- **Viewing published workbooks.** Have users who are familiar with the content try to view published workbooks to make sure they appear as expected. Test views embedded in web pages (for example, in SharePoint pages).
- **Subscriptions and extract refreshes.** Manually run some extract refreshes to confirm that they complete successfully. Run some key scheduled extract refreshes to confirm that they complete as expected.
- **Permissions.** Confirm that permissions are still set as expected for users and content.
- **Command-line utilities and APIs.** If applicable, test the command line utilities (tsm and tabcmd) and programmatic access via APIs.

Performance and user acceptance testing

Use tools like Tabjolt, Replayer, and Scout to do performance and user acceptance testing on your test environment. For more information about these and other performance testing tools, see [Performance Monitoring Tools](#) .

Test new features

Take a look at the new features that come with the version you are upgrading to, and at any features that were added between the version you currently have and the new version. Think

about how to help your users understand the benefits of the features that apply to your environment.

For more information on new features, see [What's New](#) in the Tableau Server Help.

Communicate about the upgrade

The best way to make an upgrade go smoothly is by letting your organization know ahead of time about the upgrade and how it might impact them. If you've had users help test, take advantage of their experience by having them help communicate the changes they saw while testing. You can also provide user access to the test environment if there are key people who should see the upgraded version before the actual upgrade.

Troubleshoot Tableau Server Install and Upgrade

Follow the suggestions in this topic to resolve common issues with Tableau Server. For additional troubleshooting steps based on process status viewed on the Status page, see [Troubleshoot Server Processes](#).

General Troubleshooting Steps

Many Tableau Server issues can be addressed with some basic steps:

1. Make sure there is enough disk space on each computer running Tableau Server. Limited disk space can cause a failure to install, a failure to upgrade, or problems running Tableau Server.
2. Restart Tableau Server. Issues related to processes not fully started can be resolved by restarting Tableau Server in a controlled way. To restart Tableau Server, use the `tsm restart` command. This will stop all the processes associated with Tableau Server and then restart them.
3. Reindex Tableau Server. Issues related to indexing can be resolved by reindexing

Tableau Server on Windows Help

Tableau Server. To reindex Tableau Server, use the `tsm maintenance reindex-search` command. For more information, see Reindexing Tableau Server Search & Browse below.

4. Restart the computer on which Tableau Server is running. Some issues, such as those related to data source connectivity, can be resolved by restarting the server computer.

Common Tableau Server Install Issues

Installation logs location

The installation logs are written to the `\Temp` directory of the user account that is running Setup. In most cases, this is located at `C:\Users\\AppData\Local\Temp`.

To determine where the `\Temp` directory is for the logged on user, run the following command in Windows Command Prompt: `ECHO %Temp%`.

Install program does not prompt for location to install to

When you install Tableau Server for the first time, you will be prompted for the location you want to install to. *If you do not see this prompt, you may have leftover files or directories from a previous installation, even if you uninstalled Tableau.* To completely remove all traces of Tableau version 2018.2 or later, run the `tableau-server-obliterate` script, then restart the computer and try the install again. If the previous installation was a version earlier than 2018.2, manually delete all Tableau related folders before rerunning the install program.

Important: If you created a backup of Tableau (<file>.tsbak) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

Install program does not restart Windows

When you install Tableau Server the Setup program may prompt you to restart Windows at the end of the installation. In certain cases, clicking **Restart** does not restart the computer. This can happen when a 3rd Party component installer is requesting a restart of Windows.

If clicking **Restart** does not restart Windows, complete the installation by manually restarting Windows.

TSM Install fails with "initialization failed" error

If you attempt to install Tableau Server and the installation fails with this error:

```
Tableau server initialization failed  
See install log at C:\ProgramData\Tableau\Tableau Server\logs
```

This may be related to a permissions issue on your computer. The user is signed into Windows and installing Tableau must have administrator permissions to the C drive, to C:\Windows, and C:\Windows\System32 folders, and to the cmd.exe file. This is true even if you are not installing Tableau on the C drive.

For more information, see the [Tableau Knowledge Base](#).

TSM Initialize screen does not display

When installing or upgrading Tableau Server, if the browser opens but nothing displays, you may need to add the hostname to the trusted sites list. Alternatively, clear the browser cache or use a different browser. For more information, see the [Tableau Knowledge Base](#).

Unable to log into TSM or Tableau Server (sign in screen redispays after entering credentials)

Using Internet Explorer or Edge, if you enter your credentials into the TSM or Tableau Server sign-in screen and the page redispays without signing you in, verify that the hostname or domain in your URL does not include an underscore (_). If the hostname or domain of the Tableau Server computer includes an underscore (_) Internet Explorer or Edge browsers will not set a cookie, so the page will redisplay without signing you in. To work

Tableau Server on Windows Help

around this, use "localhost" or the IP address of the computer in the URL. For example:
`https://localhost:8850.`

Note: If you are using AD for your Tableau Server identity store, you may be locked out of Active Directory if you try to sign in too many times.

For more information, see the [Tableau Knowledge Base](#).

Multiple install attempts fail

If you attempt to install Tableau Server and the install fails, any subsequent installation attempts are likely to fail unless you run the `tableau-server-obliterate` script to clean Tableau off the computer.

Important: You must run the `tableau-server-obliterate` script from a 64-bit command prompt. For example, run `cmd.exe` in the `C:\Windows\System32` folder. If you run the script from a 32-bit command prompt, the script will not completely remove Tableau, and subsequent installations may fail. To determine if you are running a 64-bit command prompt, type `echo %processor_architecture%` in your command window. If the result includes "64" (`AMD64` for example), the command prompt is a 64-bit prompt. If the result includes "x86" you are running a 32-bit prompt. For more information, see the appropriate Microsoft documentation for your versions of Windows.

A failed install attempt can leave the computer in a state that causes subsequent attempts to also fail with errors that don't seem directly related to a previous install attempt.

To fix this problem, run the `tableau-server-obliterate` script to clean up any left over remnants of the previous install attempt and then restart the computer. For more information, see [Running the tableau-server-obliterate script](#).

Important: If you created a backup of Tableau (<file>.tsbak) you want to keep (for example, to restore to your new installation), copy that file to a safe location on another computer to guarantee it is not removed when you clean up your Tableau computer.

Obliterate script generates error: "refresh-environment-variables.cmd" is not recognized as an internal or external command

If you use Control Panel to uninstall Tableau Server and then run the tableau-server-obliterate script to completely remove Tableau from your computer, the script may generate an error about the refresh-environment-variables. This occurs because a second script called by the obliterate script was not moved to the temp directory. You can ignore this error.

Install fails due to hardware requirements

Tableau Server cannot install if the computer you are installing on does not meet the minimum hardware requirements. The requirements apply to all computers on which you are installing Tableau Server. For details on minimum hardware requirements, see [Minimum Hardware Requirements and Recommendations for Tableau Server](#).

Install or upgrade fails due to CPU requirements

Beginning in version 2020.4.0 Tableau Server requires CPUs that support SSE4.2 and POPCNT instruction sets. You cannot install or upgrade Tableau Server 2020.4.0 or oater on computers that have CPUs which do not support these instruction sets.

You may see this error message when installing a new installation, or in preparation for upgrading an existing installation:

```
Your computer's processor doesn't meet the minimum requirements that Tableau requires to install the software. If you are using a VM, make sure Processor compatibility mode is off.
```

The SSE4.2 and POPCNT instruction sets have been common for more than 10 years and most newer CPUs support them, but if you get an error related to processor minimum requirements when attempting to install or upgrade Tableau Server on a Virtual Machine

(VM), Processor compatibility mode may be enabled on the VM. To successfully install or upgrade Tableau on a VM, make sure the Processor compatibility mode is turned off.

Common Tableau Server Upgrade Issues

Error: Failed to establish a connection with Active Directory

Beginning with Tableau version 2021.2, Tableau Server no longer allows insecure connections with Active Directory. If your current instance of Tableau Server is communicating with Active Directory over a non-encrypted channel, upgrade will fail.

To resolve this issue follow one of the steps below:

- Investigate and resolve the failed secure connection. See the Microsoft topic, [LDAP Over SSL Connection Issues](#).
- Run the following commands to allow an insecure connection on your current version of Tableau Server before you upgrade:

```
tsm configuration set -k wgservers.domain.allow_insecure_connection -v true --force-key
```

```
tsm pending-changes apply
```

After upgrade completes, we recommend securing the channel and then setting this option to `false`.

Note: By default (when `wgservers.domain.allow_insecure_connection` is set to `true`), Active Directory group synchronization will fail if the communication channel with Active Directory is not encrypted.

Maps do not display or display incompletely after upgrading

Beginning with Tableau version 2019.2, the internet access requirements changed for maps. If you are upgrading from version 2019.1.x or earlier to version 2019.2.x or later, and maps

are not displaying as expected, confirm that your environment is configured to allow access on port 443 to `mapsconfig.tableau.com` and `api.mapbox.com`.

In version 2019.1.x or earlier, access was necessary to `maps.tableausoftware.com`.

For more details on internet access requirements, see [Communicating with the Internet](#).

Upgrade script error: "Tableau Server Version change validation failed."

When upgrading, if you run the `upgrade-tsm` script from the `scripts.<version_code>` directory for the earlier version, the upgrade will fail with an error:

```
Tableau Server Version change validation failed.  
Tableau Server <version> is already installed.
```

If you get this error, change to the `scripts.<version_code>` directory for the version you just installed and run the script from there.

Upgrade logs location

By default the upgrade log, `app-upgrade.log`, is written to `C:\ProgramData\Tableau\Tableau Server\logs`.

Upgrade multi-node, initializing additional node fails with "Enter your credentials again" error

If you attempt to initialize an additional node when upgrading Tableau Server and see this error:

```
Enter your credentials again. The credentials you enter must  
provide administrative access to the computer where you gen-  
erated the configuration file.
```

this is an indication that the node is unable to connect to or communicate with the initial node. This can happen for multiple reasons:

- The credentials you entered are not valid or you mistyped them. The credentials must be for a user who has administrative permissions on the computer where Tableau

Tableau Server on Windows Help

Server was first installed. You do not need to use the credentials of the user who created the bootstrap file but doing so will ensure you are using valid credentials.

- The local firewall of the computer you are trying to add is not allowing communication to the initial node. For more information, see [Local firewall configuration](#).

Upgrade stops or fails at 12%, 78%, or 92%

In certain instances, the `upgrade-tsm.cmd` script can stall or fail partway through. The cause of this depends on what point the script stops.

- If the script stalls at 12% or 78% this could be due to a known issue (fixed in version 2018.2.1) related to upgrading while SSL is enabled. For more information, see the [Tableau Knowledge Base](#).
- If the script stalls at 92%, while executing the "Enabling the services required for indexing" step, this can be due to problems starting Tableau Services. You can restart Tableau Server Service Manager manually to work around this issue. For details, see the [Tableau Community](#).

Upgrading fails due to lack of disk space

If there is not enough disk space for the Tableau Server Setup program to run and do the upgrade, the installation will fail. The amount of disk space required will depend on the size of your repository database and the number and size of your extracts.

Note: When upgrading from a pre-TSM version of Tableau Server (a version earlier than 2018.2.0), the uninstall of Tableau creates a server backup file in the data directory. This backup file has a `.tsbak` extension and is required for the upgrade. *After* you upgrade successfully, you can safely delete this file to free up space (make a copy on a computer that is not part of your Tableau Server installation in case you need the file for any reason). Do not delete this file until you have completed the upgrade and know it is working.

To free up disk space:

1. Create a log archive snapshot using the `tsm maintenance ziplogs` command.

After you create the ziplogs file, save it to a safe location that is not part of your Tableau Server installation.

2. Clean up unnecessary files using the `tsm maintenance cleanup` command.

For more information, see [Remove Unneeded Files](#).

Upgrade fails on RebuildSearchIndex job

Beginning with version 2020.1.x, the final step in an upgrade is to rebuild the search index. At this point all services have been upgraded, so if this job fails, you can manually reset the search server by running the `tsm maintenance reset-searchserver` command. You do not need to obliterate and start over.

The error will be:

```
An error occurred while rebuilding search index.
```

To reset the search server :

1. On the initial node, open a command prompt as administrator.

This must be a new command prompt because the upgrade script updates system environment for the new version.

2. Rebuild the search index using the `tsm maintenance reset-searchserver` command.

Upgrade fails on 2020.4.0 or later

Beginning with version 2020.4.0, the Checkpoint Upgrade feature allows you to retry a failed upgrade. In general, this is most useful for experienced server administrators and IT professionals who are comfortable with Tableau Server log files and are willing to search through them. But the feature can help in all failed upgrades because it allows you to rerun the upgrade-tsm script, and the script is run from the last successful step, saving time. For

Tableau Server on Windows Help

those with experience, it may be possible to identify problems like disk space problems, or permissions issues, correct them, and rerun the upgrade.

If you are upgrading to version 2020.4.0 or later and the upgrade fails, the following steps may help you to complete the upgrade:

- Rerun the `upgrade-tsm` script. Upgrade failures are sometimes a result of timeouts during the upgrade process, and rerunning the script can allow the upgrade to get beyond intermittent or occasional timing issues. This is also a step that is safe to do, and easy. Rerunning the script will do no harm, and at worst, the upgrade will fail again at the same point, but without needing to go through any previous steps.

The script is located in the `\scripts` directory:

By default,

```
C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\upgrade-tsm.cmd
```

If your Tableau Server upgrade isn't successful when you rerun the `upgrade-tsm` script, and you are comfortable with Tableau Server logs, you can take these additional troubleshooting steps:

- Look at the output of the script in the command window (rerun the script if you no longer have the command window open). You need to run the script in a command windows with administrator access. Useful error messages may help you identify the cause of the upgrade failure and give you some ideas for how to correct the issue.
- Look in the `app-upgrade.log` file. Any errors that are displayed at the command line will also appear in the `app-upgrade.log` file, often with more details.
- Look in the `tabadmincontroller.log` file. Upgrade problems that aren't easily identifiable in the above two instances are likely the result of an issue in a job. The `tabadmincontroller.log` file may have more information that helps you diagnose the issue.

Note: For information about log file locations, see [Tableau Server Logs and Log File Locations](#).

Common Settings Import Issues

Import of settings file causes "not present on any node" validation error due to missing services

If you are upgrading by installing a new version of Tableau Server and importing a settings file from an earlier version, you may encounter topology validation errors when running the `tsm settings import` command.

This can happen when you export a settings file from an older version of Tableau Server and import it into a new version, and new services have been added to Tableau between the two versions.

Errors will be similar to this (the specific service may be different):

```
c:\Users\mytableau\Desktop>tsm settings import -f 20183-export.json
```

```
Pending topology set.
```

```
There are 1 topology validation errors/warnings.
```

```
Service 'elasticsearch' is not present on any node in the cluster.
```

```
Service: Elastic Server
```

To resolve this issue, add any missing services to Tableau Server:

1. For any service that generated a validation error, add the service with an instance count of 1.

For example, if the Elastic Server is not present in the cluster, set the process instance count to 1 using the service name that appears in the first line of the validation error message:

Tableau Server on Windows Help

```
tsm topology set-process -n node1 -pr elasticserver -c 1
```

Repeat this step for each service that results in an error.

2. When you have no more warnings or errors, apply the pending changes:

```
tsm pending-changes apply
```

Your settings should be imported successfully.

Import of settings file causes "configuration value you specified does not match" error

If you are installing a new version of Tableau Server and import a settings file from an earlier version, you may encounter configuration validation errors when running the `tsm settings import` command. These can occur when a settings file includes a configuration value that has since been removed from Tableau.

The error will look similar to this (the configuration key may be different):

```
c:\Users\mytableau\Desktop>tsm settings import -f 20183-export.json
Configuration error: At least one configuration value you specified does not match a known configuration key. This applies to the following keys: '[features.TsmConfigFileService]'
Use this parameter to override unknown key error: --force-keys
```

To resolve this issue, edit the settings file you are importing to remove the reference to the configuration key or keys in the error:

1. Copy the JSON settings file and save the copy for backup.
2. Open the JSON settings file in a plain text editor.
3. Locate and delete the entire line that includes the key. In this example, `features.TsmConfigFileService:`

```
"configKeys" : {
  "config.version" : 19,
  "tabadmincontroller.port" : "8850",
  "endpoints.enabled" : false,
  "endpoints.health.enabled" : true,
  "features.TsmConfigFileService" : true,
  "tableau_projects.language" : "en",
```

The above is an example of a small section of an exported settings file and is not intended to represent the entire contents of the file.

4. Save the settings file and import it again.

You may encounter additional errors related to topology validation. For information about solving those errors, see [Import of settings file causes "not present on any node" validation error due to missing services above](#).

"You cannot directly modify instances of the Coordination Service" error

This error can occur in two situations:

- When you import a Tableau Server settings file into an installation that has a different Coordination Service topology than the settings file does
- When you attempt to configure the Coordination Service using the `tsm topology set-process` command

If you see this error after importing a settings file:

The Tableau Server settings file has a different Coordination Service topology than the target server does. This can happen if you are upgrading Tableau Server by installing a new version and importing a settings file from an earlier version. If you have not explicitly deployed a Coordination Service ensemble on the target server, it has a single instance of Coordination Service, on the initial node.

To correct this error you can take either correct the mismatch from the command line, or by editing the settings import file. You can also discard all pending changes, deploy the

Tableau Server on Windows Help

Coordination Service on the target computer to match the settings in the import file, and reimport the settings file.

To correct the mismatch from the command line, for each node that generates an error, use the `tsm topology set-process` command to revert the instance count of Coordination Service.

1. Run the `tsm pending-changes list` command. The output shows you which nodes have changes.
2. Find the node or nodes where the Coordination Service count is changed.

For example, if the settings file had a Coordination Service instance on node2, but the target system did not have any Coordination Service instance on that node, the count for node 2 would show as changed from 0 to 1 by the import of the settings file:

```
C:\Windows\system32>tsm pending-changes list
Configuration
There are no pending configuration changes.
Topology
node2:
    Coordination Service
        New Instance Count:1
        Old Instance Count:0
```

3. Use the `tsm topology set-process` command to set the count back to the "Old Instance" value.

For the example above:

```
tsm topology set-process -n node2 -c 0 -pr "Coordination
Service"
```

4. Once you have reset any Coordination Service instance count that was changed, apply pending changes:

```
tsm pending-changes apply
```

If you see the error when setting the process count for Coordination Service manually:

This error can also occur if you attempt to update the Coordination Service directly, using the `tsm topology set-process` command instead of the `tsm topology` commands for managing the Coordination Service. If you tried this:

1. Use the `tsm pending-changes discard` command to discard the pending changes.
2. Use the correct commands for configuring the Coordination Service. For more information, see [Deploy a Coordination Service Ensemble](#).

Troubleshooting connections to TSM

Unable to connect to TSM

If you are able to connect to TSM from the computer where you installed Tableau (using `https://localhost:8850` for example), but cannot connect from another computer (using `https://<server-name>:8850`), you may need to configure the local firewall on the Tableau Server computer.

Beginning with version 2018.2 you need to configure the firewall manually. For more information, see [Local firewall configuration](#).

Starting Tableau Server

Tableau Server cannot determine if it fully started

In some instances Tableau Server may report that it could not determine if all components started properly on startup. A message displays: "Unable to determine if all components of the service started properly."

If you see this message after starting, verify that Tableau Server is running as expected by using a `tsm status -v` command.

Tableau Server on Windows Help

If the status shows as running ("Status: RUNNING"), then the server successfully started and you can ignore the message. If the status is DEGRADED or STOPPED, see "Tableau Server doesn't start" in the next section.

Tableau Server doesn't start

If Tableau Server does not start or is running in a degraded state, run the `tsm restart` command from a command prompt. This will shut down any processes that are running, and restart Tableau Server.

Reindexing Tableau Server Search & Browse

Problems that can be solved by rebuilding Search & Browse index

Symptoms of an index that needs to be rebuilt include:

- A blank list of sites when a user attempts to log in
- A blank list of projects when a user tries to select a project
- Missing content (workbooks, views, dashboards)
- Unexpected or inaccurate alerts (for example, an "refresh failed" alert on a workbook that does not include an extract)

If you see any of these behaviors, reset and rebuild the Search & Browse index using the `tsm maintenance reset-searchserver` command.

Activating Tableau Server

Tableau Server license activation fails

In some instances Tableau Server license activation may fail. Error messages can range from a very generic one:

- `An error has occurred`

To more specific messages:

- Function `flxActCommonLicSpcPopulateFromTS` returned error 50030, 71521,
- No license found for 'Tableau Server'

To resolve this issue, try these solutions in the order listed:

Confirm you can access the licensing server

The Tableau licensing service was moved to a new data center on October 6, 2018. This means any environments that required special configuration (static IP safe listing for example) to access `licensing.tableau.com` or `licensing.tableau.com` will need to be updated before you can activate, refresh, or deactivate a Tableau product key.

To test access, type the URL and the port of the licensing server in a browser:

```
https://licensing.tableau.com:443
```

and:

```
https://atr.licensing.tableau.com/_status/healthz
```

If you are able to access the server, a "Test success" message displays for the first server, and an "OK" message displays for the second.

Tableau Server needs to make a connection to the following internet locations for licensing purposes:

- `atr.licensing.tableau.com:443`
- `licensing.tableau.com:443`
- `register.tableau.com:443`
- `s.ss2.us`
- `ocsp.rootg2.amazontrust.com`
- `ocsp.rootca1.amazontrust.com`

Tableau Server on Windows Help

- ojsp.sca1b.amazontrust.com
- crt.sca1b.amazontrust.com
- crt.rootca1.amazontrust.com
- ojsp.sca0a.amazontrust.com
- crt.sca0a.amazontrust.com
- ojsp.sca1a.amazontrust.com
- crt.sca1a.amazontrust.com
- ojsp.sca2a.amazontrust.com
- crt.sca2a.amazontrust.com
- ojsp.sca3a.amazontrust.com
- crt.sca3a.amazontrust.com
- ojsp.sca4a.amazontrust.com
- crt.sca4a.amazontrust.com
- crl.rootca1.amazontrust.com
- crl.rootg2.amazontrust.com
- crl.sca1b.amazontrust.com

Requests to the above domains may be on port 80 or 443. Port 80 is used for certificate validation (revocation, certificate chain, etc). Port 443 is used for SSL connections.

Verify the date and time

Verify the date and time on the initial Tableau Server computer is correct. If the clock is set to a time and date earlier than the current date, Tableau Server cannot be activated.

Verify FlexNet Licensing Service has started

If the date and time on the Tableau Server computer are correct, verify that the FlexNet Licensing Service is running on the initial Tableau Server computer.

1. On the initial computer, from the Windows Start menu, open **services.msc**.
2. In the Services dialog box, verify that the status of *FlexNet Licensing Service 64* (64-bit) or *FlexNet Licensing Service* (32-bit) is **Started**.

If FlexNet is not listed as **Started**, right-click FlexNet Licensing Service and select **Start**.

If the **Start** option is grayed out, the service may be set to Disabled. To enable the service:

- a. Right-click FlexNet Licensing Service and select **Properties**.
- b. From the **Startup type** drop-down list, select **Automatic**.
- c. Click the **Start** button, and then click **OK**.

Force the product key to be read again

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.
2. Change to the Tableau Server bin directory. By default this is:

```
C:\Program Files\Tableau\Tableau Server-  
\packages\bin.<version_code>
```

3. Type the following commands:

```
tsm stop  
lmreread
```

```
tsm start
```

Tableau Server on Windows Help

Send the contents of trusted storage to Tableau Support

If FlexNet Licensing Services is installed and running but you're still seeing an error, there might be a problem with the Tableau product key information. To resolve this issue, complete the following steps to create a file of the key information located in trusted storage.

1. On the initial Tableau Server computer, sign in as administrator and open a command prompt.
2. Type the following command:

```
serveractutil -view > <machine_name>-LicResults.txt
```

This creates the `<machine_name>-LicResults.txt` file in your current directory. If you don't have write permissions for that location and see an error, change to a location where you do have permission to create a file and run the command again.

3. Contact Tableau Support (<http://www.tableau.com/support/request>) and include the `<machine_name>-LicResults.txt` file that you created.

tabcmd Installation Problems

Installing tabcmd separately

tabcmd is automatically installed on the initial Tableau Server node when you install Tableau Server, but if you want to run it on another computer, you need to download and install tabcmd separately. For details, see [Install tabcmd](#).

Problems installing tabcmd on Linux

tabcmd requires Java 11 to run properly. On RHEL-like systems, this will be installed as a dependency when installing tabcmd. On Debian-like systems, you need to install Java 11 separately if it is not already installed.

As of July 2022, Debian distributions are no longer supported. For more information, see [this Tableau Community post](#).

Java is not installed

If you see errors similar to this when installing tabcmd, confirm that Java 11 is installed on your Linux computer:

```
Cannot find 'java' in your PATH. Install 'java' and make sure it is in your PATH to continue.
```

Incorrect version of Java is installed

If you see errors similar to these, confirm that Java 11 is installed:

```
Exception in thread "main" java.lang.UnsupportedClassVersionError: com/tableausoftware/tabcmd/Tabcmd :  
Unsupported major.minor version 52.0
```

or.

```
*** Uncaught exception NoClassDefFoundError: javax/xml/bind/JAXBException  
*** See the logs for the stacktrace.
```

Uninstall Tableau Server

Do not uninstall Tableau before upgrading. For details on upgrading, see [Upgrading from 2018.2 and Later \(Windows\)](#).

Beginning with version 2018.2, you can have multiple versions of Tableau Server installed at the same time. This allows you to run most of an upgrade while an existing version is running, and reduces downtime and impact to users. Once you have upgraded, you can uninstall your previous version. Doing this frees up disk space. You do not have to uninstall the previous version.

This article explains how to uninstall previous versions, after you've upgraded to a newer version.

Uninstalling and completely removing Tableau Server

There are two primary "uninstall" scenarios that Tableau Server on Windows supports:

- **Uninstall Tableau Server:** *After you upgrade* to a new version of Tableau Server you can uninstall your previous version to free up disk space. Continue reading for information about uninstalling Tableau.
- **Remove Tableau Server:** If you want to completely remove Tableau Server from a computer, you can use a script provided by Tableau to remove Tableau Server and all related files. *This removes all data as well as server components, so should only be done if you know you want to reset the computer to a pre-Tableau state.* You might need to do this if Technical Support recommends this step when troubleshooting an installation problem. We recommend you create a backup of your data before removing Tableau. Save the backup file to a safe location on a computer that is not part of your Tableau installation. Completely remove Tableau Server without uninstalling any version first. The script will uninstall all existing versions found on the computer. If you have already uninstalled your existing version and now want to completely remove Tableau, you can find the script to do so in a temporary location. For more details, see [Remove Tableau Server from Your Computer](#).

Uninstall a Tableau Server version

When upgrading from one TSM version to another, you must leave the earlier version in place until you have finished the upgrade. *Then* you can uninstall it.

Use Control Panel to uninstall an earlier version of Tableau Server after upgrading. Starting with version 2018.2, you can have multiple versions of Tableau Server installed at the same time. All installed versions are visible in Control Panel, but only one version is running (the running version will generally be the version you upgraded to, but if you have not completed the upgrade process it could be an earlier version). After completing the upgrade you can uninstall your previous version.

Important: Beginning with version 2018.2, uninstalling Tableau Server will not create a backup of your data. As a best practice, always create a backup of your data before upgrading or uninstalling Tableau. This ensures you can reinstall and restore the data if you decide you want to do this. Save the backup to a safe location on a computer that is not part of your Tableau Server installation.

To uninstall a version of Tableau Server:

1. Open Control Panel, click **Uninstall a program**, and locate the version you want to uninstall.

Be sure you select the correct version to uninstall:

- Uninstalling previous versions of Tableau Server does not impact the running version and simply removes unnecessary files from those previous versions.
- **Do not** uninstall the current, running version. Uninstalling the current, running version of Tableau Server stops server and removes server-specific files and folders, but may leave some elements behind. Uninstalling does not create a backup of your repository data.

2. With the Tableau Server version selected, click **Uninstall**.

Remove Tableau Server from Your Computer

Warning: The steps below *completely remove* Tableau Server on Windows, and delete all related data, users, and configuration information. This includes any files in `\temp`. Tableau Server licenses are also deactivated if you include the `-l` option when running the command shown below and the computer is connected to the internet.

As a best practice, copy any backup files you want to save to a location that is not related to Tableau. This will preserve the files when you remove Tableau. You should

copy any backup files to a separate computer for safety, including backup files created when you uninstall Tableau. By default these are created in `C:\ProgramData\Tableau\Tableau Server` with a name similar to `uninstall-2018.1.tsbak`. Saving backup files on a separate computer will allow you to reinstall the version of Tableau Server that created the backup, and have the data contained in the backup, even after running the `tableau-server-obliterate` script.

If you want to uninstall a particular Tableau Server package to free up disk space (after upgrading, for example), see [Uninstall Tableau Server](#).

As part of the regular installation of Tableau Server, a script is installed that provides you a way to completely remove Tableau and all associated files from your computer. This is something you would only do if you did not care about your Tableau data, configuration, or log files, or if you are working with Tableau Technical Support and need to reinstall Tableau Server after an installation or upgrade attempt fails. The `obliterate` script will not remove any drivers you installed separately, even those you installed to use with Tableau Server.

The `tableau-server-obliterate` script is intended for when you want to completely remove Tableau Server from your computer. You might want to do this for a couple of different reasons:

- You no longer want Tableau Server installed on the computer. Use the `tableau-server-obliterate` script to remove Tableau Server completely. If this is the case, and the computer is connected to the internet, you can include a `-l` option to deactivate the Tableau Server license.
- Troubleshooting Tableau Server installation problems—If you run into issues installing Tableau, you may need to use the `tableau-server-obliterate` script to completely remove Tableau Server from your computer before reinstalling. Doing this will clean up any older settings or states and allow you to reinstall on a "clean" computer. If you are doing this, you can leave off the `-l` option to preserve licensing information on

the computer. When you omit the `-l` option, you will not need to activate your license when you reinstall Tableau Server.

Important: You must run the `tableau-server-obliterate` script from a 64-bit command prompt. For example, run `cmd.exe` in the `C:\Windows\System32` folder. If you run the script from a 32-bit command prompt, the script will not completely remove Tableau, and subsequent installations may fail. To determine if you are running a 64-bit command prompt, type `echo %processor_architecture%` in your command window. If the result includes "64" (AMD64 for example), the command prompt is a 64-bit prompt. If the result includes "x86" you are running a 32-bit prompt. For more information, see the appropriate Microsoft documentation for your versions of Windows.

What `tableau-server-obliterate` does

The intent of the `tableau-server-obliterate` script is to completely remove Tableau Server from your computer. This includes files, system settings and configurations, and, if you specify, licensing information.

When you run `tableau-server-obliterate`, the following steps are taken:

- Uninstall is run for all installed versions of Tableau Server (Control Panel uninstall).
- Most contents of the data directory is removed (by default `C:\ProgramData\Tableau\Tableau Server`). Backup and log files are preserved by default. See the section below, "Preserving Tableau Server backup and log files."
- All registry entries related to Tableau Server are removed.
- All server licenses are deactivated if you use the `-l` option and the computer is connected to the internet. This option does not work in offline situations.

Preserving Tableau Server backup and log files

Prior to version 2020.1 of Tableau Server, running the `tableau-server-obliterate` script deleted all content from the Data directory. Beginning with version 2020.1, the default behavior of the `tableau-server-obliterate` script has changed: the script copies and saves Tableau Server backup and log files to the `logs-temp` directory. The default location for the `logs-temp` directory is at `\ProgramData\Tableau\logs-temp`. You can set options on the script to disable this new functionality.

Tableau Server on Windows Help

To change the default behavior and to remove backup or log files, include one of the following options when running the `tableau-server-obliterate` script:

- `-k` Do not copy backups to logs-temp directory.
- `-g` Do not copy logs to logs-temp directory.
- `-a` Do not copy anything to logs-temp directory.

Running the `tableau-server-obliterate` script

You can completely remove Tableau Server from a computer, either preserving the licensing information, or removing the licensing information along with all other aspects of Tableau Server. You might want to preserve licensing if you are going to reinstall Tableau Server on the same computer.

An older version of `tableau-server-obliterate` may miss files from new versions of Tableau Server. Always run the obliterate script for the version of Tableau Server that is installed on the computer.

To completely remove Tableau Server without removing server licensing

The example script in this procedure also includes the `-a` option to remove Tableau Server backup and log files.

1. On the initial node, open a command prompt as administrator.
2. Run the `tableau-server-obliterate` script:

```
By default: C:\Program Files\Tableau\Tableau Server-  
\packages\scripts.<version_code>\tableau-server-oblit-  
erate.cmd -a -y -y -y
```

Note: If you have already uninstalled Tableau Server using Control Panel and now you want to completely remove it, run the copy of the `tableau-server-obliterate` script located in the `\Tableau Server\temp` folder (by

default: `C:\Program Files\Tableau\Tableau Server\temp`). If the script is not in that directory, reinstall the Tableau Server package and then run the `tableau-server-obliterate` script from the scripts folder (By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>`).

You can also get a copy of the script from this Knowledge Base article: [Obliterate Script Unavailable](#).

If you have a multi-node (distributed) installation of Tableau Server, run the `tableau-server-obliterate` script on each node in the cluster.

3. Restart each computer you ran the `tableau-server-obliterate` script on.

To completely remove Tableau Server and licensing

The example script in this procedure also includes the `-a` option to remove Tableau Server backup and log files.

1. On the initial node, open a command prompt as administrator.
2. Deactivate any active product keys.

```
tsm licenses deactivate -k <product_key>
```

3. Run the `tableau-server-obliterate` script:

By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\tableau-server-obliterate.cmd -a -y -y -y -l`

The `-l` option for the obliterate script removes all licensing files from the computer if the computer is connected to the internet. The script first attempts to deactivate any active licenses, but it will remove all licensing information whether or not deactivation

Tableau Server on Windows Help

was successful. This is why we recommend you run the `tsm licenses deactivate` command before running the `obliterate` script.

Note: If you have already uninstalled Tableau Server using Control Panel and now you want to completely remove it, run the copy of the `tableau-server-obliterate` script located in the `\Tableau Server\temp` folder (by default: `C:\Program Files\Tableau\Tableau Server\temp`). If the script is not in that directory, reinstall the Tableau Server package and then run the `tableau-server-obliterate` script from the scripts folder (By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`).

If you have a multi-node (distributed) installation of Tableau Server, run the `tableau-server-obliterate` script on each node in the cluster. You do not need to deactivate licenses on any additional nodes.

4. Restart each computer you ran the `tableau-server-obliterate` script on.

Help Output for `tableau-server-obliterate` Script

The following help content is the output when you run the following command:

```
tableau-server-obliterate -h
```

The `./tableau-server-obliterate` script is installed to By default: `C:\Program Files\Tableau\Tableau Server\packages\scripts.<version_code>\`.

Output

```
Remove Tableau Server from this computer.
```

```
This script will stop and remove all Tableau Services from this computer. It also removes data and configuration files. It leaves
```

licensing in place. It also preserves logs and backup files, which are moved to a temp directory under the Tableau data folder. You can force removal of these files, and licensing, using optional parameters.

This script is destructive and not reversible. It should only be used to clean Tableau Server from a computer. For multi-node installations, you must run the script separately on each node.

This script must be run as the Administrator.

-y Required. Yes, remove Tableau Server from this computer. Must be specified three times to confirm.

-q Optional. Quiet mode. Windows only. Do not display progress UI when removing Tableau Server.

-l Optional. Delete licensing files and data. This command will attempt to deactivate licenses before deleting licensing data. Internet access is required for license deactivation. Offline deactivation is not supported. To deactivate license before removing Tableau Server, run 'tsm licenses deactivate' before running this script.

-k Optional. Do not copy backups to logs_temp directory.

-g Optional. Do not copy logs to logs_temp directory.

-a Optional. Do not copy anything to logs_temp directory.

Manage Individual Sites

In addition to planning your sites in Tableau, you can manage users and groups, manage projects and control content access, manage your site data, and interact with views on the web.

What is a site	643
Planning a Site	646
Site Settings Reference	649
Manage Users and Groups	662
Dashboard-based Custom Portals	726
Manage Content Access	730

What is a site

You might be used to using the term *site* to mean “a collection of connected computers,” or perhaps as the short form of “website.” In Tableau-speak, we use site to mean a collection of users, groups, and content (workbooks, data sources) that’s walled off from any other groups and content on the same instance of Tableau Server. Another way to say this is that Tableau Server supports multi-tenancy by allowing server administrators to create sites on the server for multiple sets of users and content.

All server content is published, accessed, and managed on a per-site basis. Each site has its own URL and its own set of users (although each server user can be added to multiple sites). Each site’s content (projects, workbooks, and data sources) is completely segregated from content on other sites.

If you are a server administrator on your Tableau Server deployment, you can learn more about sites, when to use them (vs. projects), and more in [Sites Overview](#), in the **Manage Server** section.

Note: This article pertains to configuring sites on Tableau Server deployments. For Tableau Online, see [Site Administrator Role and Tasks](#).

Site administrator tasks

Where the Server Administrator site role gives a user unrestricted access to the entire Tableau Server deployment, the Site Administrator site roles give a user unrestricted or minimally restricted access at the site level. The differences between Site Administrator Creator and Site Administrator Explorer are in the level of data connection and publishing access. Both site roles allow administering the site itself and managing site users. For more information, see [Set Users' Site Roles](#).

Although a server administrator can work at both the server and site levels, we make a distinction between the two levels of task. The site administrator is typically in charge of creating and maintaining the framework that enables Tableau users in the organization to publish, share, manage, and connect to data sources and workbooks. In this vein, site administrator tasks include any of the following (and both site roles allow this level of access):

- Creating project hierarchies to organize the site's data sources and workbooks.

This can include delegating project-level management to project leaders.

- Creating groups and assigning permissions that allow users to access only the content they need.

- Adding and removing users, assigning their site roles.

This is allowed by default on a site; however, a server administrator can restrict this access to the server level only.

- Managing the site's extract and subscription schedules.
- Monitoring site activity.

For more information about the distinction between server administrator and site administrator, see Administrator-level access to sites, in the **Manage Server** section.

Steps for setting up your site

The table below shows a loose sequence of steps for setting up a site, along with links to topics where you can get more information. You can complete the steps in any order that makes sense for you.

However, before you perform the steps to configure the site, we recommend spending some time with the articles in this section, learning about site authentication, site roles, projects, and permissions. Ideally you would document a plan for your projects, groups, and overall permissions strategy. Then set up a few projects and add a preliminary set of users, to test the plan and resolve issues before you add the remaining users. You can change many site settings after your users are working with the site, but try to go in with the intention of minimizing post-production changes.

Plan	To supplement the recommendations above this table, get an overview of how the site components work together in Planning a Site .
Configure access	Work with the server administrator to determine how users sign in to the site, and configure the site appropriately. For example, if the server is configured for single sign-on using SAML, you might configure SAML authentication at the site level as well.
Create projects and the permissions structure	Projects help you organize content, delegate project-level content management, and manage permissions effectively. To get started, see Use Projects to Manage Content Access .

Add users	Determine the users who can sign in to the site. See Add Users to a Site .
Get your data to Tableau Server	<p>After you create your projects and permissions structure, designate approved users for publishing and managing vetted data sources to the appropriate projects on the site.</p> <p>In some organizations, people serve in multiple Tableau roles. Site administrators commonly also are data stewards. By that, we mean they create, publish, and manage the Tableau data connections. If this is you, make sure you are assigned the Site Administrator Creator site role.</p> <p>After content is published to the site, you can maintain connection information (credentials, access tokens) and refresh schedules. For more information, see Refresh Data on a Schedule.</p>
Analyze site usage and performance	Monitor usage, performance, and other metrics. See Administrative Views .

Planning a Site

Before you add users and content to a site, we recommend that you plan the following aspects of the site.

- [Projects](#)
- [Users and groups](#)

- [Site roles and permissions](#)
- [Extract refresh schedules](#)

The subsequent sections go over these site components, assuming that you are familiar with

Note: This article and section apply only to self-managed Tableau Server deployments on-premises or in the cloud. If you use Tableau Online, see [Manage Content Access](#).

Projects

You can create projects on a site, which act as containers in which you can organize related content assets (such as data sources and workbooks). For example, you might set up a project to contain all of the certified data sources and workbooks your organization uses for mission-critical decisions. Or you might set up projects by department.

Projects are also useful for managing permissions. Once you know how your users need to access content, it's usually easier to create projects based on those the type of content, and maintain permissions at the project level.

Every site has a default project named **Default**. When you create projects, the new projects get their initial set of permissions from the default project. In effect, the default project is a template for new projects. As we explain in related articles, for most environments, we recommend that you use the Default project only as a permissions template, and not as a container for published content.

For more information, see [Use Projects to Manage Content Access](#).

Users and groups

Any user who will publish content or access published content on a site must be able to sign in to the site. If the user already has an account on the server, you'll need to add that user to the appropriate site. You can add a user to more than one site as well. If the user doesn't

already exist, you need to create a user account. Either way, make a list of the users who will need to be able to sign in to each site.

Note: The server license might restrict how many users you can have, or what level of access they can have. Check with the server administrator to make sure that you'll be able to have an account for all your users.

In general, we recommend that you create groups on the server and then add users to the groups. This helps to make permissions much easier to manage. You can assign permissions on groups, to give those permissions to all users in the group. (See the next section.)

A typical strategy is to create groups for users who use content in similar ways. For example, you might create a group named SalesWBPublishers for all the users in the Sales department who publish workbooks, and a separate group named SalesDSPublishers for people in Sales who publish data sources. Each of these sets of users needs its own set of capabilities, so it makes sense to have a group for each for these needs.

Site roles and permissions

Each user has a *site role* that determines the maximum permissions that they can have on the site. As part of your site planning, you need to decide each user's site role. A user with a site role that's too restrictive might not be able to do the work they need. By the same token, a security best practice is to limit users' capabilities to only those that they need to do their work. This is referred to as following the principle of *least privilege*.

You or a site administrator you delegate this task to must also determine the permissions a user needs to work with content. Each content asset (workbook, data source, project) supports a set of *capabilities*. For example, you can **View** or **Add Comments** to a workbook. Before a user can perform tasks on a workbook, their permissions must allow those capabilities. A recommended practice is to sketch out a mapping of permissions to users outside of Tableau before you try to set this up on the server.

Permissions determine what a user can do *within the context of the site role*. A user whose site role is **Viewer** can never publish to the site, regardless of the permissions you grant them. A user whose site role is **Creator** can publish a workbook to the site, but only if that user has permission to save and view workbooks.

Extract refresh schedules

If users publish data sources or workbooks that include extracts, you usually want to make sure that the extracts are refreshed, so that they contain the latest data. Users can manually refresh an extract, but this isn't always a good idea if the extract is large, and the refresh takes a long time. Instead, you can set up schedules for when an extract should be refreshed. Another planning task for a site administrator, therefore, is to think about when extracts should be refreshed and to work out schedules.

Site Settings Reference

As a Tableau administrator, you can customize a site for your organization using the settings below. The settings available to you depend on your site configuration and whether you use Tableau Online or Tableau Server. To view and edit site settings, you must be a Site Administrator on Tableau Online or Server Administrator on Tableau Server.

Note: To find a specific setting below, press Ctrl+F (Windows) or Command+F (macOS). Tableau Online and Tableau Server present these settings in a different order.

Accessing site settings

- (Tableau Online) From the Home page, expand the side pane, and click **Settings** at bottom.

Tableau Server on Windows Help

- (Tableau Server) If you're editing an existing site, select it on the Sites page, and then select **Edit Settings**. Or, in a single-site deployment, click **Settings** at the bottom of the side pane.

General section

Setting

Description

Site Name and ID
(Tableau Server
Administrators
only)

Specifies the site name seen in the user interface and the ID seen in the site URL. (If you are editing the Default site, you cannot change the ID.)

You can't change the “#/site” portion of the URL (for example, http://localhost/#/site/sales). In multi-site server environments, these segments appear in the URL for sites other than the Default site.

Storage (Tableau
Server Admin-
istrators only)

Select either **Server Limit** or **GB**, and for the latter enter the number of gigabytes you want as a limit for storage space for published workbooks, extracts, and other data sources.

If you set a server limit and the site exceeds it, publishers will be pre-

vented from uploading new content until the site is under the limit again. Server administrators can track where the site is relative to its limit using the Max Storage and Storage Used columns on the Sites page.

Revision History (Tableau Server Administrators only)	Specifies the number of previous versions of workbooks, flows, and data sources that are stored on the server.
Tableau Prep Conductor	Controls whether users with appropriate permissions can schedule and monitor flows. Tableau Prep Conductor is part of the Tableau Data Management Add-on. For more information, see About Tableau Prep Conductor .
Web Authoring	<p>Controls whether browser-based authoring is enabled for the site. When web authoring for workbooks is disabled, users can't create or edit published workbooks from the server web environment but instead must use Tableau Desktop to republish the workbook. When web authoring for flows is disabled, users can't create or edit published flows from the server web environment but instead must use Tableau Prep Builder to re-publish the flow.</p> <p>For more information, see Set a Site's Web Authoring Access and Functions in Tableau Online Help.</p>
Managing Users (Tableau Server Administrators only)	<p>Determines whether only server administrators can add and remove users and change their site roles, or whether site administrators can too.</p> <p>If you allow site administrators to manage users, specify how many users they can add to the site by selecting one of the following:</p> <ul style="list-style-type: none"> • Server Limit adds the number of available server seat licenses. For a server with core-based licensing, there is no limit. • Site Limit lets site administrators add users up to a limit you

Tableau Server on Windows Help

specify.

- Site Role Limit lets site administrators add users of each site role up to the license limit you specify for the site.

For more information, see [View Server Licenses](#).

Guest Access

Lets people who lack a Tableau Server account see views that have guest access permissions.

Note: If you use Tableau Server, your administrator can disable Guest Access.

Tableau Catalog

Turns off Catalog capabilities when Tableau Server or a Tableau Online site is licensed with the Data Management Add-on. For more information, see [Disable Catalog](#).

Workbook Performance after a Scheduled Refresh (Tableau Server Administrators only)

Pre-computes recently viewed workbooks with scheduled refreshes to open them faster. For more information, see [Configure Workbook Performance after a Scheduled Refresh](#).

Workbook Performance Metrics (Tableau Server Administrators only)

Lets site users collect metrics on how workbooks perform, such as how quickly they load To initiate recording, users must add a parameter to the workbook's URL. For more information, see [Create a Performance Recording](#).

Managed Keychain Clean Up

Lets site administrators manage saved credential keychains for OAuth connections on the site. For more information, see [OAuth Connections](#).

Automatically Suspend Extract

To save resources, Tableau can automatically suspend extract refresh tasks for inactive workbooks. This feature applies only to

Refresh Tasks	refresh schedules that run weekly or more often. For more information, see Automatically Suspend Extract Refreshes for Inactive Workbooks in Tableau Online Help.
Linked Tasks (Tableau Server and Site Administrators only)	<p>Lets Server administrators enable users to schedule flow tasks to run one after the other. They can also enable users to trigger the scheduled flow tasks to run using Run Now.</p> <p>This setting can be applied at the server level to include all sites on Tableau Server. The setting can be disabled at the site level to include only specific sites.</p> <p>If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the Scheduled Tasks tab.</p> <p>For more information, see Schedule linked tasks.</p>
Email Settings (Tableau Server Administrators only)	Specifies the From address and message footer seen in automatic emails for alerts and subscriptions.
Site Invite Notification (Tableau Online only)	For sites with single-sign-on authentication, sends an invite email when new users are added to the site.
Site Logo	Specifies the image that appears with the site name.
Start Page	Controls which site page appears when users sign in. By default, the Home page appears, but you can instead open All Projects, All Workbooks, or other pages. For more information, see Set the Default Start Page in Tableau Online Help.

Note: If you use Tableau Server, your administrator can over-

ride this site setting.

User Visibility	Controls what user and group names are visible to other users. For more information, see Manage User Visibility in Tableau Online Help.
Availability of Ask Data	Controls whether Ask Data lenses are enabled or disabled for data sources. Ask Data lets users query data using conversational language and automatically see visualizations. For more information, see Automatically Build Views with Ask Data in Tableau user Help.
Availability of Explain Data	Controls whether site users with the appropriate permissions can run Explain Data and authors can access Explain Data Settings. For more information, see Control Access to Explain Data . To learn more about Explain Data, see Discover Insights Faster with Explain Data .
Automatic Access to Metadata about Databases and Tables	Automatically grants users certain capabilities to external assets using derived permissions. For more information, see Turn off derived permissions in Tableau Online Help.
Sensitive Lineage Data	Specifies whether sensitive lineage data should be obfuscated or filtered when users don't have the appropriate permissions to related metadata. For more information, see Sensitive lineage data .
Cross-Database Joins	Determines where the join process happens when joining data from multiple sources. For more information, see Combine Tables from Different Databases in Tableau user Help.
Extract Encryption at Rest (Tableau Server Administrators only)	Lets you encrypt .hyper extracts while they are stored on Tableau Server. Server administrators can enforce encryption of all extracts on their site or allow users to encrypt all extracts associated with particular published workbooks or data sources. For more information,

see [Extract Encryption at Rest](#).

Tableau Mobile - Enable offline favorites (Tableau Server Administrators only)	Controls whether offline previews of users' favorite views are generated for display when users access the site on Tableau Mobile. For more information, see Manage Tableau Mobile Data on Devices in the Tableau Mobile Deployment Guide.
Tableau Mobile - Enable app lock (Appears under Authentication tab for Tableau Online)	Requires a biometric method or device passcode for users to open the site on Tableau Mobile. For more information, see Enable App Lock for Added Security in the Tableau Mobile Deployment Guide.
Tableau Support Access (Tableau Online only)	Allows Tableau Support technicians access to the site to help troubleshoot support cases. By default, this feature is disabled. For more information, see Enable Support Access .
Sharing	Allows users to share items directly with other users. When an item is shared, the recipients get a notification and the item is added to their Shared with Me page. If this is not enabled, users can only copy a link to share. For more information, see Share Web Content in Tableau user Help.
Comments	Controls whether users can add remarks in a Comments side pane for each view and @mention other Tableau users to notify them via email. For more information, see Comment on Views in Tableau user Help.
Data-Driven Alerts	Lets users automatically receive emails when data reaches key thresholds. For more information, see Send Data-Driven Alerts in Tableau user Help.
Subscriptions	Lets site users subscribe to views and receive regular emails of them. On Tableau Server, these options are available only if you first configure subscription settings .

Tableau Server on Windows Help

Data Quality Warnings in Subscriptions Controls whether subscriptions include relevant upstream data quality warnings in the email. On Tableau Server, these options are available only if you first [turn on and configure subscriptions](#). For more information on data quality warnings, see [Set a Data Quality Warning](#).

Note: Data quality warnings are a feature of Tableau Catalog, which is part of the Data Management Add-on.

Tagging Specifies the number of tags that users can add to items. The default limit is 50 tags, and the maximum is 200. For more information, see [Use Tags](#).

Recommendations for Views Controls whether recommendations show on the site and whether the names of users who have looked at recommended items show on recommendation tooltips.

Note: If you use Tableau Server, your administrator can disable Recommendations.

Request Access Lets users send access requests to content or project owners. For more information, see [Let Site Users Request Access to Content](#) in Tableau Online Help.

Metrics Content Type Controls whether metrics are available on the site. When enabled, users can create metrics from views and metrics appear as a content type. When disabled, metrics won't appear on the site or continue to sync; however, you can re-enable the feature to bring back previously created metrics. For more information, see "Set Up for Metrics" in [Tableau Online Help](#) or [Tableau Server Help](#).

Web Page Objects and Web Images Controls whether these Web Page and Image objects can display target URLs. For more information, see [Security for Web Page](#)

	objects in Tableau user Help.
Personal Space	Allows Creator and Explorer site users to create and save content to a private Personal Space. When Personal Space is turned on, you can set user storage limits. For more information, see Create and Edit Private Content in Personal Space .
Site Time Zone for Extracts	The default time zone for extract-based data sources in a site is Coordinated Universal Time (UTC). Site administrators can set a different time zone. For more information, see Set the Site Time Zone for Extracts in Tableau Server Help or Set the Site Time Zone for Extracts in Tableau Online Help.
Extract Quota Limit Notifications	Sends email alerts to all site administrators when extract refresh jobs are canceled because of extract job capacity issues.
Flow Parameters (Tableau Server and Site Administrators only)	<p>Enables users to schedule and run flows that include parameters.</p> <p>Administrators can also enable flow parameters to accept any value. If this option is enabled, any flow user can enter any value in a parameter, potentially exposing data that the user should not have access to.</p> <p>Parameters can be entered in an input step for file name and path, table name, or when using custom SQL queries, in an output step for file name and path and table name, and in any step type for filters or calculated values.</p> <p>Flow parameter settings can be applied at the server level to include all sites on Tableau Server. The settings can be disabled at the site level to include only specific sites.</p> <p>For more information about using parameters, see Create and Use Parameters in Flows in the Tableau Prep help.</p>
Run Now	Controls who can run jobs manually using the Run Now option from

the web, Rest API, and Tabcmd. By default, this option is selected to allow users to run jobs manually. Clear the check box if only administrators should be allowed to run jobs manually.

Note: If you use Tableau Server, your administrator can disable this site setting.

Manage Notifications

Controls how site users can receive notifications for events such as extract jobs, flow runs, when another user shares content with them or mentions them in a comment. Notifications can be seen in their Tableau site via the notification center, sent by email, or sent to a Slack workspace. When a notification is enabled, users can configure their notification preferences on their Account Settings page.

Note: If you use Tableau Server, your server administrator can disable this site setting.

OAuth Clients Registry

For a subset of connectors, you can register a custom OAuth client for the site to override an OAuth client that has been configured for the server. By registering a custom OAuth client, you enable new and existing connections to use the site-level OAuth client instead of the server-wide OAuth client. For more information, see [Configure Custom OAuth](#).

Authentication section (Tableau Online)

Setting	Description
Authentication Types	Specifies how users can sign in to the site, and how they access it after signing in the first time. Authentication verifies a user's identity. For more information, see Authentication .
Default	Specifies how users can sign in to embedded views. By default,

Authentication Type for Embedded Views	Tableau authentication is selected.
Manage Users	Lets you add new users to the site or change the site role and authentication method for existing users.
Automatic Provisioning and Group Synchronization (SCIM)	Allows you to manage users on the site through a third-party identity provider (IdP). When enabled, the Base URL and Secret boxes are populated with values to use in the IdP SCIM configuration. For more information, see Automate User Provisioning and Group Synchronization through an External Identity Provider .
Connected Clients	Allows Tableau clients such as Tableau Mobile, Tableau Bridge, and others to stay authenticated to the server after a user provides sign-in credentials the first time. When turned off, users are required to sign in explicitly each time they visit Tableau Online. For more information, see Access Sites from Connected Clients .
App Lock for Tableau Mobile	Requires a biometric method or device passcode for users to open this site on Tableau Mobile. For more information, see Enable App Lock for Added Security in the Tableau Mobile Deployment Guide.

Bridge section (Tableau Online)

Setting	Description
Client Not Running Notifications	Sends email alerts to data source owners when a client appears to be disconnected from the site.
Pooling	Distributes live queries and refresh jobs across all clients in Bridge pools. For more information, see Configure and Manage the Bridge Client Pool in the Tableau Online Help.
Private Network Allow-	Add and manage domains that enable dedicated Bridge pool access to private network data on behalf of Tableau Online.

ist

Extensions section

Setting	Description
Dashboard Extensions	Manage and control dashboard extensions. Dashboard extensions are web applications that run in custom dashboard zones and can interact with the rest of the dashboard. For more information, see "Manage Dashboard Extensions" in Tableau Online Help or Tableau Server Help .
Analytics Extensions	Enables a set of functions that your users can use to pass expressions to analytics extensions for integration with R and Python. For more information, see "Configure Connection with Analytics Extensions" in Tableau Online Help or Tableau Server Help .
Tableau Prep Extension	When authoring flows on the web, enables users to apply Einstein Discovery-powered models to their flows to bulk score predictions for their data. For more information, see Configure Einstein Discovery Integration in the Tableau Server help.

Integrations section

Setting	Description
Slack Connectivity	Displays connections between a Slack workspace and the Tableau site. When connected, Tableau site users can see their Tableau notifications in the connected Slack workspace.

Note: In Tableau Server, a Slack administrator must

create a private Slack app and install it to a Slack workspace before a Tableau server administrator can add an OAuth Client and connect to Slack.

In Tableau Server, you can add OAuth client information for a private Slack application, then select **Connect to Slack** to finalize the connection. For more information, see [Integrate Tableau with a Slack workspace](#).

Analytics Extensions

Enables a set of functions that your users can use to pass expressions to analytics extensions for integration with R and Python. For more information, see "Configure Connection with Analytics Extensions" in [Tableau Online Help](#) or [Tableau Server Help](#).

Connected Apps section (Tableau Online)

Setting	Description
Connected Apps	Create and manage Tableau connected apps, or explicit trust relationships between your Tableau Online site and custom applications, to enable users single sign-on (SSO) access to embedded Tableau content without identity provider (IdP) integration. For more information, see Configure Tableau Connected Apps to Enable SSO for Embedded Content in the Tableau Online Help.

Manage Users and Groups

You can add users to your Tableau sites and set their site roles, which determines each user's level of access. In addition, you can create groups of users, and enable guest access

to your sites.

Add Users to a Site

Everyone who needs to access Tableau Server—whether to browse, publish, edit content or administer the site—must be added as a user. Administrators have the following options for adding users:

- Add a local user account or a user account from Active Directory, described later in this article.

You can also add users by importing an Active Directory group. See [Create Groups via Active Directory](#).

- Import Users via a CSV file that you create using the [CSV Import File Guidelines](#).

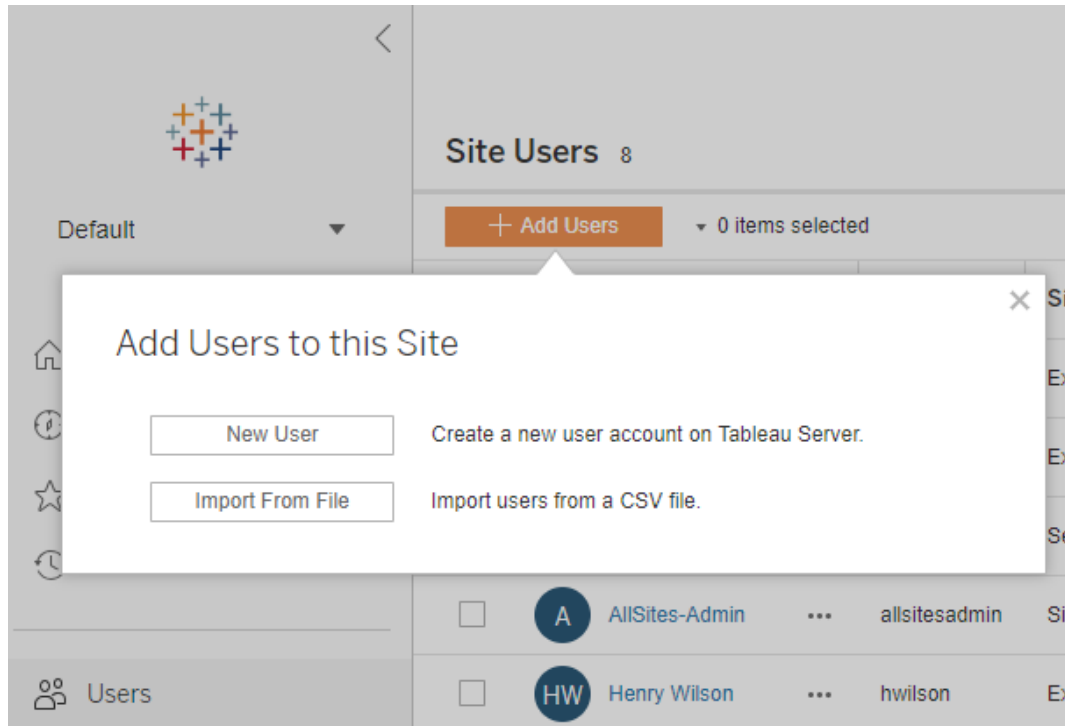

Site administrator access to user management

By default site administrators can add and remove users on a site. On the site's Settings page, server administrators can revoke that capability, so that only server administrators can manage the site's users.

A site administrator can edit an existing local user account only if the administrator has access to all of the sites the user is a member of. For example, if User1 is a member of sites A and B, an administrator of only site B cannot edit User1's full name or reset the password.

Add local users to a site

1. Sign in to Tableau Server as an administrator, and if applicable select the site.
2. Select **Users**. On the Users page, click **Add Users**, and then click **New User**.

3. Enter a user name. With local authentication, using an email address for the user name is the best way to avoid user name collisions (for example, *lrodriguez@example.com* instead of *lrodriguez*).

New User

Username:

Username available

Display name:

Password:

Confirm password:

Email (optional):

Site role: ⓘ

User names are not case sensitive. Characters not allowed in user names include the semi-colon (;) and colon (,).

Also enter information in the following fields:

- **Display Name**—Type a display name for the user (e.g., *Laura Rodriguez*).
- **Password**—Type a password for the user.
- **Confirm password**—Retype the password.
- **Email**—This is optional and can be added at a later time in the user profile settings.

4. Select a site role.

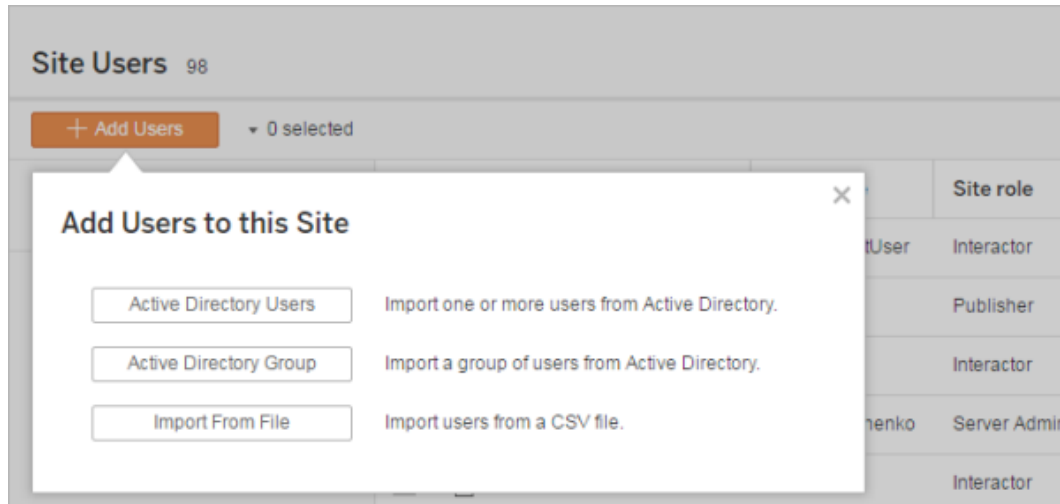

For site role definitions, see [Set Users' Site Roles](#).

5. Click **Add User**.

Add Active Directory users to a site

Before adding users to a site, be sure to review User Management in Deployments with External Identity Stores to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

1. In a site, click **Users**, and then click **Add Users**, and then click **Active Directory User**.

2. Enter one or more user names (separated by semicolons).

For example, *tdavis;jjohnson;hwilson*

If you are adding a user that is from the same Active Directory domain that the server is running on, you can type the AD user name without the domain. The server's domain will be assumed.

Note: Do not enter the user's full name in this field; it can cause errors during the importing process.

3. Select a site role.

For site role definitions, see [Set Users' Site Roles](#).

4. Click **Import Users**.

Remove local users

1. Sign in to Tableau Server as an administrator, select the site, and open the **Users** page.
2. Select the check boxes next to the users' names, and on the **Actions** menu, select **Remove**.

If a user is a member only of the current site, and they do not own any content, the user is removed from the server.

If a user you remove from the current site is a member of other sites on the server, their status remains unchanged on those sites.

Related information

- You can also [Add Users to Tableau Server](#), without site affiliation.
- Upgrading Tableau Server to version 2018.1 or later from a pre-2018.1 version, without activating user-based licenses, affects users who were assigned the **Viewer** site role in the pre-2018.1 server version.

To learn more, see the section "User-based licenses" in the [Licensing Overview](#) and see [Set Users' Site Roles](#).

Set Users' Site Roles

When you add users to a site on Tableau Server, independent of their license type, you must apply a *site role* to them. The site role signifies the maximum level of access a user can have on the site. Along with content permissions, the site role determines who can publish, interact with, or only view published content, or who can manage the site's users and administer the site itself.

Looking for Tableau Server on Linux? See [Set Users' Site Roles](#).

How user licenses, site roles, and content permissions work together

The intersection of a user's license type, site role, and content permissions determines the level of access a user has on the Tableau site.

Note: The license level count at the top of the header on the **Server Users** tab may differ than the count under the **Max User Role** filter due to the fact that some users have different roles across sites.

1. The license type is associated with the user. The site role you want to assign to the user determines the license type they will require.

In a multi-site environment on Tableau Server, a user's license applies to all sites the user is a member of.

2. The site role is also set at the user level. In a multi-site environment, you assign site roles on each site. For example, the same user can have the Site Administrator Creator site role on one site, and Viewer site role on another site.

The site role defines the maximum capabilities the user can have.

3. Whether the site role's maximum capabilities are available to the user depends on the permissions set on the content resources (projects, data sources, workbooks).

For example, let's say that a user has the following access on a site:

- Creator license (due to their access on another site)
- Explorer site role (on this site)
- Save permission capability on a project (on this site)

Tableau Server on Windows Help

In this scenario, even though the license allows connecting to and creating new data sources in the web editing environment or Tableau Desktop, and a permission rule allows them to save in a project, their site role prevents them from being able to save so their effective permissions do not include the save capability. The user can't publish content to the site.

Similarly, even if a user has a creator license and a creator site role, if they do not have the save capability on at least one project, they can't publish anything to the site.

For more information, see [Permissions](#).

Change a user's site role

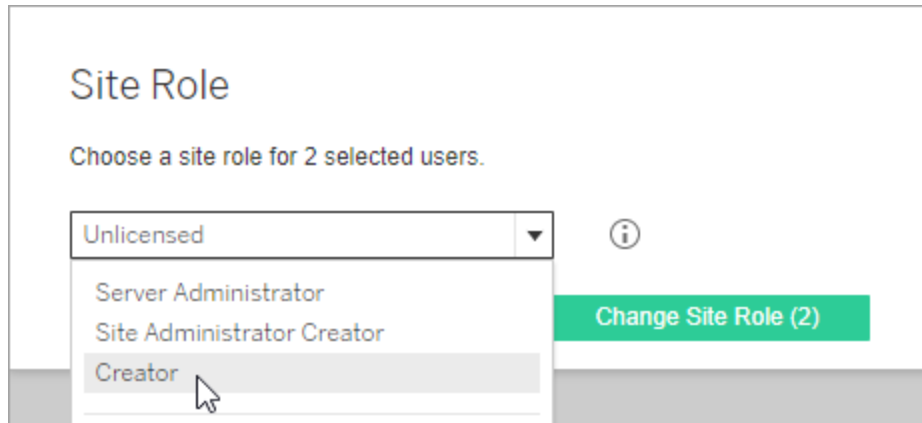

1. Sign in to the site as a server or site administrator, and go to the **Users** area.

If you are a site administrator and do not see the **Users** area, check with your server administrator on whether they have denied user management capabilities to site administrators.

2. Select the users, and then select **Actions > Site Role**.

3. Select the new site role, and then click **Change Site Role**.

You can hover the pointer over the information icon to display a matrix that shows the maximum level of general capabilities each site role allows. For more information, continue to [General capabilities allowed with each site role](#).

General capabilities allowed with each site role

The following table lists the license types as of version 2018.1, the highest level of site role allowed with each, how each site role maps to its pre-2018.1 equivalent; and summarizes the maximum capabilities each site role allows.

What this article covers and where to find what's not covered here

- This information focuses on *site* roles and is more generalized. For a list of common specific tasks available per *license* role, see the matrix on the [For Teams & Organizations](#) tab on the Tableau pricing page.
- This information describes site roles as of version 2018.1. To learn more about how core-based licensing relates to user-based licensing, how licenses transfer, or other specific licensing transition scenarios, start with the following topics:

[Migrate from Core-Based to Role-Based Licensing](#)

[Troubleshoot Licensing](#)

Tableau Server on Windows Help

Tableau site roles as of version 2018.1

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
Site roles that use a Creator license		
—Users with these site roles have access to Tableau clients such as Tableau Prep, Tableau Desktop, Tableau Bridge, and Tableau Mobile.		
Server Administrator	Server Administrator	<p>Available on Tableau Server only; not applicable to Tableau Online.</p> <p>This site role always occupies the highest license activated on the server between Creator and Explorer. It allows unrestricted access to the configuration settings for the Tableau Server browser environment, all sites on the server, users and groups, and all content assets, such as flows, projects, data sources (including connection information), and workbooks.</p> <p>Connect to Tableau published data sources or external data, from the browser, Tableau Desktop, or Tableau Prep; create and publish new data sources; author and publish workbooks.</p>
Site Administrator Creator	--	<p>This is the highest level of access for Tableau Online.</p> <p>Unrestricted access to content as described above, but at the site level. Connect to Tableau or external data in the browser, Tableau Desktop, or Tableau Prep; create new data sources; build and</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		<p>publish content.</p> <p>On Tableau Server, server administrators can determine whether or not to allow site administrators to manage users and assign site roles and site membership. By default, on Tableau Server, and always on Tableau Online, site administrators are allowed these capabilities.</p>
Creator	--	<p>This is similar to the former Publisher site role, but allows new features. This site role offers non-administrators the maximum level of <i>content</i> access.</p> <p>Connect to Tableau or external data in the browser, build and publish flows, data sources and workbooks, have access to Dashboard Starters, and use interaction features on published views. Can also connect to data from Tableau Prep or Tableau Desktop, publish (upload/save) and download flows, workbooks and data sources.</p>
Site roles that use an Explorer license		
—Users with these site roles can access the server from the browser or Tableau Mobile.		
Server Administrator	N/A	<p>Tableau Server only; not applicable to Tableau Online.</p> <p>If Explorer is the highest license type activated on the server when a new server administrator user is created, the user's site role is Server Administrator;</p>

Tableau Server on Windows Help

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		<p>however, the user will not have the full connecting and publishing capabilities that come only with the Creator license.</p> <p>With the Explorer license a Server Administrator has unrestricted access to the configuration settings for the Tableau Server browser environment, all sites on the server, users and groups, and all content assets, such as projects, flows, data sources (including connection information), and workbooks.</p> <p>However, with the Explorer license, a Server Administrator can't connect to external data from the browser to create a new data source. They can author or publish workbooks and data sources from Tableau Desktop. (they function as an Explorer (can publish) site role with regards to publishing).</p>
Site Administrator Explorer	Site Administrator	<p>Same access to site and user configuration as Site Administrator Creator, but can't connect to external data from the web editing environment.</p> <p>Can connect to Tableau published data sources to create new workbooks, and edit and save existing workbooks.</p>
Explorer (can publish)	Publisher	<p>Can publish workbooks from the web using existing data sources, browse and interact with published views, and use all interaction features.</p> <p>In the web editing environment, can edit and save</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		existing workbooks. Cannot save new standalone data sources from data connections embedded in workbooks, and cannot connect to external data and create new data sources.
Explorer	Interactor	Can browse and interact with published views. Can subscribe to content, create data driven alerts, connect to Tableau published data sources and open workbooks in the web authoring environment for ad-hoc queries, but they can't save their work.
Read Only	Viewer	<p>This site role is available only in version 2018.1, for transitioning users to the user-based Viewer (or other) license and site role. Any users in the Read Only site role prior to upgrading to version 2018.2 or later are reassigned to the Viewer site role.</p> <p>In 2018.1 versions, Read Only users can see and subscribe to published views others have created. Can't use other interaction features or save custom views.</p>
Site roles that use a Viewer license		
Viewer	N/A	<p>Can see published views others have created and use most interaction features. Can subscribe to views and download as images or summary data. Can't connect to data, create, edit, or publish content, or set data alerts.</p> <p>For a list of specific capabilities, see the Viewer</p>

Site role name as of version 2018.1	Previous site role name	Maximum capabilities this site role allows
		<p>column in the matrix on the Tableau pricing page.</p> <p>Note: Although the Viewer site role existed in previous versions, the new Viewer site role has additional capabilities.</p>
Other site roles		
Unlicensed	Unlicensed	<p>Unlicensed users can't sign in to Tableau Server or Tableau Online. Users are assigned the Unlicensed role in the following circumstances:</p> <ul style="list-style-type: none"> • You import users from a CSV file and their license level is set to unlicensed. • The number of available licenses is reached at the time you add or import users. • You remove a user who owns content on the site. The user will still own the content but not be able to do anything with it. • A product key(s) has expired. See Refresh Expiration Date for the Product Key.

Who can publish content

The following site roles allow the specified level of publishing access.

- **Server Administrator** (Tableau Server only); **Site Administrator Creator**; and **Creator** allow full connecting and publishing access.

This includes connecting to data and publishing new flows, new workbooks and new data sources from Tableau Desktop and the web editing environment. The site roles also allow editing and saving existing published workbooks, or publishing updates to existing data sources.

- **Explorer (Can Publish)** and **Site Administrator Explorer** have limited publishing capabilities, as described in General capabilities allowed with each site role.
- **Explorer, Viewer, Read Only, and Unlicensed** do not allow publishing.

Site roles and Active Directory import and synchronization

When you import users from an external directory like Active Directory, you can specify the site role. If a user is not yet a member of any site on the server, the user is added to the site with the assigned role. When you synchronize groups from an external directory, the site role is applied through the **Minimum Site Role** setting on the **Groups - Details** page.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

If a user already exists in a Tableau Server site, the site role assigned during the import or sync process will be applied if it gives the user more access in a site. Importing or synchronizing AD users and groups can promote a user's site role, but does not demote a user's site role.

If a user already has the ability to publish, that ability is maintained.

The matrix below shows the rules applied for site roles on import.

Note: The **Import Site Role** row abbreviated headers indicate the site role specified for import. The **Current Site Role** column headers represent the current user site role.

The table values represent the abbreviated resulting site role.

- Site Administrator: SA
- Site Administrator Creator: SC
- Site Administrator Explorer: SE
- Creator: C
- Explorer: E
- Explorer (Can Publish): EP
- Viewer: V
- Unlicensed: U

	Current Site Role						
Import Site Role	SC	C	SE	EP	E	V	U
Site Administrator Creator (SC)	SC	SC	SC	SC	SC	SC	SC
Site Administrator Explorer (SE)	SE	SE	SE	SE	SE	SE	SE
Creator (C)	SC	C	SE	C	C	C	C
Explorer (Can Publish) (EP)	SC	C	SE	EP	EP	EP	EP
Explorer	SE	C	SE	EP	E	E	E

	Current Site Role						
Import Site Role	SC	C	SE	EP	E	V	U
(E)							
Viewer (V)	SE	C	SE	EP	E	V	V
Unlicensed (U)	SE	C	SE	EP	E	V	U

View, Manage, or Remove Users

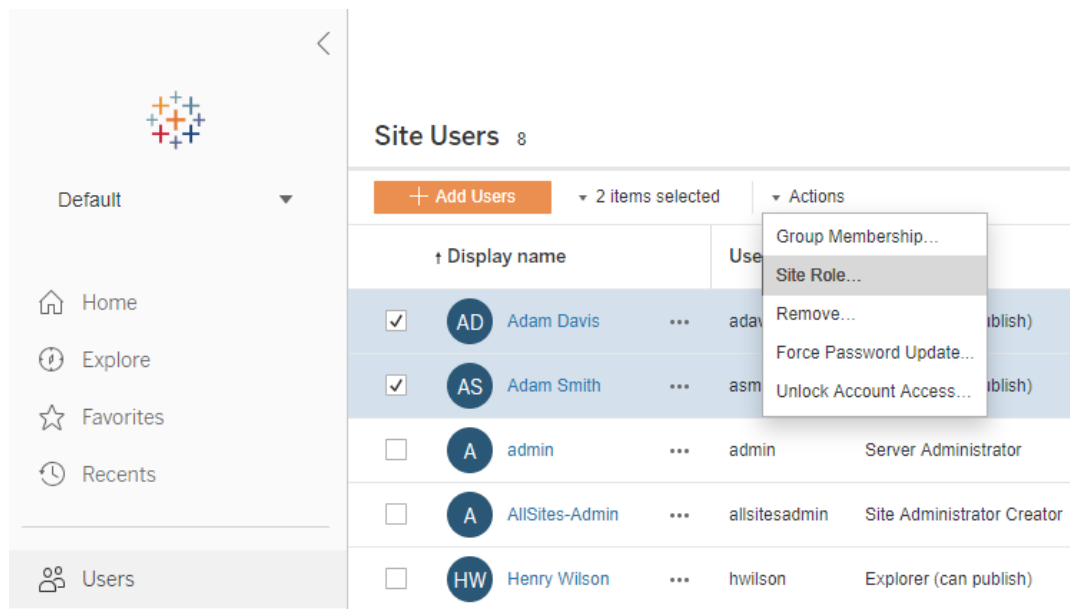

Administrators can manage a site's users such as adding and removing users, setting the groups they're members of, setting their site roles, and so on. On Tableau Server, server administrators can manage users on multiple sites at a time on the **All Sites** page.

View and manage users on a site

Sign in to a site as an administrator, and then select **Users**. On this page you can do any of the following to manage users:

- Set group membership, set site role, or remove the user from the site. If you've configured the site for SAML single sign-on, you can set the selected users' authentication type. If your server is configured for password policies and account access lockout, you can unlock access to a user's locked out account.

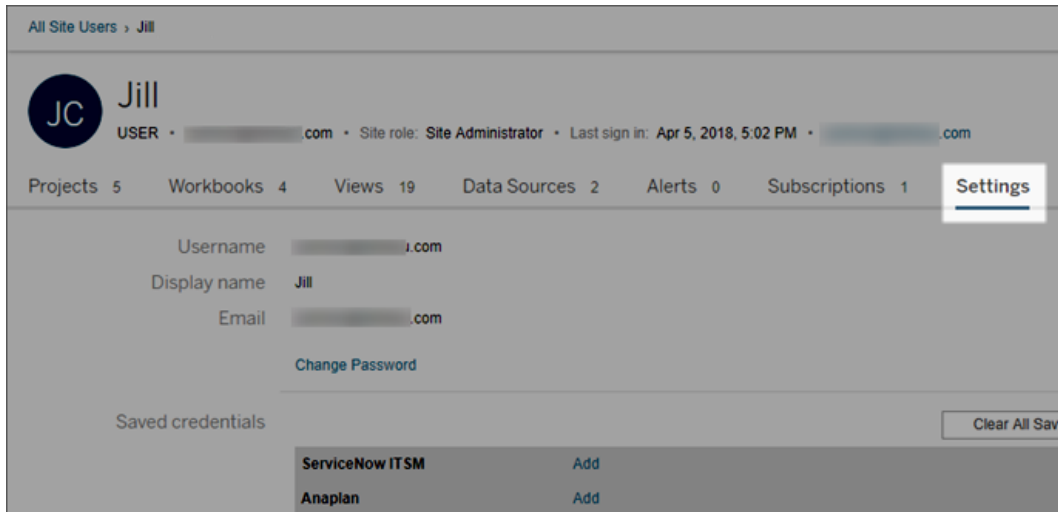

Tableau Server on Windows Help

- Select a user name to see details about them, such as content they own, views they subscribe to, and their account settings.

The user **Settings** page is available when the following conditions are true:

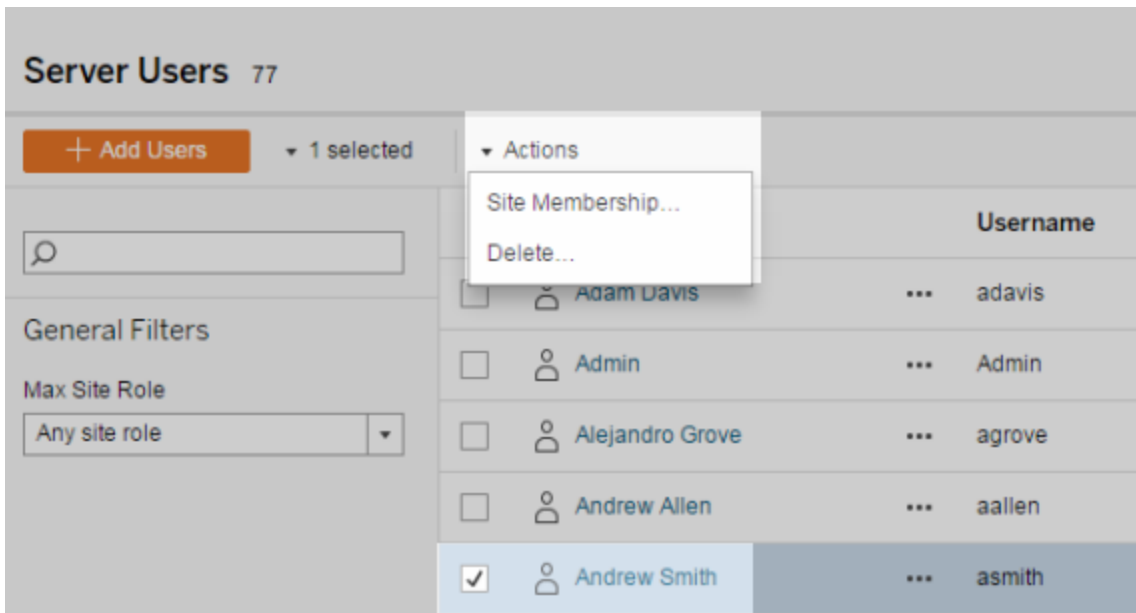

- The user is a member only of sites that the site administrator controls
- Site administrators can manage users. This is always the case for Tableau Online and is the default for Tableau Server; Tableau Server administrators can change this access for site admins.

If the server is configured to use the internal user management system (Local Authentication), you can edit the **Display Name**, **Email**, and **Password** for users after they have been added. If you are making many changes, you may find it easier to import the changes from a CSV file. For details, see [Import Users and CSV Import File Guidelines](#).

View and edit server users

Sign in to Tableau Server as a server administrator. On the site menu, select **Manage All Sites**, and then select **Users**.

Manage users' site membership

By default, server and site administrators can manage users at the individual site level. Server administrators can also manage users and their site roles on multiple sites. You do this at the **All Sites** level (at the server level).

1. In the site menu, select **Manage All Sites**, and then select **Users**.
2. On the Server Users page, select the check boxes next to the users, and then select **Actions > Site Membership**.
3. Select one or more sites, and a site role for each site, and then click **Save**.

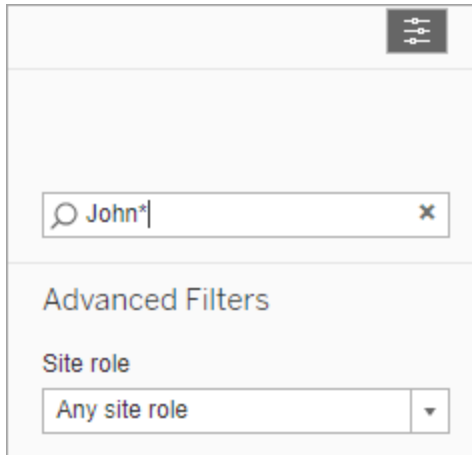

Search for users

To search for a specific user

Use the filter toggle in the upper right to display the search box and site role filter. Then use the search box or filters to find the users you want.

The search operation checks the display name and user name attributes.

You can use the asterisk (*) character as a search wildcard. For example, searching for `John*` will return all user names that start with *John*.

The screenshot shows a search interface with a search box containing the text "John*" and a clear button (X). Below the search box is an "Advanced Filters" section. Under "Advanced Filters", there is a "Site role" label and a dropdown menu currently set to "Any site role".

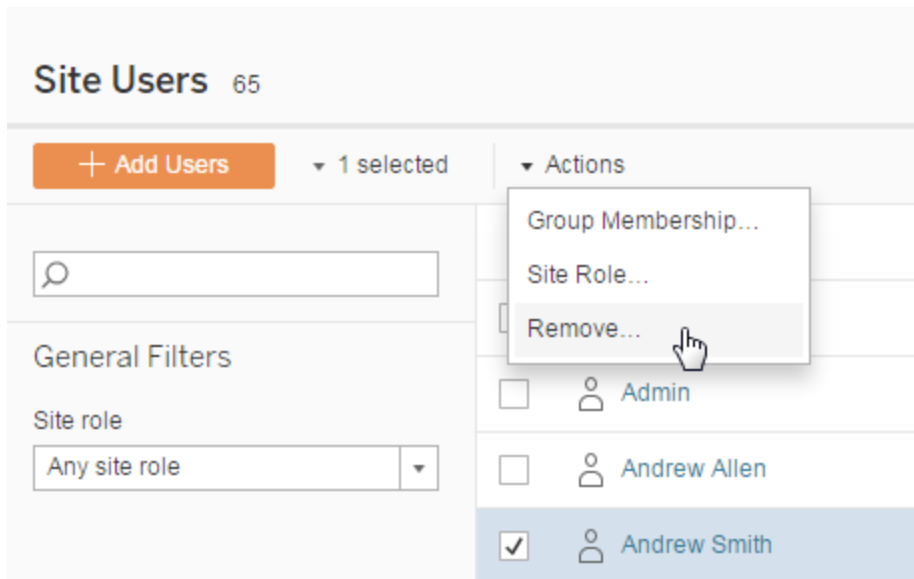

Remove users from a site

You can remove a user only if the user does not own any content (projects, workbooks, views, or data sources). If you attempt to remove a user who owns content, the user site role will be set to Unlicensed, but the user will not be removed.

If the default All Users group has enabled Grant site role on sign in, that user's content must be reassigned to another user or removed before they can be unlicensed or removed. For more information on Grant role on sign in, see [Removing users affected by Grant role on sign in](#). For more information on changing content ownership, see [Manage Content Ownership](#).

Note: On Tableau Server, when an administrator removes a user from a site (and the user belongs only to that one site), the user is also deleted from the server.

1. Sign in to a site as an administrator, and go to the **Users** area. Select one or more users to remove, and then select **Actions > Remove**.

2. Click **Remove** in the confirmation dialog.

Remove users from the server

You can remove a user only if the user does not own any content (projects, workbooks, views, or data sources). If you attempt to remove a user who owns content, the user site role will be set to Unlicensed, but the user will not be removed.

If a user is a member of multiple sites, and they own content on any of those sites, they are removed from the sites on which they don't own content. The user remains a member on sites where they own content, but demoted to the Unlicensed site role.

1. In the site menu, click **Manage All Sites**, and then click **Users**. In a single-site environment, click **Users**.

Select one or more users to delete, and then click **Actions > Delete**.

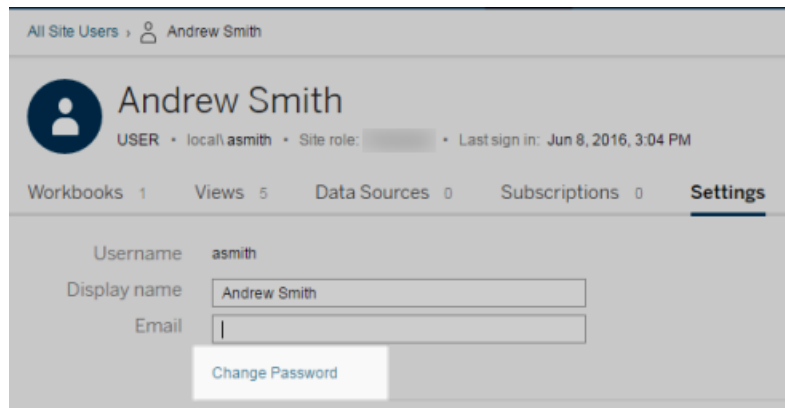

2. Click **Delete** in the confirmation dialog box.

Change passwords for users of a single site

To change the password for a user with membership to a single site, sign in to Tableau Server as a site administrator or a server administrator.

1. Ensure that the correct site is selected in the menu.
2. Click **Users**.
3. Click the display name of a user.
4. Click **Settings**.
5. Click the **Change Password** link, edit the password, and then click **Save**

Password.

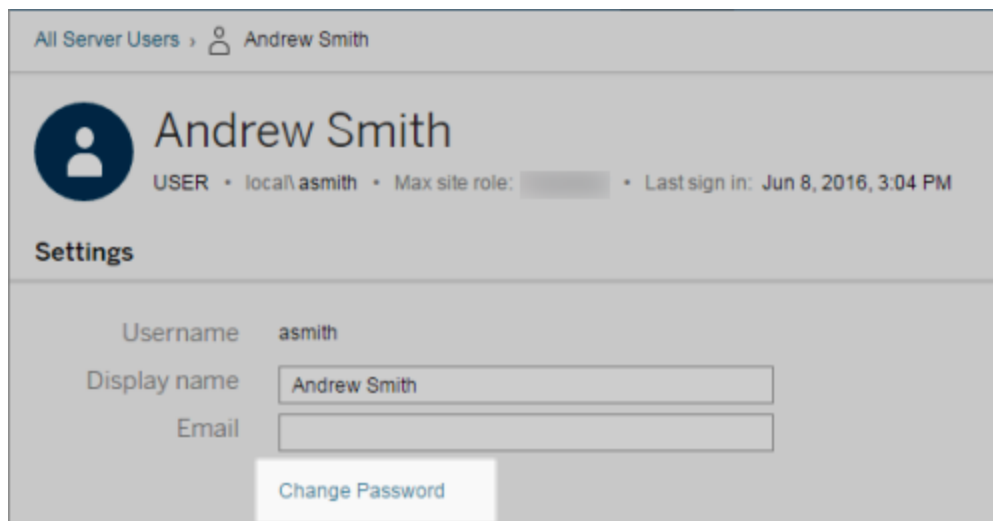

Change passwords for users of multiple sites

To change the password of a user with membership to multiple sites, sign in to Tableau Server as a server administrator.

1. In the site menu, click **Manage All Sites**.
2. Click **Users**.
3. Click the display name of a user.

4. Click the **Change Password** link, edit the password, and then click **Save Password**.

Set the User Authentication Type for SAML

On a site that has been configured for site-specific SAML, administrators can specify users' authentication type. For example, if Tableau Server was configured for site-specific SAML and server-wide SAML, administrators can specify which users authenticate with site-specific SAML and which users authenticate with server-wide SAML.

You can assign authentication type at the time you add users to Tableau Server, as well as any time afterward.

1. When you're signed in to the Tableau Server site, select **Users**.
2. On the **Site Users** page, select the check boxes next to the users you want to assign an authentication type.
3. On the **Actions** menu, select **Authentication**.

Tableau Server on Windows Help

4. In the Authentication dialog box, select **Site SAML** or **Server Default**.

Notes

- Users that authenticate with site-specific SAML can only belong to one site. If a user needs to belong to multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.
- If you change users' authentication to site-specific SAML, the next time they sign in, they will be directed to your identity provider's site to provide their credentials.

Import Users

To automate the process of adding users to a site, you can create a CSV file that contains user information, and then import the file.

Site administrators can import users to a particular site; server administrators (Tableau Server only) can import users at the server level, to later add them to multiple sites.

Note: This topic contains the steps for importing, assuming that you have already created the CSV file. If you have not created the file yet, see [CSV Import File Guidelines](#) for a list of file format requirements and import options.

Add users from a CSV file

The following steps describe how to add users to a site or to the server. The images reflect adding users at the site level.

1. Do one of the following:
 - To add users at the site level, select **Users**, and then **Add Users**.

- To add users at the server level on a **single-site** server, select **Users**, and then **Add Users**.
 - To add users at the server level on a **multi-site** server, open the list of sites, and select **Manage All Sites**. Select **Users**, and then **Add Users**.
2. Click **Import From File**, click **Browse** and navigate to the file, and then click **Import Users**.

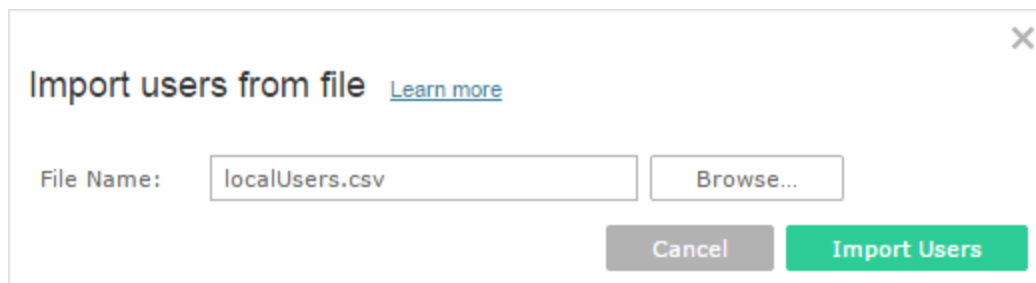

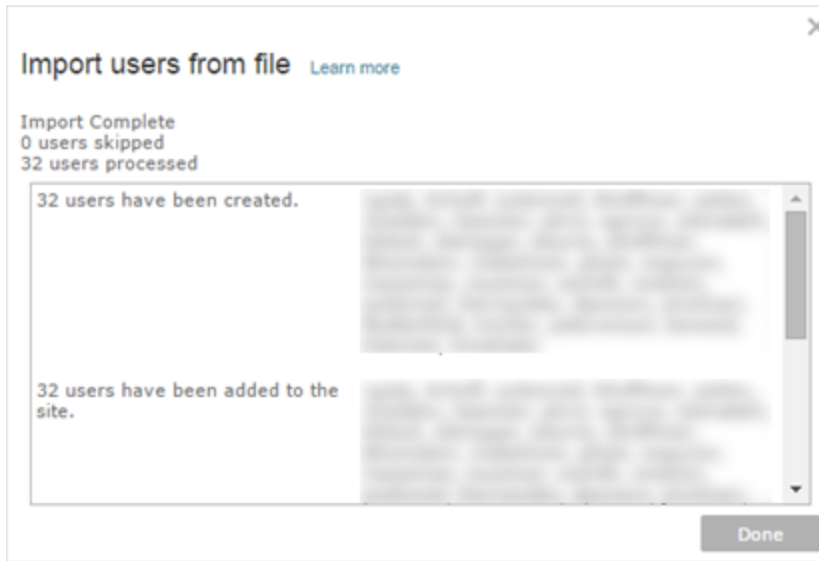

Tableau displays the results of the import process (names in this image are blurred).

3. Click **Done**.

How users' site roles are assigned or maintained

When you import at the site level or on a single-site server using `tabcmd`, you can specify the site role for all users in the CSV file. If a user already exists in the Tableau Server site, the site role assigned during the import process will be applied, even if it is more restrictive than users' existing site role. The exception is that you cannot affect a server administrator's site role.

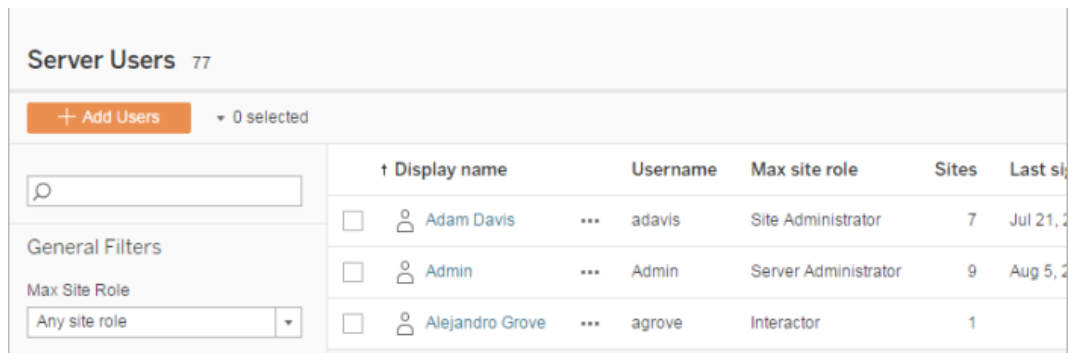

For a multi-site server, when you import users in the Server Users page, you create server users with no site affiliation. Because these users do not belong to a site, they cannot have a site role. The only site role a user can have at the server level is **Unlicensed** or **Server Administrator**.

You can also specify the user's site role when you assign site membership to a user. For information, see [Manage users' site membership](#).

Importing at the server level in multi-site environments

If the server is running multiple sites and you are a server administrator, you can import a CSV file from two locations. Where existing user accounts are concerned, each location has different capabilities.

- The **Server Users** page appears in a multi-site environment. Only server administrators can access this page.

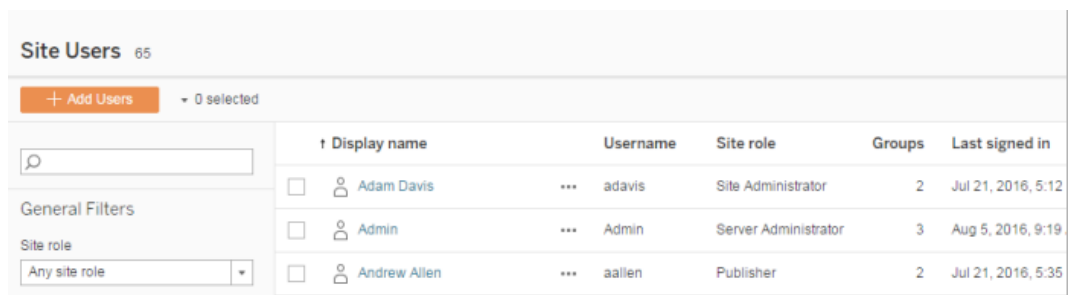

The screenshot shows the 'Server Users' page with 77 users. It includes a search bar, a '+ Add Users' button, and a '0 selected' indicator. A 'General Filters' section on the left allows filtering by 'Max Site Role' (currently set to 'Any site role'). The main table lists users with their display names, usernames, max site roles, and the number of sites they are associated with.

	↑ Display name	Username	Max site role	Sites	Last signed in
<input type="checkbox"/>	Adam Davis	adavis	Site Administrator	7	Jul 21, 2016, 5:12
<input type="checkbox"/>	Admin	Admin	Server Administrator	9	Aug 5, 2016, 9:19
<input type="checkbox"/>	Alejandro Grove	agrove	Interactor	1	

You can import the CSV file from here if you want to update existing user accounts in addition to adding new ones. For example, if you import a file that has a new password for each existing user, their passwords will be reset.

- The **Site Users** page.

The screenshot shows the 'Site Users' page with 65 users. It includes a search bar, a '+ Add Users' button, and a '0 selected' indicator. A 'General Filters' section on the left allows filtering by 'Site role' (currently set to 'Any site role'). The main table lists users with their display names, usernames, site roles, and the number of groups they are associated with.

	↑ Display name	Username	Site role	Groups	Last signed in
<input type="checkbox"/>	Adam Davis	adavis	Site Administrator	2	Jul 21, 2016, 5:12
<input type="checkbox"/>	Admin	Admin	Server Administrator	3	Aug 5, 2016, 9:19
<input type="checkbox"/>	Andrew Allen	aallen	Publisher	2	Jul 21, 2016, 5:35

Server administrators can add new user accounts with CSV imports. If the CSV file includes existing users, the **Password** and **Display Name** fields must either match

the existing or be left blank. If new passwords or full names are used, the import will fail.

Importing to a single-site environment

Server and site administrators on a single-site server perform CSV user imports from the **Users** page in a site.

The screenshot shows the 'Users' page in Tableau. At the top, it says 'Users 57'. Below that is a '+ Add Users' button and '0 selected'. There is a search bar and a 'General Filters' section with a 'Site role' dropdown set to 'Any site role'. The main part of the page is a table with the following columns: 'Display name', 'Username', 'Site role', 'Groups', and 'Last signed in'. Three users are listed: Adam Davis (Site Administrator, 4 groups, signed in May 13, 2016), Admin (Server Administrator, 2 groups, signed in Aug 5, 2016), and Alan Wang (Publisher, 4 groups).

	† Display name		Username	Site role	Groups	Last signed in
<input type="checkbox"/>	 Adam Davis	...	adavis	Site Administrator	4	May 13, 2016
<input type="checkbox"/>	 Admin	...	Admin	Server Administrator	2	Aug 5, 2016
<input type="checkbox"/>	 Alan Wang	...	awang	Publisher	4	

Multi-site versus single-site import

Users can belong to more than one site on the same server, but they must use the same credentials for each site. This becomes important when you're adding users to a site and those users might already be members of a different site. If you try to import a user who already exists, and if the user's credentials in the CSV file don't match the existing credentials, the import fails for that user.

If you're importing users to a site and think the users might already exist on the server, you can try leaving the **Password** field in the CSV file blank (while including the delimiters for the field). If a user who is defined in the CSV already exists in another site, the user is added to the site where you're importing. However, if the user *doesn't* already exist on the server, the user is created, and the CSV import window alerts you that the new user doesn't have a password. You can then use the server administrator pages to assign a password to any user who doesn't have one.

Note: If the server is configured to use Active Directory for authentication, user passwords are managed by Active Directory, and you can leave the password field in the CSV file blank.

CSV Import File Guidelines

You can automate adding users by creating a comma-separated values (CSV) file with user information and then importing the file. You can include attributes in the CSV file, such as license level and the publishing access, to apply to the users at the same time you import them.

To import users, you can use the server or site administration pages or the `tabcmd` utility. Using `tabcmd` provides an option for assigning a site role to all users in the CSV file. For information, see `Import Users` or `createsiteusers filename.csv`.

You can import users at the site or server level. If you import users to the server (not to a specific site), the users aren't assigned to a site and are imported as Unlicensed.

CSV file format requirements

When you create the CSV file for importing users, make sure that the file meets the following formatting requirements:

- The file does not include column headings. Tableau Server assumes that every line in the file represents a user.
- The file is in UTF-8 format, and includes the byte-order mark (BOM).
- Character encodings such as BIG-5 have been converted to UTF-8. You can do this by opening the file in a text editor and using the **Save As** command.
- If a user name includes an @ character that represents anything other than a domain separator, you need to refer to the symbol using the hexadecimal format: `\0x40`

Tableau Server on Windows Help

For example, `user@fremont@mycompany.com` should be `user-\0x40fremont@mycompany.com`

Required columns in the CSV file

The following values are required for each user:

- User name
- Password: If Tableau Server is configured to use Active Directory authentication, there must be a `Password` column, but the column itself should be empty. If the server is using local authentication, you must provide passwords for new users.

Additional import file options

The CSV file can contain the following fields, in the order shown here:

- User name. The user name. If the server is configured to use Active Directory, this value must match a user defined in Active Directory. If the user name is not unique across domains, you must include the domain as part of the user name (for example, `example\Adam` or `adam@example`). This is the only required field.
- Password. A password for the user. If the server is configured to use Active Directory, this value is not used.
- Display name. The display name is part of the information used to identify a user on the server. If the user's display name is already in use, Tableau Server updates the existing user information with the settings in the CSV file. If the server is configured using Active Directory, this value is not used.
- License level. This can be **Creator**, **Explorer**, **Viewer**, or **Unlicensed**.
- Administrator level (**System**, **Site**, or **None**). This setting determines whether the user is imported as an administrator.

If you are using the web UI to import users, you can set the administrator site role to **System** only if you import the file at the server (All Sites) level. If you are signed in to a specific site, and if the administrator column for a user in the CSV file is set to **System**, Tableau Server imports the user as a site administrator.

- Publishing capability (**yes/true/1** or **no/false/0**). If you are using the web UI, the publisher setting is used only if you import while signed in to a specific site. If you import users at the server (All Sites) level, this value isn't used.
- Email address. The email address is part of the information used to identify a user on the server. If the email address is already in use, Tableau Server updates the existing user information with the settings in the CSV file.

The order of the columns is significant. The first column is treated as the user name, the second as the password, the third as display name, and so on, regardless of the content in the columns. If you omit values for a field, you must still include the field's comma delimiter.

Improve performance for large CSV files passed through `tabcmd`

A server administrator can enable server settings that help to improve performance for importing large CSV files through `tabcmd` commands. You can do this using the `tsm configuration set` command with the following options:

- `vizportal.csv_user_mgmt.index_site_users`
- `vizportal.csv_user_mgmt.bulk_index_users`
- `searchserver.index.bulk_query_user_groups`

Essentially, these options index users after the CSV file is processed, instead of one-by-one as they are added to the server's database. This reduces the number of calls to the database and the memory required to process the file. These `tsm configuration set` options apply to the `tabcmd createsiteusers`, `deletesiteusers`, `addusers`, and `removeusers` commands.

For descriptions for these settings, see `tsm configuration set Options`.

Notes

- If you are not signed in to a specific site and are importing users at the server level, you can assign only the Server Administrator and Unlicensed site roles.
- If you have a user-based server installation, and if adding users would exceed the number of users allowed by your license, the users are added as unlicensed users.
- If you use `tabcmd` and specify the license, but importing users would exceed your license limits, users are imported as Unlicensed.

CSV settings and site roles

The license level, administrator, and publishing settings for a user determine how the user's site role is set during the import process. The following table shows how the settings are converted to site roles.

CSV settings	Site role
License level=(any) Administrator=System Publisher=true	Server Administrator. This setting applies to Tableau Server only, and it is valid only if you are importing users while managing the server (that is, not signed in to a specific site). The Server Administrator site role always takes a Creator license if one is available. If no Creator license is available, see Troubleshoot Licensing to learn about the way Tableau Server handles this.
License level=Creator or Explorer Administrator=Site Publisher=true	Site Administrator Creator or Site Administrator Explorer. This setting is valid only if you are importing users while signed in to a specific site.
License level=Creator	Creator

CSV settings	Site role
Administrator=None Publisher=true	
License level=Explorer Administrator=None Publisher=true	Explorer (Can Publish)
License level=Explorer Administrator=None Publisher=false	Explorer
License level=Viewer Administrator=None Publisher=false	Viewer
License level=Unlicensed Administrator=None Publisher=false	Unlicensed

CSV import example for Tableau Server

The following example shows a CSV file that contains information for several users.

```
henryw,henrypassword,Henry Wilson,Creator,
None,yes,henryw@example.com
freds,fredpassword,Fred Suzuki,Viewer,
None,no,freds@example.com

alanw,alanpassword,Alan
```

Tableau Server on Windows Help

```
Wang, Explorer, Site, yes, alanw@example.com
michellek, michellepassword, Michelle Kim, Creator, System, yes, michellek@example.com
```

If you import this file while managing a site, four users are added to that site. The `Administrator` setting for user Michelle is `System`. However, because you are importing the users into a site, Tableau Server give Michelle the Site Administrator Creator site role. Three of the users are allowed to publish.

If you import this file while managing the server, four users are added to the server, but they are not added to any site. Only one user is imported as a server administrator; the rest are set to Unlicensed.

Manage Site User Visibility

By default, all site users can see aliases, project ownership and comments by other users when permissions allow. The User Visibility setting lets administrators manage if users with Viewer and Explorer site roles see other users and groups on the site, which can be important for sites that are used by multiple clients. To learn more about site roles, see [Set Users' Site Roles](#).

Limit user visibility

Setting User Visibility to **Limited** impacts certain collaboration tools and hides user information in Tableau Online and Tableau Server. Limited User Visibility either disables the feature for Viewers and Explorers (excluding Site Administrator Explorers), or removes user information from other areas. Note that Creators and administrators will still see user information when User Visibility is set to Limited.

To limit user visibility for Explorers and Viewers (excluding Site Administrator Explorers):

- Navigate to the site's **Settings** page
- Select **Limited** in the **User Visibility** setting

The following is a list of site areas impacted when User Visibility is set to Limited. Unless noted that the feature is disabled for all users, only non-administrator Explorers or Viewers are impacted.

Area	Impact
Search	User information not displayed
Content owners	User information not displayed (Explorers and Viewers can't see themselves, but can see their content in My Content)
Profile pictures	User information not displayed
Subscriptions	User information not displayed
Recommendations	Similar users not displayed (all users)
Add/Edit Tags	Explorers and Viewers can see tags but cannot delete or modify them
"Who has seen this view?"	Disabled
Ask Data usage analytics	Disabled
Permissions dialogs	Disabled
Named sharing	Disabled (all users)
Alerts	Disabled (all users) Existing alerts paused
Comments	Disabled (all users)
Public Custom Views	Disabled (all users) Existing public custom views appear as private

Tableau Server on Windows Help

Request Access	Disabled (all users)
Tableau Desktop	Publishing workbooks disabled from Desktop User information not displayed on user filters
Tableau Catalog (with Data Management Add-on)	User information not displayed

When User Visibility is set to Limited, Tableau Server REST API and Metadata API calls behave as described in the table above.

Users on a site can interact with views and modify them, such as applying filters. If that user shares their modified view with others, or if the user creates something from that modified view (like a metric or a private custom view), then that user's name appears in the URL. Make sure that the URL for this modified view is only distributed to users who are permitted to see that person's name.

Note: If a user is a member of multiple sites, entering an email on the sign in page for Tableau Online will return the names of all sites the user is a member of.

Best practices for limiting user visibility

Administrators can also check that user and group information is not visible in these ways:

- Configure permissions to only provide content to appropriate parties. For more information, see [Permissions](#).
 - Limited User Visibility hides user identification information from search, but might return content that the user published, including when searching by owner name, if the person searching has viewing permission to that content.
 - A user publishing a workbook with a duplicate title in the same project might see a warning that a workbook with that title already exists.
- Apply row-level security when necessary.
- Check that metadata within dashboards does not contain user information.

- Check that calculations accessible to users don't contain user metadata (e.g., user filters).

Restore Full User Visibility

When administrators set User Visibility back to Full, features disabled for all users by Limited User Visibility (such as comments and alerts) remain off. Administrators can re-enable these features through the site's Settings page.

Any previous feature settings are not retained when User Visibility is set to Full, and affected features are not automatically turned on.

Guest User

Core-based licenses of Tableau Server include a Guest user option, which you can use to let people access Tableau views without an account on the server.

Guest user access is enabled by default when Tableau Server is installed with a core-based license. It is not available with user-based licensing. If you do not intend to use Guest user access, you should disable it.

Guest access allows users only to see and interact with Tableau views. The Guest user cannot browse the Tableau Server interface or see server interface elements in the view, such as user name, account settings, comments, and so on. For more information about licenses, see [Manage Licenses](#).

Tip: To share views with Guest users, either provide URL links or embed views into web pages. For more information, [see Tableau User Help](#).

Guest user permissions

A Guest user can have the following maximum capabilities:

- **Workbooks and views:** View, Export Image, Summary Data, View Comments, Filter, Full Data, Web Edit, Download (to save a local copy)
- **Data sources:** View and Download

If you add the Guest user to a group that has a higher level of access to a content resource, the Guest user's access does not exceed the capabilities listed above. However, the Guest user account will comply with more restrictive permissions settings.

Enable or disable Guest access

You must be a server administrator to change Guest account settings at either the server or the site level.

Note: Enabling the Guest user for a site can increase the number of potential simultaneous viewers beyond the user list you might be expecting. The administrative view **Status > Traffic to Views** can help you gauge the activity.

1. In the site menu, click **Manage All Sites** and then click **Settings > General**.
2. For **Guest Access**, select or clear **Enable guest access**.
3. Click **Save**.

This enables the Guest user on all sites. You can then go to the same setting for a specific site. To disallow Guest access for a site:

1. In the site menu, select a site.
2. Click **Settings**, and on the General tab, clear the **Enable guest access for this site** check box.

If the Guest account is enabled on some or all sites, and you turn off Guest access at the server level, it is turned off for all sites as well.

Note: You can turn off Guest user access at the server or site level; however, you aren't able to remove the user. So, although no one can access data or views without signing in to the server, the Guest user still appears in the Site Users list and group lists for groups you've added the Guest user to.

Additional Guest account characteristics

The Guest user is unique in the following additional ways:

- As a single user account, it represents all unauthenticated users accessing Tableau views.
- When enabled, it is a member of the All Users group.
- You can add it as a member of other groups on a site.
- You cannot edit it or select it as the owner of a content resource.
- If the Guest user needs to access a workbook with an extract connection, the Guest must also have the **View** capability on the published data source. (The Guest user is not allowed to connect to published data sources.)
- The account is not allowed to save custom views.
- Guest cannot be used in a user filter.
- You cannot delete the account; however, you can turn off access to it by clearing the check box described in the steps above.

Groups

You can create and delete user groups, add users to a group, and synchronize groups with Active Directory.

Add Users to a Group

You can organize Tableau Server users into groups to make it easier to manage multiple users. You can create groups on the server or import groups from Active Directory.

If you're managing users with an External identity store, such as Active Directory, add users to a group through the external identity store itself. Once users are added to a group in the external identity store, Tableau Server is able to update those users by synchronizing the group of users in the external identity store with the group of users on Tableau Server.

For example, to keep Active Directory group membership up to date, we recommend you review the following:

- Site administrators can synchronize selected groups on demand in a site. For more information, see [Synchronize Active Directory Groups on a Site](#).
- Server administrators can synchronize all Active Directory groups on the server based on a schedule or on-demand. For more information, see [Synchronize All Active Directory Groups on the Server](#).

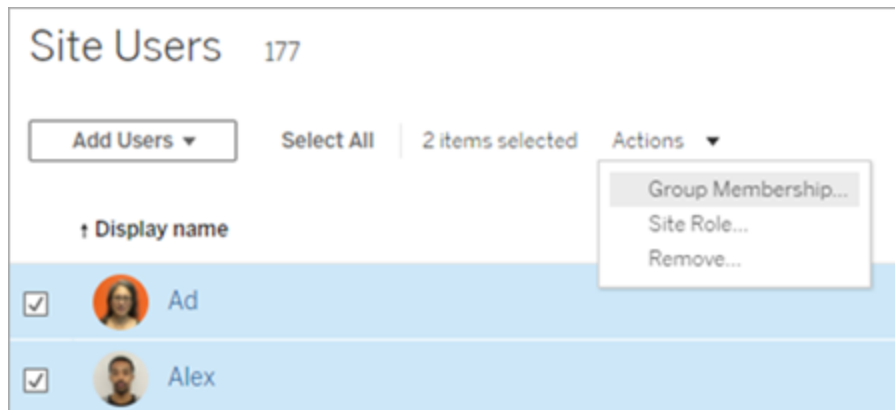

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

If you're managing users with a Local identity store, use the procedures described below to add users to a group.

To add a user to a group, the group must already exist.

Add users to a group (Users page)

1. In a site, click **Users**.
2. Select the users you want to add to a group, and then click **Actions > Group**

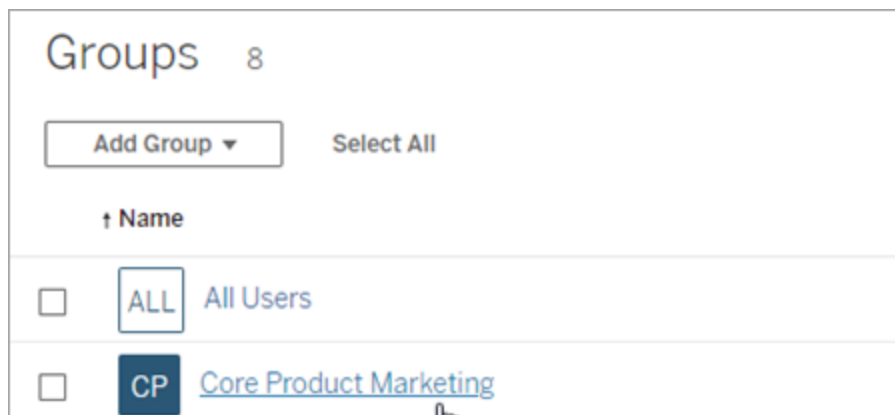

Membership.

3. In the Group Membership dialog box, select the groups and then click **Save**.

Add users to a group (Groups page)

Note: This is only possible for site administrators if the server administrator has configured the site so that both Server and Site administrators can manage users. For more information, see [Managing Users \(Tableau Server Administrators only\)](#).

1. In a site, click **Groups**, and then click the name of the group.

2. In the group's page, click **Add Users**.

Tableau Server on Windows Help

3. In the Add Users dialog box, select the users to be added, and then click **Add Users**.

Create a Local Group

Local groups are created using the Tableau Server internal user management system. After you create a group you can add and remove users, as well as set a minimum site role to grant to users in the group when they sign in.

1. In a site, click **Groups**, and then click **Local Group**.

2. Type a name for the group.
3. To set a minimum site role for the group, select **Grant site role on sign in** and select a minimum site role from the drop-down list.

4. Click **Create**.

Create Groups via Active Directory

You can import Active Directory (AD) groups to create matching groups on Tableau Server, as well as a user for each member of an AD group that is not already on the server.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory syn-

ynchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Each user is assigned a site role as part of the import process. If any of the users to be imported exist in Tableau Server, the site role assigned during the import process is applied only if it gives the user more access to the server. Importing users does not demote site roles.

Before you begin

Before importing groups, review [User Management in Deployments with External Identity Stores](#) to understand how multiple domains, domain naming, NetBIOS, and Active Directory user name format influence Tableau user management.

Import from AD to add a group

As part of adding a user group to Tableau Server, you import a group from Active Directory (AD). When importing a group, you first enter the group name to search for the group.

Entering a group name, by default, causes Tableau Server to perform a wildcard query (for example, *marketing*) against AD (or LDAP) to maximize the search results. If you're working against a large AD (or LDAP) identity store, you might experience a timeout before you can successfully select the group to import.

To help save time and avoid potential timeout issues during the import process, consider searching a group name using one of those following methods:

- **Exact match:** The most efficient method for searching a group name, enter the exact group name by including quotation marks (") preceding and following the string you enter. For example, **"marketing"**.
- **Begins with:** Enter the beginning portion of the group name followed by an asterisk (*). For example, **market***.

- **Ends with:** Enter an asterisk (*) followed by the ending portion of the group name.
For example, ***ing**.

Use one of the above search methods described above in step 2 below.

1. In a site, click **Groups**, and then click **Add Groups**.
2. Type the name of the Active Directory group you want to import, and then select the group name in the resulting list.

If you're importing a group from the same AD domain that the server is running on, you can type the AD group name without the domain. The server's domain will be assumed.

Import a Group from Active Directory

Import a group of users from Active Directory.

3. Select the minimum site role for the users.

4. (Optional) Select **Grant role on sign in** to provision new site roles and licenses when group users sign in. For more information, see Grant License on Sign In.
5. Click the **Import** button.

Note: You cannot change the name of groups imported from Active Directory. The

group name can only be changed in Active Directory.

Synchronize External Directory Groups in a Site

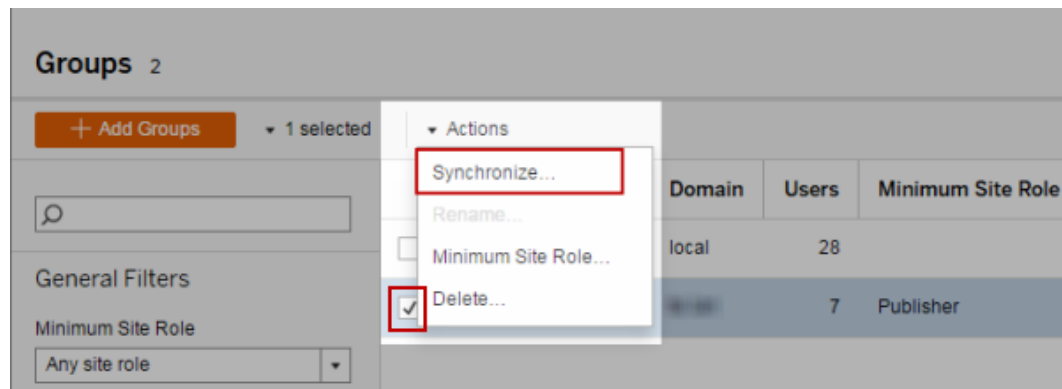

At any time, you can synchronize an external directory (such as Active Directory) group with Tableau Server to ensure new users in the external directory are also added in Tableau Server. You can synchronize individual groups or multiple groups at once.

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

1. In a site, click **Groups**.

On the Groups page, select one or more groups.

2. Click **Actions > Synchronize**.

Set the minimum site role for users in an external directory group

In the **Groups - Details** page, administrators can set the minimum site role for group users to apply during synchronization.

Tableau Server on Windows Help

This setting does not run synchronization; it sets the minimum site role to applied to the group every time synchronization runs. When you synchronize external directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role will be applied if it gives the user more access in a site. If you don't set a minimum site role, new users are added as **Unlicensed** by default.

Note: A user's site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.
2. On the Groups page, select a group, and then select **Actions > Minimum Site Role**.
3. Select the minimum site role, and then click **Change Site Role**.

What happens when users are removed in the source external directory?

Users cannot be automatically removed from the Tableau Server through an external directory sync operation. Users that are disabled, deleted, or removed from groups in the

external directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see Sync behavior when removing users from Active Directory.

What happens when a user name changes in the source external directory

By default, Tableau Server will not synchronize changes to the user display name or email address after the initial synchronization when the corresponding account is created in Tableau Server. For example, if the user name `jsmith` is used for the display name John Smith, changing the display name in external directory to Joe Smith will not synchronize to the corresponding `jsmith` user in Tableau Server. Similarly, if the user's email changes in the external directory, Tableau Server will not synchronize changes.

You can configure Tableau Server to update the name and email properties when they change in the source external directory by setting `vizportal.adsync.update_system_user` to `true`.

To change this behavior run the following tsm commands:

```
tsm configuration set -k vizportal.adsync.update_system_user -v true
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

What happens when an external directory group is removed from Tableau Server?

Many Tableau administrators use external directory groups to import and create users. After the users are imported into Tableau Server, administrators will then delete the group in Tableau Server. Deleting a group does not delete the users in it.

Synchronize External Directory Groups on the Server

As a server administrator, you can synchronize all external directory (such as Active Directory) groups (that have been configured on Tableau Server) on a regular schedule or on-demand on the **General** tab of the **Settings** page for the server.

Active Directory Synchronization

Manage the synchronization of all Active Directory groups. [Learn more](#)

[View synchronization activity](#)

Synchronize All Groups...

Synchronize Active Directory groups on a regular schedule

Frequency Hourly Daily Weekly Monthly

at 12 : 00 AM

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Before you begin

Before synchronizing groups as described in this topic, you must first import the external directory group into Tableau Server. See [Create Groups via Active Directory](#).

Synchronize external directory groups on a schedule

1. **Single-site:** Click **Settings**> **General**.

Multisite: In the site menu, click **Manage All Sites** and then click **Settings**> **General**.

2. Scroll down the page to **Active Directory Synchronization**, and then select

Synchronize Active Directory groups on a regular schedule.

Active Directory Synchronization

Last synchronized: (Server time)

[View synchronization activity](#)

Synchronize All Groups...

Synchronize Active Directory groups on a regular schedule

Frequency Hourly Daily Weekly Monthly

at 12 : 00 AM

3. Select the frequency and time of synchronization.
4. Click **Save**.

Synchronize all external directory groups on demand

At any time, you can synchronize external directory (such as Active Directory) groups with Tableau Server to ensure that new users and changes in the external directory are reflected in all external directory groups on Tableau Server.

1. **Single-site:** Click **Settings**> **General**.

Multisite: In the site menu, click **Manage All Sites**, and then click **Settings**> **General**.

2. Under **Active Directory Synchronization**, click **Synchronize All Groups**.

Note: Beginning in versions 2021.1.23, 2021.2.21, 2021.3.20, 2021.4.15, 2022.1.11, 2022.3.3, a default time limit of 4 hours limits how long a scheduled group synchronization can take before it is canceled. You can change this time limit if your scheduled synchronization is of very large groups, or taking longer than this. For more information, see [Synchronize All Active Directory Groups on a Schedule and background.under.timeout.sync_ad_group](#).

View synchronization activity

You can view the results of synchronization jobs in the **Background Tasks for Non Extracts** administrative view. **Queue Active Directory Groups Sync** is the task that queues and indicates the number of **Sync Active Directory Group** tasks to be run.

1. **Single-site:** Click **Status**.
Multisite: In the site menu, click **Manage All Sites** and then click **Status**.
2. Click the **Background Tasks for Non Extracts** link.

3. Set the **Task** filter to include **Queue Active Directory Groups Sync** and **Sync Active Directory Group**.

You can quickly navigate to this administrative view by clicking the **View synchronization activity** link in the **Settings** page for the server.

Set the minimum site role for users in an external directory group

In the **Groups - Details** page, you can set the minimum site role for group users to be applied during Active Directory synchronization.

This setting does not run synchronization; instead, it sets the minimum site role to applied to the group every time synchronization runs. The result is that when you synchronize external directory groups, new users are added to the site with the minimum site role. If a user already exists, the minimum site role is applied if it gives the user more access in a site. If you don't set a minimum site role, new users are added as **Unlicensed** by default.

Note: A user's site role can be promoted but never demoted based on the minimum site role setting. If a user already has the ability to publish, that ability will always be maintained. For more information on minimum site role, see Site roles and Active Directory import and synchronization.

1. In a site, click **Groups**.
2. On the Groups page, select a group.

Click **Actions > Minimum Site Role**.

3. Select the minimum site role, and then click **Change Site Role**.

What happens when users are removed in the source external directory?

Users cannot be automatically removed from the Tableau Server through an external directory sync operation. Users that are disabled, deleted, or removed from groups in the external directory remain on Tableau Server so that administrators can audit and reassign the user's content before removing the user's account completely. For more information, see [Sync behavior when removing users from Active Directory](#).

Improving group synchronization performance

External directory synchronization is performed by the background process. The Background process is the same process that is used for managing and creating extracts, and is also used to generate subscription content. In large organizations with dynamic group membership and heavy extract usage, the external directory group synchronization process may be disruptive. We recommend running group synchronization during non-business hours.

By default, the Background process performs synchronization in a serial operation. This means that each group is synchronized, one after the other, in a single Background process. If you are running multiple instances of Background processes either on a single Tableau Server or across a distributed deployment, consider enabling parallel processing for

external directory synchronization. When parallel Backgrounder processing is enabled, the group synchronization is distributed across multiple Backgrounder processes for better performance.

To enable parallel backgrounder processing for group synchronization, open TSM CLI and enter the following commands:

```
tsm configuration set -k backgrounder.enable_parallel_adsync -v true
```

```
tsm pending-changes apply
```

Synchronize All Active Directory Groups on a Schedule

After you import Active Directory groups in Tableau Server, you can make sure they stay synchronized in Tableau Server by setting up a schedule. You can also synchronize all Active Directory groups on the server on-demand, at any time. The minimum site role setting for the group is applied when users are synchronized.

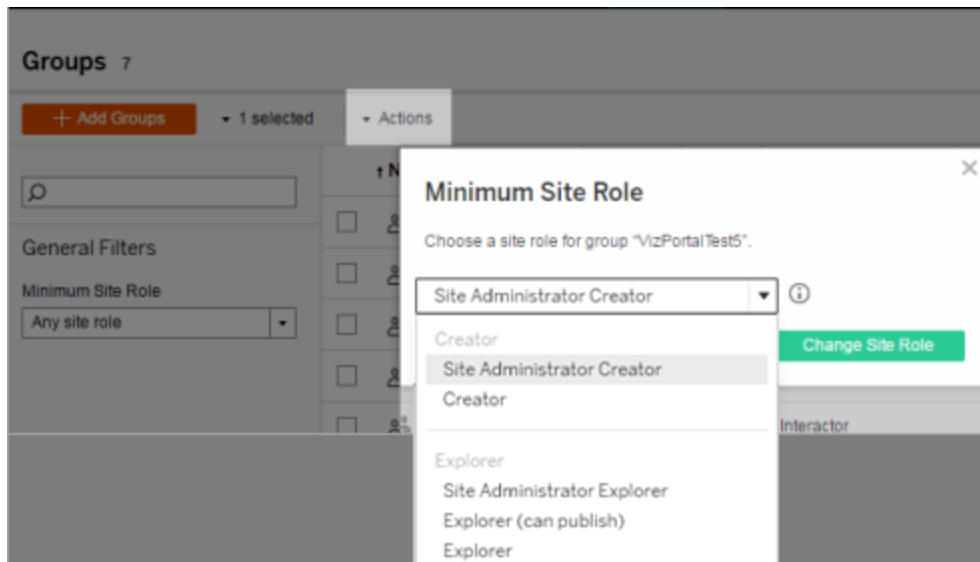

Note: In the context of user and group synchronization, Tableau Server configured with LDAP identity store is equivalent to Active Directory. Active Directory synchronization features in Tableau Server function seamlessly with properly configured LDAP directory solutions.

Beginning in versions 2021.1.23, 2021.2.21, 2021.3.20, 2021.4.15, 2022.1.11, 2022.3.3, you can set a maximum time limit for how long a scheduled group synchronization can take before it gets canceled. The default time limit is 4 hours. For more information, see `backgrounder.timeout.sync_ad_group`.

Tableau Server on Windows Help

1 Set a minimum site role for synchronization

In a site, click **Groups**. Select a group, and then click **Actions**> **Minimum Site Role**. Select the minimum site role, and then click **Change Site Role**. Server and site administrators can set the minimum site role for group users to be applied during Active Directory synchronization. If you don't set a minimum site role, new users are added as **Unlicensed**.

Synchronizing can promote a user's site role, but will never demote a user's site role.

2 Set the schedule

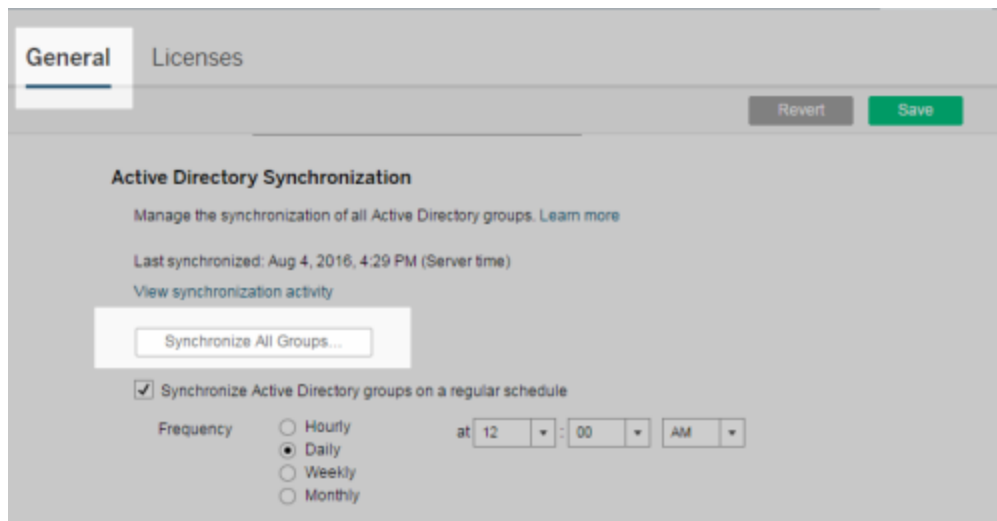

Server administrators can enable synchronization for all Active Directory groups on the **General** tab of the **Settings** page for the server. Enable synchronization, select the frequency settings, and then click **Save**.

All Active Directory groups on the server are synchronized according to the same schedule.

3 Run synchronization on-demand (optional)

On the **General** tab of the **Settings** page, click **Synchronize All Groups** to synchronize all Active Directory groups on Tableau Server immediately. Click this button at any time to ensure new users and changes are reflected in all Active Directory groups on the server.

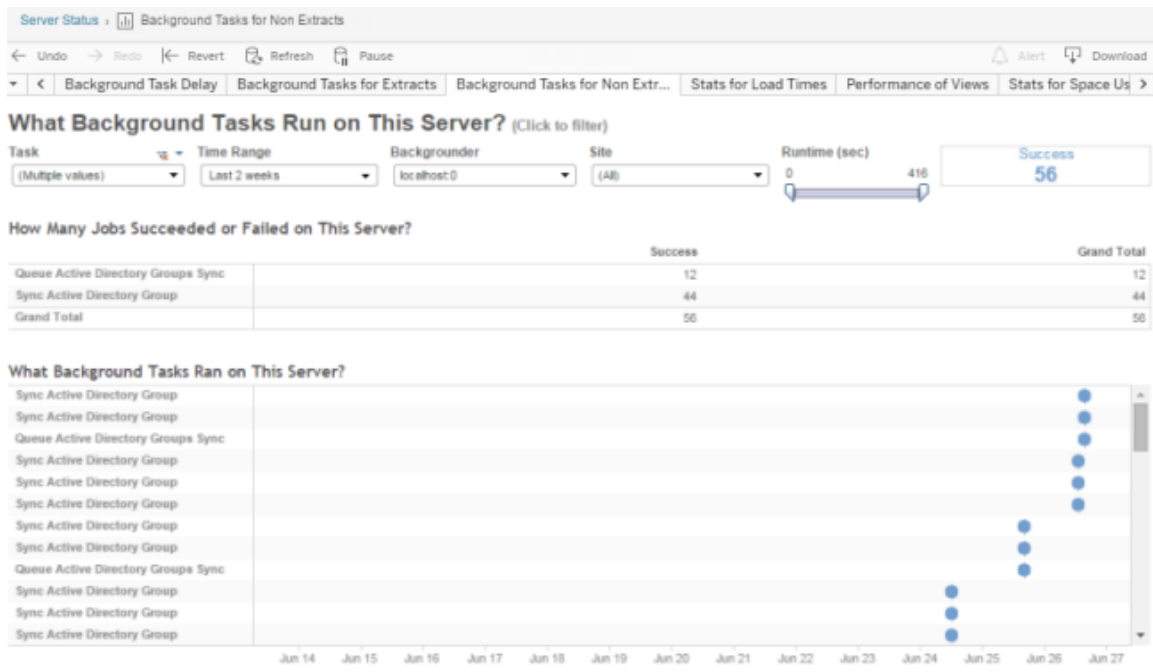

Click **Synchronize All Groups** to synchronize all Active Directory groups on the server outside of a schedule.

Tableau Server on Windows Help

4 View the status of synchronization tasks

Server and site administrators can view the results of Active Directory synchronization jobs in the **Background Tasks for Non Extracts** administrative view. On the server or in a site, click **Status**. Under **Analysis**, click **Background Tasks for Non Extracts** and filter on the **Queue Active Directory Groups Sync** and **Sync Active Directory Group** tasks.

Queue Active Directory Groups Sync queues the **Sync Active Directory Group** tasks to be run.

Grant License on Sign In

Grant license on sign in (Grant role on sign in) lets unlicensed users in specific groups become licensed when they sign into a Tableau site. This streamlines license provisioning for administrators and removes the user's need to request a license before using Tableau.

For more information about site role capabilities and minimum site roles, see [Set Users' Site Roles](#).

For example, imagine an Active Directory group called Marketing with 100 users, but only 25 users need to access Tableau Server. A site or server administrator can import all users in the Marketing Active Directory group, set the group's minimum site role to Explorer, and select **Grant role on sign in**. When any of the Tableau users in Marketing sign into their Tableau site, they'll be granted Explorer licenses. Users who don't need Tableau Server remain unlicensed unless they sign in.

Note: For more information about benefits and best practices, see [Grant Role on Sign In](#) in Tableau Blueprint, Tableau's planning tool for data-driven organizations.

Activate Grant role on sign in

You can enable Grant role on sign in on new or existing groups. The following steps walk through how to use Grant role on sign in to add new users that are eligible for a license but may not consume one. This may be the case when your company has a lot of eligible users, but limited Tableau licenses.

1. In a site, click **Groups**, and then click **Add Group**.

Add new users by importing an Active Directory group. Type the name of the group you want to import, and then select the group name in the resulting list.

Import a Group from Active Directory

3. Click **Import**.

Note: Grant Site Role on Sign In can also be activated in local groups to provision minimum site roles to group members when they sign in to Tableau Server. For more information, see [Create a Local Group](#).

Tableau Server on Windows Help

Modifying user roles with Grant role on sign in

If a user is part of a group using Grant role on sign in, then that user role can't be set to unlicensed or downgraded to a role lower than the minimum site role set for the group, whether or not they sign in. Administrators can upgrade a user's site role manually, however.

To downgrade a user's site role, or unlicense the user from the site, remove the user from the group(s) that have Grant role on sign in enabled.

In accordance with the terms of the [End User License Agreement](#), licenses granted on an Authorized User basis may be permanently reassigned to new users. Users may only be downgraded to a lower site role (including Unlicensed) when they will permanently discontinue access to Server Software at the higher role.

Removing users affected by Grant role on sign in

You can remove a user from a site only if the user does not own content. If you attempt to remove a user who owns content, the user site role will be set to Unlicensed and removed from all groups, but the user will not be removed from the site. To remove content owners, remove owners from group with Grant site role enabled or reassign content ownership to another user. For more information, see [Remove users from a site in the View, Manage, or Remove Users help topic](#).

If the default All Users group has Grant site role enabled, users who own content can't be removed from the site or unlicensed. To remove or unlicense these users, reassign content ownership to another user, then remove or unlicense the user.

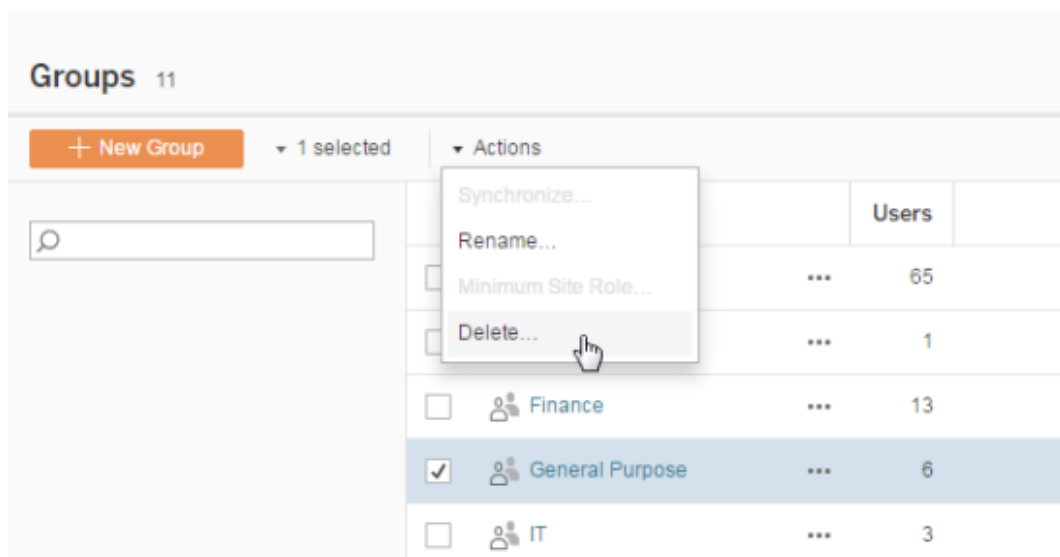

REST API can be used to reassign content ownership of a workbook. For more information, see [Update Workbook](#) in the REST API documentation. REST API can also be used to remove users from the site and transfer content ownership to another user. For more information, see [Remove User from Site](#) in the REST API documentation.

For more information on changing content ownership in Tableau Server, see [Manage Content Ownership](#).

Delete Groups

You can delete any group from the server (with the exception of the All Users group). When you delete a group, the users are removed from the group but they are not deleted from the server.

1. In a site, click **Groups**.
2. On the Groups page, select one or more groups to delete.
3. Select **Actions > Delete**.

Dashboard-based Custom Portals

Note: This overview was inspired by the work of Tableau Zen Master Mark Jackson. For more details about the process, [check out Mark's blog](#).

The [standard Tableau Online or Tableau Server interface](#) works great for many organizations, but if you want to create a company-branded experience and don't have API developer skills, consider creating a custom portal based on a Tableau dashboard. A

custom portal lets you organize content around specific departments or job roles, and you can even incorporate training that helps people interact with data more fully. As the volume of Tableau content grows, a custom portal guides your users directly to the data they need, while providing ready access to related views and Tableau Server search so they can easily explore further.

Sketch out a portal design

Begin outside of Tableau, on paper or in a wireframing application. Consider the structure of your organization and the number of Tableau views that apply to each group of users. Do you simply need one level of navigation that points immediately to content? Or might you need to start with a main page that provides navigational links for separate groups of users or report types, followed by a second level with related dashboards and views?

After you get buy-in on your design from key stakeholders and data consumers, you're ready to move on to the next phase.

Gather images for logos and navigation elements

Start thinking about images while refining your initial mockup, and then gather them from libraries of clip-art or approved brand graphics, or create them from scratch in an application like Photoshop or SnagIt. PowerPoint can also be a good source if you plan to create navigation thumbnails of common chart types.

Lay out text, images, and selected sheets on a dashboard

Create a workbook with a dashboard for the portal, using a [tiled layout](#) for more predictable positioning and scaling of elements on different devices. Then start adding Text and Image objects, as well as any sheets for data views you want to highlight right up front in your portal. To refine spacing between these dashboard elements, insert Blank objects and adjust their size. For more information, see [Create a Dashboard](#).

Tip: For dynamic elements that show popular or recently created content, include sheets based on [custom administrative views](#).

Link dashboard elements to content

If you have a second level of navigation in your portal, use [filter actions](#) to point to a secondary dashboard from the main one. To create links that directly open data views, right-click Image objects and choose Set URL. (In our example below, each colored arrow and accompanying text is an image that links to a view URL.) You can even point to empty views with preloaded data sources, encouraging users to create new Tableau content in the web-authoring workspace.

Tip: To add hyperlinks to text objects, include the full URL (for example, `http://www.tableau.com`).

The screenshot shows a Tableau Data Portal interface for 'Health Group'. At the top left, there is a brown header with the text 'Health Group' and a starburst icon. To its right, the text 'Data Portal' is displayed. Below the header, there are three main categories, each with a colored vertical bar and a list of data items with right-pointing arrows:

- Medical** (brown bar):
 - Illness trend report
 - Patient demographics
- Facilities** (teal bar):
 - Hospital occupancy
 - Real estate transactions
- Accounting** (green bar):
 - Billing by department
 - Year over year taxes

At the bottom of the portal, there are two sections:

- Learn how to explore geo data**: Accompanied by a world map with a play button icon, suggesting a video tutorial.
- Create your own view of geo data**: Accompanied by an icon of a document with a plus sign, suggesting a tool for creating custom views.

Publish, test, and refine your portal

Publish the workbook to your server and distribute the dashboard URL to your users. Portal design, like data analysis itself, is a cyclical process. Now that your portal is out in the wild, start gathering user feedback so you can continuously improve the experience

Tip: As a finishing touch, hide the Tableau toolbar to give your portal a custom feel.

After the question mark at the end of the dashboard URL, add `:embed-d=y&;:toolbar=n`

Manage Content Access

You can manage who can access content on your site and set the permissions that govern content ownership.

Set a Site's Web Authoring Access and Functions

Tableau Server administrators can specify at the site level whether to allow users to edit published views in the web environment and configure other web authoring functionality.

By default web authoring functionality is enabled for all sites. Users with the **Web Edit** capability can create and edit workbooks directly on the server. Turn off web authoring if you want users to be able to view and interact with published workbooks but not make any changes to the core information.

The steps below describe how to set web authoring and other associated functionality for an entire site. For more granular control over which users can use web editing, you can use projects, groups, and permissions. See [Set Web Edit, Save, and Download Access on Content](#).

For information about how to enable authoring for flows on the web, see [Create and Interact with Flows on the Web](#).

Turn web authoring on or off for a site

1. In a web browser, sign in to the server as an administrator and go to the site in which you want web authoring to be enabled. In that site, click **Settings**.
2. In the **Web Authoring** section, select **Workbooks. Let users edit workbooks in**

their browser. to enable the functionality.

Clear the check box to turn off web authoring for that site.

Web Authoring

Users with the appropriate permissions can edit content in their browser.

- Workbooks. Let users edit workbooks in their browser.
- Flows. Let users edit flows in their browser.

3. If your site is already in production, and you want the change to take effect immediately, restart the server.

Otherwise, the change takes effect after server session caching expires or the next time users sign in after signing out.

Notes

- When you enable web authoring, make sure that, on the appropriate workbooks or views, the permission rule for a user or group allows the **Web Edit** capability.
- If you turn off web authoring on a production site and do not complete the last step to restart the server, users might continue to have authoring access until their session caches expire or they sign out.

See which sites allow web authoring

To confirm which sites allow web authoring, on the site-selection menu at the top, select **Manage All Sites**, and then go to the **Sites** page.

Sites 9										
+ New Site 0 selected										
	Name	Users	Site administrators	Max users	Storage used	Max storage	Status	Metrics	Web authoring	
<input type="checkbox"/>	Customer Support	...	4	2	Server limit	0 B	Server limit	Active	✓	
<input type="checkbox"/>	Default	...	63	8	Server limit	25.6 MB	Server limit	Active	✓	✓
<input type="checkbox"/>	Development	...	4	2	Server limit	0 B	Server limit	Active	✓	✓
<input type="checkbox"/>	Documentation - 20 User Limit	...	5	1	20	3.2 MB	Server limit	Active	✓	
<input type="checkbox"/>	Finance	...	13	2	Server limit	9.8 MB	Server limit	Active	✓	✓

Configure cross-database join options

To improve performance for cross-database joins, users can allow Tableau to perform the join using the live database they are connected to instead of using Hyper. While this option is faster, if Tableau uses the connected database to perform the join, data from the file data source that the user is connected to is temporarily moved into temp tables in the database. Because this moves data outside of Tableau, as an administrator you may want to restrict access to this feature for users with web authoring permissions.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want web authoring to be enabled. In that site, click **Settings**.
2. In the **Cross-Database Joins** setting, select one of the following options:
 - **Use Tableau or existing databases** - Select this option if you want to allow users to choose whether they want to allow Tableau to use the live database to perform cross database joins. Published data sources with this option enabled will continue to use the user's database for cross-database joins.
 - **Use Tableau only** - Select this option to restrict users to use only Hyper to perform cross data-base joins.

Cross-Database Joins

Choose where the join process happens when joining data from multiple sources. Allowing Tableau to use an existing database connection can be faster, but this means that data from the file connection may be temporarily moved to the live database connection. [Learn more](#)

Use Tableau or existing databases

Use Tableau only

Tableau Server on Windows Help

If you select **Use Tableau only**, the option to choose how Tableau performs the cross-database join won't display in the canvas when the user connects to a supported data source and supported database. For more information about this feature, see [Improve performance for cross-database joins](#).

Set Web Edit, Save, and Download Access on Content

If you're enabling web authoring functionality on your site, you can configure more precisely which users on the site have access to this functionality. Using site roles and permissions rules at the content level, you can grant or deny **Web edit**, **Save**, or **Download** capabilities on projects, workbooks, and data sources.

Note: This document strives to use the phrase *Web edit* to specify the name of the capability in permissions rules, and *web authoring* to refer to the general functionality of creating and modifying workbooks on the server. However, you might otherwise see these two phrases used interchangeably.

Why allow users to work on the site directly

As an administrator, your initial thought about allowing people to populate a site with content, seemingly indiscriminately, might be one of skepticism. However, with a few controls, you can limit where this is done, while providing important benefits that centralized content management offers both you and your users.

Web authoring pros and cons

For publishers and business users, some benefits of web authoring include the following:

- It provides analyst teams who work collaboratively with a central location in which to provide input.

- It enables people who do not have Tableau Desktop to connect to data sources and create workbooks.
- It enables people to access content when they are away from their Tableau Desktop computer or VPN, whether on a computer or a hand-held device.
- It can provide a framework for enabling consistency across Tableau reports. (By making template workbooks available on the site, analysts can download or create new workbooks with data connections, branding, and formatting already in place.)

For administrators, benefits can include the following:

- Fewer Tableau Desktop deployments to manage and support.
- Fewer computers that need to have database drivers installed.
- Capacity to govern content.
- More accurate monitoring of what people are doing with Tableau.

Some disadvantages to web editing include the following:

- For analysts, web editing functionality is not as extensive as in Tableau Desktop (although it continues to evolve toward that parity).
- For administrators, more people working on the server might mean upgrading systems.
- Without publishing guidelines, content proliferation on the site is expected. This can confuse the people who rely on published Tableau dashboards and data sources, degrade server performance and data quality, and potentially affect data security.

Managing permissions to help users avoid content proliferation

To help users to avoid content proliferation on the site, many Tableau administrators use projects to allow varying levels of access to content. For example, one project can be configured to allow all users to edit and save workbooks; another can allow only approved publishers to save new content.

To get a better idea how this works, see the following resources:

- [Configure Projects, Groups, and Permissions for Managed Self-Service](#)
- [Projects and Content Permissions](#) in *Everybody's Install Guide*

- [Governed Self-Service at Scale](#), a Tableau whitepaper by Rupali Jain.
To view the PDF, you might need to provide your Tableau website credentials. These are the same ones you use for the community forums or to submit support cases.

Coordinate edit and save capabilities with site roles for the appropriate level of access

To edit, save, and download workbooks, users must have a site role that allows those actions, along with the capabilities—defined in permissions rules—that grant or deny editing-related access.

Site role access

- When the appropriate permissions are set at the content level, the **Creator** or **Explorer (can publish)** site role allows both **Save** (overwrite) and **Save As/Download**.

Note that **File > Save** is only available to the workbook owner. When the **Save** permission capability has been granted at the project and workbook level, a non-owner user can overwrite the existing workbook in web authoring by selecting **File > Save As** and using the same workbook name. This overwrites the existing content and they become the owner and gain full access to the content.

- The **Explorer** site role can be granted the **Web Edit** and **Save As/Download** capabilities, but they will not be able to save (neither overwriting existing nor saving changes to a new workbook).

For more information, see [Web Editing and Web Authoring](#).

Configure Projects, Groups, and Permissions for Managed Self-Service

Tableau Online and Tableau Server each provide an environment for easy open publishing and collaborative analysis of visualizations created in Tableau Desktop or web authoring. With that flexibility comes the challenge of making sure the *right* content is easy to find for the

people who rely on it for their work. Likewise, making sure the access you allow doesn't create performance or management nightmares on the site.

To address these challenges, many administrators set up their Tableau sites for what we'll refer to as *managed self-service*. This is just a way of saying that the site allows areas of open collaboration and web editing, alongside areas in which access to data and reports is more controlled. As the site administrator, you put guidelines in place to help users figure out where to go for the type of work they need to do.

To get started with a managed self-service approach, the following sections discuss how you as the site administrator can meet the following objectives:

- Create projects on the Tableau Server or Tableau Online site to match the ways people need to work with content.
 - For example, some projects are open to all for collaboration; others are visible only to authorized publishers.
- Create user groups based on the type of access users need to the content.
- Create a clear and scalable permissions strategy.

Note: The information provided here is adapted and simplified from practices of existing Tableau Zen Masters and customers who have shared their experiences. Links to their talks are available at the [bottom of this page](#).

Create a project team and adopt a permissions strategy

Although changing the project structure on your site after your users are publishing to it is not impossible, it's difficult and can be daunting. So before you make any lasting decisions or take definitive actions on your Tableau site, we recommend that you recruit users from various segments of your Tableau population, to create a project team of people who have differing uses for Tableau content.

Your permissions strategy will help your environment scale as you add new Tableau users. Make sure it incorporates two important practices: manage permissions only for groups, and set permissions only at the project level. Setting permissions at the individual user level

and on individual content resources becomes unmanageable quickly. If you need to deviate from this practice, make sure you document and communicate your strategy to other administrators and project leaders.

Important: We strongly recommend familiarizing yourself with Tableau's Permissions before proceeding.

Steps to coordinate projects and groups

To get projects and permissions (content) to work together with groups (people) in a managed self-service environment, you generally take the following steps:

1. 1. Plan your permissions: Find common themes in the type of access users need. This helps determine projects and groups.
2. 2. Remove permissions that will cause ambiguities
3. 3. Create groups
4. 4. Assign permissions to the groups
5. 5. Create projects and adjust permissions
6. 6. Lock permissions in each project

If you decide to follow the guidelines described here, you might want to Automate working with groups and projects.

1. Plan your permissions

Before you create groups and start assigning permissions, create a list of people who need access to content, and arrange them in groups according to what they'll want to do.

For example, someone who publishes or moves a data source to a *certified* content project would need different level of access than someone who only consumes published reports. (We use the term "certified" to mean "trusted" — these are the data sources or reports that your Tableau community can trust to be a source of truth for your organization.)

Keep in mind also that you can set permissions differently for each project. So someone who is a data steward for the Ops department might not get the equivalent access to the Marketing content.

This exercise, done outside of the Tableau environment, can be the most challenging part of setting up a site.

Use a closed permissions model for managed content

General models for setting permissions are *open* or *closed*. In an open model, users get a high level of access, and you explicitly deny capabilities. This model can work when your organization is very small, and everyone has a similar level of responsibility.

In a closed model, users get only the access they need to do their jobs. This is the model security professionals advocate, and the examples in this article will attempt to show.

2. Remove permissions that will cause ambiguities

Every site has a **Default** project and an **All Users** group. Any user added to the site becomes a member of the All Users group automatically. The Default project works as a template for new projects in the site and cannot be deleted, but you can change the permissions. Creating groups and setting baseline permissions here helps you to know and manage exactly who gets what level of access for each new project.

In the managed self-service context, setting baseline permissions means *removing* the permissions from the **All Users** group, so that the permissions are enabled only on groups you create and have control over.

1. Select the **Content** tab to open the top-level projects on the site.
2. On the **Default** project's **Action (...)** menu, select **Permissions**.
3. Next to the **All Users** group name, select **...**, and then select **Edit**.
4. For the tabs for **Project**, **Workbooks**, and **Data Sources**, use the template drop down and select **None**.
5. Select **Delete** to apply the changes.

3. Create groups

You create groups to match what people need to do with a set of content. In this case “a set of content” refers to the workbooks and data sources in a project.

When you create your groups, use descriptive names that make sense for your organization. For example, one possible set of groups might be as follows:

- **Project leaders.** You might also think of these as project-level administrators. Users who can perform all available capabilities on data sources, with the possible exception of setting permissions on them. People in this group can be site administrators, or users whose job it is to approve or certify data models or reports. To grant administrator capabilities at the project level, you can assign the **Project Leader** setting to users with the appropriate site roles. For more information, see [Permissions](#).
- **Analysts/Publishers.** This group is for users who can publish workbooks to production and other open projects, use web editing on some projects, and connect to data sources certified by the data stewards. This group is not allowed to set permissions on content or move it between projects.
- **Business Users.** This group is the most likely to include people who do not use Tableau Desktop, but use data to answer questions and make business decisions. They can view and interact with workbooks only in specific projects, and they can't publish, edit, save, or delete anything.
- **Administrators.** Depending on the size of your deployment, managing site or server administrators as a group helps you keep track of who has that level of access.

Note: Users with the Server Administrator or Site Administrator Creator site role have access to everything on the site, regardless of the groups you add them to.

If you have multiple Tableau roles per department, creating corresponding groups manually can be labor intensive. For alternatives, see [Automate working with groups and projects](#) later in this article.

Learn more: Add Users to a Group

4. Assign permissions to the groups

After you create groups, you can assign permissions in one of the following ways:

- In the Default project, apply a core set of permissions on each group that will stay more or less the same for all projects. You can then make minor adjustments in specific projects.
- Or
- Keep the Default project clean, and apply permissions only on projects you create.

For more information, see Permissions.

For the example we're using, it makes more sense to set permissions templates in the Default project. You will want to explicitly deny some capabilities across the board, and then allow them on only a few projects where you want to allow more open access.

Create permission rules

1. While you have the Default project open, on the **Actions** menu (...), select **Permissions**.
2. Create a permission rule for each group as follows:
 - a. Click **+ Add Group/User Rule** and start typing to search for a group or user.
 - b. For each tab, choose an existing template from the drop-down or create a custom rule by clicking the capabilities.
 - i. Templates are predefined sets of capabilities that make setup easier.
 - ii. One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).
 - c. When finished, click Save.
3. **Lock permissions to the project.**

Remember, a capability is only granted to a user if they are expressly allowed it. Leaving a capability as Unspecified will result in it being denied. For more information, see Permissions.

Tableau Server on Windows Help

Example

For the groups defined above, here is one way you might set default permissions.

	Project tab	Workbooks tab	Data Sources tab
Project Leader group			
Analyst Publisher group	Publish template	Publish template	Publish template
Business User group	View template	Explore template Set Web Edit and Download Full Data to Unspecified*	Explore template

* This assumes you want to allow web editing and downloading data only on select projects. You can allow those capabilities on specific projects or workbooks.

5. Create projects and adjust permissions

After the Default project is set with your custom permissions template, you can create projects that allow the content use cases you identified. For each project, you can adjust the default permissions as appropriate.

Example project structure

One way to structure projects could be to reflect the following use cases:

Workbooks shared for open collaboration on the server

Anyone in the department can publish to the open-collaboration project while their content is in development. Colleagues can collaborate using web editing on the server. Some people

call this a sandbox, some call it staging, and so on. On this project you can allow web editing, saving, downloading, and so on.

Here you want not only to enable collaboration, but also to enable people who don't have Tableau Desktop to contribute and provide feedback.

Shared reports that cannot be edited

This could be a project that people who create workbooks and data sources (Analysts and Data Stewards) could publish to when they want to make content available to business users for viewing, with confidence that their work cannot be "borrowed" or modified.

For this type of project, you would deny all capabilities that allow editing or getting the data off of the server for reuse. You would allow viewing capabilities.

Vetted data sources for Analysts to connect to

This would be where Data Stewards publish the data sources that are meet all of your data requirements and become the "source of truth" for your organization. Project leaders on this project can certify these data sources, so that they rank higher in search results and are included in recommended data sources.

You would allow authorized Analysts (that is, the Publishers group described earlier) to connect their workbooks to data sources in this project, but not download or edit them. You would deny the view capability to the Business Users group for this project, so those users would not even see this project.

Inactive content

Another possibility is to segregate workbooks and data sources that the site's administrative views show haven't been used for a period of time. You could give content owners a time limit before their content is removed from the server.

Tableau Server on Windows Help

Whether you do this or delete directly from the working projects is up to your organization. In an active environment, don't be afraid to be intentional about removing content that is not being used.

Source for workbook templates

This is a project that people can download from but not publish or save to, where authorized publishers or project leaders make template workbooks available. Templates that have your organization's approved fonts, colors, images, and even data connections built in can save authors a lot of time and keep your reports looking consistent.

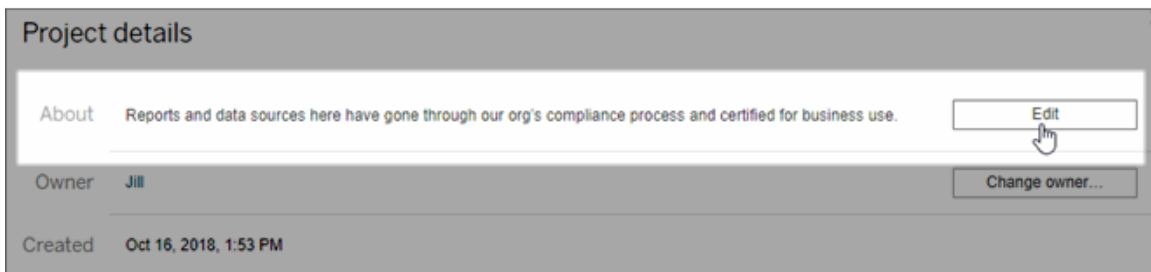

Help project leaders manage content and users find it

- Devise a scalable project-naming scheme that makes sense in your organization.

For example, basic structure might be **<Department> - <ContentUse>**; such as **Ops - Production**.

- Use the project's **Description** field.

The description you enter when you create a project appears when you hover the pointer over the project thumbnail, as well as on the **Project details** page.

6. Lock permissions in each project

After you refine the capabilities for each group in a project, you can lock the project's permissions, either for the project itself or all projects in the hierarchy. Do this on the Default project, too.

To configure the **Content Permissions**:

1. You must be logged into the site as an administrator, project owner, or project leader
2. Open the permissions dialog box for a project
3. Click the Content Permissions **Edit** link in the upper left and select the desired option in the Content Permissions dialog box

Locking permissions prevents publishers from setting permissions explicitly as part of the publishing process in Tableau Desktop. Instead, content inherits permissions set on the project it's published to, and only administrators and project leaders can set permissions.

For more information, see [Permissions](#).

Automate working with groups and projects

Creating multiple groups and projects and setting permissions manually can get a little tedious. To automate these processes, as well as make them repeatable for future updates, you can perform these tasks using [REST API](#) commands.

You can use `tabcmd` commands for tasks such as adding or deleting a single project or group and adding users, but not for setting permissions.

Next steps

Besides projects, groups, and permissions, other data governance themes include:

User education

Help *all* of your Tableau users become good data stewards. The most successful Tableau organizations create Tableau user groups, have regular training sessions, and so on.

Tableau Server on Windows Help

For a common approach to orienting users to the site, see [Dashboard-based Custom Portals](#).

For publishing and data certification tips, see the following topics:

- [Use Certification to Help Users Find Trusted Data](#)
- [Prepare for Publishing a Workbook](#) (links to Tableau Help)
- [Best Practices for Published Data Sources](#) (links to Tableau Help)

Optimize extract refresh and subscription activity

If you use Tableau Server, create policies for extract refresh and subscription schedules, to avoid them dominating the site's resources. The TC customer presentations by Wells Fargo and Sprint address this subject in detail. In addition, see the topics under [Performance Tuning](#).

If you use Tableau Online, see the following topics to become familiar with the ways people can refresh extracts:

- [Keep Data Fresh](#)
- [Use Tableau Bridge to Expand Data Freshness Options](#)

Monitoring

Use administrative views to keep an eye on the site's performance and content use.

[Administrative Views](#)

Learn how Tableau and some of our customers address governance and self-service

The following list contains links to data governance and Center of Excellence (COE) presentations given at the Tableau Conference over recent years. Even if Tableau versions have evolved, the principles remain the same. You can explore the playlists for other videos related to COE, managing Tableau at scale.

[Content Strategies in Tableau](#) (TC 17)

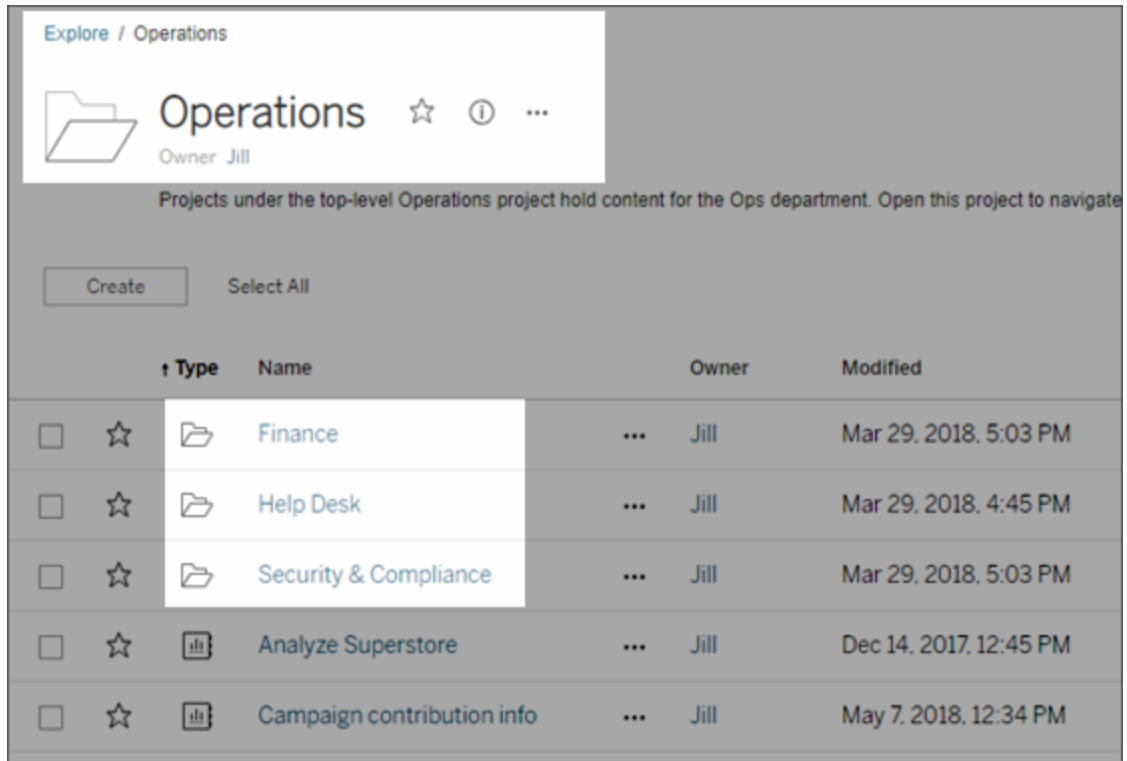

Use Projects to Manage Content Access

When Tableau Desktop users publish a workbook or data source to a site on Tableau Server, they can select a *project* to publish it to. If they don't specify a project, their content is published to the **Default** project.

As an administrator, you can create projects to hold and organize related *content*, or to delegate content management. Content on Tableau Server are workbooks, views, metrics, Ask Data lenses, data sources, and the projects that hold them. If the Data Management Add-on is present, content types also include flows, data roles, and virtual connections.

The following image shows content within the top-level Operations project in the web authoring environment. The Operations project contains a few child projects (highlighted) and published workbooks. A project can also contain other content types, such as data sources and flows.

Tableau Server on Windows Help

Why use projects

Projects help you to create a scalable process for managing access to the content published to Tableau Server. Advantages they have include:

- They enable administrators to delegate content management to project leaders who work with the content more closely, without having to give them administrator access to site or server settings.
 - Project leaders can create nested projects under their top-level project, enabling them to maintain their team's content within a single hierarchy.
 - **Note:** Project owners can delete top-level projects they own. Project leaders cannot delete top-level projects.
- They can make the site easier to navigate for self-service users.
 - They segment the Tableau Server site into areas that give users access based on how they use the data published to those areas, or on the Tableau user group they work with.

- You can hide projects from groups who don't need to use them, create a distinguishable project-naming scheme, and take advantage of project descriptions to clarify how to use the project.
- They enable you to track permissions effectively.
 - You can create groups based on the level of content access users in the group need, and set default permissions on projects. This enables you to know exactly which capabilities new users get by default, and likewise which capabilities all users get when a new project is created.

When to create project hierarchies (example)

Many organizations have several or more distinct groups of Tableau users, each with its own priorities and leaders. These groups might share some organization-wide content (or even draw from an org-wide pool of data sources), but primarily they use data and reports that are specific to their team. In this or similar scenario, an example for using project hierarchies might look as follows:

1. You, as a site or server administrator, can create top-level projects for each of your distinct Tableau teams.
2. On each top-level project, you assign the Project Leader status to team leads, and change project ownership. Project leaders effectively are the content administrators, so it's important that they understand how permissions work in Tableau, along with Tableau content management best practices.
3. Each project leader can manage their project, creating the structure within the project that works for their team. That is, they can create child projects they need, based on how their team members collaborate and share data and reports.

The benefit to you as the site administrator is that you can focus on system health. The benefit to your Tableau users is that people who know the best practices for working with Tableau and data can manage these things for their teams, without having to submit IT requests to change permissions or add projects.

Why not use sites?

If you manage your own Tableau Server deployment, you can create as many sites as you want. However, for managing data and reports across your company, projects allow the flexibility you need to administer shared data and reports, and users who might belong to

multiple groups. Many Tableau administrators configure projects as described in the previous section, to expose only what's necessary to users who need to work with it. Projects work better than sites for evolving content from development to staging to production.

Sites work well when content can remain completely separate during all phases, and there is little to no user overlap. A good (and common) example for using multiple sites is to create a site for each of multiple external clients, whose published content you manage as a consultant or vendor. Our own Tableau Online is an example of this on a large scale. Another example might be to use a separate site for sensitive content that you want only specific Human Resources or medical staff to use.

Project-level administration

As a server or site administrator, you can delegate administration of projects and their content, without exposing access to your site or server settings. You can do this by changing the ownership of a project or granting a group or user project leader status on a project.

The **project owner** is always one individual user. By default, the user who creates a project is its owner. The project owner has administrative access to the project and content in it—including making someone else the owner and assigning Project Leader permissions.

The **project leader** setting provides a way to allow multiple users administrative access to a project, its child projects, and all workbooks and data sources in those projects.

A project leader does not have to be a project owner or administrator. In addition to server and site administrators, the full scope of Project Leader permissions is available to users with a **Creator** or **Explorer (can publish)** site role.

Project ownership and project leader access in project hierarchies

In a multi-level project hierarchy, a user or group that is set as a project leader, at any level within the hierarchy, is implicitly given project leader access to all of that project's child projects and their content items.

To remove the project leader access, you must do so at the parent level in the hierarchy on which the ownership or setting was explicitly assigned.

Similarly, the owner of a project at any level has project leader access to all content in that project, as well as to any of its child projects, even if they do not own the child projects.

Only a project owner or administrator can change ownership of a content resource, and this can be done regardless of whether the project permissions are locked.

Actions project-level administrators can take on projects

Project leaders and owners can perform the tasks in the following list, as can server or site administrators.

- Create and delete projects as follows:
 - Server or site administrators can create or delete top-level or nested projects anywhere on the site.
 - Project owners and project leaders can create and delete child (nested) projects in projects they own, or on which they have project leader status.
- Project owners can change ownership of their projects. Both project owners and project leaders can assign the project leader status to groups or users.
 - As a project leader or owner, if you assign the project leader status to someone else, remember that full access to this role's capabilities depends on the user's site role, as specified earlier in this section.
- Set permissions for a project, as well as the child projects, workbooks, and data sources in it.
- Lock permissions to apply the project's default settings to all workbooks, data sources, and optionally child projects and their content. For information, see [Permissions](#).
 - Permissions can be modified only from the project they're locked on. Only admins, the owner, or project leaders can change permissions.
- Move workbooks and data sources to another project to which they have project leader or owner access. Moving the project can affect permissions. For information, see [Move content](#).
- Run, add, or remove extract refresh schedules.

See also [Permissions](#).

How the Default project acts as a permissions template

Tableau creates a **Default** project with every site.

The Default project serves as a template for new top-level projects you create on the site. When you create a new top-level project, settings and permissions from the Default template are applied to the new project, including permissions set on content within the project.

Note: Nested projects (projects you create within other projects) take the permissions set at their parent project, not the Default project.

Before you create other top-level projects, you can take steps to set up the Default project, to help you to know exactly:

- Which type of user gets what level of access for each new project.
- How you might need to modify permissions for each new project.

For more information, see [Steps to coordinate projects and groups in the topic Configure Projects, Groups, and Permissions for Managed Self-Service](#).

Prevent publishers from changing permissions on content they own

Administrators and project leaders can prevent users from changing the permissions for workbooks and data sources in a project hierarchy. For example, you can disable the option to set permissions during the publishing process, and prevent publishers and content owners from changing them after publishing. To do this, you *lock* content permissions to the project. For more information, see [Permissions](#).

Add Projects and Move Content Into Them

A content resource (workbooks and data sources) can live in only project. Server and site administrators can add or remove top-level projects on a site, and move published content from one project to another. Project leaders with appropriate site roles can add or remove child projects and move content between projects on which they have Project Leader access.

This article contains the steps for creating and moving projects. We recommend becoming familiar with the following related content as well:

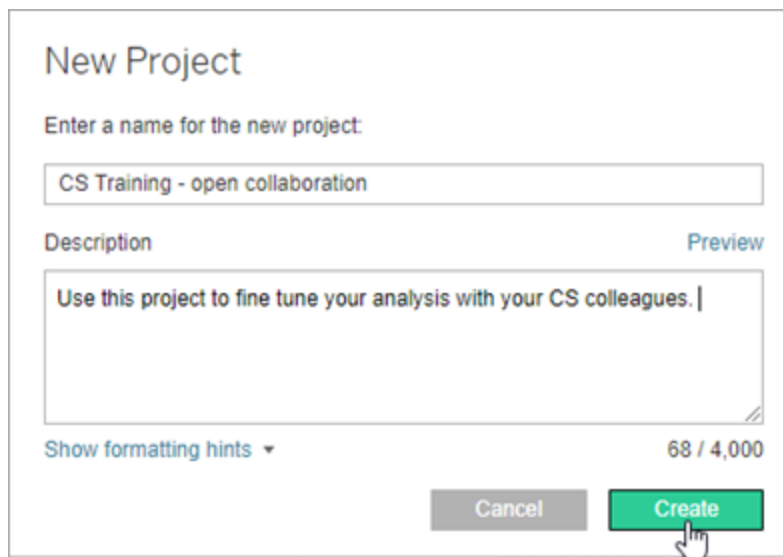

- To learn about projects and when or why to use them, see Use Projects to Manage Content Access.
- Before you create project hierarchies, become familiar with Permissions.
- To see the specific site roles that allow full Project Leader access, see Project-level administration.

Add a top-level or child (nested) project

1. While you're signed in to Tableau Server as an administrator or project leader, select the **Content** tab, and then do one of the following:
 - Select **New > Project** to create a new top-level project (only administrators can do this).
 - Navigate to and open the project in which you want to create a sub-project, and then select **New > Project**.

If you're not sure where to find a child project, display filters, and select **Show all projects**.

2. Enter a name and description for the project, and then click **Create**.

New Project

Enter a name for the new project:

CS Training - open collaboration

Description Preview

Use this project to fine tune your analysis with your CS colleagues. |

Show formatting hints ▾ 68 / 4,000

Cancel Create

Tableau Server on Windows Help

You can include formatting and hyperlinks in the project description. Select **Show formatting hints** for syntax.

Note: To edit a project description later, select it to open it, select the information icon next to its name, and then click **Edit**.

Move a content resource to another project

1. On the **Content** tab, find the content resource you want to move.

If you're not sure where to find a child project, display filters, and select **Show all projects**.

For other content types, you can navigate through its project hierarchy, or by selecting the content type on the **Explore** menu.

2. On the workbook's **Actions(...)** menu, select **Move**.
3. Select the new project for the workbook, and then click **Move Content**.

Moving a project includes moving everything in it, including child projects and their content.

How moving projects affect permissions

When you move a project, Project Leader permissions adapt to the new project environment.

- When the target project hierarchy is **locked**, previous Project Leader permissions are removed, and new Project Leader permissions are granted according to those set at the top-level of the target hierarchy.
- When the target project hierarchy is **unlocked** (managed by owner), previous implicitly granted Project Leader permissions are removed, explicitly set Project Leader permissions are retained, and new Project Leader permissions are granted according to those set at the top-level of the target hierarchy.

Tableau Server on Windows Help

When you move project and content, permissions may be impacted. For more information, see [Permissions](#).

Delete a project

When you delete a project, all of the workbooks and data sources in the project are also deleted from the site. If you want to delete a project but not its content, move the content to another project, and then delete the project.

Important

- You cannot undo deleting a project.
- Deleting a project deletes all content in it, including child projects and their content.
- You cannot delete the **Default** project.

To delete a project:

1. On the **Content** tab, find the project you want to remove.

If you're not sure where to find a child project, display filters, and select **Show all projects**.

2. On the project's **Actions (...)** menu, select **Delete**.
3. Confirm that you want to delete the project.

Required access level for moving content

Moving content is effectively like removing it from one project and publishing it to another. For non-administrators, the permissions needed on the source project are different than those needed on the destination project.

Required site role

To move content, users must have one of the following site roles:

- Server Administrator (Tableau Server only)
- Site Administrator Creator or Site Administrator Explorer
- Creator or Explorer (Can Publish)

Users with a Server Administrator or Site Administrator site role do not need any additional capabilities.

Required permissions for the project that users move content *to*

Non-administrators must have the **Publish** permission capability for the project that is the move destination.

Required permissions for the project that users move content *from*

Non-administrator users must

- Be the project owner, project leader, or content owner
- OR
- Have the **Move** permission capability for the content (or, for data sources, be the data source owner).

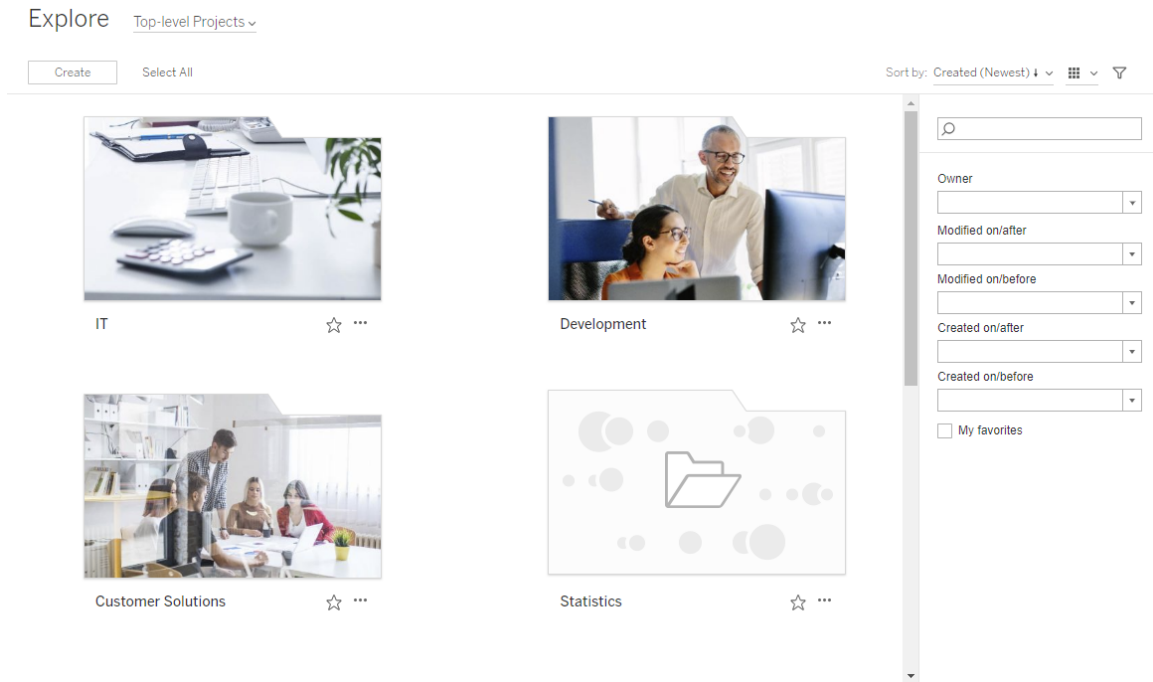

For more information, see [Move content](#).

Add a Project Image

To help distinguish projects you manage on Tableau Server (and help your users find them), you can add an image that appears in the thumbnail. Your image must meet the following requirements:

- The image must be accessible using HTTPS protocol. Shared network directory and related protocols (UNC, SMB, AFP, NFS, etc) are not supported. HTTP protocol for project images is not supported by Google Chrome.
- All users who access the project must have, at a minimum, "read-only" permission on the target image.
- The image must be common internet format: .jpg, png, or gif.

Tableau Server on Windows Help

Set a project image

1. Sign in to a site on Tableau Server. In the list of **Top-level Projects** you have access to, select or navigate to the project you want to update. In this example, we'll add an image to the Statistics project folder.

If you're not sure where to find a child project, use the **Explore** drop-down list and select **All Projects**.

2. Click the **Details** icon (i), to open the **Project details** dialog box, and then click **Edit**.

3. In the **About** field, you can enter a description for your project (optional), for example "Global and US statistics." At the end of the project description, add the URL for your image using the following syntax:

`!http://www.example.com/image.png!`

Tableau Server on Windows Help

Select **Show formatting hints** to see how you can format description text.

Note: Images embedded in project descriptions cannot be resized or positioned. Recommended size is (300 x 184 pixels). Images that are not 300 x 184 pixels may be stretched, shrunk, or cropped to fit the width of the thumbnail. In addition, they must be added at the end of the project description and be enclosed in ! (exclamation marks), otherwise they will not be displayed as the thumbnail.

4. Click **Save**.

Let Site Users Request Access to Content

Permissions determine if a user has viewing access to workbook, view, or content inside a project. If an existing site user clicks on content or a project they don't have access to, they can select **Request Access** to send a request to the owner controlling permissions for that piece of content.

When someone requests access, the owner who controls permissions for that content (either at the project or workbook level) receives an email with the name and email of the requester, the content or project requested, and a link to the project or content controlling permissions on the requested item.

Tableau Server on Windows Help

For example, if a user requests access to a workbook and content permissions are locked to the project, then the project owner receives the request. Likewise, if a user requests access to a workbook and project permissions are managed by the workbook owner, then the workbook owner receives the request.

Once permission is granted, the owner can email the requester to let them know they have view capability to the project or workbook.

Default settings

The Request Access setting is enabled by default on a new site. To enable the setting if it's been disabled:

1. Go to the General tab of the Settings page for your site.
 - If you have a single site, on the side navigation, click **Settings** and **General**.
 - If you have multiple sites, select the site you want to configure and click **Settings** and **General**.
2. On the General tab, scroll down to Request Access and select **Let users request access to projects, workbooks, and views**.
3. Click **Save**.

Configure project permissions

You can control who will receive the access request by adjusting the project's content permissions. If content permissions are:

- Locked to the project: the project owner receives the request.
- Managed by the owner: The workbook owner receives the request.

To manage content access using projects, see [Use Projects to Manage Content Access and Permissions](#).

For more information about how permission rules are evaluated, see [Permissions: Evaluate permission rules](#).

Change project permissions

For administrators and project leaders

Permissions can be set at the project level for both the project itself and for any content in the project. For example, if workbook permissions are configured at the project level, all workbooks published into that project inherit those default permissions. However, the Creator can choose to change the permissions during publishing, or certain users can change the permissions on published content. To enforce the permissions established at the project level, **Content Permissions** can be locked to the project. For more information, see Lock content permissions.

To set permissions at the project level:

1. Navigate to the project
2. Open the Actions menu (...) and click **Permissions**. The permissions dialog box opens.

This dialog box has two main areas: permission rules at the top and the effective permissions grid below. Use the tabs to navigate between types of content.

Permissions for Project "My Project"

Download Summary Data: Denied (by user rule)

Tableau Server on Windows Help

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering over a capability indicator provides information about why the capability is allowed or denied for that specific user.

- To modify an existing permission rule, select the rule and click the capability boxes to toggle through allowed/denied/unspecified.
- To create a new rule,
 - Select **+ Add Group/User Rule**.
 - Select a group or user from the drop-down box. This creates a row where you can configure the permission rule.
- In the row for the permission rule
 - choose an existing permission role template from the drop-down box for each content type tab.

- Or create a custom rule by navigating to a content type tab and clicking the capabilities. One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).
- When finished, click **Save**.

Change content permissions

For administrators, project leaders, and content owners

If project permissions are not locked, permissions for individual pieces of content can be modified.

Warning: Tableau recommends managing permissions at the project level within the Tableau site. These steps are relevant only for content in projects where permissions are managed by the owner.

Set permissions on content

1. Navigate to the content (workbook, data source, flow, data role)
2. Open the Actions menu (...) and click **Permissions**. The permissions dialog box opens.

This dialog box has two main areas: permission rules at the top and the effective permissions grid below.

The screenshot displays the Tableau permissions dialog box. At the top, there is a search bar with the placeholder text "Search for a user to view their permissions" and a note: "Permissions for views are controlled independently". Below this is a table of permission rules:

User / Group	Permissions	View	Interact/Edit	Edit
All Users (39)	None	[Icons]	[Icons]	[Icons]
Site Roles (8)	Editor	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]

Below the table is a "+ Add a user or group rule" button. The bottom section is titled "User Permissions Site Roles (8)" and shows a grid of permissions for various roles:

User	Role	View	Interact/Edit	Edit
Creator	Editor	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Explorer	Custom	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Explorer (can publish)	Editor	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Server Administrator	Administrator	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Site Administrator Creator	Administrator	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Site Administrator Explorer	Administrator	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Unlicensed	Custom	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]
Viewer	Custom	[Green Checkmarks]	[Green Checkmarks]	[Green Checkmarks]

A tooltip is visible over the "Explorer (can publish)" row, stating: "Save: Denied (by user's site role)".

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering over a capability square provides information about why the capability is allowed or denied for that specific user.

3. To modify an existing permission rule, open the Actions menu (...) for that row and click **Edit**.

Tableau Server on Windows Help

4. To create a new rule,
 - a. Select **+ Add a user or group rule**.
 - b. If necessary, use the drop-down box on the right to change between groups and users.
 - c. Select a group or user from the drop-down box. This creates a row where you can configure the permission rule.
5. In the row for the permission rule, choose an existing permissions role template from the drop-down box or create a custom rule by clicking the capabilities.

One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).

6. When finished, click **Save**.

Set permissions on a view

In some situations, it may be valuable to specify permissions on a view independently from the workbook that contains it. To set permissions on a published view, navigate to the view within a published workbook and follow steps above.

Warning: While it is possible to set view-level permissions within a workbook, we strongly recommend managing permissions at the project (or workbook) level as much as possible. For views to inherit permissions, the project must be locked or the workbook must be published with **Show Sheets as Tabs**. See [Let Site Users Request Access to Content](#) for more information.

Permissions

Permissions determine how users can interact with content such as workbooks and data sources. Permissions are set in the permission dialog or via the [REST API](#). At the top of the dialog, permission rules configure capabilities for groups or users. Below, the permissions grid displays the effective permissions for users.

Permissions for Project "My Project"

There are several interrelated topics that discuss how to think about, set, and manage permissions. The main topics are:

- This topic, which covers the fundamentals, how to set permission rules for projects and other content, and permission considerations for specific scenarios.
- Permission Capabilities and Templates, which covers in detail the various capabilities that are used to build permission rules.
- Manage Permissions with Projects, which covers using projects to manage permissions and how nested and locked projects impact permissions.
- Effective permissions, which covers how permission rules are evaluated and how final permissions are determined.
- Permissions, Site Roles, and Licenses, which covers how permissions interact with site roles and licenses to determine what a user can do on a site.

Additionally, if the Data Management Add-on is present, permissions for external assets have additional considerations. For more information, see [Manage Permissions for External Assets](#).

Permissions fundamentals

Projects and groups

Tableau sites use *projects* to organize content and *groups* to organize users. Managing permissions is easier when permission rules are:

- Set at the project level instead of on individual pieces of content.
- Established for groups instead of individuals.

Permissions can only be established for users, groups, projects, or content that already exist. For more information about creating users and groups, creating projects, and publishing content, see [Manage Users and Groups](#), [Use Projects to Manage Content Access](#), and [Publish Data Sources and Workbooks](#).

Capabilities and permission rules

Permissions are made up of *capabilities*—the ability to perform actions like view content, web edit, download data sources, or delete content. *Permission rules* establish what capabilities are allowed or denied for a user or group on a piece of content.

Note: When talking about permissions in general, it's common to see a phrase like “a user must have the delete *permission*.” This is easy to understand in a broad context. However, when working with permissions at a technical level like in this article, it's more accurate to say “the delete *capability*.” In this topic we'll use the more precise term *capability*, but you should be aware that you might see *permission* in other places.

Group/User	Template	View	Interact	Share	Export	Import	Administer	Manage	Connect	Refresh	Refresh	Refresh	Refresh	Refresh	Refresh	Refresh	Refresh	Refresh
All Users	View	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Group	Explore	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Evie	Publish	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Lari	Administer	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
Maris	Custom	✓	✓	✓	✓	✓	✗	✓	✗	✓	✓	✓	✓	✓	✗	✓	✓	✓

+ Add Group/User Rule

The interplay between license level, site role, and potentially multiple permission rules factor into the final determination of what a user can or can't do. For each user this becomes their *effective permissions*. For more information, see [Effective permissions](#).

Some tasks such as creating new workbooks from a browser (web authoring) or moving content might require specific configurations of several capabilities rather than being captured in a single capability. For more information, see [Permission settings for specific scenarios](#).

Set permissions

Permission rules are set differently at the project level, at the content level, or when publishing content from Tableau Desktop.

Note: The phrase “project permissions” can have two meanings. There are the permission capabilities for a project itself—View and Publish—that control how a user can interact with a project. There is also the concept of project-level permission rules for other content types. In this article “project-level permissions” means permission rules for workbooks, data sources, and the other content that are configured in the permission dialog for a project. This is in contrast to “content-level” permission rules that can be set on a specific workbook, data source, etc.

Project-level permissions

For administrators, project owners, and project leaders

To set permissions at the project level:

Tableau Server on Windows Help

1. Navigate to the project
2. Open the Actions menu (...) and click **Permissions**.

The permissions dialog opens. This dialog has two main areas: permission rules at the top and the effective permissions grid below. Each content type has a tab. The image below shows the Workbook tab.

Permissions for Project "My Project"

Will	Unlicensed	✓	✗	✗	✗	✗	✗

Download Summary Data: Denied (by user rule)

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering provides information about why the capability is allowed or denied for that specific user.

- To modify an existing permission rule, select the appropriate tab for that content type and click a capability.
- To create a new rule, click **+ Add Group/User Rule** and start typing to search for a group or user. For each tab, choose an existing template from the drop-down box or create a custom rule by clicking the capabilities.

One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).

- When finished, click **Save**.

Tip: Permission rules set at the project level act as a default for content saved in that project and any nested projects it contains. Whether those project-level default rules are enforced or only preliminary depends on the **content permission** setting. This setting can be

Tableau Server on Windows Help

configured in two ways, either **Locked** or **Customizable**. For more information, see Lock content permissions.

Content-level permissions

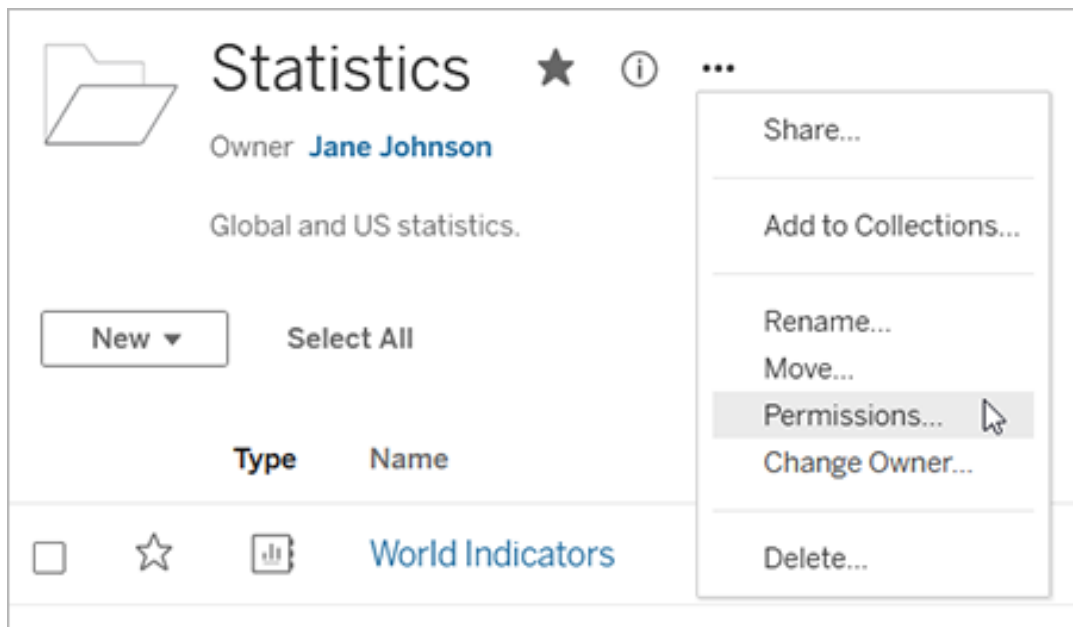

For administrators, project leaders, and content owners

If project content permissions are customizable, permissions for individual pieces of content can be modified. The information below is not relevant to content in locked projects. For more information, see Lock content permissions.

Tip: While it is possible to set permissions on individual content in customizable projects, we recommend managing permissions at the project level.

Set permissions on content

1. Navigate to the content (workbook, data source, flow, data role)
2. Open the Actions menu (...) and click **Permissions**.

The permissions dialog opens. This dialog has two main areas: permission rules at the top and the effective permissions grid below. (Note the lack of tabs across the top—a content-level permissions dialog has no tabs.)

The screenshot shows the 'Permissions for Workbook' dialog. The 'Permission Rules' section is as follows:

Group/User	Template	Capabilities
All Users	View	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)
Clients Development	Explore	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)
Collaboration Team	Publish	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)
Development Group	Administer	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)
Group	Custom	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)

The 'Effective Permissions' section shows the following:

User	Site Role	Capabilities
Lari McEdward	Site Administrat...	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)
Maris McEdward	Explorer (can pu...	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)
Will Pitts	Unlicensed	View, Add, Edit, Delete, Export, Import, Refresh, Connect, Disconnect, Disconnect All, Disconnect All (Force), Disconnect All (Force) (Admin), Disconnect All (Force) (Self), Disconnect All (Force) (Other), Disconnect All (Force) (All), Disconnect All (Force) (None)

With a row selected at the top, the effective permissions grid populates. Use this to verify permissions. Hovering over a capability square provides information about why the capability is allowed or denied for that specific user.

- To modify an existing permission rule, click a capability.
- To create a new rule, click **+ Add Group/User Rule** and start typing to search for a group or user. Choose an existing template from the drop-down or create a custom rule by clicking the capabilities.

One click sets the capability to **Allowed**, two clicks sets it to **Denied**, and a third click clears the selection (**Unspecified**).

- When finished, click **Save**.

Tableau Server on Windows Help

Set permissions on a view

Tip: While it's possible to set view-level permissions within a workbook, we strongly recommend managing permissions at the project or workbook level.

If a workbook is published with **Show Sheets as Tabs** checked, the views in that workbook will inherit all permissions set for the workbook. The permission dialog for a view will be read-only.

In some situations, it may be valuable to specify permissions on a view independently from the workbook that contains it. If the workbook is published with **Show Sheets as Tabs** unchecked, the views will start with the workbook permissions but will be independent thereafter and can be set independently. Note that this means if the permission rules are modified for the workbook, those changes won't be applied to the views—each view's permissions will need to be managed individually.

See Show or Hide Sheet Tabs for more information.

Set permissions at publish

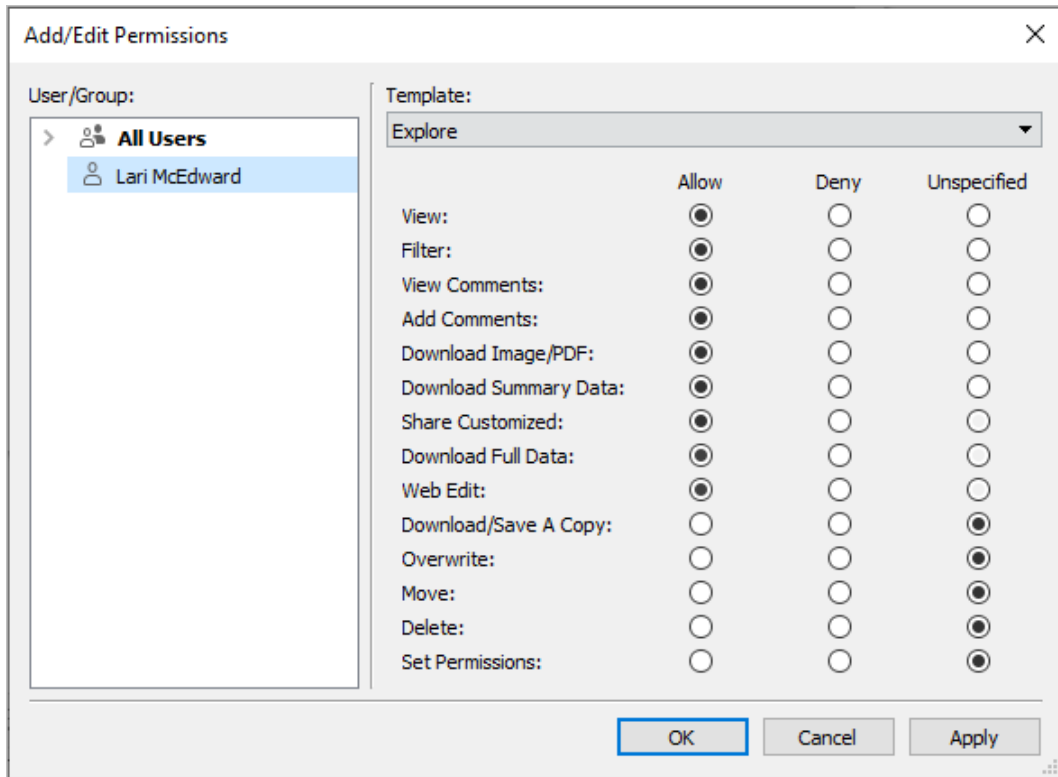

For content publishers

If project content permissions are customizable, permissions for individual content can be set when publishing from Tableau Desktop. The information below is not relevant for content in locked projects. For more information, see Lock content permissions.

Tip: While it's possible to set permissions on individual content in customizable projects, we recommend managing permissions at the project level.

1. From the publishing dialog, click the Edit link for **Permissions**.
If the Edit link is unavailable, permissions are locked to the project and can't be modified except by the project owner, project leader, or an administrator.
2. The Add/Edit Permissions dialog shows any existing permission rules. Click **Add** to add a new permission rule or **Edit** to modify an existing permission rule
 - a. Select the group or user from the left pane. You can expand a group to see which users it contains.

- b. Use the selector at the top of the right pane to choose an existing template, or use the radio buttons to create a custom rule.

Note that effective permissions can't be inspected from the publishing dialog.

3. When finished, click **OK** and resume publishing.

Note: Permissions can't be set while publishing flows from Tableau Prep Builder. To set permissions on a flow, refer to the steps for Project-level permissions or Content-level permissions.

Tip: By default, all users are added to an "All Users" group that has basic permissions for content. To start with a clean slate when building your own permission rules, we recommend that you delete the rule entirely or edit the rule for All Users to remove any permissions (set the permission role template to None). This will help prevent any ambiguity

down the road by reducing the number of rules that applies to any given user and therefore making effective permissions easier to understand.

Permission settings for specific scenarios

Certain actions require combinations of permission capabilities and possibly site roles. The following are some common scenarios and their necessary permission configurations

Saving, publishing, and overwriting

In the context of permissions, saving is essentially publishing. As such, the **Overwrite** and **Save a Copy** capabilities can only be given to users with a site role that allows publishing: Administrator, Creator, or Explorer (can publish). Explorer or Viewer site roles can't publish, overwrite, or save a copy.

(Prior to version 2020.1, the *Publish* and *Overwrite* capabilities were called *Save*, and the *Download Workbook/Save a Copy* capability was called *Download Workbook/Save As*.)

- The **Publish** capability for a project allows a user to publish content into that project.
- The **Overwrite** capability allows a user to save over an existing piece of content. By saving over the content, the user becomes the owner of that content. The **Overwrite** capability also allows users to edit minor aspects of existing pieces of content, such as the description for a metric or the synonyms for a data role. Editing the existing content in this way doesn't change the owner of the content.
- The **Save a Copy** capability allows a user to save a new copy of the content. This is usually done in conjunction with web authoring and means the user can save their modifications.

It's important to note that users aren't able to Save or Save As a piece of content unless they have the **Publish** capability for at least one project, because all content must be published into a project. Without the **Publish** capability at the project level, the content can't be published.

In web editing, the **Save** option in the File menu only appears to the content owner. If a user who is not the owner has the **Overwrite** capability (allowing them to save the content), they must use **File > Save As** and name the workbook the exact same name. This prompts a

warning that they are about to overwrite the existing content, which they can do. Conversely, a user with only the **Save a Copy** capability trying to use the same name gets an error stating they don't have permission to overwrite the existing content.

If a user who is not the content owner overwrites content, they become the owner, with all the permissions that entails. The original owner's access to the content is then determined by their permissions as a user rather than the owner.

Note: Download Workbook/Save a Copy is a joint capability for workbooks.

Explorers can be given this capability but they are only able to download the workbook, not save a copy. Giving the capability to Explorer (can publish), Creator, or Administrator site roles gives them both the ability to download workbooks *and* save a copy.

Web Editing and Web Authoring

Web editing and web authoring refer to the general ability for users to edit or create workbooks directly in the browser. The permission capability is called *Web Edit* and the site setting is called *Web Authoring*. This section will refer to any web-based editing or publishing action as *web authoring*.

To enable this functionality, there are several requirements.

- **Site setting:** Web authoring must be turned on for the entire Tableau site. See [Set a Site's Web Authoring Access](#). Without this setting enabled, no users can create new workbooks or edit existing workbooks from the browser, *even if they have the web edit capability*.
- **User site role:** The user must have the appropriate site role.
 - Viewers can never web edit.
 - Explorers can be given the web edit capability but can't publish. Essentially, they can use web editing to answer deeper questions based on existing content on the fly, but can't save their edits.
 - Explorers (can publish) or Site Administrator Explorers can publish, but they can only use data that is already published to the site.
 - Creators, Site Administrator Creators, and Server Administrators can publish and create new data sources.

Tableau Server on Windows Help

- **Permission capabilities:** The user must have the necessary permission capabilities based on the desired functionality.

Required Permission Capability Settings

Desired functionality	Minimum Site Role	 Web Edit	 Download/ Save a Copy	 Overwrite (<i>workbook</i>)	 Publish (<i>project</i>)	 Connect (<i>data source</i>)
Web author without being able to save	<i>Explorer</i>	 Allow	 Deny	 Deny	Optional	 Allow
Web author and save as new content	<i>Explorer (can publish)</i>	 Allow	 Allow	 Deny	 Allow	 Allow
Web author and save (overwrite) content	<i>Explorer (can publish)</i>	 Allow	 Allow	 Allow	 Allow	 Allow
Web author with new data and save new content	<i>Creator</i>	 Allow	Optional	Optional	 Allow	Optional

Optional indicates this capability is not involved in the desired functionality

Data access for published Tableau data sources

Data sources published to a Tableau site can have native authentication as well as permissions within the Tableau environment.

When the data source is published to the Tableau site, the publisher can choose how to [Set Credentials for Accessing Your Published Data](#) which addresses how data source credentials are handled (such as requiring users to log into a database or enter their credentials)

for Google Sheets). This authentication is controlled by whatever technology holds the data. This can be embedded when the data source is published, or the data source publisher can choose to prompt the user for their credentials to the data source. For more information, see [Publish a Data Source](#).

There are also data source capabilities that allow or deny users the ability to see (**View**) and connect to the published data source (**Connect**) in the context of Tableau. These capabilities are set like any other permissions in Tableau.

When a workbook is published that uses a published data source, the author can control how the Tableau authentication will behave for someone consuming the workbook. The author sets the workbook's access to the published data source, either as **Embed password** (using the author's Connect access to the data source) or **Prompt users** (using the Connect access of the person viewing the workbook), which may require data source authentication as well.

- When the workbook is set to **Embed password**, anyone who looks at the workbook will see the data based on the author's access to the data source.
- If the workbook is set to **Prompt users**, the Tableau-controlled access is checked for the data source. The person consuming the workbook must have the Connect capability for the published data source to see the data. If the published data source is also set to Prompt user, the viewer must also enter their credentials for the data source itself.

Workbook authentication to the data source	Data source authentication to the data	How data access is evaluated for someone consuming the workbook
Embed password	Embed password	User sees the data as if they were the workbook author
Embed password	Prompt user	User sees the data as if they were the workbook author. (The author is prompted for data source authentication, not the user.)
Prompt user	Embed password	User must have their own Connect capability to the

	word	published data source
Prompt user	Prompt user	User must have their own Connect capability to the published data source and are prompted for their credentials to the underlying data

Note that this applies to consuming a workbook, not web editing. To web edit, the user must have their own Connect capability.

Move content

To move an item, open its Action menu (...) and click **Move**. Select the new project for the item, then click **Move Content**. If Move is unavailable or there are no available destination projects, verify the appropriate conditions are met:

- Administrators can always move content and projects to any location.
- Project leaders and project owners can move content and nested projects among their projects.
 - Note that non-administrators can't move projects to become top-level projects
- Other users can move content only if all three of the following requirements are met:
 - Creator or Explorer (Can Publish) site role.
 - Publishing rights (**View** and **Publish** capabilities) for the destination project
 - Owner of the content, or—for workbooks and flows—having the **Move** capability.

When a project is moved, the permissions for its content might change.

- Project leaders or project owners always gain permissions for items moved into their projects.
- When a project is moved into a **locked (including nested)** project, the permission templates for the locked project are enforced on the moved project and all its content and nested projects. (Note that this might strip the user moving the project of their ability to move it again if they don't have the correct permissions in the locked project.)
- When a project is moved into an **unlocked** project (customizable), the existing permissions are retained for the moved project and its content. If the project leader status has only implicitly been granted (from a higher-level project), that status is removed, though any explicitly set project leader status is retained.

Metrics

Metrics are created from views in published workbooks. Users can create metrics if they:

- Are a Creator or Explorer (can publish) site role
- Have the **Publish** capability on a project
- Have the **Create/Refresh Metric** capability for the relevant workbook

For more information, see [Create and Troubleshoot Metrics](#) and [Set Up for Metrics](#).

Note: Prior to 2021.3, the ability to create a metric on a view was controlled by the Download Full Data capability.

Because metrics are independent content, it's important to note that the permissions for metrics are managed independently from the view they were created from. (This is unlike data-driven alerts and subscriptions, where the content of the alert or subscription can only be seen if the user has the correct permissions for the view itself.)

Although the capabilities for metrics are straightforward, the **View** capability should be considered carefully. It may be possible for a workbook with restricted permissions to be the basis for a metric with more open permissions. To protect sensitive data, you might want to deny metric creation for specific workbooks.

Metrics display data from their owner's perspective

When you create a metric, you capture your perspective of the data from that view. This means that any users who can access your metric will see the data as it appears to you. If the data in the view is filtered based on your credentials, the data you see might be different from what other users see when they access the same view. Limit the **View** capability for your metric if you're concerned about exposing your perspective of the data.

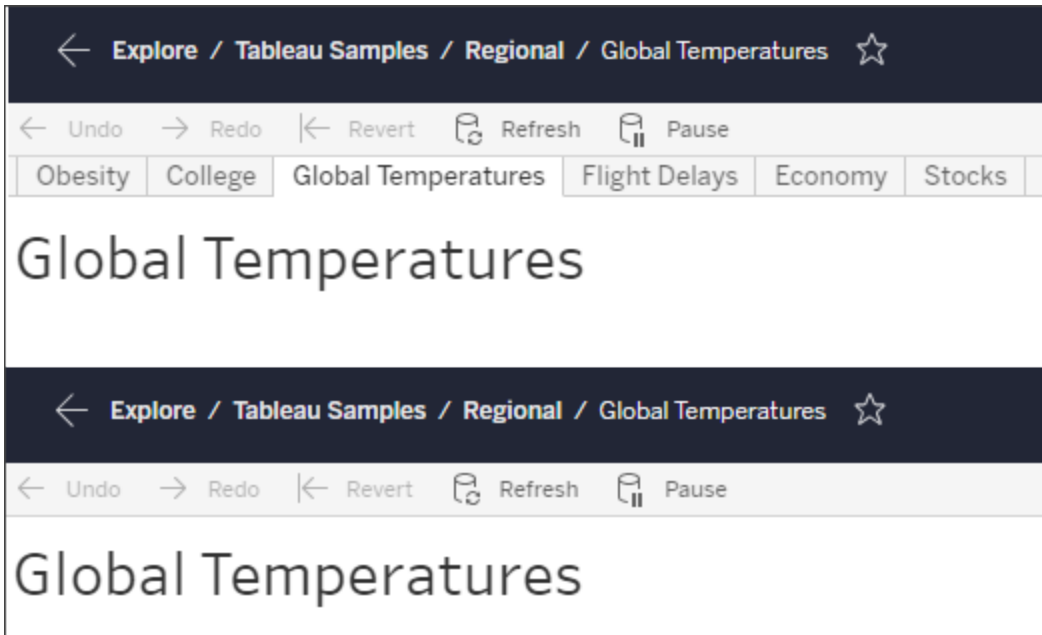

Show or Hide Sheet Tabs

In the context of published content, sheet tabs (also referred to as tabbed views) is a distinct concept from sheet tabs in Tableau Desktop. Showing and hiding sheet tabs in Tableau

Tableau Server on Windows Help

Desktop refers to hiding sheets in the authoring environment. For more information, see [Manage Sheets in Dashboards and Stories](#).

Showing and hiding sheet tabs (turning tabbed views on or off) for published content refers to navigation in a published workbook. When sheet tabs are shown, published content has navigational sheet tabs along the top of each view.

This setting also impacts how permissions function and may have security implications (see note).

Note: It is possible to have the **View** capability for a view without the **View** capability for the workbook or project that contain it. Normally if a user lacks the View capability for a project and workbook, they would not know those assets exist. If they have the View capability for a view, however, a user may be able to see the project and workbook name when looking at the view, such as in the navigational breadcrumb. This is expected and accepted behavior.

Turn off tabbed views to allow independent view permissions

Although it is not recommended as a general practice, there are times when it can be useful to set permissions on views independently of the workbook that contains them. To do so, three conditions must be met:

1. The workbook must be published—there is no way to set view permissions during publishing.
2. The workbook must be in a customizable project.
3. The workbook can't show sheets as tabs (tabbed views must be hidden).

When a workbook shows sheets as tabs, all views inherit the workbook permissions and any changes to the workbook permissions affect all of its views. **When a workbook in a customizable project does not show tabbed views, all views assume the workbook permissions upon publication, but any subsequent changes to the workbook's permission rules *will not be inherited by the views*.**

Changing the configuration of sheets as tabs on a published workbook will also impact the permission model. Show Tabs will override any existing view-level permissions and reinstate the workbook-level permissions for all views. Hide Tabs will break the relationship between the workbook and its views.

- To configure sheets as tabs on a published workbook, open the Actions menu (...) for the workbook and select **Tabbed Views**. Choose **Show Tabs** or **Hide Tabs** as desired.
- To configure sheets as tabs during publishing, refer to [Show sheets as tabs](#).
- To set view-level permissions, see [Set permissions on content](#).

Important: In a customizable project, any modifications to the workbook-level permissions will *not* be applied if navigational sheet tabs are hidden (aka tabbed views are off). Changes to permissions must be made on individual views.

Collections

Unlike projects, which contain content, a collection can be thought of as a list of links to content. Project permissions can be inherited by the content in the project, but permissions for a collection have no affect on the content added to the collection. This means that different

Tableau Server on Windows Help

users might see different numbers of items in a collection, depending on which items they have permission to view. To make sure that users can see all items in a collection, adjust the permissions for those items individually.

Permissions for a collection can be changed either by using the permissions dialog or by granting access upon sharing a collection, if you're an administrator or the collection owner. For more information, see [Manage Collection Permissions](#).

Private collections

When a collection is created, it is private by default. A private collection appears on the owner's My Collections page, but it doesn't appear in the list of all collections on a site. Private collections are simply collections with no permission rules added. Unlike other types of content, collections don't have the "All Users" group added by default. When you add permission rules to a collection, it is no longer flagged as private. To return a collection to a private state, remove the permission rules.

Private collections can be viewed by the collection owner as well as by administrators, whose site role gives them effective permissions to view all collections.

Explain Data

When Explain Data is available, a user can select a mark in a view and click Run Explain Data in the mark's Tooltip menu. A combination of settings must be enabled to make Explain Data available in editing mode and viewing mode.

Requirements for authors to run Explain Data or edit Explain Data settings in editing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer (can publish)
- Permissions: **Run Explain Data** capability set to **Allowed**. Allowed by default.

Note: The **Download Full Data** capability for a Creator or Explorer (can publish) controls whether they see the View Full Data option in Extreme Values explanations. Viewers are always denied the Download Full Data capability. However, all users can see

record-level details when the Extreme Values explanation type is enabled in Explain Data settings.

Requirements for all users to run Explain Data in viewing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer, or Viewer
- Permissions: **Run Explain Data** capability set to **Allowed**. Allowed by default.
- Workbook setting: **Allow Explain Data to be used in this workbook when viewed online** selected in the Explain Data Settings dialog box. Not allowed by default.

To allow all users (including Viewer site role) to run Explain Data in viewing mode, the workbook author must select the option **Allow Explain Data to be used in this workbook when viewed online** in the Explain Data Settings dialog box. For more information, see [Control Access to Explain Data](#).

Permission Capabilities and Templates

Permissions are made up of capabilities, or the ability to perform a given action on a piece of content, such as view, filter, download, or delete. Each row in the Permission Rules area of the dialog is a *permission rule*. Permission rules are the setting for each capability (allowed, denied, or unspecified) for the group or user in that row. Permission rules have *templates* available that make it easier to assign capabilities quickly. Permission rules can also be copied and pasted.

Note: In the permission dialog for projects, there are tabs for each content type (Projects, Workbooks, Data Sources, Ask Data Lenses, Data Roles, Flows, Metrics and—if you have the Data Management—Virtual Connections). When a permission rule is added, the default for all capabilities across all content types is Unspecified. To allow or deny capabilities for each content type, you must go to each tab in turn. In the per-

Tableau Server on Windows Help

mission dialog for a specific piece of content, there are no tabs and the permission rules only apply to that piece of content.

Templates

Templates group sets of capabilities that are often assigned together based on common user scenarios, **View**, **Explore**, **Publish**, and **Administer**. When you assign a template, its included capabilities are set to **Allowed**, with the rest left as **Unspecified**. The templates are cumulative, so the Explore template includes everything from the View template plus additional capabilities. All content also has a template for **None** (which sets all capabilities to unspecified) and **Denied** (which sets all capabilities to denied).

Templates are meant to be a starting point and can be adjusted after they are applied. Capabilities can also be granted or denied without using a template at all. In both cases, the template column then shows **Custom**.

Copy and paste permissions

If there is a permission rule that needs to be assigned to multiple groups or users, you can copy and paste from one rule to another. You can't copy from or paste onto a rule that involves Project Leader status.

1. Open the action menu (...) for the existing rule you want to copy from and select **Copy Permissions**. This is available only when the rule is not in edit mode.
2. Select an existing rule you want to paste over. You can also create a new rule by clicking **+ Add Group/User Rule** and selecting a group or user.
3. Open the action menu (...) and select **Paste Permissions**.

Capabilities

Each content type has specific capabilities:

Projects

Projects have only two capabilities and two templates. Prior to Tableau 2020.1, Project Leader was treated as a permission capability rather than a setting. For more information

about project leaders and how to assign them in Tableau 2020.1 and later, see Project administration.

View template

 **View** lets a user see the project. If a user hasn't been granted the view capability, the project won't be visible to them. Granting the view capability for a project does not mean a user can see any content in the project, just the existence of the project itself.

Publish template

 **Publish** lets a user publish content to the project from Tableau Desktop or Tableau Prep Builder. The publish capability is also required to move content into the project or save content to the project from web authoring. Prior to Tableau 2020.1, this capability was called Save.

Workbooks

View template

 **View** lets a user see the workbook or view. If a user hasn't been granted the view capability, the workbook won't be visible to them.

 **Filter** lets a user interact with filters in the view, including keep only and exclude filters. Users lacking this capability won't see filter controls in the view.

 **View Comments** lets a user view the comments associated with the views in a workbook.

 **Add Comments** lets a user add comments to views in a workbook.

 **Download Image/PDF** lets a user download each view as a PNG, PDF, or PowerPoint.

Download Summary Data lets a user view the aggregated data in a view, or in the marks they've selected, and download that data (as a CSV).

Run Explain Data lets a user run Explain Data on marks in editing and viewing mode. Note that for Explain Data to be displayed as an option when a user selects a mark in a workbook, the feature must also be enabled as a site setting. To make Explain Data available in viewing mode, the feature must also be allowed by the author from within a workbook in Explain Data settings. For more information, see [Control Access to Explain Data](#).

Explore template

Share Customized lets users add their custom views to the list of “Other Views” visible on a workbook. When this capability is denied, users won't see the “Make visible to others” option when they create a custom view. For more information, see [Use Custom Views](#). This capability doesn't impact the ability to share a custom view with the share dialog or by copying the link.

Download Full Data lets a user view the underlying data in a view, or in the marks they've selected, and download that data (as a CSV).

Web Edit lets a user edit the view in a browser-based authoring environment.

- Note that creating new content in the browser or saving views from the web edit interface requires a specific combination of capabilities. For more information, see [Web Editing and Web Authoring](#).
- The Web Editing feature must also be enabled for the entire site or even users with this capability allowed won't be able to web edit. For more information, see [Set a Site's Web Authoring Access](#).

Publish template

Download Workbook/Save a Copy lets a user download a packaged workbook (as a TWBX). Lets a user save (publish) a copy from the web edit interface as a new workbook.

Prior to Tableau 2020.1, this capability was called Download Workbook/Save As.

 **Overwrite** lets a user overwrite (save) the content asset on the server. Prior to Tableau 2020.1, this capability was called Save.

- When allowed, the user can re-publish a workbook, data source, or flow, or save a workbook or flow in web authoring, thereby becoming the owner and gaining access to all permissions. Subsequently, the original owner's access to the workbook is determined by their permissions just like any other user.

 **Create/Refresh Metrics** lets a user create metrics on the views in a workbook and lets any metrics that a user creates from those views refresh. For more information, see [Create and Troubleshoot Metrics](#).

Administer template

 **Move** lets a user move workbooks between projects. For more information, see [Move content](#).

 **Delete** lets a user delete the workbook.

 **Set Permissions** lets a user create permission rules for the workbook.

Views

In a workbook that is not in a locked project and does not show sheets as tabs for navigation, views (sheets, dashboards, stories) inherit the workbook permissions at publication, but any changes to permission rules must be made on individual views. View capabilities are the same as those for workbooks, except for **Overwrite**, **Download Workbook/Save a Copy**, and **Move** which are only available at the workbook level. We recommend showing navigational sheet tabs whenever possible so views continue to inherit their permissions from the workbook.

View template

 **View** lets a user see the data source on the server.

 **Connect** lets a user connect to a data source in Tableau Desktop, Tableau Prep Builder, Ask Data, or web editing.

- If a workbook author embeds their credentials to a published data source in a published workbook, they are essentially embedding their **Connect** capability. Therefore, users can see the data in the workbook regardless of their own **Connect** capability for that data source. If the workbook author doesn't embed their credentials to the published data source, the user needs their own **Connect** capability to the data source to consume the workbook. For more information, see [Data access for published Tableau data sources](#).
- A user must have the **Connect** capability for a data source to use Ask Data and to create Ask Data lenses. For more information, see [Enable Ask Data for Sites and Data Sources](#).

Explore template

 **Download Data Source** lets a user download the data source from the server (as a TDSX).

- Cube data sources, like those for Microsoft Analysis Services or Oracle Essbase connections, must be used locally. To download the published data source to Tableau Desktop, the user must have the Download capability. For more information, see [Cube Data Sources](#).

Publish template

 **Overwrite** lets a user publish a data source to the server and overwrite the data source on the server. Prior to Tableau 2020.1, this capability was called Save.

Administer template

 **Delete** lets a user delete the data source.

 **Set Permissions** lets a user create and edit permission rules for the data source.

Ask Data Lenses

View template

 **View** lets a user see the lens.

Publish template

 **Overwrite** lets a user edit the lens.

- By default, users with a site role of Explorer (can publish) and Creator have the Overwrite capability for lenses. This means that any user with the appropriate role can edit the name, description, fields, synonyms, and suggested questions for a lens.
- To limit who can edit a lens, deny the Overwrite capability for specific users or entire groups. To limit all lenses in a project, deny the Overwrite capability for lenses at the project level and lock the content permissions for the project.

Administer template

 **Move** lets a user move the lens between projects.

 **Delete** lets a user delete the lens.

 **Set Permissions** lets a user create permission rules for the lens.

Virtual connections

View template

 **View** lets a user see the virtual connection.

 **Connect** lets a user connect to data using a virtual connection. Note that by default, virtual connections have a Custom template that sets the View capability to Allowed but not the Connect capability. Be sure to set the Connect capability to Allowed so users can connect using the virtual connection.

Publish template

 **Overwrite** lets a user edit the virtual connection.

Administer template

 **Move** lets a user move the virtual connection between projects.

 **Delete** lets a user delete the virtual connection.

 **Set Permissions** lets a user create permission rules for the virtual connection.

Other content types

	View template	Explore template	Publish template	Administer template
Flows	 View lets a user view the flow.	 Download flow lets a user download the flow (as a TFLX).	 Run lets a user run the flow.  Overwrite* lets a user publish a flow and overwrite the published flow.	 Move lets a user move content between projects. For more information, see Move content.  Delete lets a user delete the content.

Data Roles	 View lets a user view data roles.	n/a	 Overwrite * lets a user publish data roles, overwrite published data roles, and edit a published data roles' synonyms.	 Set Per- missions lets a user create permission rules for the content.
Metrics	 View lets a user view metrics.	n/a	 Overwrite * lets a user overwrite a metric and edit a metric's details.	
Collections	 View lets a user view collections.	n/a	n/a	n/a

*Prior to Tableau 2020.1, the Overwrite capability was called Save.

Manage Permissions with Projects

Using projects can simplify permission management through features such as nested project hierarchies, hiding projects from certain users or groups, authorizing project leaders, and locking permissions.

Tip: How permissions are set at the project level is very important, especially for the Default project. When a new top-level project is created it inherits its default permission rules (for all content types) from the Default project. When a new project is created nested inside another project, the child project inherits its default permission rules from the parent project.

Project administration

Projects are containers used to organize and manage access to content. By giving non-administrators privileges to manage projects, certain content administration tasks can be handled at the project level.

Project Leaders: Projects can have project leaders, users who have been set as a **project leader**. This setting automatically grants a user their maximum capabilities—depending on their site role—for that project and all content in that project. Project leaders with site role of Explorer (can publish) and above will therefore have all capabilities. Project leaders are essentially local admins for the project without access to site or server settings.

Hierarchy: Only administrators can create top-level projects. Project owners and project leaders can create nested projects inside their projects. Project owners and leaders have full administrative access to the project and its content, as well as any nested projects it contains. In a hierarchy, project leaders are implicitly given project leader access to all child content. To remove project leader access, you must do so at the level in the hierarchy where the role was explicitly assigned.

Ownership: A project can have multiple project leaders, but each project has exactly one owner. By default, a project is owned by the user who created it. A project's owner can be changed (by the existing owner or an administrator, but not a project leader) to any user with a site role of Explorer (can publish) or Creator, or an administrator site role. Project ownership can be changed regardless of whether the project permissions are locked. Note that this refers to project ownership. Content ownership can be changed by project owners, project leaders, and administrators.

Deleting: Content can only exist inside a project. Only administrators can create and delete top-level projects, but project leaders can create or delete nested projects. Deleting projects also deletes all the content and nested projects they contain. To delete a project without losing its content, move the content to another project first. Deleting projects can't be undone.

For a deeper dive into project administration, see [Use Projects to Manage Content Access and Add Projects and Move Content Into Them](#).

Set a project leader

Project leaders are users who have administrator-like access for a specific project or project hierarchy. Prior to 2020.1, **Project Leader** was a capability that could be set to allowed, denied, or unspecified like any other capability. Starting in 2020.1, project leaders are now assigned through the action menu and function as a setting rather than a capability.

To assign project leader status to a group or user

1. Open the permission dialog for the appropriate project.
2. Select an existing permission rule, or click **+ Add Group/User Rule** and chose the desired group or user.
3. Open the action menu (...) for that permission rule and select **Set Project Leader...**

Note: If the action menu includes an option for **Enable “Set Project Leader”**, this will need to be selected before the group or user can be set as a project leader. This option only appears when that group or user was denied the Project Leader capability (prior to 2020.1). That denied capability needs to be removed before they can be set as a project leader.

Once a permission rule has been used to establish a group or user as a project leader, the templates and capabilities are no longer editable because all capabilities are allowed for project leaders. If a project leader is established on a project that contains nested projects, they will have inherited project leader status on all nested projects and their content.

Project leader status is always applied downward through the entire project hierarchy and can only be removed from the level where it was set. To remove project leader status, follow the same steps as above but select **Remove as Project Leader** from the action menu.

Once a group or user has been removed as project leader, that permission rule will have all capabilities set to Unspecified. This may mean their access to and capabilities for that project will be removed if there is no other permission rule giving them permissions to the content. To keep their access to the project and its content, they will need to have capabilities set like any other group or user.

Tableau Server on Windows Help

Lock content permissions

Permission rules set at the project level act as a default for content saved in that project and any nested projects it contains. Whether those project-level default rules are enforced or only preliminary depends on the **content permission** setting. This setting can be configured in two ways, either **Locked** (recommended) or **Customizable**. Locking a project removes the ability for content owners to modify the permission rules on their content. Locking permissions can be applied to nested projects or just to the parent project itself.

- When the content permissions are **locked (including nested projects)**, permission rules set at the project level are enforced for all content in the project and all nested projects. (This was the default behavior for locking projects prior to 2020.1)
- When the content permissions are **locked** (not including nested projects), permission rules set at the project level are enforced for content in the project, but nested projects can be configured independently with their own permission rules and as locked or customizable. (This is new behavior for locking projects as of 2020.1)
- When the content permissions are **customizable**, permission rules set at the project level are applied to all content in the project by default. However, permission rules can be modified for individual pieces of content during or after publishing. (This was called **Managed by the owner** prior to 2020.1)

Note: Whether permission rules are locked or customizable, the permissions on content are always applied. *Locked* and *customizable* refer only to how project-level permissions are inherited by content in the project and who can change them. Even in a project with customizable permissions, only specific users can modify permissions (content or project owner, project leader, admins, or those with the Set Permission capability).

In a locked project:

- The project permission rules per content type are applied to all content.
- Only administrators, project owners, and project leaders can modify permissions.
- Content owners lose the Set Permission capability but retain all other capabilities on their content.
- Permissions are predictable for all content in the project.

In a customizable project:

- The project permission rules are applied by default when content is published into the project or nested projects are created, but permissions can be modified during publication or after the content is created.
- Any user with the Set Permissions capability can modify permission rules for that content.
- Content owners have all capabilities on their content.
- Permissions can be different across content in the project.

Set content permissions (lock a project)

New top-level projects inherit all initial permission rules from the Default project but not the content permissions setting, which is set to **Customizable**. This can be changed to **Locked** if desired.

To configure the **Content Permissions**:

1. You must be logged into the site as an administrator, project owner, or project leader
2. Open the permissions dialog for a project
3. Click the Content Permissions **Edit** link in the upper left and select the desired option in the Content Permissions dialog

Content Permissions

Locked: Content inherits project permission rules and content-level permissions can't be modified. (Recommended)

Apply to nested projects

Customizable: Content starts with project permission rules and permissions can be modified by content owners.

Cancel Save

Note: If the upper left corner doesn't show an **Edit** link in step 3 above, you may be on the permissions dialog for (a) a nested project or a piece of content in a locked project, in which case the link should bring you to the managing project, (b) a piece of content in

a customizable project, which won't show anything, or (c) a view, which will indicate how the view permissions are tied to the workbook. For more information on the interplay of permissions for views and workbooks, see Show or Hide Sheet Tabs.

Change content permissions

When the content permission setting for a project is changed, the outcome depends on the new setting. Changes to permission rules in a locked hierarchy must be done at the level of the managing project.

Changing from	Changing to	Outcome
Locked (including nested projects)	Locked	Doesn't modify existing permission rules. Any nested projects become customizable.
	Customizable	Doesn't modify existing permission rules, though they become customizable. Any nested projects become customizable.
Locked	Locked (including nested projects)	Overwrites existing custom permission rules for all nested projects and their content. This can't be undone.
	Customizable	Doesn't modify existing permission rules, though they become customizable. Any nested projects retain their content permission settings and permission rules.
Customizable	Locked (including nested projects)	Overwrites existing custom permission rules for content in the project, as well as all nested projects and their content This can't be undone.

Locked	Overwrites existing custom permission rules for content in the project. This can't be undone.
	Any nested projects retain their permission rules and remain customizable.

Move projects and content

When a project is moved into another project, the permissions settings on the project being moved are maintained unless the destination project is scoped to include nested projects.

- If the destination project is set to **locked (including nested projects)**, the permissions for the project being moved are overwritten.
- If the destination project is set to **locked** (not including nested projects), the permissions for the project being moved are not overwritten. Whether or not the moved project is locked or customizable is preserved from its original setting.
- If the destination project is set to **customizable**, the permissions for the project being moved are not overwritten but they are now editable.
 - If the project being moved was previously nested under a parent that was *locked (including nested projects)*, when moved, the project takes on the setting of *locked (including nested projects)* and becomes the managing project for any projects it contains. Note: This is the same outcome if a project is moved to become a top-level project.

Effective permissions

A permission rule establishes who is impacted (a group or user) and what Capabilities they are **Allowed**, **Denied**, or **Unspecified**. While it seems straightforward to simply set a permission rule and have that be the whole story, whether a user has a capability may be unclear because of membership in multiple groups and the interplay of site roles and ownership with permission rules.

Multiple factors are evaluated in a specific order, yielding *effective permissions* on a piece of content.

Tableau Server on Windows Help

Tip: To help keep things as straightforward as possible, we recommend (1) setting permission rules for groups instead of users, (2) managing permissions locked at the project level instead of setting permissions on individual content, and (3) deleting the All User group's permission rule or setting all capabilities to None.

A capability is allowed for a user if and only if the following three conditions are all met:

- The capability is within the scope of their site role.
- They have that capability:
 - based on a specific user scenario (such as being the content owner or a project leader, or they're an administrator site role),
OR
 - because they have been allowed the capability as a user,
OR
 - because they are both in a group that has been allowed the capability and no rules deny them the capability as a user or member of another group.
- There is no conflicting permissions settings at another content level that takes precedence.

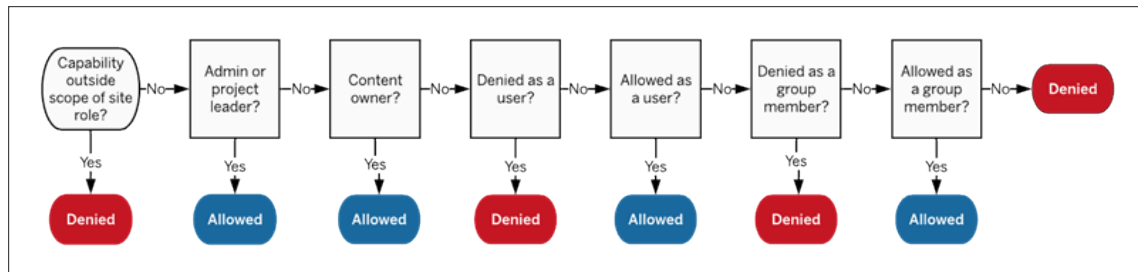

Any other situation denies the user the capability.

Hovering over a capability brings up a tooltip that explains the effective permission. Here are some common examples of why effective permissions—what the user can or can't do in actuality—might appear different than what a given permission rule states:

- A user might have a capability they are denied in a permission rule because their site role includes it (administrators).
- A user might have a capability they are denied in a permission rule because their user scenario allows it (because they own the content or are a project owner or leader).
- A user might lack a capability they are allowed in a permission rule because their site role doesn't allow it.
- A user might lack a capability they are allowed in a permission rule because a conflicting group or user rule denied it.
- A user might lack a capability they are allowed in a permission rule at one level of content (such as a workbook) because another level of content denied it (such as a view).

Evaluate permission rules

Permissions in Tableau are restrictive. Unless a capability is granted to a user, they are denied permission. The following logic evaluates if a capability is allowed or denied for an individual:

1. **Site role:** If a site role doesn't permit a capability, the user is denied. If the user's site role does permit the capability, then specific user scenarios are evaluated.
 - For example, a Viewer site role can't web edit. See [General capabilities allowed with each site role](#) for more information on what each site role can do.
2. **Specific user scenarios:**
 - If the user is an admin they have all capabilities on all content.
 - If the user is a project owner or project leader, they have all capabilities on all content in their projects.
 - If the user is the content owner, they have all capabilities* on their content.
 - If these scenarios do not apply to the user, then user rules are evaluated.

*Exception: Content owners won't have the **Set Permissions** capability in projects where permissions are locked. Only administrators, project owners, and project leaders can set permission rules in locked projects.

3. **User rules:** If the user is denied a capability, it is denied. If they are allowed a capability, it is allowed. If a capability is unspecified, then group rules are evaluated.
4. **Group rules:** If the user is in *any* group that is denied a capability, it is denied. If the user is in a group that is allowed a capability (and not in any groups that are denied that capability), it is allowed.
 - That is to say, if a user is a member in two groups, and one is allowed a capability and one is denied the same capability, the denial takes precedence for that user and they are denied.

Tableau Server on Windows Help

5. If none of the above conditions apply, the user is denied that capability. In effect, this means that capabilities left as unspecified will result in denied.

A final effective permission of **Allowed** therefore occurs in three circumstances:

- Allowed by site role (Server Administrator, Site Administrator Creator, Site Administrator Explorer)
- Allowed because the user is the content owner, project owner, or project leader
- Allowed by a group or user rule (and not denied by a rule of higher precedence)

Denied occurs in three circumstances:

- Denied by site role
- Denied by a rule (and not allowed by a rule of higher precedence)
- Not granted by any rule

Evaluate permissions set at multiple levels

If project content permissions are *customizable*, it's possible to configure permission rules in multiple places. There are specific rules that determine what permissions are applied on the content.

- If there are nested projects, permissions set at the child level take precedence over permissions set at the parent level.
- Changes to permissions at the project level are not enforced for existing content.
- If there are permissions set on content (workbook, data source, or flow) during or after publication, these take precedence over rules set at the project level.
- If a workbook doesn't show navigational sheet tabs, any changes to the workbook-level permissions *won't* be inherited by the views and any changes to permissions must be done on the view.
- Configuring the workbook to show navigational sheet tabs will override existing view-level permissions and sync them with the workbook-level permissions. See [Show or Hide Sheet Tabs](#).

This image shows how capabilities are evaluated through multiple levels of content.

Permissions on views

In a workbook that is not in a locked project and does not show sheets as tabs for navigation, views (sheets, dashboards, stories) inherit the workbook permissions at publication, but any changes to permission rules must be made on individual views. View capabilities are the same as those for workbooks, except for **Overwrite**, **Download Workbook/Save a Copy**, and **Move** which are only available at the workbook level.

We recommend showing navigational sheet tabs whenever possible so views continue to inherit their permissions from the workbook. For more information, see [Show or Hide Sheet Tabs](#).

Permissions, Site Roles, and Licenses

Adding a user to a Tableau Server requires a license. (Users can also be added as unlicensed and configured so they will consume a license only when they first sign in. For more information, see [Grant License on Sign In](#).) For each site the user belongs to they have exactly one site role, restricted by their license. A user has permissions for content on the site, restricted by what their site role allows.

Licenses and site roles apply to users. Permission capabilities apply to content.

Licenses are assigned to a user when they are created (or sign in for the first time) on the Tableau Server or Tableau Online site. Users are licensed as a **Creator**, **Explorer**, or **Viewer**.

- License levels are consumed based on the maximum *site role* a user can have on that server.
 - Server Administrator, Site Administrator Creator, and Creator site roles use a Creator license.
 - Site Administrator Explorer, Explorer (can publish), and Explorer site roles use at least an Explorer license.
 - Viewer site role uses at least a Viewer license.
 - An unlicensed user can exist on the server but they cannot log in unless they were added with grant site role on sign in.
- For Tableau Server, a user consumes only one license per server, even if they are a member of multiple sites. If a user is a member of multiple sites, their required license level is determined by their highest site role. (For example, if a user has a Creator site role in one site and a Viewer site role in two others, they consume a Creator license.)

Site roles are assigned to a user for each site they are a member of.

- Site roles determine the maximum capabilities a user can have in that site. (For example, a user with a site role of Viewer will never be able to download a data source even if that capability is explicitly granted to them on a specific data source.)
- Site roles do not inherently grant any capabilities in and of themselves—with the exception of the administrator site roles. Administrators always have all capabilities applicable to their license level.

Permissions consist of *capabilities*, like the ability to save to a project, web edit a workbook, connect to a data source, etc. They apply to group or user on a specific piece of content (project, data source, workbook, view, or flow).

- Permission capabilities are not given to a group or user in a vacuum but rather in the context of content. A user can have different capabilities for different content assets.
- Permissions are evaluated based on the interplay of a user's site role and the permission rules for that user or any groups they are members of.
- Some actions such as web authoring might require combinations of capabilities. For more information, see Permission settings for specific scenarios.

Site roles and their maximum capabilities

These tables indicate what capabilities are available to each site role. There may be other ways for a user with a site role to perform a similar action. For example, although Viewers can't be given the **Share Customized** capability to make their custom views visible to others on the workbook, they can share custom views by copying the view URL. See General capabilities allowed with each site role for more information on what each site role can do.

* Although the Explorer role can be given the **Move** capability, they can't have the **Publish** capability on a project and therefore there is no place for them to move content to. The **Move** capability should therefore be considered not possible for Explorer site roles.

Quick Start: Permissions

A permission rule is a set of capabilities that defines what access a group or user has to a piece of content, such as a workbook, project, or data source.

The most efficient way to manage permissions is to remove permissions from the **All Users** group before you create new groups for your environment. Then create permission rules for groups at the project level.

1 Add users to groups

A common way to manage permissions is to create groups for users who should have the same permissions.

1. Within a site, select **Groups**.
2. Select a group name, and then select **Add Users**.

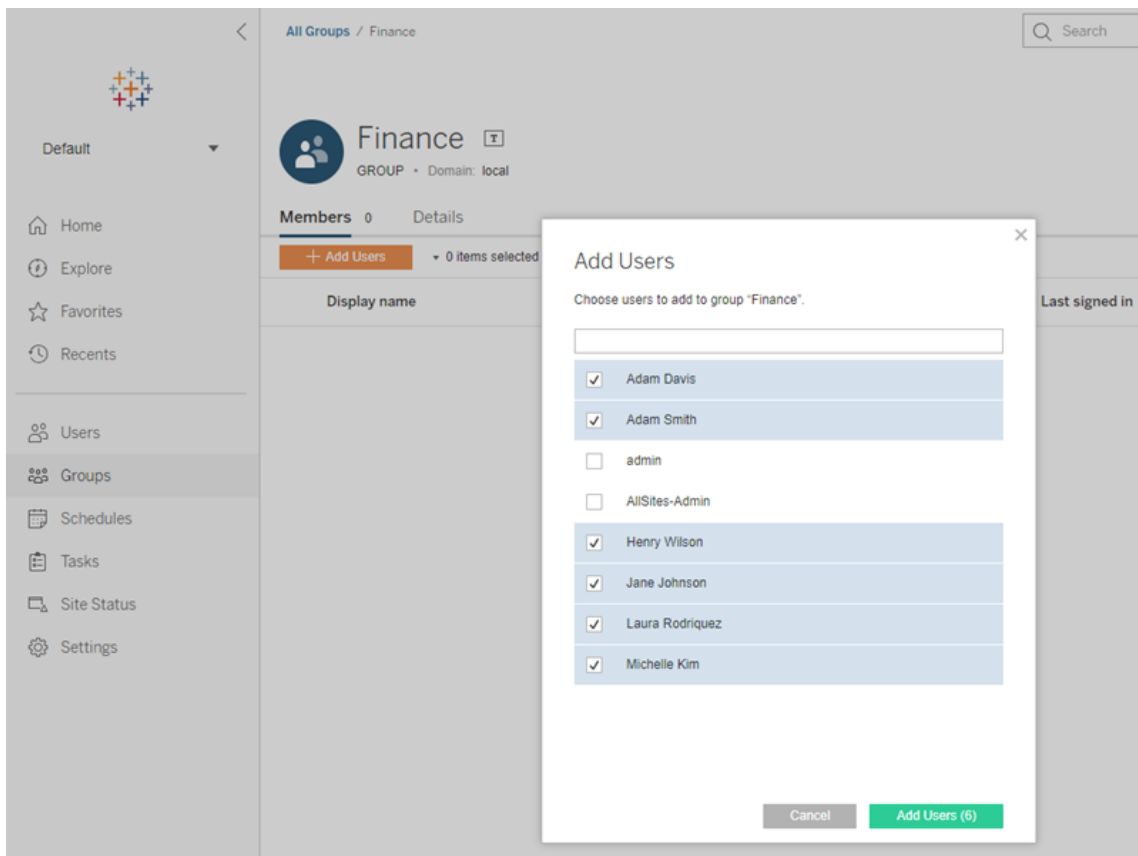

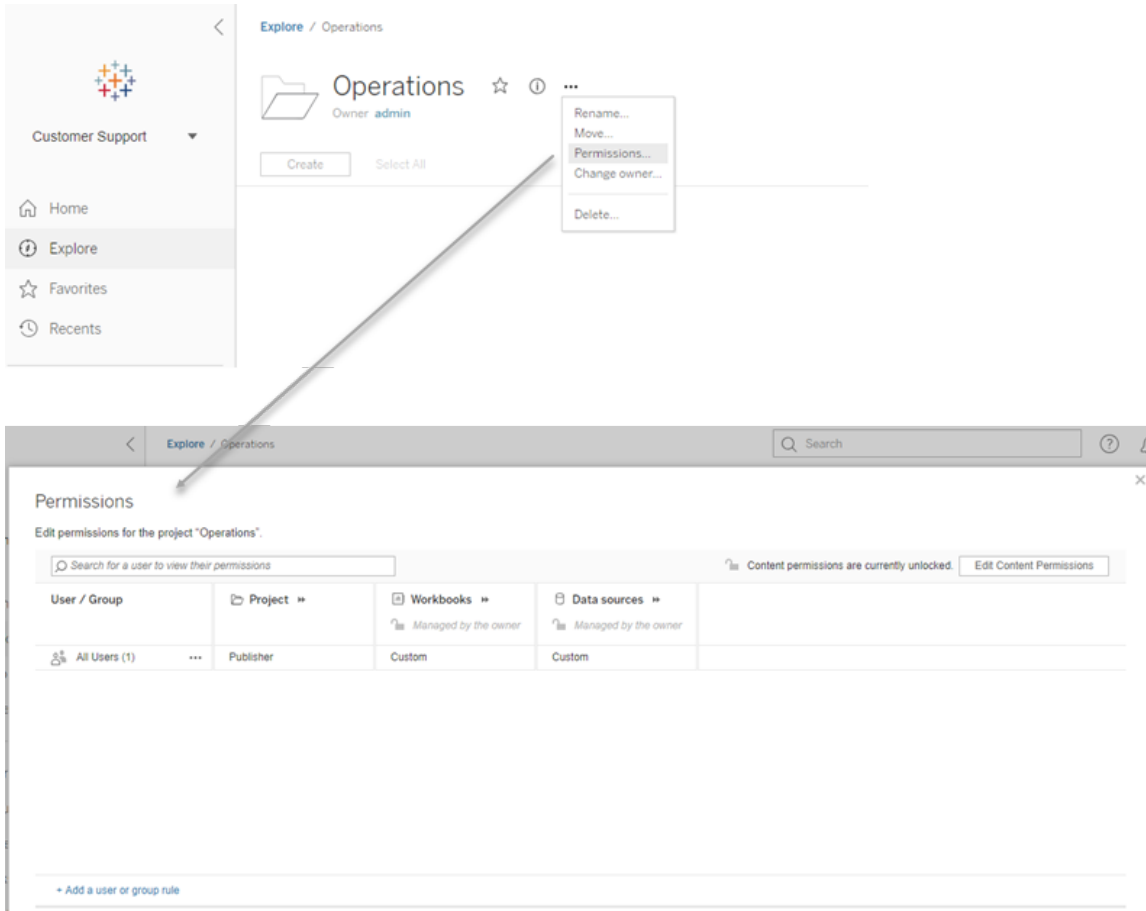

Tableau Server on Windows Help

A maximum of ten results will be returned.

2 Open a project's permissions settings

The site's **Content** page shows the top-level projects. Navigate to the project you want to update, select its **Actions (...)** menu, and then select **Permissions**.

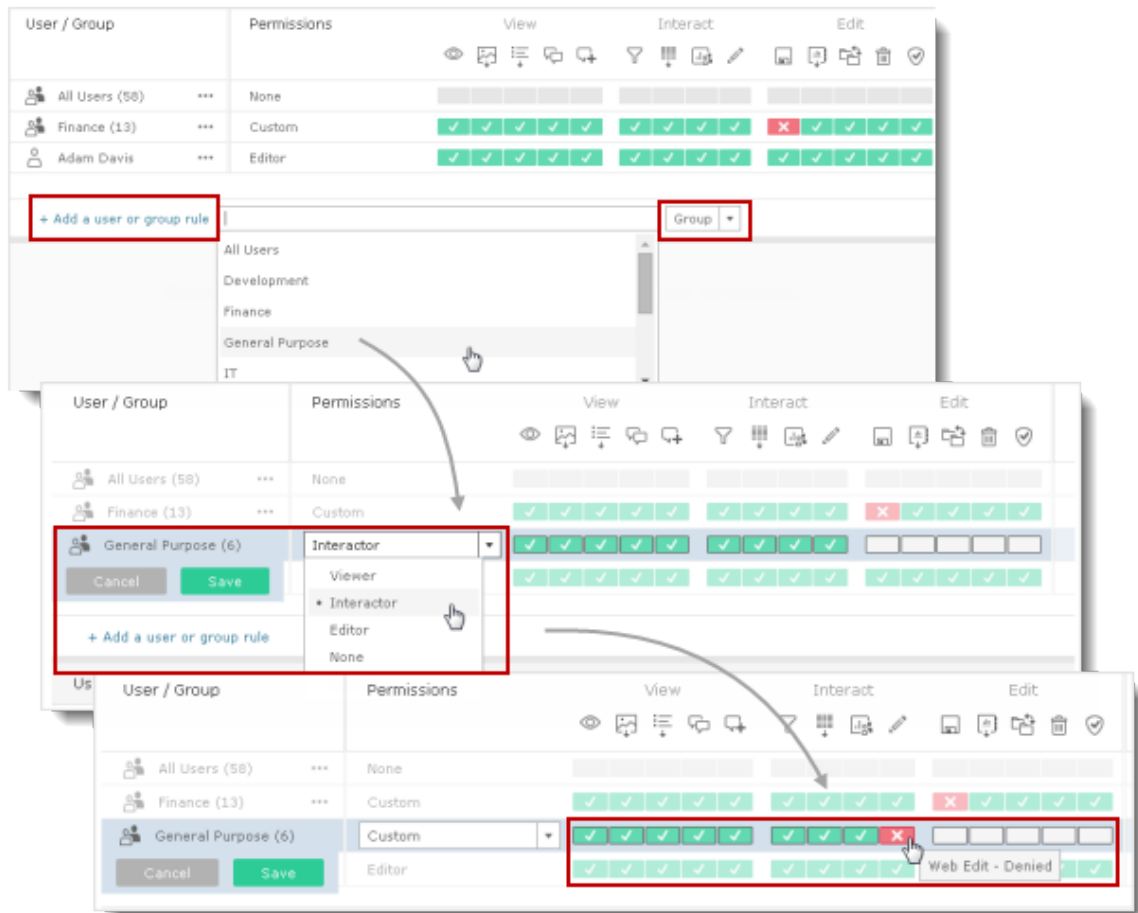

If you're not sure where to find a child project, display filters, and select **Show all projects**.

3 Create a permissions rule

Click **Add a user or group rule**, select **Group**, and then find and select the group.

Select a permissions role template to apply an initial set of capabilities for the group. Click a capability to set it to **Allowed** or **Denied**, or leave it **Unspecified**. Click **Save** when you are done.

Whether a user can set permissions is based on their site role and how their **Set Permissions** capability is set.

4 View a user's effective permissions

After you save the permissions rule for the group, you can view the effective permissions for that content.

Click a group name to see the group's users and their permissions. Hover over a capability box to see a tooltip with details on whether a capability is allowed or denied.

Tableau Server on Windows Help

User / Group	Permissions	View	Interact	Edit
All Users (58)	None			
Finance (13)	Custom	✓	✓	✓
General Purpose (...)	Custom	✓	✓	✗
Adam Davis	Editor	✓	✓	✓

User Permissions <i>General Purpose (6)</i>	
Harold Pawlan	Custom
Henry MacAllister	Viewer
Henry Wilson	Administrator
Irene Maddox	Custom
Janet Molinari	Custom
Karen Daniels	Viewer

Custom indicates a user’s capabilities have been changed from the initial settings for their site role or content role.

For more information, see [Permissions](#).

Site roles

A user’s site role determines the maximum permissions allowed for that user.

- Server and site administrators can access all site content and take actions on it.
- Owners always get full access to the content they’ve published. When the parent project permissions are not locked, owners can change permissions for their published content.

For more information, see [Set Users’ Site Roles and Use Projects to Manage Content Access](#).

Permissions evaluation

- **Denied** takes precedence over **Allowed**.
- **Unspecified** results in **Denied** if no other permissions are specified.

- Specific user permissions on content take precedence over group permissions on content. In other words, user permissions trump group permissions.

For a couple of best-practice steps for how to implement permissions, see the following:

- [Configure Projects, Groups, and Permissions for Managed Self-Service](#)
- [Structure Content Projects, Groups, and Permissions](#) (links to *Everybody's Admin Guide*)

Manage Content Ownership

When you publish a data source or workbook on Tableau Server or when you create a project, you become its *owner*. A content owner, a project leader with an appropriate site role, or an administrator can change ownership of a content asset. After ownership is reassigned, the original owner has no special connection to the content item, and their ability to access it is determined by their permissions on the project or that specific item.

Who can change or be given ownership, by content type

Whether you can change or be given ownership depends on your permissions and your relationship to the content asset, as described in the following table.

Note: Full project leader access is available only with some site roles. For information, see Project-level administration.

Content asset type	Who can change ownership	Who can be given ownership
Top-level projects	Server administrator ¹ Site administrator	Server administrator Site administrator (Creator and Explorer) Creator Explorer (can publish)
Child (nested) projects	Server administrator Site administrator Project owner	Any administrator or owner, excluding Explorer and Viewer.
Workbooks and data	Server administrator	Any administrator or user of the

sources	<p>Site administrator</p> <p>Workbook or data source owner</p> <p>Project leader or owner of the project that contains the item</p>	<p>site, excluding Explorer and Viewer.</p>
Metrics	<p>Server administrator</p> <p>Site administrator</p> <p>Metric owner</p> <p>Project leader or owner of the project that contains the item</p>	<p>Any administrator or user of the site, excluding Explorer and Viewer.</p>
Ask Data lenses	<p>Server administrator</p> <p>Site administrator</p> <p>Lens owner</p> <p>Project leader or owner of the project that contains the item</p>	<p>Any administrator or user of the site, excluding Explorer and Viewer.</p>
Flows	<p>Server administrator</p> <p>Site administrator</p>	<p>Starting in version 2021.2, server and site administrators can only change the owner to themselves.</p>

Data Roles	Server administrator Site administrator Data role owner Project leader or owner of the project that contains the item	Any administrator or user of the site, excluding Explorer and Viewer.
Collections	Server administrator Site administrator Collection owner	Any administrator or user of the site, including Explorer and Viewer.
Virtual Connections²	Server administrator Site administrator Virtual connection owner	Server administrator Site administrator Creator

¹ The Server Administrator site role applies to Tableau Server only; not Tableau Online.

² Virtual connections require the Data Management Add-on. See About Data Management Add-on for details. Note that to edit a virtual connection, you must have the database credentials.

Considerations for changing content ownership

- Before you remove a user from Tableau Server, make sure they do not own any content assets.

If the user does own content, you must first reassign ownership of those assets before you can delete the user. Otherwise, their site role is set to **Unlicensed**, but they are not deleted, and only an administrator can take certain actions on that content.

- If you change the ownership of a workbook or data source that includes embedded

credentials to connect to underlying data, the embedded credentials will be deleted. For flows, embedded credentials are preserved when changing ownership. Connections to published data sources are authenticated using the flow owner and authorized based on their permissions.

You can update the embedded credentials by editing the connection information on Tableau Server. For more information, see [Edit Connections](#). Alternatively, the new owner can download the flow, workbook, or data source and open the item in Tableau Desktop to update the embedded credentials and then re-publish the content.

- If you do not lock permissions to projects, make sure users you give content ownership to know your permissions guidelines, or you account for permissions as you change ownership. In unlocked projects, by default, content owners can set permissions on their content. For more information, see [Permissions](#).
- While it is possible to change the owner of a metric to a user with a site role of Viewer or Explorer, it is not recommended, because doing so will cause the metric refresh to be suspended. A site role of Creator or Explorer (can publish) is required to refresh, overwrite, or delete a metric.

Change the owner of a content resource

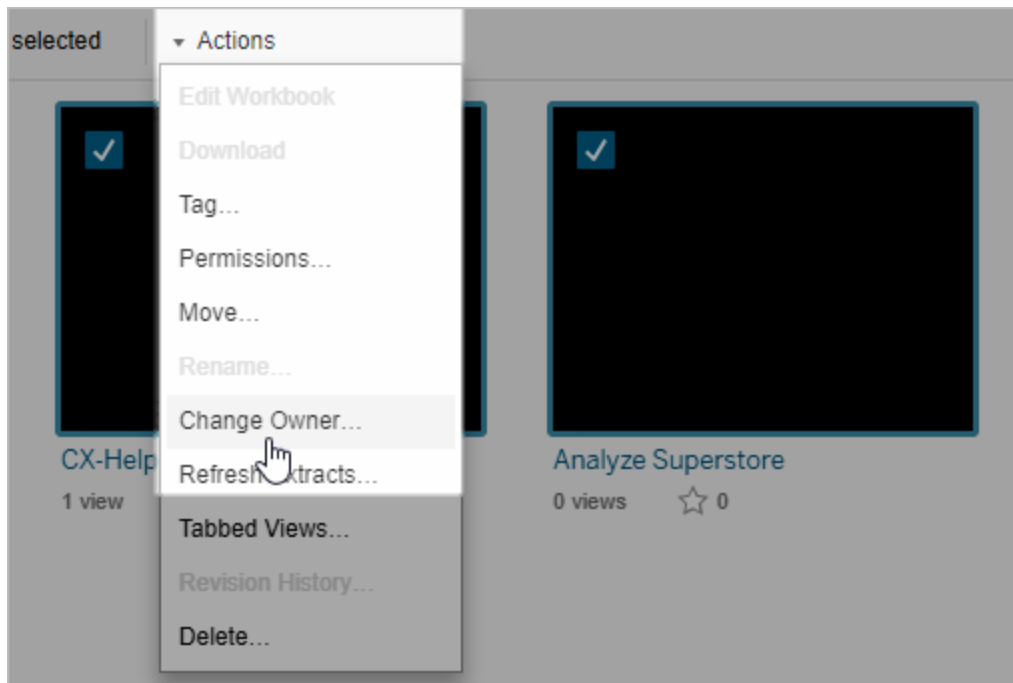

1. Sign in to the Tableau Server web environment, and from the navigation menu, select **Explore**.
2. Navigate to the content you want to assign to someone else.
 - If you want to reassign multiple of the same type of content, for example, multiple workbooks, select the content type from the drop-down menu.
 - If you want to reassign multiple items within the same project, navigate to the project.

Tableau Server on Windows Help

If you're not sure where to find a child project, display filters, and select **Show all projects**.

- If you want to reassign multiple content items with the same owner, find the user on the **Users** page.
3. Select the items you want to reassign, and then select **Actions > Change Owner**.

The other menu commands you see will depend on the content type.

4. Type the name of a user or select a user from the list.

5. Click **Change Owner**.

Manage Permissions for External Assets

Tableau Online and Tableau Server provide a space for accessing and managing published content. When Tableau Online or Tableau Server is licensed with the Data Management, you have access to Tableau Catalog. Tableau Catalog adds a complementary space and a set of features across your site to track and manage metadata and lineage of external assets used by the content published to your site.

Tableau Catalog indexes content and assets

Catalog discovers, tracks, and stores metadata from the content that you publish to Tableau Online or Tableau Server.

Catalog indexes metadata for the following:

- **Tableau content:** workbooks, data sources, flows, projects, metrics, users, and sites
- **External assets:** databases and tables associated with Tableau content

Catalog classifies the metadata of any data that comes from outside the Tableau environment as external assets. The data that comes from outside the Tableau envir-

Tableau Server on Windows Help

onment is stored in many different formats, such as a database server or a local .json file.

Catalog tracks only the metadata of the external data and does not track the underlying data in any form (raw or aggregated).

Catalog metadata includes the following:

- **Lineage information** or the relationship between items. For example, the Sales table has a relationship with both the Superstore data source and the Superstore Sample workbook.
- **Schema information.** Some examples include:
 - Table names, column names, and column types. For example, Table A contains Columns A, B, and C, which are types INT, VARCHAR, and VARCHAR.
 - Database name and server location. For example, Database_1 is a SQL Server database at <http://example.net>.
 - Data source name, and the names and types of the fields the data source contains. For example, Superstore data source has fields AA, BB, and CC. Field CC is a calculated field that refers back to both field AA and field BB.
- **User curated, added, or managed information.** For example, item descriptions, certifications, user contacts, data quality warnings, and more.

How does Tableau Catalog work?

Tableau Catalog indexes all content published to Tableau Online or Tableau Server to track lineage and schema metadata. For example, the metadata comes from workbooks, packaged workbooks, data sources, and the Tableau Server or Tableau Online repository.

As part of the indexing process, lineage and schema metadata about external assets (databases and tables) used by the published content are also indexed.

Note: In addition to accessing Catalog from Tableau Online or Tableau Server, indexed metadata can also be accessed from the Tableau Metadata API and Tableau Server REST API. For more information about the Tableau Metadata API or metadata methods in

the REST API, see [Tableau Metadata API](#) and [Metadata Methods](#) in the Tableau Server REST API, respectively.

Permissions on metadata

Permissions control who is allowed to see and manage external assets and what metadata (for both Tableau content and external assets) is shown through lineage.

Note: If Tableau Online or Tableau Server is not licensed with the Data Management, then by default, only admins can see database and table metadata through the Tableau Metadata API. This default can be changed to use "derived permissions," as described below.

Access metadata

The permissions used to access metadata through Catalog (or Metadata API) work similarly to permissions for accessing content through Tableau Online or Tableau Server, with some additional considerations for sensitive data that can be exposed through lineage and the capabilities granted on external assets.

Permissions on Tableau content

Catalog uses view and manage capabilities that are already used by existing Tableau content to control the metadata that you can see and manage on Tableau content. For more general information on these capabilities, see [Permissions](#).

Permissions on external assets using derived permissions

When Tableau Online or Tableau Server is licensed with the Data Management, by default Catalog uses *derived permissions* to automatically grant you capabilities to external assets in the following scenarios:

For **View** capability:

- If you are the owner of a workbook, data source, or flow, you can see the database

Tableau Server on Windows Help

and table metadata used *directly* by that workbook, data source, or flow. See Additional notes about lineage.

- If you are a project owner or project leader, you can see all the database and table metadata used by the content published to your project.
- Embedded files use the permissions of the source (such as the workbook, data source, or flow), rather than the derived permissions of the external asset (the database or table). For example, if you can see the workbook with an embedded file, you can see the embedded file and its metadata used by that workbook.

For both **Overwrite** and **Set Permissions** capabilities:

- If you are the owner of a flow, you can edit and manage permissions for the database and table metadata used by the flow output.

Note: For the flow cases above, the capabilities apply only after there has been at least one successful flow run under the current owner of the flow.

Check permissions

As an admin or someone who has been given the capability to set permissions for an asset, you can validate who has derived permissions by following the steps below.

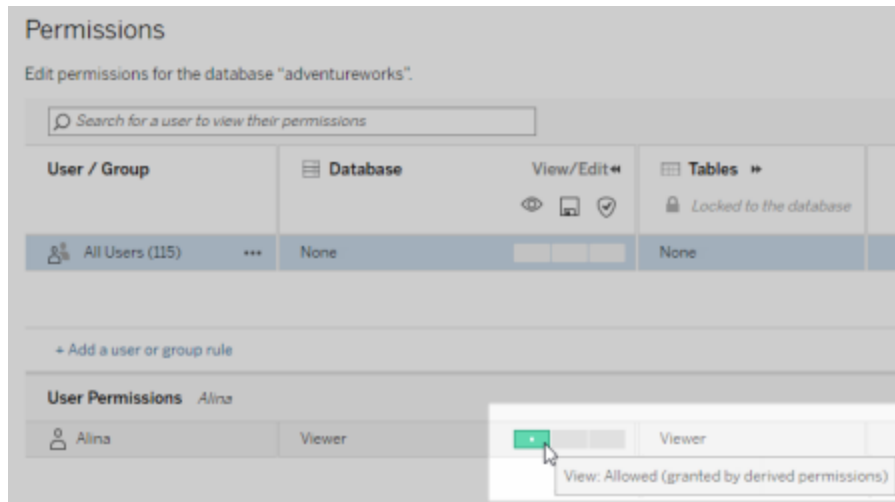

1. Sign in to Tableau Online or Tableau Server.
2. From the left navigation pane, click **External Assets**.
3. From the drop-down menu, select **Databases and Files** or **Tables**.

Note: Local files, like .json or .csv files are grouped as external assets under **Databases**.

4. Select the check box next to the database or table whose permissions you want to modify, and then select **Actions > Permissions**.
5. In the Permissions dialog box, click **+ Add Group/User Rule** and start typing to

search for a group or user.

6. Validate the permissions by clicking a group name or user name in the permission rules to see the effective permissions below.

Order of precedence in which Tableau evaluates derived permissions for external assets

When derived permissions are configured for your Tableau Online site or Tableau Server, each user's level of access to external assets depends on the associated Tableau content and the order of precedence of rules Tableau uses for its content.

Tableau follows the rules below, continuing on to the next rule, only if the current rule evaluates to "denied." If any rule evaluates to "allowed," the capability is allowed and Tableau stops evaluating. This rules list is based on the Permissions.

For **View** capability:

1. Admin role
2. License
3. Project leader (Tableau content)
4. Project owner (Tableau content)
5. Content owner (Tableau content)

Tableau Server on Windows Help

6. *Derived permissions* (applies only to external assets and the View capability)
 - a. Admin role
 - b. License
 - c. Project leader (external assets)
 - d. Project owner (external assets)
 - e. Content owner (external assets)
7. Explicit permissions

For **Overwrite** and **Set Permissions** capabilities:

1. Admin role
2. License
3. Project leader (Tableau content)
4. Project owner (Tableau content)
5. Content owner (Tableau content)
6. Explicit permissions (Tableau content)
7. *Derived permissions* (applies only to external assets and the Overwrite and Set Permissions capabilities for flow outputs)
 - a. Admin role
 - b. License
 - c. Project leader (external assets)
 - d. Project owner (external assets)
 - e. Content owner (external assets)

Turn off derived permissions

As an admin, you can turn off the derived permissions default setting for a site in favor of manually granting explicit permissions to databases and tables.

1. Sign in to Tableau Online or Tableau Server as an admin.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Automatic Access to Metadata about Databases and Tables, clear the **Automatically grant authorized users access to metadata about databases and tables** check box.

Note: Data quality warning messages on databases and tables that are visible to users though derived permissions remain visible to those users even when the check box is not selected.

Set permissions on individual external assets

In order to grant additional users permissions to view, edit (overwrite), and manage external assets, an admin can grant those capabilities explicitly on individual databases or tables for users or groups.

Database permissions act as a permissions template

Database permissions function like Permissions. In other words, when permissions are set at the database level, those permissions can serve as a template for any newly discovered and indexed child tables of that database. Furthermore, database permissions can also be locked so that the child tables will always use the permissions set at the database level.

Granting permission at the database level can help create a scalable process for enabling permissions to tables.

Summary of permissions capabilities

The following table shows the capabilities you can set for external assets (databases and tables):

Capability	Description	Template
 View	See the database or table asset.	View
 Overwrite	Add or edit data quality warnings and descriptions of the database or table asset. Prior to version 2020.1, the Overwrite capability was called Save.	Publish
 Set Per-	Grant or deny permissions for the database or table asset.	Administer

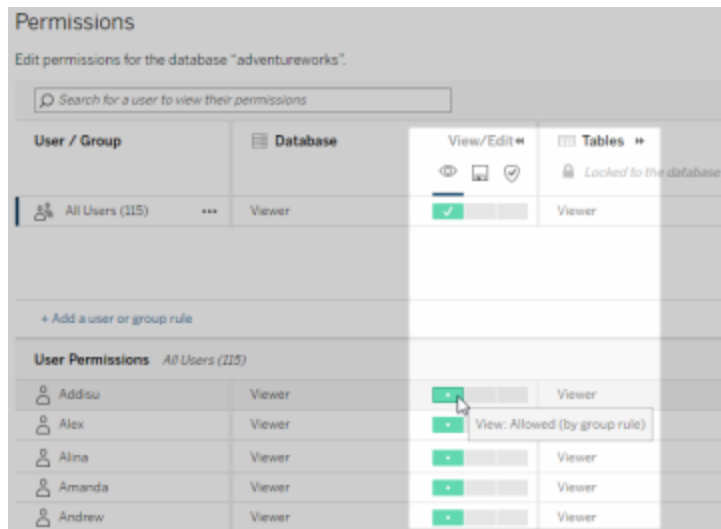

missions

Set permissions on a database or table

To set permissions on databases or tables, use the following procedure.

1. Sign in to Tableau Online or Tableau Server as an admin or someone who has been granted the "Set Permissions" capability.
2. From the left navigation pane, click **External Assets**.
3. From the drop-down menu, select **Databases and Files** or **Tables**.
Note: Local files, like .json or .csv files are grouped as external assets under **Databases**.
4. Select the check box next to the database or table whose permissions you want to modify, and then select **Actions > Permissions**.
5. In the Permissions dialog box, click **+ Add Group/User Rule** and start typing to search for a group or user.
6. Select a permission role template to apply an initial set of capability for the group or user, and then click **Save**. Available templates are: View, Publish, Administer, None, and Denied.
7. To further customize the rule, click a capability in the rule to set it to Allowed or Denied, or leave it unspecified. Click save when you are done.
8. Configure any additional rules you want for other groups or users.
9. Validate the permissions clicking a group name or user name in the permission rules

to see the effective permissions below.

Lock permissions to the database

To lock (or unlock) permissions to the database, use the following procedure.

1. Sign in to Tableau Online or Tableau Server as an admin or someone who has been granted the "Set Permissions" capability.
2. From the left navigation pane, click **External Assets**. By default, the External Assets page shows a list of databases and files.
3. Select the check box next to the database whose permissions you want to lock, select **Actions > Permissions**, and then click the Table Permissions **Edit** link .
4. In the Table Permissions in Database dialog box, select **Locked** and click **Save**.
5. To unlock permissions, click **Edit** again, and select **Customized**.

Access lineage information

Catalog (and the Metadata API) can expose relationship and dependencies metadata, also referred to as *lineage*, among the content and assets on Tableau Online or Tableau Server.

Lineage can show three primary things:

Tableau Server on Windows Help

- How items relate to each other, either directly or indirectly
- How many of those items relate to each other
- With the appropriate permissions, shows sensitive data about items in the lineage

Sensitive lineage data

In some cases, lineage can contain sensitive data, such as data quality warning messages, content or asset names, or related items and metadata.

By default, complete lineage information displays for all users while its sensitive data is blocked from specific users who don't have the appropriate View capabilities. The concept of blocking sensitive data is called obfuscation.

Obfuscation allows all metadata in the lineage to be visible while keeping its sensitive data blocked from specific users who don't have the appropriate View capabilities. This default enables workflows that rely on a complete impact analysis.

If obfuscating sensitive data in the lineage is not enough for your organization, certain parts of the lineage, including its sensitive data, can be filtered.

Filtering omits certain parts of the lineage (and lineage-related areas like data details) for specific users who don't have the appropriate View capabilities to its sensitive data. Because filtering omits parts of lineage, it prevents workflows that rely on a complete impact analysis.

To change how sensitive data is handled, do the following:

1. Sign in to Tableau Online or Tableau Server as an admin.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under **Sensitive Lineage Information**, select the radio button that best handles lineage information for all users on your Tableau Online site or Tableau Server.

Additional notes about lineage

- **If you have the View capability on related assets**, you can see when and what assets and content are related to each other, and their sensitive metadata.

For example, you can see 1) the names, data quality warnings, and total number of related upstream databases and tables and 2) the combined number of sheets (visible and hidden) in the lineage of the downstream workbook of the asset you are evaluating.

- If you *don't* have the **View capability on related assets**, you can always see when assets relate to each other.

For example, you can see 1) whether related upstream databases and tables exist in the lineage and 2) the total number of databases or total number of tables that are related to the asset you are evaluating.

However, you can't see the metadata associated with those assets when you don't have the view capability for them. When metadata is blocked because of limited permissions, or the asset is in a Personal Space, you see **Permissions Required**.

	Type	Name	Workbooks
<input type="checkbox"/>	Table	Permissions Required	2
<input type="checkbox"/>	Table	Permissions Required	0
<input type="checkbox"/>	Table	Price	0
<input type="checkbox"/>	Table	Product	74
<input type="checkbox"/>	Table	User	109
<input type="checkbox"/>	Table	Permissions Required	1

- If you *don't* have the **View capability on related assets**, you can always see

Tableau Server on Windows Help

whether the assets are certified.

However, the level of detail that you can't see if you don't have View capability is the sensitive information related to the certification, like the names of the related databases and tables. When metadata is blocked because of limited permissions, or the asset is in a Personal Space, you see **Permissions Required**.

The screenshot shows a table titled 'Tables (6)' with columns for 'Type', 'Name', 'Workbooks', and 'Data Sources'. The table contains six rows. The first five rows have 'Permissions Required' in the Name column, and the sixth row has 'REI'. A tooltip is displayed over the 'Permissions Required' entry in the fifth row, showing the text: 'On this asset', 'Under maintenance', 'Permissions Required', 'Set by workgroupuser', and 'Aug 7, 2019, 10:23 AM'.

	Type	Name	Workbooks	Data Sources
<input type="checkbox"/>	Table	Permissions Required	1	1
<input type="checkbox"/>	Table	Permissions Required	0	1
<input type="checkbox"/>	Table	Permissions Required	0	1
<input type="checkbox"/>	Table	REI	2	4
<input type="checkbox"/>	Table	Permissions Required	0	1
<input type="checkbox"/>	Table	Permissions Required	0	5

For more information about lineage see [Use Lineage for Impact Analysis](#).

Additional notes about tags discoverable through lineage data

In addition to Tableau content, external assets can also be tagged. Although tags are always visible, tagged items that you see through lineage data can either be obfuscated (default) or filtered as described earlier in this topic.

When tagged items are obfuscated:

- **If you have the View capability for tagged items**, you can see the tagged items and related tagged items, and all metadata.
- **If you don't have the View capability for tagged items:**

- You can see the type of tagged and related tagged items but you can't see sensitive metadata about the items. For example, suppose you use a tag filter to see items with the tag "Noteworthy." Although you can see that there are database items tagged with "Noteworthy," you can't see the names of the tagged databases.
- You can see how many related tagged items there are. For example, suppose you do a tag query on "Noteworthy." Your query returns five tagged databases.

When tagged items are filtered, the tagged and related tagged items you see are limited to only the items that you have the View capability for.

For more information about tags, see [Tagged Items](#) in the Tableau User Help.

Potential mismatch between asset results and content results

When Catalog shows lineage information, it provides information between content and assets. Catalog lineage always shows the true count or result of associated items. However, elsewhere in Tableau Online or Tableau Server, you might see fewer number of items. One reason for this is because of your View capabilities. Outside of Catalog, or elsewhere in Tableau Online or Tableau Server, you see a filtered count or result of the content that you have access to according to your content permissions.

For example, suppose you're looking at the Superstore data source. The lineage for the Superstore data source can show how many upstream underlying tables the data source connects to and how many downstream workbooks rely on the data source. However, because you might not have the View capability on all of those downstream workbooks, the total number of related workbooks might be different when you're looking at Catalog lineage information versus the total number of workbooks represented in the **Connected Workbooks** tab.

There might be other reasons why, which are not related to permissions, you might see a mismatch between asset counts and content counts. For more information, see [Use Lineage for Impact Analysis](#).

Tableau Server on Windows Help

Who can do this

The following information summarizes the types of users who can do the tasks described in this topic.

Tableau Online site or Tableau Server admin

Data Management	Capability	Requirements
Licensed	See assets and their metadata	None

Data Management	Capability	Requirements
	Edit assets and their metadata	None
	Change permission on assets and their metadata	None
	Grant users ability to see assets and their metadata	<p>Default: When “derived permissions” is on, your users can see metadata on external assets for the content that they own, or for the content that is published to a project that they are a project leader or project owner of.</p> <p>Ad-hoc: You can configure explicit View permissions on a specified external asset.</p>
	Grant users ability to edit assets and their metadata	You can configure explicit "write" or Overwrite permissions on a specified external asset (if not automatically granted because the user is a flow owner) .
	Grant users ability to change permissions on assets and their metadata	You can configure explicit "edit" or Set Permissions on a specified external asset (if not automatically granted because the user is a flow owner) .

Data Management	Capability	Requirements
Not licensed	See all assets and their metadata	Applies to Metadata API only
	Edit assets and their metadata	Requires the Data Management
	Change permission on assets and their metadata	Requires the Data Management
	Grant users ability to see assets and their metadata	Applies to Metadata API only: You can turn on derived permissions as described above. If “derived permissions” is on, your users can see metadata on external assets for the content that they own, or for the content that is published to a project that they are a project leader or project owner of.
	Grant users ability to edit assets and their metadata	Requires the Data Management
	Grant users ability to change permissions on assets and their metadata	Requires the Data Management

User with Creator or Explorer license

Manage Data

You can connect to and manage the data you that you use in Tableau.

Tableau Server Data Sources

When your Tableau users want to share data connections they've defined, they can publish data sources to Tableau Server. When a data source is published to the server, other users can connect to it from their own workbooks, as they do other types of data. When the data in the Tableau data source is updated, all workbooks that connect to it pick up the changes.

Looking for Tableau Server on Linux? See [Tableau Server Data Sources](#).

A Tableau Server data source consists of metadata that describes the following:

- **The connection information:** Defines whether the data is in a live database or an extract, and which of that data to bring in to Tableau.
- **Customization and cleanup:** Includes information that facilitates efficient use of the data. For example, calculations, sets, groups, bins, parameters, custom field formatting, and so on.
- **Data access and refresh instructions:** Includes the location of the underlying database server (whether on-premises or in the cloud), network paths for file-based data, security information such as credentials or access tokens, and related information.

In addition to helping your users create data consistency and reliability, using Tableau data sources offers advantages to you as the administrator. Because multiple workbooks can connect to one data source, you can minimize data source proliferation and save on storage space and processing time. When someone downloads a workbook that connects to a Tableau data source that in turn has an extract connection, the extract stays on the server, reducing network traffic. Finally, if a connection requires a database driver, you need to install and maintain the driver only on the server, instead of on each user's computer. If you use Tableau Online, all supported drivers are available to data sources published to your site.

Managing data sources

You can perform some or all management tasks on a data source if you have one of the following levels of access:

- Site or server administrator
- Project leader or owner of the project the data source is published to

Full project leader access is available only with some site roles. For information, see [Project-level administration](#).

- Data source owner

Unless you're a site or server administrator, you might not have access to all management tasks. For example, if the Permissions menu is not available, chances are that the project permissions are locked, which denies setting permissions on individual workbooks and data sources.

Tip: A best practice is to designate a person or team to manage all data sources published to a project or to the whole site, so that all data sources can be maintained under the same set of guidelines.

To perform the management tasks that you have access to, do the following:

1. Sign in to the site, and on the **Content** tab, select **Explore > Data sources**.
2. On a data source, select the **Actions (...)** menu.

- **New workbook or Download:** Create a new workbook in the browser environment that connects to this data source. Or download the data source to use locally.
- **Tag:** Add or remove keyword tags. Tags can contain a single word or multiple words, delimited by a comma.
- **Move:** Move a data source from one project to another. This requires specific settings on each project. For information, see [Required access level for moving content](#).
- **Permissions:** View or update permissions that specify which users or groups can connect to, modify, or download the data source. As mentioned at the beginning of this section, if this action is not available, the project permissions might be locked, and only the project leader or administrator can change permissions.
- **Change owner:** Making someone an owner gives them complete access to it.
- **Refresh extracts:** If a data source includes an extract, you can assign the extract to a refresh schedule.

For information, see [Refresh Data on a Schedule](#).

- **View the data source's revision history**
- **Delete:** Deleting a data source affects workbooks that connect to the data source. Before you delete a data source, ensure that there are no workbooks that connect to the data source or edit the workbooks to use another data source.

In addition, for data sources that are proxy connections, administrators can stay aware of how users authenticate to the database, and whether the appropriate drivers are installed. For information, see [Database Drivers and Data Security](#).

Restrictions

Published data sources often function as curated and trustworthy data sources. As such, there are restrictions on how they can be modified and used.

Aliases and calculations can't be edited.

- New aliases also can't be created. Fields can be duplicated and the copy can be aliased.
- New calculations can be created. Existing calculation can also be copied and the copy can be edited.

Relationships and joins can't be edited.

Published data sources cannot be used in joins or relationships.

- Use blends if you need to combine published data sources.

Extract Upgrade to .hyper Format

Beginning in version 10.5, new extracts use the .hyper format instead of the .tde format. Extracts in the .hyper format take advantage of an improved data engine, which supports the same fast analytical and query performance as the data engine before it, but for even larger extracts.

This article covers what you and your users should be aware of as a result of the extract format change in version 2021.4 and how the change impacts your users.

Changes to extracts in version 10.5

With the introduction of Tableau's improved data engine technology, Hyper, comes a change to the extract format. As mentioned above, extracts created in version 2021.4 use the .hyper format. Though Tableau version 2021.4 can continue to read .tde extracts, it cannot create new .tde extracts. The impact of this format change means that when certain extract tasks are performed either by a user or by Tableau Server, such as an extract refresh or append data, the .tde extract is automatically upgraded and converted to a .hyper extract.

After an extract is upgraded to a .hyper extract, your users can interact with the .hyper extract as they would a .tde extract. However, your users should be aware of the following backward limitations:

- The upgrade can't be reversed. An upgraded extract can't be converted back to a .tde extract.
- The upgraded extract can't be opened in Tableau Desktop 10.4 and earlier.
- Workbooks that contain upgraded extracts can't be published as an older version from Tableau Desktop to Tableau Server.
- Workbooks that contain upgraded extracts can't be downgraded as an older version in Tableau Desktop.
- Workbooks that contain an upgraded extract, which are downloaded from Tableau Server using the **Download Tableau Workbook** option, cannot be opened in Tableau Desktop 10.4 and earlier.

Tasks that cause extract upgrade

There are three distinct ways a .tde extract can get upgraded to a .hyper extract: 1.) during an extract refresh (full or incremental), 2.) when appending data to an extract, and 3.) when

an extract is upgraded manually using Tableau Desktop 2021.4. After an extract has been upgraded, the original .tde extract is automatically removed from Tableau Server if it's not being reference by other workbooks.

The followings tasks on Tableau Server automatically upgrades and converts a .tde extract to a .hyper extract:

- Manual extract refresh
- Scheduled extract refresh
- Automated refresh task that's performed through tabcmd
- Automated refresh task that's performed through the Extract Command-Line Utility
- Automated append data to an extract using tabcmd
- Automated append data to an extract using the Extract Command-Line Utility
- Encryption of a .tde extract. For more information, see [Extract Encryption at Rest](#).

Impact of extract upgrade

Tableau recommends that the Tableau Desktop version in your environment be upgraded to match Tableau Server 2021.4. If they don't match, extract compatibility can be an issue depending on the task your users want to perform.

To get a better understanding of when extract upgrades can occur and potential compatibility issues your users might experience, review a detailed explanation of the [extract compatibility scenarios](#) on the Tableau Support page or a summary explanation below.

Note: In the tables below, "10.4" represents Tableau 10.4 and earlier and "10.5" represents Tableau 10.5 and later.

Tableau Server on Windows Help

Performing tasks on Tableau Server 10.5

When working with extracts created in Tableau Desktop 10.4 and earlier, your users should be aware of the following extract-related compatibility scenarios around common tasks performed on Tableau Server 10.5.

Task	10.4 workbook	10.5 workbook	
	.tde extract	.tde extract	.hyper extract
Publish from Tableau Desktop 10.4	√	Not possible	Not possible
Publish from Tableau Desktop 10.5	√	√	√
Refresh, scheduled refresh, or append	Workbook version remains unchanged, but extract upgrades to .hyper format	Workbook version remains unchanged, but extract upgrades to .hyper format	√
Edit/save in web authoring	Workbook version changes to 10.5, extract remains in .tde format	√	√
Edit/save in web authoring then refresh or append	Workbook version changes to 10.5, and extract upgrades to .hyper format	Workbook version remains unchanged, but extract upgrades to .hyper format	√

Downloading from Tableau Server 10.5

When working with extracts created in Tableau Desktop 10.4 and earlier, your users should be aware of the following extract-related compatibility scenarios when downloading from Tableau Server 10.5.

Task		10.4 work-book	10.5 workbook	
		.tde extract	.tde extract	.hyper extract
Download and open	in Tableau Desktop 10.4	√	Can't open workbook; you see a "this workbook uses a .hyper extract and is not compatible with this version; open the workbook in version 10.5 or later" error message, and then asked to locate the extract	Can't open workbook; you see a "this file was created by a newer version; upgrade Tableau" error message
Download and open	in Tableau Desktop 10.5	√	√	√
Export As Version	from Tableau Desktop 10.5	√	√	Option is greyed out

Tableau Server on Windows Help

Automating refresh and append tasks

When working with extracts created in Tableau Desktop 10.4 and earlier, your users should be aware of the following extract-related compatibility scenarios around automating refresh and append tasks using `tabcmd` or the Tableau Command-Line Utility.

Task		10.4 workbook	10.5 workbook	
		.tde extract	.tde extract	.hyper extract
Refresh or append	using 10.4 <code>tabcmd</code>	Workbook version remains unchanged, but extract upgrades to .hyper format	Workbook version remains unchanged, but extract upgrades to .hyper format	√
	using 10.5 <code>tabcmd</code>	Workbook version remains unchanged, but extract upgrades to .hyper format	Workbook version remains unchanged, but extract upgrades to .hyper format	√
Publish	using 10.4 <code>tabcmd</code>	√	√	Not possible
	using 10.5 <code>tabcmd</code>	Not possible	Not possible	√
Refresh or append	using 10.4 Tableau Command-Line Utility	√	Not possible	Not possible
	using 10.5 Tableau Command-Line Utility	Workbook version remains unchanged, but extract upgrades to .hyper format	Workbook version remains unchanged, but extract upgrades to .hyper format	√

Why keep an extract in .tde format?

If the version of Tableau Desktop cannot be upgraded to match Tableau Server 2021.4, your users will need to keep their extracts in .tde format.

How to keep an extract in .tde format

To keep an extract in the .tde format, the extract should not be upgraded. To help your users keep their extracts from upgrading, advise them against performing any of the tasks listed above in the Extract Upgrade to .hyper Format section. Then, consider the following suggestions to maintain a .tde version of an extract:

- Disable existing extract refresh schedules on Tableau Server until you can identify which extracts should and shouldn't be upgraded.

Note: To access an extract's refresh schedule, you must be a data source owner, or be a server administrator, site administrator, or Project Leader. For more information about which site roles allow full Project Leader capabilities, see [Project-level administration](#).

- Continue to perform extract refresh and append data tasks using Tableau Server 2021.4, but maintain an earlier version of Tableau Desktop and the ability to connect to the original data in case you need to recreate the .tde extract.
- Use an earlier version of Tableau Desktop to perform extract tasks, such as extract refresh or append data.

What to expect after extract upgrade

After an extract upgrade has taken place, your users should expect some additional changes when working with extracts in version 2021.4. For more information, see [After an extract upgrade](#) section in Tableau Help.

Set the Site Time Zone for Extracts

The default time zone for extract-based data sources in a site is Coordinated Universal Time (UTC). Server administrators can set a different time zone.

To set the site time zone for extracts:

1. Sign in to Tableau as an administrator.
2. On the site you want to configure, click `Settings`.
3. In the `Site Time Zone for Extracts` section, select a time zone and then click `Save`.

In calculated fields, functions such as `NOW()` or `TODAY()` look at the time zone. For more information about Extracts, see [Extract Your Data](#) in the Tableau Desktop help.

The timezone setting, in addition to being used for extract-based data sources, also affects internal extracts. For example, when Tableau connects to file-based data sources like text files, an extract is automatically created internally. Similarly, this happens where Tableau uses an internal extract to integrate data from different sources.

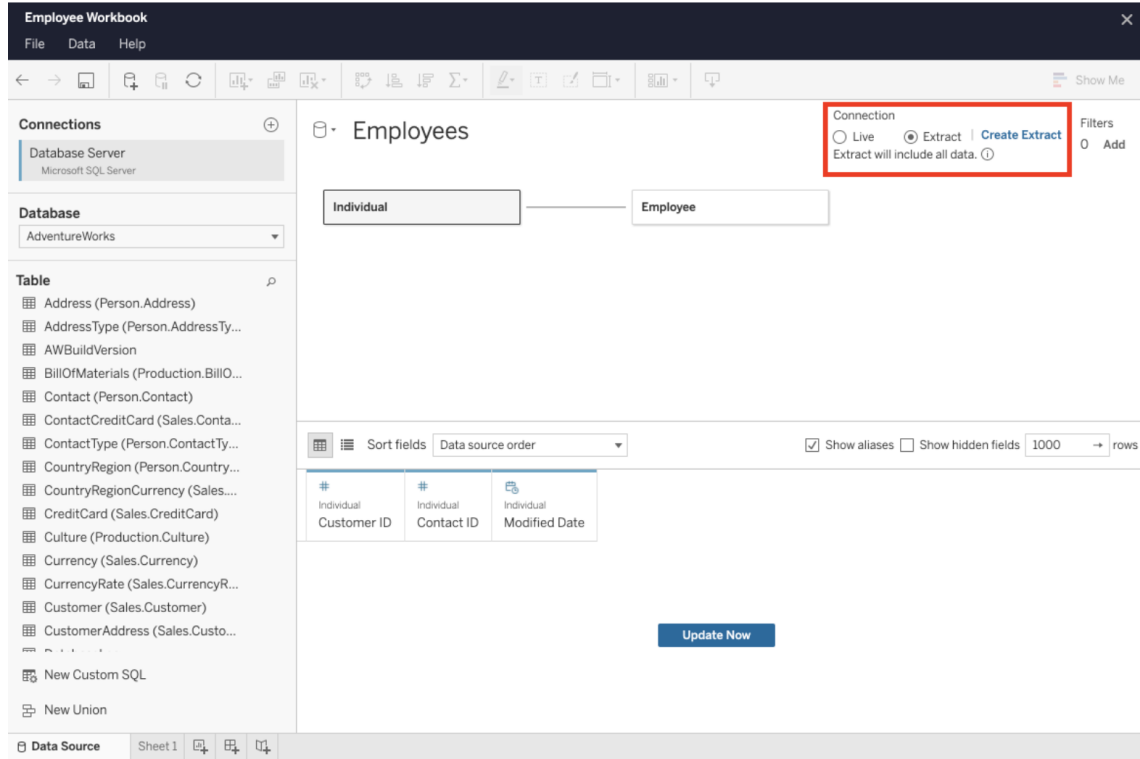

Create Extracts on the Web

You can extract your data sources in the web (without using Tableau Desktop) to improve data source performance and support additional analytical functions. When you extract your data source, Tableau will copy the data from your remote data store to Tableau Server or Online. To learn more about the benefits of extracting your data, see [Extract Your Data](#). In the web, you can extract while in Web Authoring or while in Content Server.

Create extracts in Web Authoring

You can create extracts directly in web authoring with default extract settings.

Extract an Embedded Data Source in Web Authoring

To create an extract in web authoring:

Tip: It is recommended to finalize your data model before you create the extract. Extract creation may take a long time and any changes to your data model, such as adding new logical tables, will invalidate the extract.

1. Click the **Data Source** tab in the bottom left corner of the web authoring pane. For new workbooks, you will start in the **Data Source** tab.
2. In the top-right corner, change the connection type from **Live** to **Extract**.
3. Click **Create Extract**. You will see the **Creating Extract** dialog box.

Extract creation might take a long time and you can close your authoring session while the extract is being created. To ensure your extract creation is not lost, in the dialog box, click **Notify Me When Complete** to specify a location for the extracted workbook to be saved. If your extract succeeds, your workbook will be saved to the specified location and you will be

Tableau Server on Windows Help

notified that you can continue your web authoring session. If your extract creation fails, you will be notified that the extract could not be created and you can restore your unsaved changes by reopening the original workbook in web authoring.

Define your Extract Settings

Extract Data [Close]

Specify how to store data in the extract

Logical Tables Physical Tables

Store data using one table for each logical table. [Learn more](#)
Use this option if you need to use extract filters, aggregation, or other extract settings.

Specify how much data to extract

Filters
0 [Edit](#)

Aggregation
No [Edit](#)

Number of Rows
All rows [Edit](#)

Optionally, configure one or more of the following options to tell Tableau how to store, define filters for, and limit the amount of data in your extract:

- **Decide how the extract data should be stored**

You can choose to have Tableau store the data in your extract using one of two structures (schemas): logical tables (denormalized schema) or physical tables (normalized schema). For more information about logical and physical tables, see [The Tableau Data Model](#).

The option you choose depends on what you need.

- **Logical Tables**

Stores data using one extract table for each logical table in the data source. Physical tables that define a logical table are merged and stored with that logical table. For example, if a data source was made of a single logical table, the data would be stored in a single table. If a data source was made of three logical tables (each containing multiple physical tables), the extract data would be stored in three tables—one for each logical table.

Select **Logical Tables** when you want to limit the amount of data in your extract with additional extract properties like extract filters, aggregation, Top N, or other features that require denormalized data. Also use when your data uses pass-through functions (RAWSQL). This is the default structure Tableau uses to store extract data. If you use this option when your extract contains joins, the joins are applied when the extract is created.

- **Physical Tables**

Stores data using one extract table for each physical table in the data source.

Select **Physical Tables** if your extract is comprised of tables combined with one or more equality joins and meets the conditions for using the Physical Tables option listed below. If you use this option, joins are performed at query time.

Tableau Server on Windows Help

This option can potentially improve performance and help reduce the size of the extract file. For more information about how Tableau recommends you use the Physical Tables option, see [Tips for using the Physical Tables option](#) in the Tableau Desktop help. In some cases, you can also use this option as a work-around for row-level security. For more information about row-level security using Tableau, see [Restrict Access at the Data Row Level](#) in the Tableau Desktop help.

Conditions for using the Physical Tables option

To store your extract using the Physical Tables option, the data in your extract must meet all of the conditions listed below.

- All joins between physical tables are equality (=) joins
- Data types of the columns used for relationships or joins are identical
- No pass-through functions (RAWSQL) used
- No incremental refresh configured
- No extract filters configured
- No Top N or sampling configured

When the extract is stored as physical tables, you cannot append data to it. For logical tables, you can't append data to extracts that have more than one logical table.

Note: Both the Logical Tables and Physical Tables options only affect how the data in your extract is stored. The options do not affect how tables in your extract are displayed on the Data Source page.

- **Determine how much data to extract**

Click **Add** to define one or more filters to limit how much data gets extracted based on fields and their values.

- **Aggregate the data in the extract**

Select **Aggregate data for visible dimensions** to aggregate the measures using their default aggregation. Aggregating the data consolidates rows, can minimize the size of the extract file, and increase performance.

When you choose to aggregate the data, you can also select **Roll up dates** to a specified date level such as Year, Month, etc. The examples below show how the data will be extracted for each aggregation option you can choose.

<p>Original data</p>	<p>Each record is shown as a separate row in your data.</p> <table border="1"> <thead> <tr> <th></th> <th>Date</th> <th>Region</th> <th>Sales</th> </tr> </thead> <tbody> <tr><td>2</td><td>1/1/2009</td><td>South</td><td>\$500</td></tr> <tr><td>3</td><td>1/1/2009</td><td>West</td><td>\$200</td></tr> <tr><td>4</td><td>1/1/2009</td><td>West</td><td>\$100</td></tr> <tr><td>5</td><td>1/1/2009</td><td>East</td><td>\$300</td></tr> <tr><td>6</td><td>1/2/2009</td><td>South</td><td>\$600</td></tr> <tr><td>7</td><td>1/2/2009</td><td>South</td><td>\$400</td></tr> <tr><td>8</td><td>1/2/2009</td><td>East</td><td>\$100</td></tr> <tr><td>9</td><td></td><td></td><td></td></tr> </tbody> </table>		Date	Region	Sales	2	1/1/2009	South	\$500	3	1/1/2009	West	\$200	4	1/1/2009	West	\$100	5	1/1/2009	East	\$300	6	1/2/2009	South	\$600	7	1/2/2009	South	\$400	8	1/2/2009	East	\$100	9				<p>There are seven rows in the extract.</p>

	Date	Region	Sales																																			
1	1/1/2009	East	\$400																																			
3	1/1/2009	South	\$1,500																																			
4	1/1/2009	West	\$300																																			
5																																						

- **Choose the rows to extract**

Tableau Server on Windows Help

Select the number of rows you want to extract.

You can extract **All rows** or the **Top *N* rows**. Tableau first applies any filters and aggregation and then extracts the number of rows from the filtered and aggregated results. The number of rows options depend on the type of data source you are extracting from.

Notes:

- Not all data sources support sampling. Therefore, you might not see the **Sampling** option in the Extract Data dialog box.
- Any fields that you hide first in the Data Source page or on the sheet tab will be excluded from the extract.

Limitations

- You can't create extracts for embedded data sources that reference published data sources. As a workaround, create the extract directly on the published data source. For more information, see [Extract a Published Data Source on Content Server](#).
- You can't create extracts for file-based data sources. File-based data sources already have special performance features and adding extraction will have no performance benefit.
- This feature does not apply to bridge-based data sources in Tableau Online.

Create extracts in Content Server

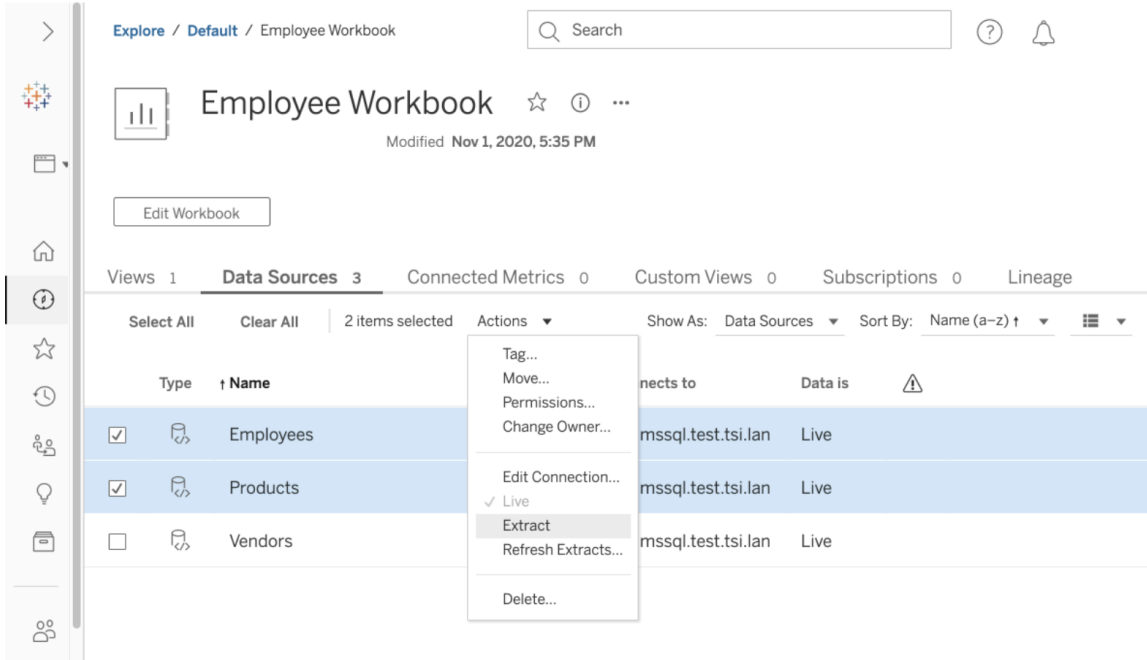

Extract a Published Data Source on Content Server

To extract a published data source:

1. Sign in as an administrator or as the owner of the data source.
2. On the Content tab, select **Explore > Data sources**.
3. Select a data source by clicking on the Data Source name.
4. At the top of the screen, under the Data Source name, select the drop-down menu that says **Live**.
5. Change the connection type from **Live** to **Extract**. If the extract encryption at rest feature is enabled on the site, select either **Encrypted** or **Unencrypted**.
6. If you see an error message about embedded credentials, embed your credentials in the data source. To do this, click **Edit Connection**. Select "Embedded password in connection" and then click **Save**.

Extract an Embedded Data Source on Content Server

To extract one or more data sources that are embedded in a published workbook:

1. Sign in as an administrator or as the owner of the data source.
2. Navigate to the published workbook.
3. Navigate to the Data Sources tab
4. Select one or more of the data sources.
5. Click the **Action** button.
6. Click **Extract**. If the extract encryption at rest feature is enabled on the site, select either **Encrypted** or **Unencrypted**.

Limitations

- Your connection credentials must be embedded in the data source.
- In the web, you can't specify extract settings like incremental refresh and extract filters.
- You can't create extracts for embedded data sources that reference published data sources. As a workaround, create the extract directly on the published data source.

- You can't create extracts for file-based data sources. File-based data sources already have special performance features and adding extraction will have no performance benefit.
- This feature does not apply to bridge-based data sources in Tableau Online.

Keep Extracted Data Fresh

After data is extracted, you can optionally set up an extract refresh schedule to keep the data fresh. For more information, see [Refresh Data on a Schedule](#).

Monitor and Manage Extracts

Server administrators can monitor extract creation on the **Background Tasks for Extracts** admin view. For more information, see [Background Tasks for Extracts](#).

Server administrators can manage extracts on the Jobs page. For more information, see [Managing Background Jobs in Tableau Server](#).

Extract creation jobs, like extract refresh jobs, have a maximum query limit before they timeout. This is to prevent jobs from running forever and using an unbounded amount of server resources. The extract query limit timeout can be configured by server admins using the TSM command line interface configuration setting `backgrounder.querylimit`. For more information, see [tsm configuration set Options](#).

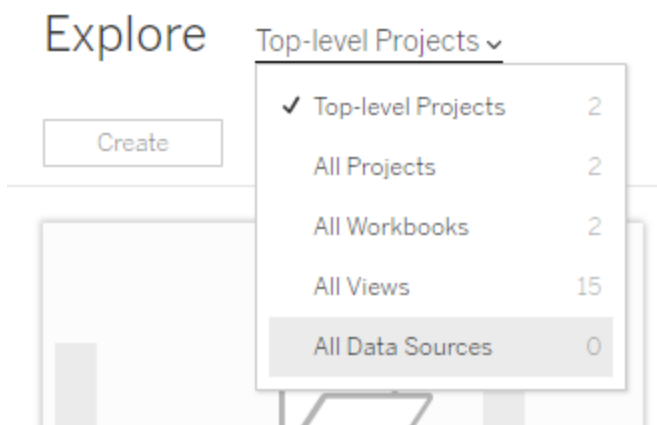

Server administrators can manage web authoring. For more information, see [Set a Site's Web Authoring Access and Functions](#).

View Data Source Attributes

In the **Content** area of the Tableau Server web authoring environment, you can filter the view to show only data sources or connections and their attributes.

View data sources by name

To filter by data source name, under **Explore**, select **Data sources**.

Attributes in the data source name list include the following:

- **Type**—The icon next to the data source name indicates whether the data source is published as a live connection (📄), an extract connection (📄), or is embedded in a workbook (📄).
 - Select the name of a published data source to open its data source page, with tabs for viewing connections and workbooks that connect to it.
 - Select the name of an embedded data source to open the workbook associated with it, as well as tabs for viewing other data it connects to.
- **Connects To**—Indicates the name of the database server or data file. This could be a database outside of Tableau Server, an extract, or a published data source.
- **Live or Last Extract**—This column tells you whether the connection to the data is live, or, if it is a connection to an extract, when the extract was last updated.

View a list of connections

To filter by connection type, in the **View** list, select **Connections**.

Connection attributes include:

- **Connects to**—Indicates the name of the database server or data file. This could be a database outside of Tableau Server, an extract, or a published data source.
- **Connection type**—Shows the type of data. **Tableau Server** indicates that the connection is to a data source published on the site. **Tableau Data Engine** means the data source has an extract stored on the Tableau data server.

Use Certification to Help Users Find Trusted Data

In a self-service environment with multiple publishers, it's common for a project on Tableau Server to contain a variety of content that is named similarly, or is based on the same or similar underlying data, or is published without any descriptive information about it. When this is the case, analysts might lack confidence about the data they should use.

To help your users find the data that's trusted and recommended for their type of analysis, you can *certify* the data that complies with your organization's data standards.

Certification complements the Recommendations Training Schedule feature by offering a way to promote data through curation.

Starting in 2019.3, Tableau Catalog is available in the Data Management Add-on to Tableau Server and Tableau Online. When Tableau Catalog is enabled in your environment, in addition to certifying published data sources, you can also certify the databases and tables that are associated with your workbook, flow, or data source content. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Online](#) Help.

Tableau Server on Windows Help

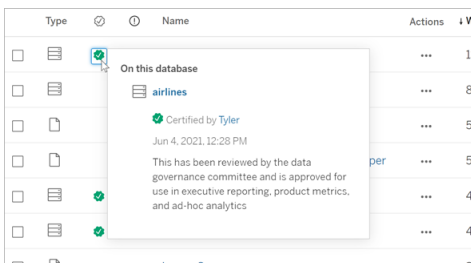

How certification helps users find trusted data

When you certify a data source (or database or table, if you have Tableau Catalog in your environment), users see a green badge or green check mark, depending on where the asset is being viewed.

Certified data sources rank higher in search results and are added to recommended data sources.

In addition, you can provide notes about the certification status, which appear when users click the badge, or in a tooltip when they hover over the data source icon in web authoring or Tableau Desktop. The information also shows who certified the data source.

For more information, see the How to certify data steps below.

Create guidelines for selecting data to certify

As with most Tableau functionality, certification is flexible. You can define for your organization the criteria you use to determine when to certify a data source (or database or table). As you do this, you might want to document and share your guidelines. As new data sources are published, the guidelines can help you and other administrators or project leaders to be consistent with your certification choices. They can also help users understand what certification means.

Whether you use the same certification criteria across all projects, or define unique criteria for each project, the important thing is to be clear about what certification means in your environment.

Who can certify data

To certify a data source, you must

- be an administrator, or
- have a site role of Explorer (Can Publish) or Creator and have the Project Leader capability on the project containing the data you want to certify.

To certify databases or tables, you must have Tableau Catalog enabled in your environment and either of the following permissions levels:

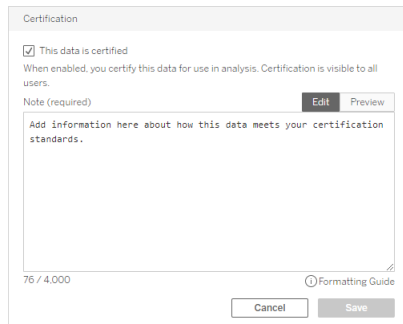

- Site Administrator site role.
- "Manage permissions" capability on a database to certify that database or any tables within that database.

How to certify data

The data you can certify depends on whether you have Tableau Catalog enabled in your environment. All users with the right permissions can certify data sources. Tableau Catalog users with the right permissions can also certify databases, tables, and files.

Tableau Server on Windows Help

1. Sign in to Tableau Server.
2. This step depends on the type of asset you want to certify:
 - Data source - on the **Explore** page, select **Data Sources**.
 - Database or table - on the **External Assets** page, select **Databases and Files** or **Tables**.
3. On the page, select the More actions menu (...) next to the asset name you want to certify.
4. Select **Edit Certification** and then do the following:
 - Select the **This data is certified** check box.
 - Add a note that gives users context for the certification status, intended use for the data, or other helpful information, and then click **Save**.

Information you add to the **Note** section appears in the certification badge or tooltip, mentioned earlier in How certification helps users find trusted data.

Keep Data Fresh

You can manually refresh data, as well as schedule data refreshes.

Manage Refresh Tasks

Administrators can change the priority of scheduled extract refreshes relative to other server tasks, manually refresh extracts, or delete their schedules.

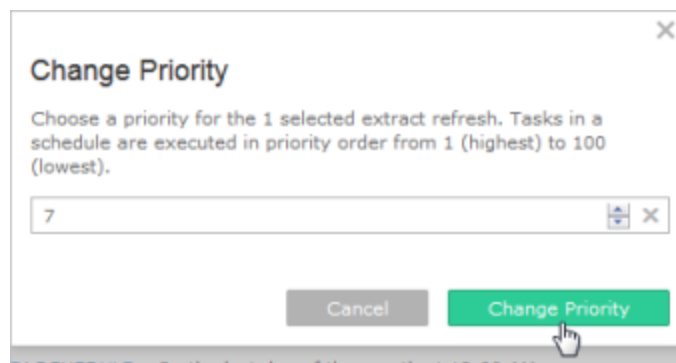

1. Sign in to the site that has the schedules you want to manage, and then click **Tasks**.
2. Select one or more scheduled extract refreshes.

3. From the **Actions** menu, do any of the following:

- Select **Change Schedule**, and choose a new schedule from the list.
- Select **Run Now** to refresh manually.

Note: If an extract does not have a scheduled refresh, you can refresh it on demand from the Data Connections page.

- Select **Change Priority**, and enter a number between 1 and 100 to move the extract up or down in the priority list.

- Select **Delete** to completely remove the schedule for the selected data sources.

Enable Extract Refresh Scheduling and Failure Notification

Refresh Data on a Schedule

You can schedule refresh tasks for published extract data sources and published workbooks that connect to extracts. New schedules can be created by Tableau Server Administrators on the **Schedules** page. For more information, see [Create or Modify a Schedule](#).

Note: When a refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a .tde extract), the extract is upgraded to a .hyper extract automatically. While there are many benefits of upgrading to a .hyper extract, your users won't be able to open the extract with earlier versions of Tableau Desktop. For more information, see [Extract Upgrade to .hyper Format](#).

For information on how to refresh flow outputs, see [Schedule a Flow Task](#).

1. When you're signed in to Tableau Server, select **Explore** from the left navigation pane, and then, depending on the type of content you want to refresh, select **All Workbooks** or **All Data Sources** from the drop-down menu.
2. Select the check box for the workbook or data source you want to refresh, and then select **Actions > Refresh Extracts**.
3. In the Refresh Extracts dialog, select **Schedule a Refresh**, and complete the following steps:
 - Select the schedule you want.
 - If available, specify whether you want a full or incremental refresh.

A full refresh is performed by default. Incremental refresh is available only if you configured for it in Tableau Desktop before publishing the extract. For more information, see [Refreshing Extracts](#) in the Tableau Help.

- Click **Schedule Refresh**.

Refresh Extracts

Cancel Schedule Refresh

Quick Start: Refresh Extracts on a Schedule

For published workbooks that connect to data extracts, you can set up the server to refresh the extracts on a recurring schedule, so all workbooks connected to them always show the most up-to-date data.

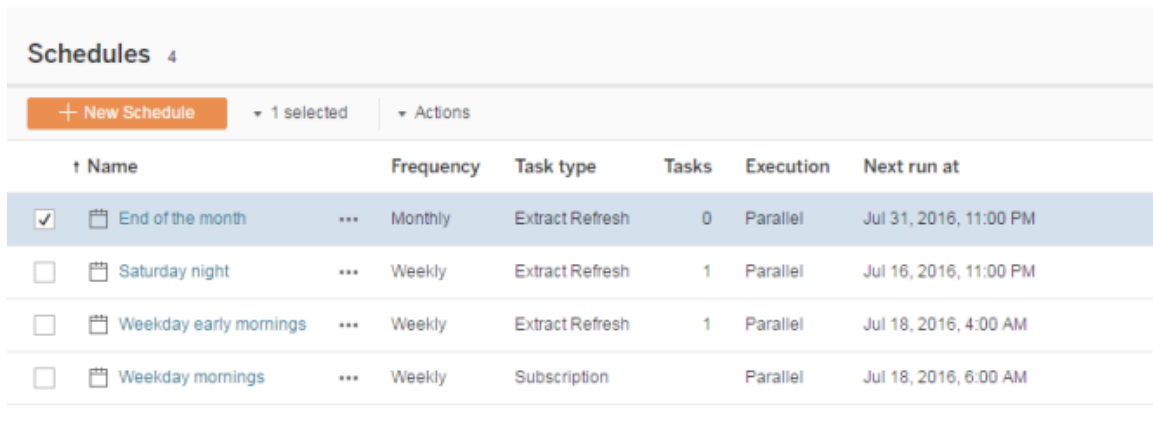

To schedule refreshes you need to have administrator or data owner permissions.

Note: This topic applies to extracts published to Tableau Server. For Tableau Online, how you refresh extracts depends on the underlying data they connect to. For more information, see [Keep Data Fresh](#).

1 Set up a schedule on the server

Sign in to the server, go to the **Schedules** page, and click **New Schedule**.

Tableau Server on Windows Help

Schedules 4						
+ New Schedule		▼ 1 selected		▼ Actions		
† Name	Frequency	Task type	Tasks	Execution	Next run at	
<input checked="" type="checkbox"/> End of the month	Monthly	Extract Refresh	0	Parallel	Jul 31, 2016, 11:00 PM	
<input type="checkbox"/> Saturday night	Weekly	Extract Refresh	1	Parallel	Jul 16, 2016, 11:00 PM	
<input type="checkbox"/> Weekday early mornings	Weekly	Extract Refresh	1	Parallel	Jul 18, 2016, 4:00 AM	
<input type="checkbox"/> Weekday mornings	Weekly	Subscription		Parallel	Jul 18, 2016, 6:00 AM	

Tableau provides a few refresh schedules. You create additional schedules you need.

2 Enable scheduled extract refreshes and failure emails

As a server or site administrator, you can enable schedules, as well as email notification when extract refreshes fail.

Select **Settings**, and then go to the **General** page.

- Under Email Notification, select **Send email to data source and workbook owners when scheduled refreshes fail**.
- Under **Embedded Credentials**, select both check boxes to allow publishers to

embed credentials and schedule extract refreshes.

3 Publish a workbook with an extract

In Tableau Desktop, select **Server > Publish Workbook**. Sign in to the server if you're not already. In the **Publish Workbook to Tableau Server** dialog box, click **Schedules & Authentication**. Under **Extract Schedule**, select the schedule from the list.

Tableau Server on Windows Help

If the original data requires authentication, you will also need to select how you want people to access it.

4 Monitor refresh performance

You can monitor scheduled tasks by viewing **Background Tasks for Extracts** on the **Status** page.

Server Status	
Traffic to Views	Usage and users for published views.
Traffic to Data Sources	Usage and users for published data sources.
Actions by All Users	Actions for all users.
Actions by Specific User	Actions for a specific user, including items used.
Actions by Recent Users	Recent actions by users, including last action time and idle time.
Background Tasks for Extracts	Completed and pending extract task details.

Automate Refresh Tasks

You can associate extract refresh tasks with schedules in Tableau Server to automate refreshing extracts. You can also automate extract refreshes using `tabcmd`, a command line utility that you can download for use with Tableau Server. In particular, you can use the `refreshextracts` command in combination with other commands in your own script.

For example:

```
tabcmd login - http://mytabserver -u jsmith -p P@ssw0rd!  
refreshextracts --datasource salesq4
```

Note: When an extract refresh is performed on extracts created in Tableau 10.4 and earlier (that is, a `.tde` extract), the extract is upgraded to `.hyper` extract automatically. While there are many benefits of upgrading to a `.hyper` extract, your users won't be able open the extract with earlier versions of Tableau Desktop. For more information, see [Extract Upgrade to .hyper Format](#).

For information about downloading the `tabcmd` utility, see [tabcmd](#).

Handle Extract Refresh Alerts

When Tableau Server cannot complete a scheduled refresh, an alert appears to indicate that the refresh has failed. If a scheduled refresh fails five consecutive times, Tableau Server suspends the refresh. When a refresh is suspended, Tableau Server does not try to run it again until someone takes an action that attempts to correct the cause of the failure.

Note: The number of consecutive failures for a refresh is set to five by default, but can be changed by a Tableau Server administrator, using the `back-grounder.failure_threshold_for_run_prevention` option. For more information, see [tsm configuration set Options](#).

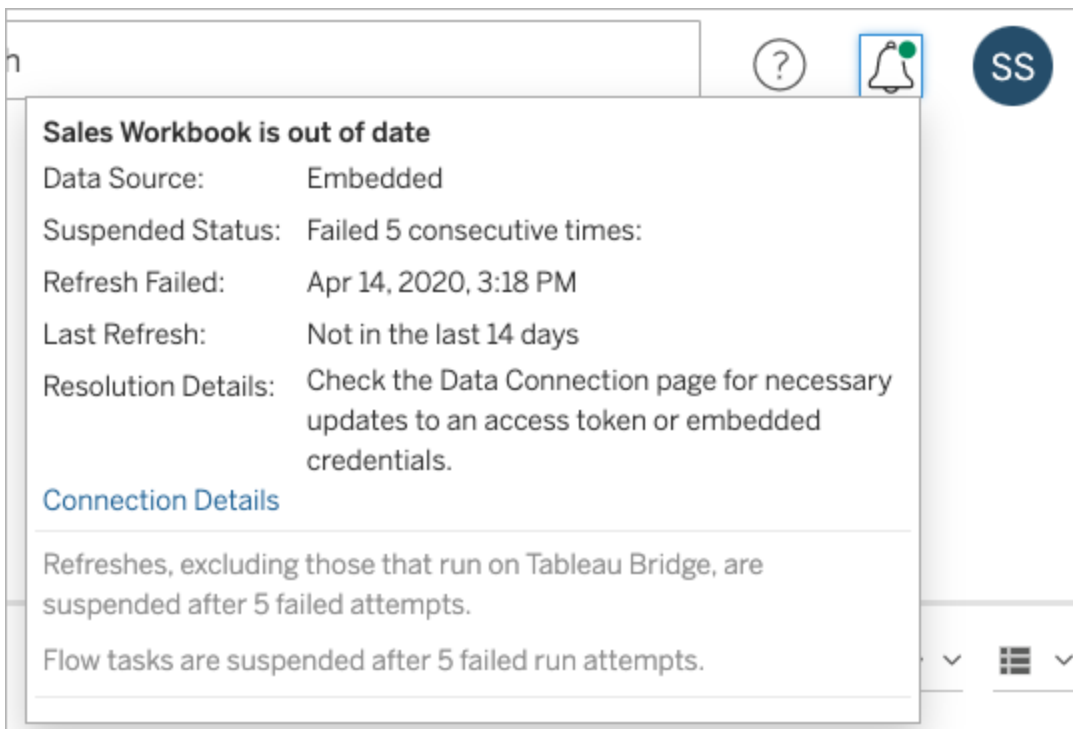

Tableau Server on Windows Help

You will see the Alerts menu only if an extract refresh failed and you are:

- A system or site administrator
- The author of the workbook or data source that couldn't be refreshed
- The author of a workbook that connects to a data source that couldn't be refreshed

When you open the Alerts menu you can see more information about the refresh failure(s):

When a **Data source** is listed as **Embedded** it means that the data source definition (which includes things like the data source credentials or the database name) is embedded, or resides, within the workbook itself, originally created in Tableau Desktop.

When a data source name or workbook name is listed as the **Data source** (for example, **Data source: sales_data**), it means that the data source is a Tableau Server data source. The data source definition resides on Tableau Server.

In the Data pane on Tableau Desktop, you can determine whether the data source is on Tableau Server or is local. If the data source is on the server, a Tableau icon is displayed next to the data source name instead of a database icon :

Resolving Extract Refresh Problems

To resolve refresh issues, you can take any of these actions, based on the cause indicated in the alert:

- **Errors related to access token validation or user credentials**

You can resolve some extract refresh problems by clicking the **Connection Details** in the alert. Select the check box next to the problematic data source, click **Actions > Edit Connection**, and then enter the missing information. Click **Save** when you're done. After you update the connection information, Tableau Server restarts the refresh schedule.

If you originally embedded the credentials or other data connection information when you published the workbook or data source from Tableau Desktop, you can also republish the workbook or data source. As part of the publishing process, you can choose to set a new refresh schedule. If you don't choose a new schedule, Tableau Server restarts the existing schedule.

- **Errors that indicate the database was unreachable**

Tableau Server on Windows Help

Confirm that the database is online and that you can sign in to access the data. You can use the **Try again** link in the alert to restart the refresh schedule.

- **Errors when using user filters or impersonation**

See the [Tableau Knowledge Base](#).

If the problem cannot be corrected by editing the data connection, you will need to resolve it in Tableau Desktop and republish the workbook.

Tip: Administrators can edit data connections at any time on the **Data Connections** page, accessible from each site by clicking the **Content** tab and Data Connections

Automatically Suspend Extract Refreshes for Inactive Workbooks

To save resources, Tableau can automatically suspend extract refresh tasks for inactive workbooks. This feature applies to full extract refreshes only, not to incremental extract refreshes. This feature only applies to refresh tasks that run more frequently than weekly, not to weekly or less frequent refresh tasks. This feature only applies to extracts that are embedded in workbooks and not to published data sources.

If any of these events occur, the workbook inactivity countdown timer is reset.

- Viewing the workbook sheets
- Setting up a data-driven alert or subscription on the workbook
- Downloading the workbook
- Moving the workbook's location or changing the owner

Configure the feature

1. Sign in to Tableau Server as a server administrator.
2. Go to the General tab of the Settings page for the site:
 - If you have a single site, at the top the browser window, click **Settings** and **General**.

- If you have multiple sites, select the site you want to configure and click **Settings** and **General**.
3. On the **General** page, do the following:
- Under **Automatically Suspend Extract Refresh Tasks**, select the **Automatically suspend extract refresh tasks for inactive workbooks** check box.
 - Specify the number of days, from 7 through 100, that a workbook should be inactive before extract refresh tasks are suspended. The default is 32 days.
 - Click **Save**.

Note: This feature is only configurable on Tableau Server. It is not configurable on Tableau Online.

Notifications

An email notification is sent three days before the extract refresh schedule is suspended.

Another email notification is sent when the extract refresh schedule is suspended.

Resume suspended extract refreshes

Suspended extract refreshes won't resume automatically if someone uses the workbook. It must be done manually.

To view and resume extract refreshes that were suspended:

1. Sign into the site and click **Tasks**.
2. Click the **Extract Refreshes** tab.
3. Select one or more items.
4. From the **Actions** menu, select **Resume**.

Edit Connections on Tableau Server

Administrators and data source owners can manage the information that describes how a published data source connects to the underlying data. This information includes the data-

Tableau Server on Windows Help

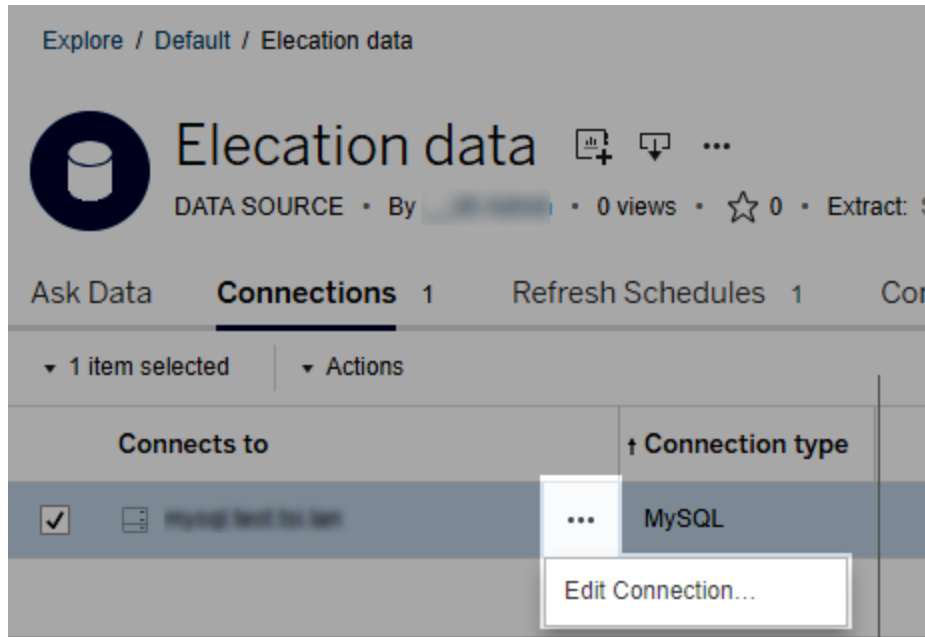

base server name or address, the server port, the database user name, and whether or not the password is embedded in the connection.

Note: Ability to edit connections is determined primarily by your site role, rather than by your permissions on the data source. To edit connections, your site role must be **Server Administrator**, **Site Administrator**, or **Creator**. If your site role is **Creator**, you also must be the data source owner.

1. Sign in to the site that has the data sources you want to modify, and on the **Content** tab, select **Explore > Data sources**.
2. Select the name of the data source with the connection you want to update.

Display filters to search for the data source or narrow the scope of the data source list. The values you type into the **Server name** and **Database username** fields are treated as regular expressions.

3. In the **Connections** view, select the **Actions (...)** menu for the data source, and then select **Edit Connection**.

To edit multiple data sources, select the data sources you want to edit, then click the **Actions** menu and **Edit Connection**.

4. Update the connection information.

For **Server name**, if you want to use an IP address, make sure the database or its driver supports that type of connection. If it doesn't, enter the database server name.

See also Authentication types for Google, Salesforce, and WDC data later in this topic.

5. Click **Save**.
6. Refresh the browser page for your changes to take effect.

Authentication types for Google, Salesforce, and WDC data

Google BigQuery, Google Analytics, Salesforce.com, and many web data connector (WDC) connections use the OAuth authentication standard, which uses secure access tokens instead of “raw” user name and password credentials. With OAuth, database credentials do not need to be stored in Tableau, and all users connect through this access token, including Tableau Desktop users who want to create or edit workbooks that connect to the data source.

The following sections describe Google and Salesforce connection options. Web data connector options vary, but all involve signing in through the provider’s web-based sign-in form to establish the access token.

Google authentication options

When you edit Google BigQuery or Google Analytics connections, select either of the following options in the **Edit Connection** dialog box:

- Select **Embed Google BigQuery (or Google Analytics) credentials in the connection** to authenticate through a designated account, and then select an existing account from the list or select **authenticate account now...** to add a new one.

When you add a new account, the Google sign-in page appears. After you provide your database credentials, Google prompts you to confirm Tableau access to the data. When you click **Accept**, Google returns an access token to use for connecting to the data.

Note: If you create extracts of your Google data source, select this first option, so that you can schedule refresh tasks.

- Select **Prompt user for Google BigQuery/Analytics credentials** to require users to connect through their own individual access tokens or sign in each time they connect.

Salesforce.com authentication options

Note: This applies only if Tableau Server is configured to use saved credentials for Salesforce with OAuth. If the server is not configured for this, use the standard process above for modifying connections. For more information about configuring Tableau Server to use saved credentials with OAuth, see [Change Salesforce.com OAuth to Saved Credentials](#).

When you edit Salesforce.com connections, you can select any of the following options in the Edit Connection dialog box:

Tableau Server on Windows Help

- Select **Embedded Salesforce username and password in the connection** to use a traditional authentication method.
- Select **Embedded Salesforce credentials in the connection** to use an OAuth connection and schedule refresh tasks, and then select an existing account from the list or click **Add a Salesforce Account** to add a new one.

When you add a new account, the Salesforce.com sign-in page appears. After you provide your database credentials, Salesforce.com prompts you to confirm Tableau access to the data. When you allow Tableau access, Salesforce.com creates an access token through which it connects to the data.

Edit Connection

Edit the selected data connection.

Authentication

Embedded Salesforce username and password in the connection

Username

Password

Embedded Salesforce credentials in the connection

No Salesforce authentication

Use this option if you do not need to schedule data extract refreshes

- Select **No Salesforce authentication** to require users to sign in to Salesforce.com each time they connect. (This option does not allow scheduled extract refreshes.)

Monitor progress

When you save your changes in the **Edit Connection** dialog box, the dialog displays the progress. If you close the dialog box, the modifications continue to run in the background until completed. Tableau Server will make as many changes as possible. Any failures will be skipped, but they will not impede other changes. For example, if you try to change the server name and add a password to several connections, the server names will be

changed, and the passwords on workbooks will be changed. However, because you cannot add a password to a data source, the passwords for the data sources will not be changed.

For information about checking the progress of these tasks, see [Background Tasks for Extracts](#).

Cube Data Sources

Cube (multidimensional) data sources have certain characteristics that make them unique in Tableau.

Cube data sources do not support pass-through connections. This means that when a cube data source is published, you cannot make a connection from Tableau Server using the data source. It also means you cannot create a workbook using the data source in Tableau Server.

Publishing a cube data source to Tableau Server gives you the ability to store the data source on the server. However, to use the data source, you must download the data source to Tableau Desktop and use it locally. To download a published data source you need:

- The **Download/Save As** permission for the data source. For more information, see [Permissions](#).
- Correct drivers installed and ports opened on computer running Tableau Desktop.

For information about using cube data sources with Tableau Desktop, see [Cube Data Sources](#).

Web Data Connectors in Tableau Server

Web data connectors (WDCs) are web pages that provide a data connection that is accessible over HTTP for data sources that don't already have a connector in Tableau. WDCs allow users to connect to almost any data that is accessible over the web and to create extracts for their workbooks. Data sources for a WDC can include internal web services, JSON data, REST APIs, and other sources that are available over HTTP or HTTPS. Users can create

their own WDC or use connectors that were created by others.

For information about how to use a WDC in Tableau Desktop, see [Web Data Connector](#) in the Tableau Desktop documentation.

For information about how to create a WDC, see the [Web Data Connector documentation](#) on Github.

Before you run connectors on Tableau Server

As a security measure, Tableau Server won't run WDCs unless you approve the connector, as explained in this topic.

Note: You must be a server administrator to approve WDCs for use on Tableau Server.

WDCs require your approval because they contain executable code and typically make requests to third-party websites. Before a user can use a WDC with Tableau Server, you must add the domain and port used by the connector to a safe list and also include the domains that a connector can send requests to and receive requests from on a secondary safe list. Before you do this, we recommend that you vet and test the connector so that you know what the connector does and what sites it connects to. For more information, see [Testing and Vetting Web Data Connectors](#).

When you add a connector to the safe lists, you configure Tableau Server to allow connections to a particular URL where the connector is hosted and from a URL which the connector can query. This is the only way to allow Tableau Server to run WDCs. The connectors can then be hosted on a server inside your organization's firewall or on an external domain. Importing WDCs is not supported for Tableau Server.

Manage connectors in a safe list

To add a WDC to the safe list, use the `tsm data-access web-data-connectors add` command. This command and the related commands described below let you perform the following tasks:

- Add WDCs to the safe list and secondary safe list.
- Allow or disallow all WDCs, or WDC refreshes.
- Remove one or more connectors from the safe list.
- List all WDCs on the safe list and secondary safe list.

Updating WDC safe lists requires a server restart

After running any commands that make changes to WDCs, you need to apply your pending changes using the `tsm pending-changes apply` command.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Add connectors to the safe list and secondary safe list

To add a connector to the safe list and secondary safe list, use the `tsm data-access web-data-connectors add` command, providing the name, safe list URL, and secondary safe list URLs. You can also manage WDCs using the `web-data-connector-settings` Entity. After running this command, you need to apply your pending changes using the `tsm pending-changes apply` command. A prompt warns you that the command will restart Tableau Server. If Tableau Server is currently running it is restarted, and if it is stopped it is left in a stopped state with no restart.

```

tsm data-access web-data-connectors add --name "USGS Earth-
quakes" --url https://tableau-
ableau-
.git-
hub.io:443/webdataconnector/Examples/html/earthquakeUSGS.html -

quake.usgs.gov-
/.*,https://max-
cdn-
boot-
strap-
cdn-
com/.*,https://ajax.googleapis.com/.*,https://connectors.tableau.com/.*

```

Notes on formatting:

- Be sure to use straight quotes (" and '), not curly or "smart" quotes, around the name of the WDC. Use double quotes (") if the name contains a space.
- For many WDCs, the port specified for the `--url` option is 443 or 80, but you can check the value for your connector by looking at the data source details on Tableau Server. You must specify the port number as part of the URL if the WDC is using SSL (HTTPS). For example, to use the default port for HTTPS, the URL might look like the following: `https://example.com:443/WDC/`.
- If a WDCs send requests to and receive data from multiple domains, use a comma-delimited list of URL for the `--secondary` option. Note that if you do not add a secondary list, all requests are allowed. For increased security, be sure to include a

Tableau Server on Windows Help

secondary list that specifies the domains that provide the libraries and sources the WDC needs access to.

- To add an entire domain to the secondary safe list, end the domain URL with a wildcard expression. Use `.*` as the wildcard to indicate the entire domain, as in the following example: `https://example.com/.*`.

Allow or disallow WDCs or WDC extract refreshes

To allow or disallow WDCs, or WDC extract refreshes, use the `tsm data-access web-data-connectors allow` command with the `-t` or `-r` options. By default, WDCs and WDC extract refreshes are allowed. If you change this setting, you need to run the `tsm pending-changes apply` command. For more information about the command and the command options, see [tsm data-access web-data-connectors allow](#).

Remove one or more WDCs from the safe list

To remove one or more WDCs from the safe list, use the `tsm data-access web-data-connectors delete` command. If you change this setting, you need to run the `tsm pending-changes apply` command. For more information, see [tsm data-access web-data-connectors delete](#).

List all WDCs on the safe list

To list all WDCs on the safe list, use the `tsm data-access web-data-connectors list` command. For more information, see: [tsm data-access web-data-connectors list](#).

Refresh the extract for a connector

When a user creates a workbook that uses a WDC, Tableau Server creates an extract from the data returned by the connector. If the user then publishes the workbook, the publish process sends the workbook and the data extract to the server.

Tableau can refresh an extract that was created by a WDC, the same as it can refresh any extract. If the connector requires credentials to sign in to the web-based data source, you need to ensure that the credentials are embedded with the data source, and that the WDC is

on the safe list for the server. Tableau Server cannot refresh the extract if the connector requires credentials and they are not embedded with the data source. This is because the refresh can occur on a schedule or in some other background context, and the server cannot prompt for credentials.

Currently, there is no way to re-authenticate a data source from Tableau Server directly. If the data source has credentials that expire, or was published without embedding the credentials, the workbook and data extract need to be published again with the new embedded credentials.

If the background process that performs the refresh operation fails, it creates an alert and a log entry that indicates this issue. Users will be able to see that the timestamp on the extract does not change.

To disable refresh for all WDCs, use the `tsm data-access web-data-connectors allow -r false` command.

Troubleshooting

If the server experiences problems with adding connectors to the safe list, you can examine the log files. Be sure to check the log files on both the initial server node and on the other nodes that are running the gateway process. For more information about log files, Tableau Server Logs and Log File Locations.

If the issue is that Tableau Server will not refresh an extract that was created by a WDC, make sure that the `webdataconnector.refresh.enabled` configuration setting has been set to `true`. If it is set to `false`, run the following command to allow extract refreshes for all WDCs on the server:

```
tsm data-access web-data-connectors allow -r true
```

Note: The safe list is the only way of allowing Tableau Server to run web data connectors. Importing web data connectors was deprecated starting with version 10.5.

Testing and Vetting Web Data Connectors

Web Data Connectors (WDCs) contain JavaScript that typically connects to data on another site. Because of this, you should test and vet web data connectors before users use them as data sources for a workbook, and before you use them with Tableau Server.

This topic includes some suggestions for testing and vetting web data connectors.

Examine the source

The code in a web data connector is in JavaScript, so you can open the file (and any external files that the connector uses) and examine the source code.

Many connectors reference external JavaScript libraries, such as the jQuery library or API libraries for third parties. Validate that the URL for external libraries points to a trusted location for the library. For example, if the connector references the jQuery library, make sure that the library is on a site that is considered standard and safe. If it is practical for you to change the source code of the connector, use HTTPS protocol (`https://`) to reference external libraries (if the source site supports HTTPS) to help verify the site's authenticity.

To the extent possible, make sure you understand what the code is doing. In particular, try to understand how the code is constructing requests to external sites, and what information is being sent in the request.

Note: Experienced JavaScript programmers often compress (minify) their code to reduce the size of the code for download. Dense blocks of code that use cryptic function and variable names are not uncommon. While this can make it more difficult to examine the code, it is not a sign that the code was written to be deliberately difficult to understand.

Test the web data connector in an isolated environment

If possible, test the web data connector in an environment that is isolated from your production environment and from user computers. For example, add a web data connector to a

safe list on a test computer or virtual machine that's running a version of Tableau Server that is not used for production.

Monitor the traffic created by the web data connector

When you test a web data connector, use a tool like [Fiddler](#), [Charles HTTP proxy](#), or [Wireshark](#) to examine the requests and responses that the connector makes. Make sure that you understand what sites the connector makes requests to and what content the connector is requesting. Similarly, examine the responses and their content to be sure that the connector is not reading data or code that is not directly related to the connector's purpose.

Test the performance and resource usage of the web data connector

When you test a web data connector, use tools to monitor its CPU and memory usage. Remember that the web data connector will run on Tableau Server, which is an environment in which many processes are already running. You want to make sure that when the connector fetches data, the connector does not have an undue impact on server performance.

Check whether the connector writes to disk. If it does, check how much disk space it occupies, and examine the output to make sure you understand what it's writing and why.

Enable Tableau Catalog

[Tableau Catalog](#) discovers and indexes all of the content on your Tableau Online site or Tableau Server, including workbooks, data sources, sheets, metrics, and flows. Indexing is used to gather information about the content, or metadata, about the schema and lineage of the content. Then from the metadata, Catalog identifies all of the databases, files, and tables used by the content on your Tableau Online site or Tableau Server.

Catalog is available with the Data Management. For more information, see [About Data Management Add-on](#).

In addition to Catalog, metadata about your content can also be accessed from both the [Tableau Metadata API](#) and the Tableau REST API using [Metadata Methods](#).

Before enabling Catalog

As a Tableau Server admin, there are a few things that you need to consider before and while enabling Catalog to ensure optimal performance of Catalog in your Tableau Server environment.

Required versions

Before enabling Catalog, make sure you're running *one* of the following versions of Tableau Server:

- At least Tableau Server 2019.3.4 or later
- At least Tableau Server 2019.4.2 or later
- At least Tableau Server 2020.1.0 or later
- At least Tableau Server 2020.2.15 or later
- Tableau Server 2020.3 and later

For more information about why these versions are required, see the [Tableau Knowledge Base](#).

What to expect when enabling Catalog

When Catalog is enabled, the content that already exists on your Tableau Server is immediately indexed.

Initial ingestion

The indexing process is comprised of two primary components, one of which is called initial ingestion. Initial ingestion can be broken down into two additional components:

- Content backfill
- Lineage backfill

The status of content backfill and lineage backfill are important to note later on when monitoring progress and validating that Catalog has been successfully turned on and is running in your Tableau Server environment.

Initial ingestion speed

The time it takes Catalog to index the content for the first time depends on a couple of factors:

- **Amount of content on Tableau Server:** The amount of content is measured by the total number of workbooks, metrics, published data sources, and flows published to Tableau Server. For more information, see [Disk space to store metadata](#).
- **Number of non-interactive microservices containers:** Catalog uses the non-interactive microservices container to index all the content on Tableau Server. For more information, see [Memory for non-interactive microservices containers](#).

Understanding the factors that impact initial ingestion can help you gauge how long it might take to enable and run Catalog in your environment.

Disk space to store metadata

During initial ingestion, metadata is generated and stored in the Tableau Server repository ("relationship" PostgreSQL database). The amount of disk space needed to store the metadata is roughly up to half of the disk space currently used by the repository ("work-group" PostgreSQL database).

For example, suppose the repository uses 50 GB of disk space prior to enabling Catalog, the repository can use up to 75 GB of disk space after enabling Catalog.

Memory for non-interactive microservices containers

Initial ingestion runs inside of the non-interactive microservices container. The non-interactive microservices container is one of two [Tableau Server microservices containers](#) processes. By default, one instance of the non-interactive microservices container is added to every node that has a background process installed.

By default, initial ingestion on a single instance of the non-interactive microservices container can use up to 4 GB of memory on the background node. If the amount of content on Tableau Server exceeds 10,000, a non-interactive microservices container may require up

Tableau Server on Windows Help

to 16 GB of memory on the backgrounder node. Therefore, when enabling Catalog, ensure that every backgrounder node has the available capacity to support each non-interactive microservices container during the initial ingestion process. If capacity needs to be increased, you must update the JVM heap size for non-interactive containers to allocate up to 16 GB of memory on the backgrounder nodes. For more information, see `non-interactivecontainer.vmopts`.

If you are planning to add more non-interactive microservices containers to decrease the time of initial ingestion, first determine how many total containers are needed (using [Step 2: Estimate how long initial ingestion will take](#), below) and then verify if your Tableau Server environment is configured with enough capacity to support *all* non-interactive microservices containers. Depending on how your Tableau Server environment is already configured, you might not be able to add all the additional non-microservices containers that you need to decrease initial ingestion time.

Best practices for enabling Catalog

Because the speed of initial ingestion and requirements are unique to each Tableau Server environment, Tableau recommends that when you enable Catalog you do one or more of the following:

- Make sure there is enough disk space that the Tableau Server repository can use to support the additional metadata that initial ingestion will generate and store. As a general rule, the repository will need an additional 50% of disk space currently used by the repository. For more information about Tableau Server disk usage, see [Server Disk Space](#).
- Depending on the amount of content on Tableau Server, make sure each backgrounder node has at least 4-16 GB of available memory for each instance of a non-interactive microservices container during initial ingestion.
- Perform the process over the weekend to allow initial ingestion to complete before your users start using Catalog capabilities.

- Perform the process in a test environment with production content first. This is because the type of content that needs to be ingested can play a significant role on ingestion speed.

Summary of steps to enable Catalog

The following steps summarize the process to turn on and run Catalog on Tableau Server. The steps must be performed sequentially.

1. Determine the amount of content on Tableau Server
2. Estimate how long initial ingestion will take
3. Decrease the time of initial ingestion
4. Activate the Data Management Add-on
5. Turn off Catalog capabilities
6. Run the `tsm maintenance metadata-services` command
7. Monitor initial ingestion progress and validate its status
8. Configure SMTP
9. Turn on Catalog capabilities

Note: Because indexing metadata about Tableau content on Tableau Server is powered by the Metadata API, enabling the Metadata API is required to run and use Catalog.

Enable Catalog

Step 1: Determine the amount of content on Tableau Server

To determine the amount of content on Tableau Server, do the following:

1. Sign in to Tableau Server using your admin credentials.
2. Go to the **Explore** page.
3. Click the Top-Level Project drop-down menu and add the numbers next to **All Workbooks**, **All Metrics**, **All Data Sources**, and **All Flows** together. This is the total amount of content on Tableau Server.

Tableau Server on Windows Help

Step 2: Estimate how long initial ingestion will take

To estimate the time it will take Catalog to ingest content on Tableau Server for the first time (initial ingestion), compare *your* Tableau Server setup to a *baseline* Tableau Server setup.

For a Tableau Server with the following setup, initial ingestion could take about 6 hours to complete.

Components	Baseline values
Content	17,000 workbooks, metrics, published data sources, and flows
Non-interactive microservices containers	10
Ingestion	~6 hours

If you have roughly *half* the content in your Tableau Server environment, initial ingestion might take half the time to complete.

For example: 8,500 (workbooks, metrics, published data sources, and flows) + 10 non-interactive microservices containers = ~3 hours (initial ingestion)

If you have roughly *double* the content in your Tableau Server environment, initial ingestion might take double the time to complete.

For example: 34,000 (workbooks, metrics, published data sources, and flows) + 10 non-interactive microservices containers = ~12 hours (initial ingestion)

Step 3: Decrease the time of initial ingestion

As a general rule, the time it takes for Catalog to perform initial ingestion is correlated to the number of non-interactive microservices containers. To help decrease the time of initial ingestion, you can increase the number of non-interactive microservices containers.

Increase the number of non-interactive microservices containers

By default, one non-interactive microservices container is added to every node that has a backgrounder. To help decrease the time of initial ingestion, Tableau recommends that you increase the number of non-interactive microservices container using the `tsm topology set-process` command.

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the command: `tsm topology set-process --count <process_count> --node <node_ID> --process <process_name>`

For example, to increase the non-interactive microservices container on the initial node to 4 containers, run the following command:

```
tsm topology set-process --count 4 --node node1 --process noninteractive
```

For more information about running the command and its global options, see [tsm topology](#).

Important: Before increasing the number of non-interactive microservices containers, review the following:

- The recommendation for increasing non-interactive microservices containers is for total number of non-interactive microservices containers, not total non-interactive microservices containers per node. For example, suppose you have 4 nodes but you want to increase the number of non-interactive containers to 8. The `--count` value you use in the `tsm` command is 2.
- For each non-interactive microservices container added, 4 GB of additional memory will be used on the node and load will be added to the Tableau Server repository (PostgreSQL database).

Tableau Server on Windows Help

- Tableau recommends that you incrementally increase non-interactive microservices containers by no more than 2 at a time while closely monitoring your Tableau Server environment to avoid issues with CPU utilization of the Tableau Server repository (PostgreSQL database).
- Be aware that when too many non-interactive microservices are added, CPU utilization of the PostgreSQL database might spike and failover. Symptoms to watch for include SQLException errors in the vizportal logs. For more information, see [Repository Failover](#) topic.

Step 4: Activate the Data Management

(Requires the Data Management)

If not already done, you can activate the Data Management. For more information, see [License the Data Management Add-on](#).

Step 5 (optional): Turn off Catalog capabilities for each site

(Requires the Data Management)

As part of the Data Management activation, Catalog capabilities are turned on by default. Because of the indexing process and the estimated time it takes to complete, consider temporarily turning off Catalog capabilities for each site so that Tableau Server users can't access Catalog capabilities until Catalog is ready and able to provide complete and accurate results.

1. Sign in to Tableau Server using your admin credentials.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Tableau Catalog, clear the **Turn on Tableau Catalog** check box.
4. Repeat steps 2-3 for each site on your Tableau Server.

Step 6: Run the `tsm maintenance metadata-services` command

Run the `tsm maintenance metadata-services` command to enable the Tableau Metadata API. Running the command begins initial ingestion. If your Tableau Server is licensed with the Data Management Add-on, running the command also turns on Catalog capabilities (if it wasn't turned off earlier).

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the command: `tsm maintenance metadata-services enable`

For more information about running the `tsm` command, see [tsm maintenance](#).

Notes: When running this command, keep the following points in mind:

- This command stops and starts some services used by Tableau Server, which causes certain functionality, such as the Recommendations capability, to be temporarily unavailable.
- A new index of metadata is created at this time. Running this command any subsequent times will create and replace the previous index.

Step 7: Monitor initial ingestion progress and validate its status

Running the `tsm` command above starts the initial ingestion process. To ensure that the initial ingestion process is going smoothly, you can monitor its progress using the Backfill API. For more information, see [Get Initial Ingestion Status](#).

Step 8: Configure SMTP Setup

If not already set up for Tableau Server, configure SMTP Setup. SMTP supports sending email to owners who need to be contacted about changes to data. For more information about configuring SMTP, see [Configure SMTP Setup](#).

Step 9 (optional): Turn on Catalog capabilities for each site

(Requires the Data Management)

Tableau Server on Windows Help

If you turned off Catalog capabilities before enabling Catalog in one of the procedures above, you must turn on Catalog to make its capabilities accessible to your users.

1. Sign in to Tableau Server using your admin credentials.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Tableau Catalog, select the **Turn on Tableau Catalog** check box.
4. Repeat steps 2-3 for each site on your Tableau Server.

Troubleshoot Catalog

You or your users might encounter one of the following issues when using Catalog.

Timeout limit and node limit exceeded messages

To ensure that Catalog tasks that have to return a large number of results don't take up all Tableau Server system resources, Catalog implements both timeout and node limits.

- **Timeout limit**

When tasks in Catalog reach the timeout limit, you and your users see the following message:

"Showing partial results, Request time limit exceeded. Try again later." or TIME_LIMIT_EXCEEDED

To resolve this issue, as a Tableau Server admin, you can increase the timeout limit using the `tsm configuration set -k metadata.query.limits.time` command. For more information, see the [tsm configuration](#) and [tsm configuration set Options](#) topics.

Important: Increasing the timeout limit can utilize more CPU for longer, which can affect the performance of other processes on Tableau Server.

- **Node limit**

When tasks in Catalog reach the node limit, you and your users see the following message:

NODE_LIMIT_EXCEEDED

To resolve this issue, as a Tableau Server admin, you can increase the node limit using the `tsm configuration set -k metadata.query.limits.count` command. For more information, see the [tsm configuration](#) and [tsm configuration set Options](#) topics.

Important: Increasing the timeout limit can affect system memory.

Missing content

- If you suspect, after initial ingestion, content is missing from Catalog, you can use the Eventing API to help troubleshoot. Eventing handles indexing content on Tableau Server after initial ingestion. For more information, see [Get Eventing Status](#).
- When the connection between an embedded external asset and its downstream Tableau content is removed, it remains in Catalog (or the Tableau Metadata API) until it's automatically deleted by a background process that runs everyday at 22:00:00 UTC (coordinated universal time). For example, suppose a workbook, initially published with an embedded text file A, is republished with an embedded text file B. File A remains visible (or query-able) as an external asset until the background process is able to delete it.

You can disable this background process from running if you do not want to remove these types of external assets or if you believe that it takes up system resources that you don't want to dedicate to this process. Alternatively, you can adjust the number of external embedded assets that are deleted. For more information, see [features.DeleteOrphanedEmbeddedDatabaseAsset](#) and `databaseservice.max_database_deletes_per_run`.

You can monitor this process in one of two ways:

Tableau Server on Windows Help

- Filter on the **One-time job re-canonicalize existing database/table assets after a canonicalization logic change** task type in the [Background Tasks for Non Extracts](#) admin view.
- Refer to the **Finished removal of orphaned embedded databases or database_service_canonicalization_change** events in the [Tableau Server log files](#).

Performance after initial ingestion

In some Tableau Server environments where specific content that is updated very frequently (for example, through high-frequency schedules or command line or API requests), the indexing process might get over saturated. In these cases, as the server admin, you might consider enabling event throttling to better preserve Catalog performance. For more information, see `metadata.ingestor.pipeline.throttleEventsEnable`.

Note: When event throttling is enabled, users might notice an intended delay in content changes in Catalog.

Out of memory errors

In some cases, Tableau Server out of memory errors can occur as a result of problems with ingesting complex content. If you suspect ingestion is the cause of the out of memory errors on your Tableau Server, contact and work with Tableau Support to `metadata.ingestor.blocklist` from being ingested to help resolve the issue.

Disable Catalog

As a Tableau Server admin, you can disable Catalog in one of two ways.

Turn off Catalog capabilities for each site

(Requires the Data Management)

You can turn off Catalog capabilities at any time. When Catalog capabilities are turned off, the features of Catalog, such as adding data quality warnings or the ability to explicitly manage permissions to database and table assets, are not accessible through Tableau Server.

However, Catalog continues to index published content and the metadata is accessible from the Tableau Metadata API and metadata methods in the Tableau REST API.

1. Sign in to Tableau Server using your admin credentials.
2. From the left navigation pane, click **Settings**.
3. On the General tab, under Tableau Catalog, clear the **Turn on Tableau Catalog** check box.

Stop indexing metadata on Tableau Server

To stop indexing the published content on Tableau Server, you can disable the Tableau Metadata API. To disable the Metadata API, run the `tsm maintenance metadata-services disable` command. For more information, see [tsm maintenance](#).

Get Initial Ingestion Status

After enabling the Tableau Metadata API using the `tsm maintenance metadata-services` command, you can use the Backfill API to monitor progress of initial ingestion and get status information for content and lineage backfills.

The steps described below must be performed by a server admin and recommended to be used in conjunction with Step 7: Monitor initial ingestion progress and validate its status in the Enable Tableau Catalog topic.

Step 1: Authenticate using the REST API

To access the Backfill API, you must first authenticate against Tableau Server and get a token. You can do this using the Tableau REST API. For more information, see [Signing In and Signing Out \(Authentication\)](#) in the REST API Help.

Alternatively, you can sign in to Tableau Server using your admin credentials.

Step 2: Make a GET request

Make the following GET request or paste the URL into your browser:

Tableau Server on Windows Help

`http://my_tableau_server/api/metadata/v1/control/backfill/status`

The request initially returns information about content backfill. When content backfill is complete, lineage backfill information is returned.

- For content backfill, the request returns a status summary and additional status information for each content type depending on what content is available on Tableau Server. Indexing for each content type happens concurrently.
- For lineage backfill, the request returns a status summary.

Status values from the response

The following values are returned by the Backfill API.

- **contentBackfillTotalDurationSeconds** and **lineageBackfillTotalDurationSeconds** is how much time has progressed, in seconds, on the respective backfill type. When **backfillComplete** is `true`, **contentBackfillTotalDurationSeconds** and **lineageBackfillTotalDurationSeconds** is the total time spent to complete the respective backfill type.

For content backfill:

- **contentType** can show the following content types: `PublishedDatasource`, `Database`, `DatabaseTable`, `Metric`, `Workbook`, and `Flow`.
- **contentId** is the identifier of the last indexed item.
- **successfullyIngestedCount** is the number of items successfully indexed.
- **failedIngestedCount** is the number of items that could not be indexed.
- **durationSeconds** is the time spent, in seconds, to index items for the content type.
- **totalCount** is the total number of items to index.
- **checkpointCreatedTime** is the last recorded time, in UTC, an item was indexed. The Backfill API checks for the last indexed item every five minutes.
- **backfillComplete** is `true` when indexing is complete for all items of the content type.

For lineage backfill:

- **totalCount** is the total number of lineage relationships to index.
- **processedCount** is the number of indexed lineage relationships.
- **lastLineageConnection** is the last indexed lineage relationship.
- **backfillComplete** is `true` when indexing is complete for all lineage relationships.

Example response

The request returns JSON text. To view the JSON in a more readable format, you can use a JSON viewer or browser add-on.

```
{
  "contentBackfillTotalDurationSeconds": 362,

  "processedCount": 18,
  "lastLineageConnection": "CloudFile downstreamWorkbooks Workbook",
  "backfillComplete": false
}
```

Get Eventing Status

After you have enabled Tableau Catalog (or the Tableau Metadata API) in your Tableau Server environment, you can use the Eventing API to gauge indexing performance.

The steps described below must be performed by a server admin.

Step 1: Authenticate using the REST API

To access the Eventing API, you must first authenticate against Tableau Server and get a token. You can do this using the Tableau REST API. For more information, see [Signing In and Signing Out \(Authentication\)](#) in the REST API Help.

Alternatively, you can sign in to Tableau Server using your admin credentials.

Step 2: Make a GET request

Make the following GET request or paste the URL into your browser:

```
http://my_tableau_server-  
/api/metadata/v1/control/eventing/status
```

Status values from the response

The following values are returned by the Eventing API.

- **contentType** is the content type that was most recently indexed.
- **queueSize** is the number of items in the indexing queue. The larger the queue size, the longer it can take for items to show in Catalog or Metadata API. If the queue size increases over time, you might need to adjust background capacity to support the non-interactive containers and indexing process. For more information, see [Memory for non-interactive microservices containers](#).
- **checkpointCreatedTime** is the last recorded time, in UTC, an item was indexed. The Eventing API checks for the last indexed item every five minutes.

Example response

The request returns JSON text. To view the JSON in a more readable format, you can use a JSON viewer or browser add-on.

Tableau Server on Windows Help

```
{  
  
  "contentType": "PublishedDatasource",  
  
  "queueSize": 312,  
  
  "checkpointCreatedTime": "2020-07-29T23:50:25.763Z"  
  
}
```

Use Lineage for Impact Analysis

Knowing where your data comes from is key to trusting the data, and knowing who else uses it means you can analyze the impact of changes to data in your environment. The lineage feature in Tableau Catalog helps you do both these things.

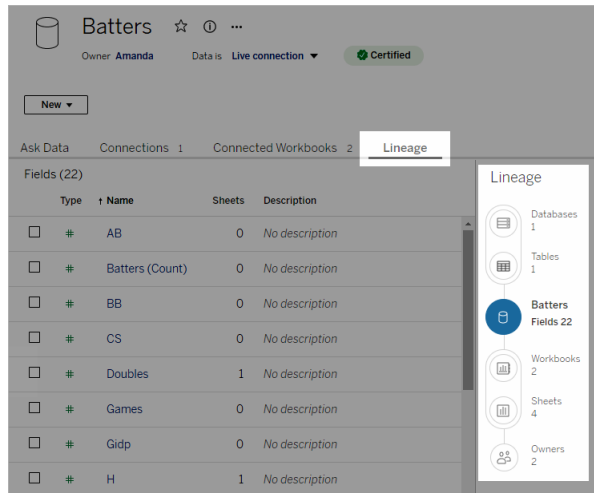

Lineage requires the Data Management Add-on. Starting in 2019.3, Tableau Catalog is available in the Data Management Add-on to Tableau Online and Tableau Server. When Tableau Catalog is enabled in your environment, you have access to lineage for your data sources, metrics, flows, databases, and tables. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Online](#) Help.

Navigate lineage

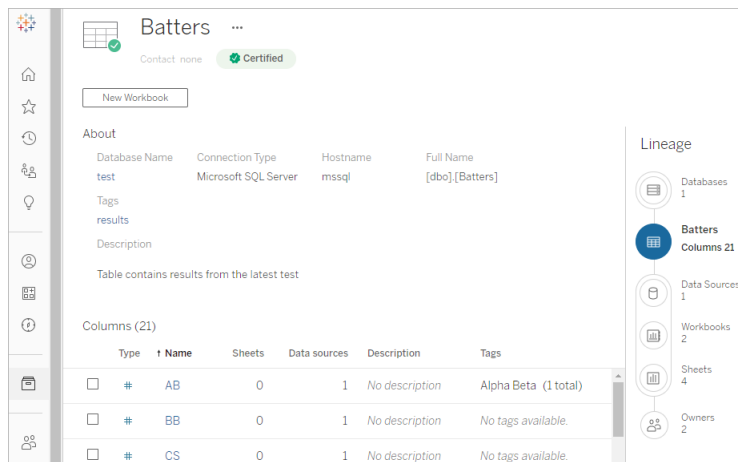

How you navigate to the **Lineage** pane depends on what kind of asset you're working with.

To see the lineage for Tableau content such as data sources or flows, from **Explore**, navigate to and open the content asset, and then select the **Lineage** tab.

Note: Lineage data for flows won't show if the flow includes parameter values. For more information about using parameters in flows see [Create and Use Parameters in Flows](#) in the Tableau Prep help.

To see lineage for external assets, such as databases and tables, from **External Assets**, navigate to and select an asset from the list. When you select a table, for example, a page opens with information about that table, for example, the name, type, full name, description, columns, and details about each column. To the right of the table information is the Lineage pane, which shows the lineage for that table.

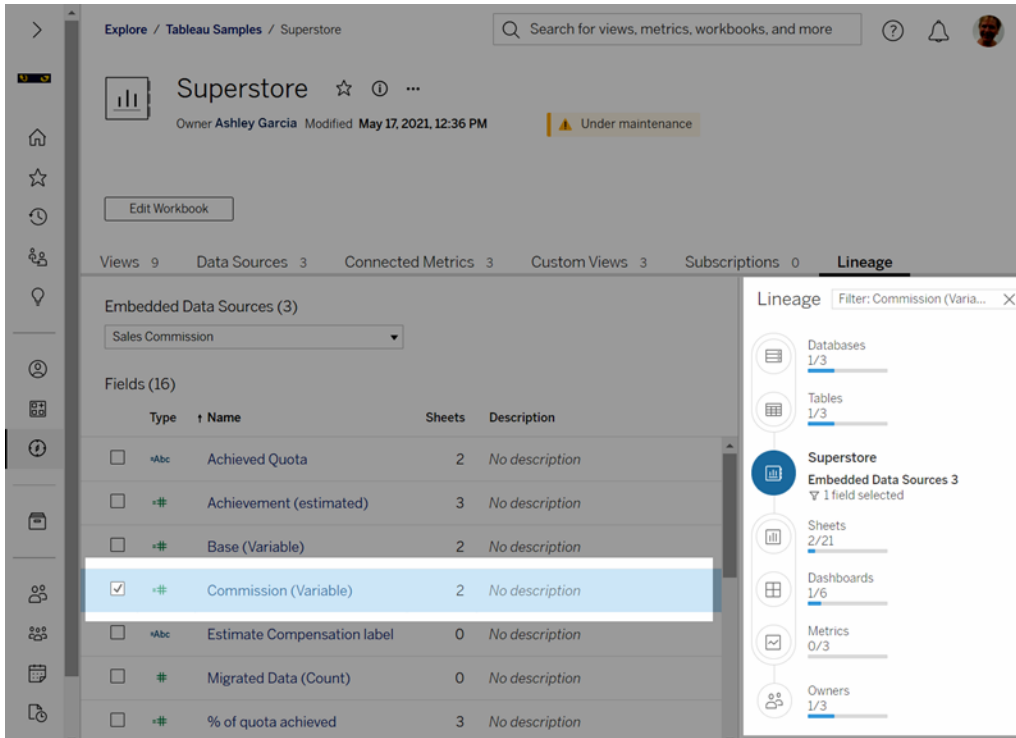

Lineage shows dependencies in relationship to the lineage anchor, which is the asset selected. A lineage anchor can be a database, table, workbook, published data source, or a flow. (In the first example, the anchor is the Sample - Superstore data source and in the second example, it's the TestResult table). All the assets below the anchor depend, either directly or indirectly, on the anchor and are called outputs or downstream assets. The assets above

Tableau Server on Windows Help

the anchor are the assets the anchor is either directly or indirectly dependent on and are called inputs or upstream assets.

When you select a field in a data source or a column in a table, the lineage is filtered to show only downstream assets that depend on the field (or column) or upstream inputs to the field (or column) as in this 'Superstore' workbook example that shows the lineage filtered for the Commission (Variable) field:

You can select an upstream or downstream asset in the Lineage pane to see its details. For example, when you select Metrics, the list of metrics depending on this workbook appears to the left of the Lineage pane.

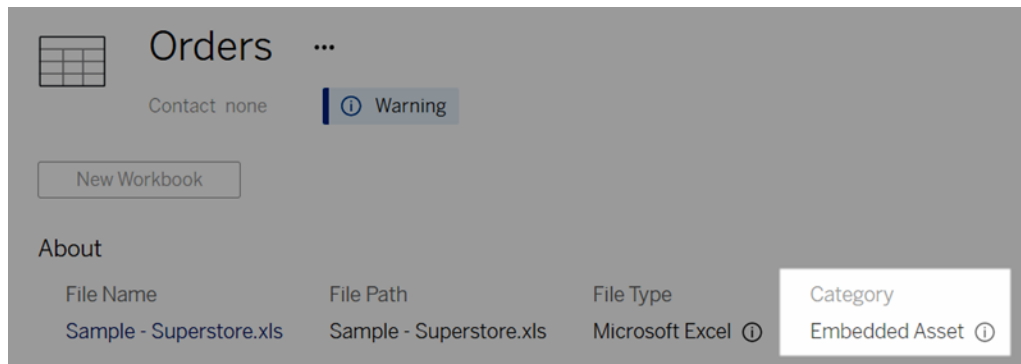

From the Lineage pane, you can navigate to any asset related to your initial choice, in this case the workbook, by following the links that interest you.

Note: Workbooks, data sources, and flows that use virtual connections show limited lineage information. Only assets downstream from the Tableau content appear; upstream assets don't appear.

Embedded asset appears in External Assets

Tableau Catalog treats an external asset as 'embedded' if the **Include external files** check box is selected when a data source or workbook is published. When an external asset (database, table, or file) is embedded in published Tableau content (workbooks, data sources, and flows), the external asset is used by the content, but is not shareable with other users. That embedded external asset appears in the lineage upstream from its Tableau content and is listed in External Assets.

To see if an external asset is embedded, go to the external asset's detail page and see if "Embedded Asset" is listed under **Category**.

For information about embedded data, see [Publishing data separately or embedded in workbooks](#) in Tableau Desktop and Web Authoring Help.

Lineage and custom SQL connections

When you view the lineage of a connection that uses custom SQL, keep in mind the following:

Tableau Server on Windows Help

- Lineage might not be complete.
- Catalog doesn't support showing column information for tables that it only knows about through custom SQL.
- Field details cards might not contain links to connected columns, or might not show any connected columns at all.
- Column details cards might not contain links to fields that use the column, or might not show any fields at all.

For more information, see [Tableau Catalog support for custom SQL](#) in the Tableau Desktop and Web Authoring Help.

Catalog doesn't support cubes

Cube data sources (also known as multidimensional or OLAP data sources) are not supported by Tableau Catalog. Tableau content (such as a data source, view, or workbook) that relies on cube data does not display any cube metadata or cube lineage in Catalog.

Mismatch between lineage count and tab count

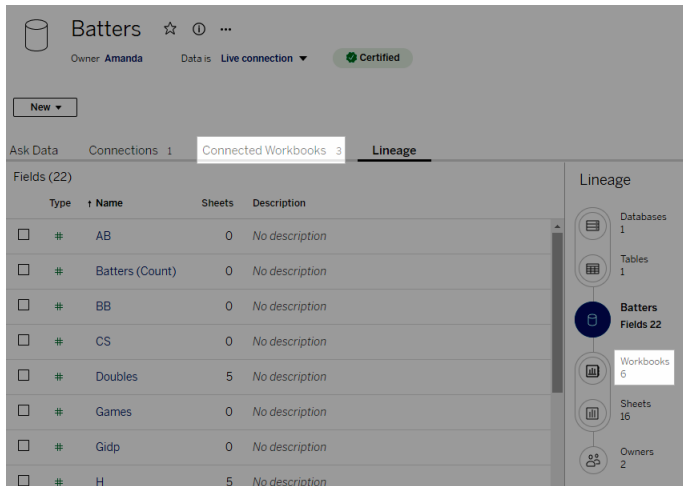

You might notice a mismatch in the count of assets between the Tableau Catalog Lineage tool and the tabs in Tableau Server or Tableau Online.

The count mismatch is explained by the fact that each—lineage count vs. tab count—counts assets a different way. For example, at any given point in time, Catalog can count only assets that are indexed, whereas Tableau Server or Tableau Online counts any assets that are published. Other reasons for count differences include whether:

- You have "View" permissions for the asset.
- An asset is hidden.
- Any fields are used in a workbook.
- An asset is directly or indirectly connected to.
- An asset is in a Personal Space.

Workbook count mismatch example

As an example, here's how the tab count vs. the lineage count is determined for workbooks.

Connected Workbooks tab counts workbooks that meet both these criteria:

- Connects to the data source (whether or not any fields are actually used in the workbook).
- The user has permissions to view (whether it's a worksheet, dashboard, or story).

Tableau Catalog Lineage counts workbooks that meet all these criteria:

- Has been indexed by Tableau Catalog.
- Connects to the data source and uses at least one field in the data source.
- Contains worksheets, including dashboards or stories that contain a worksheet, that use at least one field in the data source.

When metadata is blocked because of limited permissions, or the asset is in a Personal Space, Catalog still counts the workbook. But instead of seeing some of the sensitive metadata, you see **Permissions required**. For more information, see Access lineage information.

Use email to contact owners

At the end of the lineage is Owners. The list of owners includes anyone assigned as the owner or contact for any content downstream from the lineage anchor.

You can email owners to let them know about changes to the data. (To email owners, you must have the 'Overwrite' (Save) capability on the lineage anchor content.)

Tableau Server on Windows Help

1. Select **Owners** to see the list of people who are impacted by the data in this lineage.
2. Select the owners you want to send a message to.
3. Click **Send Email** to open the email message box.
4. Enter the Subject and your message in the text box, and click **Send**.

Set a Data Quality Warning

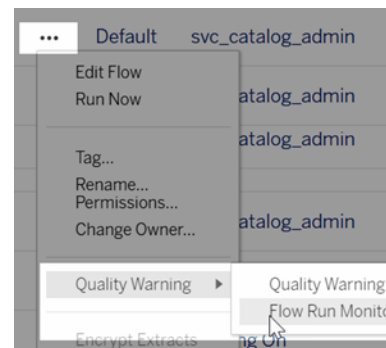

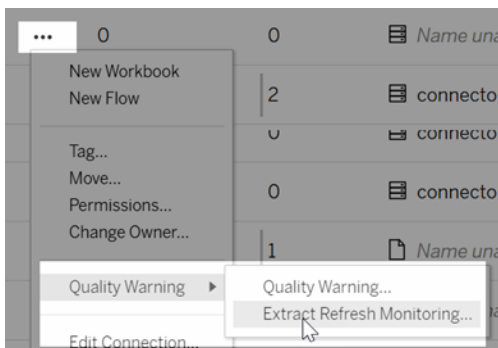

Data quality warnings are a feature of Tableau Catalog. Starting in 2019.3, Tableau Catalog is available in the Data Management Add-on to Tableau Online and Tableau Server. When Tableau Catalog is enabled in your environment, you can set data quality warnings. For more information, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Online](#) Help.

You can set a warning message on a data asset so that users of that data are aware of issues. For example, you might want to let users know that a data source has been deprecated, or that a refresh has failed for an extract data source, or that a table contains sensitive data.

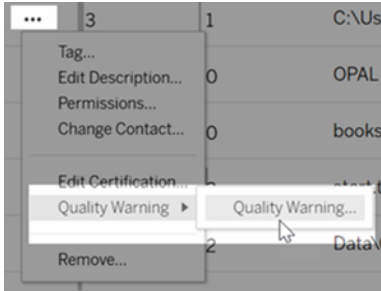

About data quality warnings

There are two kinds of data quality warnings you can set. The first kind is visible to users until you remove it. The second kind is generated by Tableau when you set Tableau to monitor for refresh failures of extract data sources or flow run failures.

For extracts and flows, you can set one data quality warning of each kind per asset.

For live data sources and for databases and tables, you can set only one quality warning.

When you set the first kind, it's visible to users until you remove it using the data quality dialog box. You can also use the dialog box to make any updates to the quality warning you set.

When you set Tableau to monitor for extract data source refresh failures or flow run failures, if a warning is generated, it's visible to users until the extract refresh or flow run is successful. You can update or remove a warning by opening and editing the contents in the dialog box.

Note: You can set both kinds of data quality warnings and enable high visibility using REST API. For more information, see [Add Data Quality Warning](#) in the Tableau REST API Help.

Who can see the data quality warning

When you set a warning, the warning is visible to users of the asset and any assets downstream from it. For example, a warning set on a table is visible to users looking at a dashboard with an upstream dependency on that table - users see a warning icon on the dashboard's Data Details tab and can open the pane to see the details. Warnings are visible elsewhere in Tableau as described in [Set high visibility for a data quality warning](#). This applies to Tableau Server and Tableau Online users.

Tableau Server on Windows Help

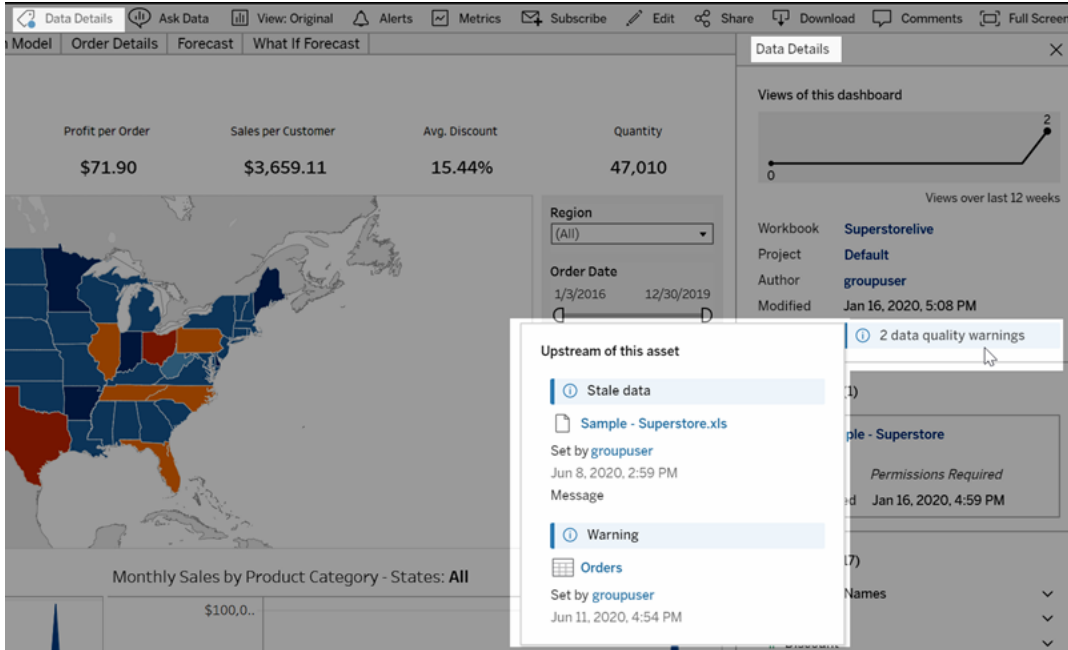

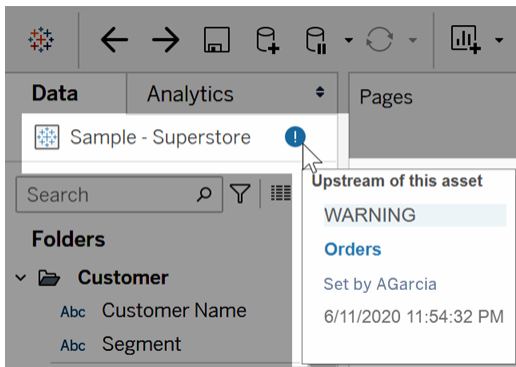

Tableau Desktop users see a warning icon (either a blue circle or a yellow triangle with an exclamation point) on the Data tab in a workbook sheet when a warning is set on a data source, table, or database used in the workbook. To see the details of the warning, hover over the warning icon with a mouse.

Data quality warnings in subscriptions

Administrators can turn on data quality warnings in email subscriptions so that when users subscribe to a view, for example, the email they get includes any data quality warnings associated with that view. Emails with data quality warnings contain:

- Links to relevant views or workbooks with their **Data Details** pane open.
- Links to relevant upstream assets, such as data sources, tables, or databases.

Administrators can turn on data quality warnings in email subscriptions by selecting the **Data Quality Warnings in Subscriptions** option on the Tableau Server or Tableau Online site settings page. For more information, see *Data Quality Warnings in Subscriptions* in the *Site Settings Reference*.

How to set a quality warning

There are several types of data quality warnings you can set on an asset:

- Warning
- Deprecated
- Stale data
- Under maintenance
- Sensitive data

In addition to showing the type of data quality warning, you can include an optional message with more details about the warning.

To set a data quality warning:

1. Select the More actions menu (. . .) next to the asset you want to create a warning for, and then select **Quality Warning**.
2. Select the **Enable warning** check box.
3. Select the **Warning type** from the drop-down list.
4. (Optional) Select the **Enable high visibility** check box.
5. Enter a message to display to users.
6. Click **Save**.

Tableau Server on Windows Help

Data Quality Warning

2nd level Flow -> PDS

Enable warning

When enabled, the warning you set is visible to users of this asset and of any asset downstream from it. [Learn more](#)

Select the warning to display:

Warning type
Deprecated

Enable high visibility

When enabled, a notification appears when you open a published view affected by this warning. The warning is also more visible elsewhere in Tableau.

Message (required) Edit Preview

This database is deprecated and will be no longer available starting *August 1*. Any dashboards, workbooks, and data sources need to be updated to use the SQL database before then to continue to work. Contact the data steward team or the workbook author for more information.

How to set a monitoring quality warning

You can set Tableau to monitor for two events: extract data source refresh failure and flow run failure. When the event occurs, Tableau generates a quality warning that appears in the same places that a manual quality warning appears.

To set Tableau to monitor for either event:

1. Select the More actions menu (. . .) next to the extract data source or flow you want to create a warning for, and then select the appropriate option:

- Quality Warning > Extract Refresh Monitoring
 - Quality Warning > Flow Run Monitoring
2. In the dialog box, select the monitoring check box.
 3. (Optional) Select the Enable high visibility check box.
 4. (Optional) Enter a message to display to users. To see text formatting tips, click the information (i) icon above the Save button.
 5. Click Save.

Flow Run Monitoring

CityFlow

Generate a quality warning when one or more flow outputs fail. Select 'High visibility' to show a notification when users open a published view affected by this warning and to raise visibility elsewhere in Tableau. [Learn more](#)

Flow run monitoring

Enable high visibility

Message (optional) Edit Preview

The flow run failed. If you can't resolve the issue, contact Ashley Garcia.

Set high visibility for a data quality warning

There are times when you want to make sure that users of a visualization know important information about the data they're viewing, whether it be that the data is stale or that the source has been deprecated or that the flow run has failed. You can do this by selecting the **Enable high visibility** check box in the Data Quality Warning dialog box, as described in step 4 of How to set a data quality warning.

Tableau Server on Windows Help

When enabled, a notification appears when anyone opens a published view affected by this warning.

High visibility warnings are identified with a yellow warning symbol, which makes them more visible elsewhere in Tableau, as in these examples:

On the External Assets page:

On a database page:

On the Data Details pane:

The screenshot displays the 'Data Details' panel in Tableau. At the top, there is a navigation bar with icons for 'Data Details', 'Ask Data', 'Edit', 'Share', 'Download', and 'Full Screen'. The main content area is divided into several sections:

- Views of this dashboard:** A line chart showing the number of views over the last 12 weeks. The y-axis ranges from 0 to 3. The chart shows a steady increase from 0 to 3 views.
- Metadata:**
 - Workbook: **Book3**
 - Project: **CM's Project**
 - Author: **Chris Mac**
 - Modified: **May 28, 2019, 4:00 PM**
- Warnings:** A yellow warning box with a triangle icon and the text: **2 data quality warnings**.
- Data Sources (1):** A list of data sources, including:
 - CM Test Datasource:** Includes a warning icon, a refresh icon, and the text 'Connects to CM Test Datasource' and 'Last Refreshed May 28, 2019, 10:09 AM'.
- Fields in Use (7):** A section for fields currently in use, which is partially obscured by a dark blue bar.

On metrics. Warnings appear when you open a metric in Tableau Mobile, and in Tableau Server and Tableau Online when you hover over a metric in grid view and on the metric details page, as shown below:

You can change a high visibility warning to normal visibility by clearing the **Enable high visibility** check box in the Data Quality Warning dialog box.

Remove a data quality warning

When a warning no longer applies, you can remove it by navigating to the data asset with the warning.

1. Select the More actions menu (. . .) next to the data asset and select **Quality Warning**.
2. Clear the **Enable warning** check box to remove the warning.
3. Click **Save**.

Who can do this

To set a data quality warning, you must either

- be a server or site administrator, or
- have the Overwrite capability for the asset.

Manage Dashboard Extensions in Tableau Server

Dashboard extensions are web applications that run in custom dashboard zones and can interact with the rest of the dashboard using the [Tableau Extensions API](#). Dashboard extensions give users the ability to interact with data from other applications directly in Tableau.

Note: You must be a server administrator to enable dashboard extensions on the server, or to block specific extensions from running. You must be a server administrator to add extensions to the safe list and to control the type of data the extensions can access. The server administrator can also configure whether users on the site will see prompts when they add or view extensions in a dashboard. For information about extension security and recommended deployment options, see [Extension Security - Best Practices for Deployment](#)

For information about using dashboard extensions in Tableau, see [Use Dashboard Extensions](#).

Looking for Tableau Online? See [Manage Dashboard Extensions in Tableau Online](#).

Before you run extensions on Tableau Server

Tableau supports two types of dashboard extensions: Network-enabled extensions, which can be hosted on web servers located inside or outside of your local network and have full access to the web, and Sandboxed extensions, which run in a protected environment without access to any other resource or service on the web.

Note: Beginning with version 2021.1.0 Tableau supports integration with Einstein Discovery through the Einstein Discovery Dashboard extension. This is a special extension that has access to data in Salesforce.com and is allowed by default. It is not considered a Network-enabled extension or a Sandboxed extension. For more

information on Einstein Discovery integration, see [What's New and Changed in Tableau Server](#).

Sandboxed extensions are hosted by Tableau and employ W3C standards, such as Content Security Policy (CSP), to ensure the extension can't make network calls outside of the hosting Tableau Server. A Sandboxed extension can query data in the dashboard, but it can't send that data anywhere outside of the sandbox. Sandboxed Extensions are supported in Tableau 2019.4 and later. By default, Sandboxed extensions are allowed to run if extensions are enabled for the site.

Network-enabled dashboard extensions are web applications and could be running on any computer set up as a web server. This includes local computers, computers in your domain, and third-party web sites. Because Network-enabled extensions could be hosted on third-party sites and could have access to the data in the dashboard, you want to only allow the extensions you trust. See [Test Network-enabled extensions for security](#).

For security, you can use the settings for dashboard extensions on Tableau Server to control and limit the dashboard extensions that are allowed to run.

- By default, Sandboxed extensions are allowed to run if extensions are enabled for the site.
- By default, no Network-enabled extensions are allowed unless they have been explicitly added to the safe list.
- By default, only extensions that use the HTTPS protocol are allowed, which guarantees an encrypted channel for sending and receiving data (the only exception is for `http://localhost`).
- If the Network-enabled extension requires full data (access to the underlying data) the extension will not be able to run on Tableau Server unless you explicitly add the extension to the safe list and grant the extension access to full data.

Control dashboard extensions and access to data

Server administrators can control a global setting to allow extensions for all sites on the server. Server administrators can also put extensions, including Sandboxed extensions, on a global block list to prevent them from running (see Block specific extensions). By default, all Sandboxed extensions are enabled on the server, but site administrators can choose to override the default and prohibit Sandboxed extensions for the site.

Change the global setting enabling extensions on the server

1. To change this setting for the server, go to **Manage All Sites > Settings > Extensions**. If the server just has a single site, the global controls appear on the settings page for the site.
2. Under Dashboard Extensions, select or clear the **Let users run extensions on this server** checkbox. If this option is not selected, extensions are not allowed to run. This global setting overrides the **Let users run extensions on this site** settings for each site.

Change the default settings for a site

Server administrators can control whether to enable extensions for the site and whether to allow Sandboxed extensions on the site. That is, if extensions are enabled on the server, the default site settings allow Sandboxed extensions to run on the site, provided the extension is not specifically blocked on the server. The default site settings allow Network-enabled extensions to run that appear on the safe list for the site. Individual Sandboxed extensions can also be added to the safe list, if Sandboxed extensions are not allowed by default.

1. To change these settings for the site, go to **Settings > Extensions**.
2. Under Dashboard Extensions, configure these options:
 - **Let users run extensions on this site**
 - **Let Sandboxed extensions run unless they are specifically blocked by a server administrator**

Tableau Server on Windows Help

Server administrators can add or remove Network-enabled and Sandboxed extensions from the safe list for a site. When you add an extension to the safe list, you can control whether to allow the extension to have access to full data. See [Add extensions to the safe list and configure user prompts](#).

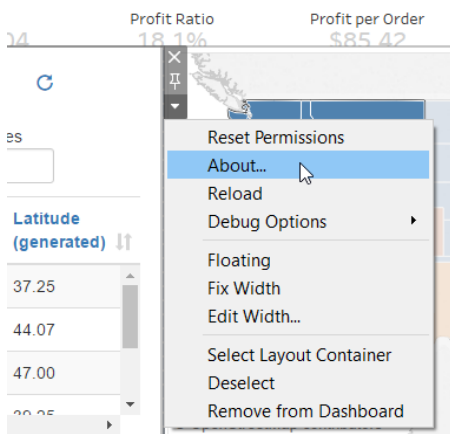

Identifying an extension

As a web application, an extension is associated with a URL. You use this URL to test and verify the extension. You also use the URL to add the extension to the safe list to allow full data access, or to the block list to prohibit any access.

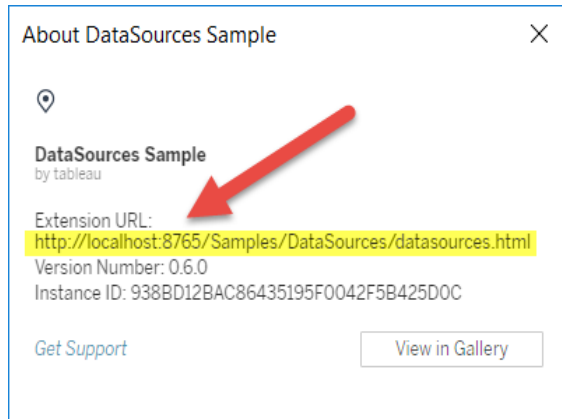

If you have the extension manifest file (.trex), an XML file that defines properties for the extension, you can find the URL from the `<source-location>` element.

```
<source-location>  
  <url>https://www.example.com/myExtension.html</url>  
</source-location>
```

If you have added the extension to the dashboard, you can find the URL from the extension properties. From the **More Options** menu, click **About**.

The About dialog box lists the name of the extension, the author of the extension, the web site of the author, along with the URL of the extension.

Add extensions to the safe list and configure user prompts

To ensure that users can use Network-enabled extensions that are trusted, you can add them to the safe list for the site. You can also add Sandboxed extensions to the safe list, if Sandboxed extensions aren't enabled by default on the site.

On the safe list, you can control whether to grant the extension full data access. By default, when you add an extension to the safe list, the extension only has access to the summary (or aggregated) data. You can also control whether users will see a prompt asking them to allow the extension access to data. You might want to add an extension to the safe list (for example, a Sandboxed extension) so that you can configure whether or not users see the prompts. When you hide the prompt from users, the extension can run immediately.

1. Go to **Settings > Extensions**.
2. Under **Enable Specific Extensions**, add the URL of the extension. See Identifying an extension.
3. Choose to **Allow** or **Deny** the extension **Full Data Access**.

Full data access is access to the underlying data in the view, not just the summary or aggregated data. Full data access also includes information about the data sources, such as the names of the connection, fields, and tables. In most cases, if you are adding an extension to the safe list so that it can run, you will also want to allow the

extension to have access to full data, if the extension requires it. Before adding extensions to the safe list, be sure to Test Network-enabled extensions for security.

4. Choose to **Show** or **Hide** the **User Prompts**.

Users see the prompts by default when they are adding an extension to a dashboard, or when they are interacting with a view that has an extension. The prompt tells users details about the extension and whether the extension has access to full data. The prompt gives users the ability to allow or deny the extension from running. You can hide this prompt from users, allowing the extension to run immediately.

Block specific extensions

The default global policy allows all Sandboxed extensions and those Network-enabled extensions that appear on the safe list for a site. Server administrators can keep specific extensions from running by adding them to the block list for the server. If an extension is on the global block list it overrides any settings for the extension on the safe list for a site.

1. To add an extension to the blocked list for the server, go to **Manage All Sites > Settings > Extensions**. On single-site installations, the block list is on the site **Extensions** settings page.
2. Under **Block Specific Extensions**, add the URL of the extension. See Identifying an extension.

Test Network-enabled extensions for security

Dashboard extensions are web applications that interact with data in Tableau using the Extensions API. Network-enabled dashboard extensions could be hosted on web servers inside or outside of your domain, and can make network calls and have access to resources on the Internet. Because of this and the potential vulnerabilities, such as cross-site scripting, you should test and vet Network-enabled dashboard extensions before users use them in dashboards on Tableau Desktop, and before you allow the extensions on Tableau Server.

Examine the source files

Dashboard extensions are web applications and include various HTML, CSS, and JavaScript files, and an XML manifest file (*.trex) that defines the properties in the extension. In many cases, the code for a dashboard extension is publicly available on GitHub and can be examined there or downloaded. In the manifest file (*.trex), you can find the source location, or URL indicated where the extension is hosted, the name of the author, and the web site of the author or company to contact for support. The `<source-location>` element specifies in the URL, the `<author>` element, specifies the name of the organization and the web site to contact for support (`website="SUPPORT_URL"`). The web site is the **Get Support** link user see in the **About** dialog box for the extension.

Many dashboard extensions reference external JavaScript libraries, such as the jQuery library or API libraries for third parties. Validate that the URL for external libraries points to a trusted location for the library. For example, if the connector references the jQuery library, make sure that the library is on a site that is considered standard and safe.

All extensions are required to use HTTPS protocol (`https://`) for hosting their extensions. You should examine the source files for the extension to ensure that any reference to external libraries is also using HTTPS or is hosted on the same web site as the extension. The one exception to the requirement of HTTPS is if the extension is hosted on the same computer as Tableau (`http://localhost`).

To the extent possible, make sure you understand what the code is doing. In particular, try to understand how the code is constructing requests to external sites, and what information is being sent in the request. In particular, check if any user-supplied data is validated to prevent cross-site scripting.

Understand data access

The Tableau Extensions API provides methods that can access the names of the active tables and fields in the data source, the summary descriptions of the data source connections, and the underlying data in a dashboard. If an extension uses any of these methods in a view, the extension developer must declare that the extension requires full data permission in the manifest file (*.trex). The declaration looks like the following.

Tableau Server on Windows Help

```
<permissions>
  <permission>full data</permission>
</permissions>
```

Tableau uses this declaration to provide a prompt to users at run time that gives them the option of allowing this access or not. If the extension uses any one of these four methods, without declaring full-data permission in the manifest file, the extension will load but the method calls will fail.

For information about how an extension accesses data from the dashboard, and the JavaScript methods used, see [Accessing Underlying Data](#) in the Tableau Extensions API. To get a better understanding about what the extension can find out about the data, you can use the [DataSources](#) sample dashboard extension (available from the [Tableau Extensions API GitHub repository](#)) to see what data is exposed when the `getDataSourcesAsync()` method is called.

Test the extension in an isolated environment

If possible, test the dashboard extension in an environment that is isolated from your production environment and from user computers. For example, add a dashboard extensions to a safe list on a test computer or virtual machine that's running a version of Tableau Server that is not used for production.

Monitor traffic created by the dashboard extension

When you test a Network-enabled dashboard extension, use a tool like [Fiddler](#), [Charles HTTP proxy](#), or [Wireshark](#) to examine the requests and responses that the extension makes. Make sure that you understand what content the extension is requesting. Examine the traffic to be sure that the extension is not reading data or code that is not directly related to the purpose of the extension.

Configure Connections with Analytics Extensions

Tableau supports a set of functions that your users can use to pass expressions to analytics extensions for integration with R, Python, and Einstein Discovery.

This topic describes how to configure sites on Tableau Server with analytics extensions.

Because Tableau Server provides an authentication mechanism, it can be more secure to expose analytics extensions functionality to users through Tableau Server than in Tableau Desktop.

For more information about user scenarios and configuring Tableau Desktop, see [Pass Expressions Analytics Extensions](#), in the *Tableau Desktop and Web Authoring Help*.

The configuration steps in this article are specific to Workbooks. For information about how you can use R and Python scripts to incorporate predictive modeling data into your flow, see [Use R and Python scripts in your flow](#) in the *Tableau Prep Help*.

Feature change history:

- 2021.2 — You can configure multiple analytics extension connections for each site. (You are limited to a single Einstein Discovery connection per site.)

For information about how to determine analytics extension usage in workbooks, see [Determining analytics extensions usage](#).

- 2021.1 — Einstein Discover is included as an analytics extension option. Einstein Discovery in Tableau is powered by [salesforce.com](#). Consult your agreement with [salesforce.com](#) for applicable terms.
- 2020.2 — You can configure a different analytics extension connection for each site on your server. Prior to this change a single analytics extension configuration applied globally to all sites on the server.
- 2020.1 — This functionality is now called *analytics extensions*. Previously the feature was called "external services."

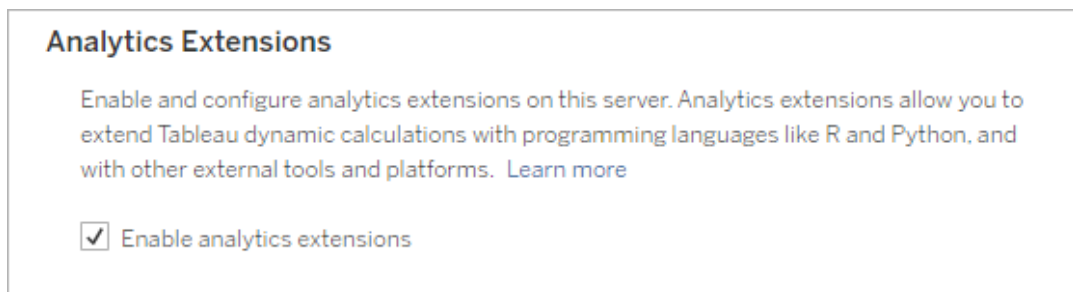

Server SSL

To configure SSL for analytics extensions, you must install a valid certificate on the computer running Tableau Server. The certificate must be trusted by the computer running Tableau Server. The certificate Subject field or one of the SAN entries on must exactly match the URI of the analytics extensions service configuration.

Enable analytics extensions

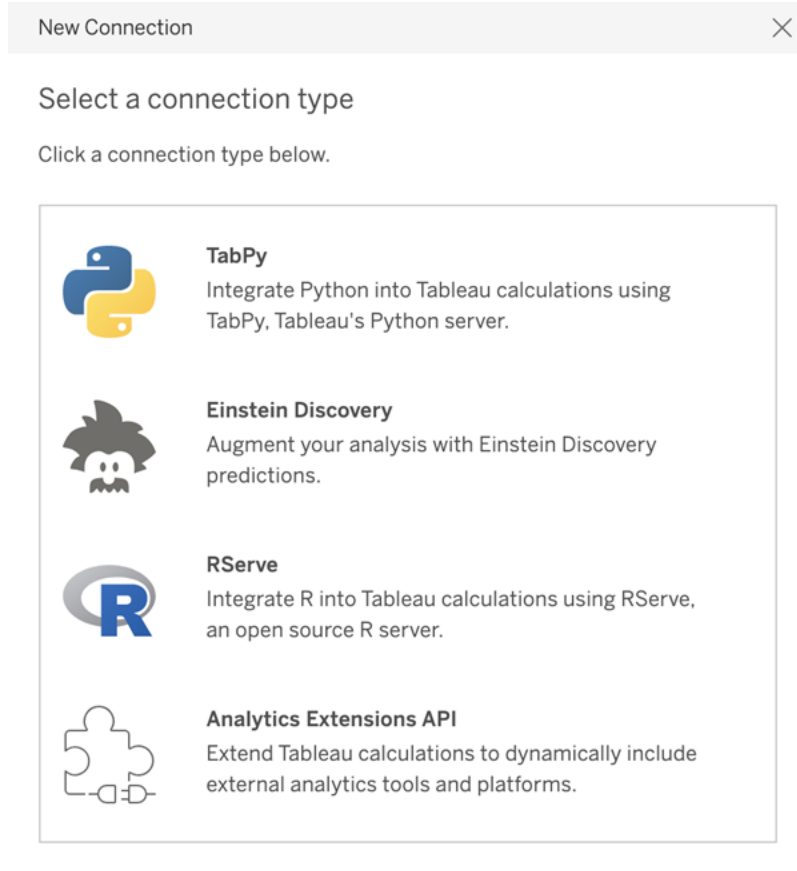

Before you configure extensions, you must enable analytics extensions server-wide.

1. Sign in to the Tableau Server Admin Area.
 - If you only have a single site (default) on your server, click **Settings**, and then go to Step 2.
 - If you have multiple sites on your server:
 - a. Under **All Sites**, click **Manage all sites**.
 - b. Click the **Extensions** tab.
2. Scroll to **Analytics Extensions**, select **Enable analytics extensions**, and then click **Save**.

Configure analytics extensions settings

1. Sign in to the Tableau Server Admin Area.
2. On the Settings page, click the **Extensions** tab and then scroll to **Analytics Extensions**. (On multi-site deployments of Tableau Server, navigate to the site where you want to configure analytics extensions, and then click **Settings>Extensions**.)
3. **Multi-site deployments only**: you must enable Analytics Extensions on each site. Under Analytics Extensions, select **Enable analytics extensions for site**.
4. Under Analytics Extensions, click **Create new connection**.
5. In the **New Connection** dialog, click the connection type you want to add, then enter the configuration settings for your analytics service:

6. The options you need to configure depend on the connection type you choose:
- For an Einstein Discovery connection, click **Enable**.
 - For TabPy, RServer and Analytics Extensions API connections, enter the following information:
 - **Connection Name:** (Required) Specify the server type you are connecting to. RSERVE supports connections to R using the RServe package. TABPY supports connections to Python using TabPy, or to other analytics extensions.
 - **Require SSL** (Recommended): Select this option to encrypt the connection to the analytics service. If you specify a `HTTPS` URL in the **Host-name** field, then you must select this option.
 - **Hostname:** (Required) Specify the computer name or URL where the analytics service is running. This field is case sensitive.

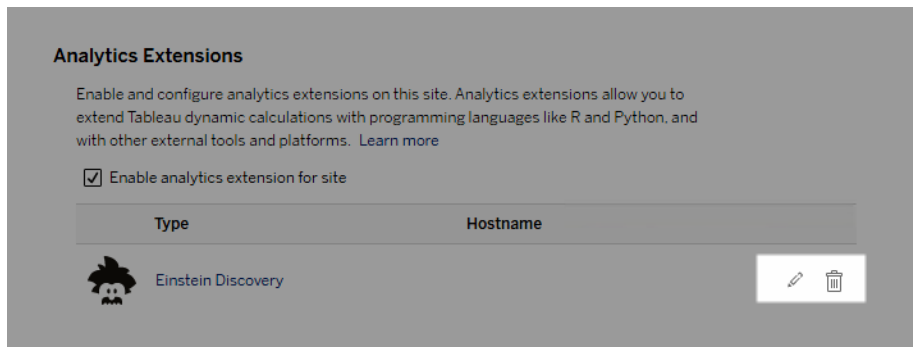

Tableau Server on Windows Help

- **Port:** (Required) Specify the port for the service.
- **Sign in with a username and password**(Recommended): Select this option to specify user name and password that is used to authenticate to the analytics service.

7. Click **Create**.

Edit or delete an analytics extension connection

To edit or delete a configuration, navigate to **Analytics Extensions** on the **Extensions** tab of your site.

Click the **Edit** or **Delete** icon and follow the prompts to change the configuration.

Client requirement: Intermediate certificate chain for Rserve external service

As of Tableau Server version 2020.1, you must install a full certificate chain on Tableau Desktop computers (Windows and Mac) that are connecting to a Rserve external connection through Tableau Server. This requirement is due to how Rserve manages the handshake on secure connections.

Importing a root certificate on the Tableau Desktop is not sufficient, the entire certificate chain must be imported onto the client computer.

Script errors

Tableau cannot verify that workbooks that use an analytics extension will render properly on Tableau Server. There might be scenarios where a required statistical library is available on a user's computer but not on the analytics extension instance that Tableau Server is using.

A warning will be displayed when you publish a workbook if it contains views that use an analytics extension.

This worksheet contains external service scripts, which cannot be viewed on the target platform until the administrator configures an external service connection.

Determining analytics extensions usage

Beginning with version 2021.2, analytics extensions configurations are mapped at the workbook level. This allows administrators to use custom views to query the Tableau Repository and determine which workbooks are using which extensions, and how often they are used.

To do this you need to join the workbook connections table to tables showing workbook usage. For details about creating and using custom administrative views, see [Collect Data with the Tableau Server Repository and Create Custom Administrative Views](#).

Configure Einstein Discovery Integration

Beginning with version 2021.1.0, Tableau Server supports integration with Einstein Discovery, making Einstein Discovery predictions available to authors and viewers of workbooks and dashboards. Starting in version 2021.2.0, Einstein Discovery predictions is also now available when authoring flows on the web.

Einstein Discovery in Tableau is powered by [salesforce.com](https://www.salesforce.com). Consult your agreement with [salesforce.com](https://www.salesforce.com) for applicable terms.

To integrate Einstein Discovery with Tableau Server, there are several necessary configuration steps, including some in Tableau Server, and some in the Salesforce org running

Tableau Server on Windows Help

Einstein Discovery. This overview outlines these steps for Dashboard extensions, Analytics extensions, and Tableau Prep extensions, and provides links to specific topics with steps for completing the server configuration.

For details on how to use Einstein Discovery predictions in Tableau, including licensing and permission requirements, see [Integrate Einstein Discovery Predictions in Tableau](#) in the Tableau Desktop and Web Authoring Help. For information about adding predictions in flows, see [Add Einstein Discovery Predictions to your flow](#).

Einstein Discovery dashboard extensions

The Einstein Discovery dashboard extension allow workbook authors to surface real-time predictions in Tableau. The dashboard extension delivers predictions interactively, on-demand, using source data in a Tableau workbook and an Einstein Discovery-powered model deployed in Salesforce.

To configure Tableau Server for the Einstein Discovery dashboard extension you need to do the following:

1. In Tableau Server:
 - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens
 - b. Enable Dashboard extensions for the server. See: Manage Dashboard Extensions in Tableau Server
2. In Salesforce, in the organization running Einstein Discovery:
 - a. Configure CORS in Salesforce.com for Einstein Discover Integration in Tableau Server.
 - b. In Salesforce, in the organization running Tableau CRM, create a connected app. See Step 1: Create a Salesforce connected app.
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. Step 2: Configure Tableau Server for Salesforce.com OAuth

Einstein Discovery analytics extensions

The Einstein Discovery analytics extension gives your users the ability to embed predictions directly in Tableau calculated fields. A table calc script requests predictions from a model deployed in Salesforce by passing its associated prediction ID and input data that the model requires. Use Model Manager in Salesforce to auto-generate a Tableau table calculation script, and then paste that script into a calculated field for use in a Tableau workbook.

To configure Tableau Server for either the Einstein Discovery analytics extension you need to do the following:

1. In Tableau Server:
 - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. Allow Saved Access Tokens
 - b. Enable analytics extensions for the server and configure a connection type.
See: [Configure Connections with Analytics Extensions](#)
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See [Step 1: Create a Salesforce connected app](#).
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. [Step 2: Configure Tableau Server for Salesforce.com OAuth](#)

Einstein Discovery Tableau Prep extensions

Supported in Tableau Server and Tableau Online starting in version 2021.2.0

The Einstein Discovery Tableau Prep extension enables users to embed Einstein predictions directly in their flows when authoring flows on the web.

To configure Tableau Server or Tableau Online for the Einstein Discovery Tableau Prep extension you need to do the following:

1. In Tableau Server:
 - a. Enable saved OAuth tokens for data connections and extensions in Tableau Server. See [Allow Saved Access Tokens](#)

Tableau Server on Windows Help

- b. Enable Tableau Prep Extensions for the server. See [Enable Tableau Prep Extensions](#).
2. In Salesforce, in the organization running Einstein Discovery, create a connected app. See [Step 1: Create a Salesforce connected app](#).
3. In Tableau Server, configure server for saved SF OAuth credentials using information from the connected app. [Step 2: Configure Tableau Server for Salesforce.com OAuth](#)

Integrate Tableau with a Slack workspace

Beginning with version 2021.3, Tableau Server and Tableau Online support integration with Slack, making Tableau notifications available to licensed Tableau users in their Slack workspace.

The Tableau for Slack integration lets you connect your Tableau site with a Slack workspace. Once it's enabled, Tableau users can see notifications in Slack when teammates share content with them, when they're mentioned in a comment, or when data meets a specified threshold in a data-driven alert. If a site administrator in Tableau Online or a server administrator in Tableau Server enables notifications on a site, users can control which notifications they receive in Slack by configuring their [Account Settings](#). For more information, see [See Tableau notifications in Slack](#).

To integrate Slack with your Tableau site, there are a few necessary configuration steps, including some in your Tableau site, and some in the Slack workspace you want to connect. This overview outlines these steps for both Tableau site administrators on Tableau Online or a Tableau Server Administrator on Tableau Server, and Slack workspace administrators.

Requirements

Enabling Tableau in Slack requires both a Slack workspace administrator and either a Tableau site administrator in Tableau Online, or a Tableau server administrator in Tableau Server.

Connect a Tableau Server site to a Slack workspace

A Tableau Server administrator can connect a Slack workspace to one Tableau Server site.

Connecting your Tableau site to a Slack workspace consists of three tasks:

- **Slack workspace administrator:** Create a private Slack application on the Slack API platform
- **Tableau administrator:** Use the app information to add an OAuth client
- **Tableau administrator:** connect your Tableau site to Slack

For information about creating Slack apps, see Slack's [Best practices and guidelines for Slack platform](#).

Note: You are limited to one Slack workspace connection per Tableau site.

Step 1: Create a Tableau Slack app

Slack workspace administrator:

1. Go to Slack's [API documentation](#) and select **Create New App**
2. Select **From Scratch**, then add an app name and the workspace for the app to exist within. Select **Create New App**.
3. Give your app a name and select a Slack workspace.
4. You'll be taken to the app's basic information settings. From here, you can modify the app's privileges, description, and more.
5. Select **Bots** from the Add features and functionality section, then select **Review Scopes to Add**.
6. Under Bot Token Scopes, add these scopes:
 - `chat:write`
 - `files:write`
 - `users:read`
 - `users:read.email`

Tableau Server on Windows Help

7. Select **OAuth & Permissions** from the navigation menu.

Important: Opting in to token rotation for your Tableau Slack app will cause notifications to stop working in Slack. Token rotation can't be removed after it's added.

8. Select **Add New Redirect URL**.
9. Add a fully qualified URL `https://<url>/auth/add_oauth_token`
10. Select **Basic Information** from the navigation menu.
11. Give the Client ID, Client Secret, and Redirect URL to the Tableau server administrator.
12. Add the Tableau app into the Slack workspace by selecting Basic Information from the Settings menu, then **Install**.

Note: Administrators can share their app with other Slack workspaces by activating a distribution option. For more information, see [Manage Distribution](#) in Slack's documentation.

Step 2: Add an OAuth client to the Tableau site

Tableau server administrator:

The Tableau server administrator will add the OAuth client from the Slack workspace administrator, then connect the Tableau site to Slack.

1. Sign in to the site you'd like to connect to Slack. On the Settings page of your site, select the **Integrations** tab.

2. Under Slack Connectivity, select **Add OAuth Client**.
3. Add the **Client ID**, **Client Secret**, and **Redirect URL** from the Slack workspace administrator, then select **Add OAuth Client** in the dialog.
4. The connection type and Client ID will appear in the table.

Step 3: Finalize the connection

When the OAuth client is added under Slack Connectivity:

1. Select **Connect to Slack**.
2. Follow the prompt to sign in to your Slack workspace.
3. Select **Allow** to give your Tableau site access to the Slack workspace.

The Tableau site and Slack workspace are now connected. In the Slack workspace, licensed Tableau users can receive Slack notifications when someone shares Tableau content, when a data-driven alert is triggered, or when someone is @mentioned in a comment on a view or workbook.

Disconnect a Tableau Server site from Slack

You can disconnect a Tableau site from a Slack workspace by selecting **Disconnect from Slack** in the Integrations tab of site settings. Users will continue to receive notifications for some time. The OAuth client information you added in Step 2 is retained and can be used to connect to a new workspace, if needed.

Update your Tableau Slack application

When a new version of the Tableau Slack application is available, Tableau recommends reinstalling the application to maintain app performance and use new features.

To reinstall the Tableau for Slack app, select **Disconnect** from Slack in the Integrations tab of your site settings, then go through the connection steps in Integrate Tableau with a Slack workspace.

Creators: Connect to Data on the Web

Before you can create a new workbook and build a view on the web to analyze your data on the web, you need to connect to your data. Tableau supports connecting to data sources on the web published through Tableau Desktop, or, connecting to data directly through Tableau Online, Tableau Server, or Tableau Public.

Starting in 2019.3, Tableau Catalog is available in the Data Management Add-on to Tableau Server and Tableau Online. When Tableau Catalog is enabled in your environment, in addition to navigating and connecting to data from Explore, you can navigate

Tableau Server on Windows Help

and connect to more kinds of data, like databases and tables, from Tableau Catalog. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Online](#) Help. Starting in 2021.4, the Data Management Add-on includes virtual connections, a central access point to data. For more information, see "About Virtual Connections and Data Policies" in the [Tableau Server](#) or [Tableau Online](#) help.

Note: Data connections created in Tableau Server or Tableau Online are **live connections** only. If you need to use an extract for web authoring, you can publish your data source through Tableau Desktop. To publish through Tableau Desktop, see [Publish Data Sources and Workbooks](#). However, data connections in Tableau Public are extracts only, and there is no way to publish a data source.

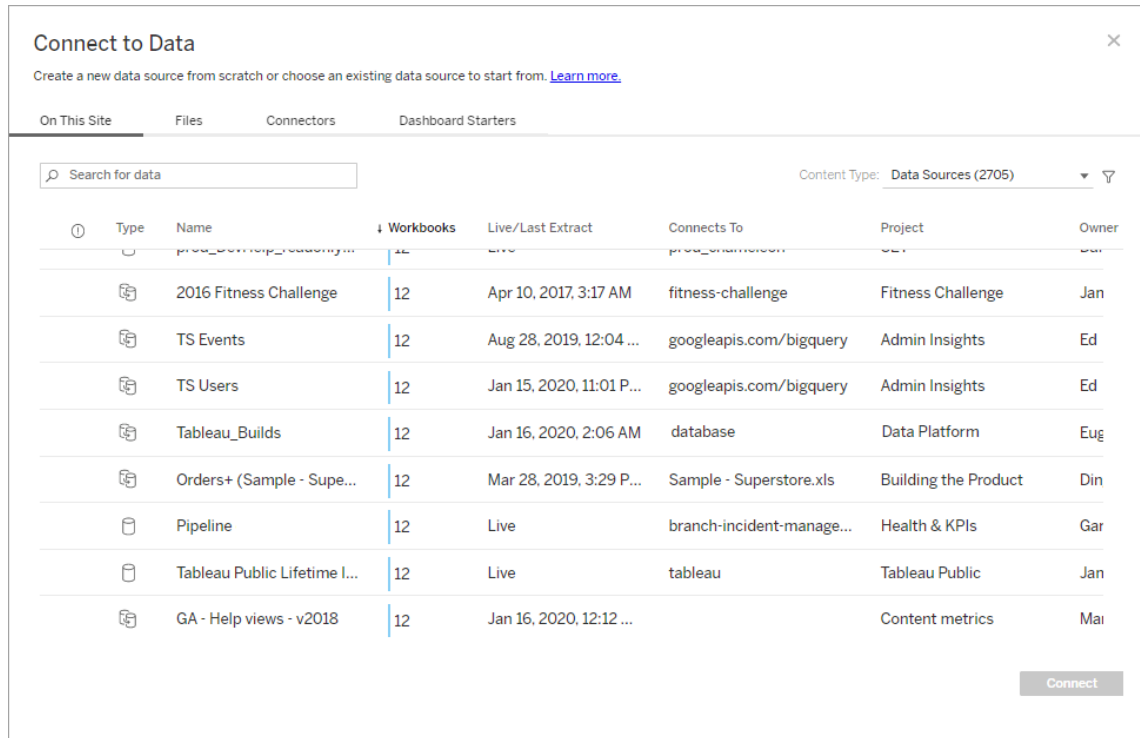

Open the Connect to Data page

On the web, you use the Connect to Data page to access data to connect to. After you sign in to Tableau Server or Tableau Online, you can open this page two ways:

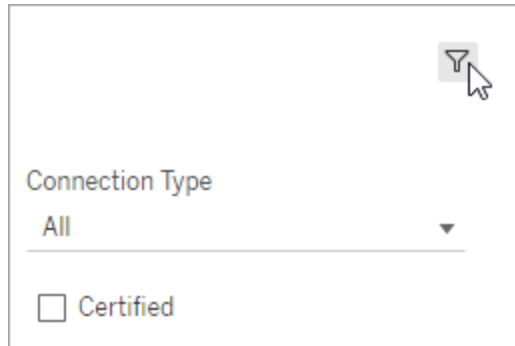

- **Home > New > Workbook**
- **Explore > New > Workbook**

If you're on Tableau Public, you can open this page from your author profile:

- **My Profile > Create a Viz**

Select the filter icon to filter by Connection Type and by Certified.

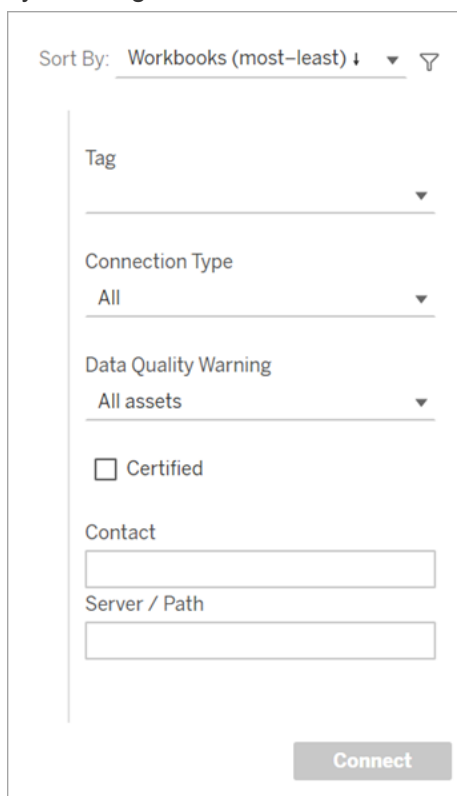

In addition to connecting to data sources, when you have the Data Management Add-on, you can connect to data with a virtual connection. When Tableau Catalog is enabled you can also connect to databases, files, and tables.

- You can select from **Data Sources**, **Virtual Connections**, **Databases and Files**, or **Tables** to search for data.

Tableau Server on Windows Help

- When you select **Databases and Files** or **Tables**, you can filter assets by Data Quality Warning: All assets, Assets without warnings, and Assets with warnings.

A screenshot of the 'Connect' dialog box. At the top, it says 'Sort By: Workbooks (most-least)'. Below that, there are several filter options: 'Tag' (dropdown), 'Connection Type' (dropdown set to 'All'), and 'Data Quality Warning' (dropdown set to 'All assets'). There is also a checkbox for 'Certified'. Below these are two text input fields: 'Contact' and 'Server / Path'. At the bottom right, there is a 'Connect' button.

On the Connect to Data page, the tabs you see depend on the product you have.

Tableau Server

On Tableau Server, select from the following tabs to connect to data: On this site, Files, and Connectors.

Connect to data On this site

1. Select **On this site** to browse to or search for published data sources.
2. Select the data source under **Name** and click the **Connect** button.

Note: In addition to connecting to data sources, when you have the Data Management Add-on, you can use **On this site** to connect to data using a virtual connection. When Tableau Catalog is enabled you can also connect to databases, files, and tables.

Connect to files

Tableau supports uploading Excel, text-based data sources (.xlsx, .csv, .tsv), and spatial file formats that only require one file (.kml, .geojson, .topojson, .json, and Esri shapefiles and Esri File Geodatabases packaged in a .zip) directly in your browser. In the **Files** tab of the **Connect to Data** window, connect to a file by dragging and dropping it into the field or clicking **Upload from Computer**.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database or on a server in your enterprise. You need to supply connection information for each data connection that you make. For example, for most data connections, you need to supply a server name and your sign-in information.

[Supported Connectors](#) has information on how to connect Tableau to each of these connector types to set up your data source. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Online or Tableau Server for web authoring. Learn more about how to [Publish a Data Source](#) in Tableau Desktop.

Tableau Server on Windows Help

When Tableau successfully connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see [Creators: Prepare Data on the Web](#).

*Not available on Linux servers.

**Google BigQuery requires OAuth when creating data sources from the web. Learn more about how server administrators can [Set up OAuth for Google](#).

***Teradata web authoring currently does not support query banding functionality. See [Teradata](#) for details.

‡Supports virtual connections if you have the Data Management Add-On. See [About Virtual Connections and Data Policies](#) in the Tableau Server help for details.

Tableau Catalog Supported Connectors

Tableau Catalog supports making a connection with a subset of the data connectors that Tableau Server supports. If a data source, database, file, or table is grayed out, you can't connect from Tableau Server. You can, however, connect from the Tableau Desktop **Connect** pane, if you have the correct permissions.

Tableau Online

On Tableau Online, select from the following tabs to connect to data: On this site, Files, Connectors, and Dashboard Starters.

Connect to data On this site

1. Select **On this site** to browse to or search for published data sources.
2. Select the data source under **Name** and click the **Connect** button

Note: In addition to connecting to data sources, when you have the Data Management Add-on, you can use **On this site** to connect to data using a virtual connection. When Tableau Catalog is enabled you can also connect to databases, files, and tables.

Connect to files

Tableau supports uploading Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser. In the **Files** tab of the Connect to Data window, connect to an Excel or text file by dragging and dropping it into the field or clicking **Upload from Computer**.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database or on a server in your enterprise. You need to supply connection information for each data connection that you make. For example, for most data connections, you need to supply a server name and your sign-in information.

[Supported Connectors](#) has information on how to connect Tableau to your data using connectors. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and publish your data source to Tableau Online or Tableau Server for web authoring. Learn more about how to [Publish a Data Source](#) in Tableau Desktop.

Note: If you're unable to connect to your data from Tableau Online, check to see if the database is publicly accessible. Tableau Online can only connect to data that's accessible from the public internet. If your data is behind a private network, you can connect using Tableau Bridge. To learn more, see [Publishers: Use Tableau Bridge to Keep Tableau Online Data Fresh](#).

Tableau Online Connectors

**Teradata web authoring currently does not support query banding functionality. See [Teradata](#) for details.

‡Supports virtual connections if you have the Data Management Add-On. See [About Virtual Connections and Data Policies](#) in the Tableau Online help for details.

Tableau Server on Windows Help

Tableau Catalog Supported Connectors

Tableau Catalog supports making a connection with a subset of data connectors that Tableau Online supports. If a data source, database, file, or table is grayed out, you can't connect from Tableau Online. You can, however, connect from the Tableau Desktop **Connect** pane, if you have the correct permissions.

Use Dashboard Starters

On Tableau Online, you can author and analyze data from LinkedIn Sales Navigator, Oracle Eloqua, Salesforce, ServiceNow ITSM, and QuickBooks Online using Dashboard Starters. On the **Dashboard Starter** tab, from the list of pre-built designs, select an option and click **Use Dashboard**. See [Dashboard Starters for Cloud-based Data Sources](#) for details.

Tableau Public

On Tableau Public, you can connect to data by uploading a supported file.

Connect to files

Tableau supports uploading Excel or text-based data sources (.xlsx, .csv, .tsv) directly in your browser. In the **Files** tab of the Connect to Data window, connect to an Excel or text file by dragging and dropping it into the field or clicking **Upload from Computer**. If you don't have a data set, check out the free [sample data sets](#) on the Tableau Public website.

Use connectors

From the **Connectors** tab, you can connect to data housed in a cloud database. You need to supply connection information for each data connection that you make. For example, for most data connections, you need to supply your sign-in information.

[Supported Connectors](#) has information on how to connect Tableau to your data using connectors. If the connector you need doesn't appear in the Connectors tab, you can connect to data through Tableau Desktop and create an extract.

Note: If you're unable to connect to your data from Tableau Public, check to see if the database is publicly accessible. Tableau Public can only connect to data that's accessible from the public internet.

Tableau Public Connectors

Google Drive

OData

After you connect

When Tableau connects to your data, the Data Source page opens so that you can prepare the data for analysis and begin building your view. To learn more, see [Creators: Prepare Data on the Web](#).

Keep data fresh in web authoring

Update uploaded files in Tableau Online or Tableau Server: If you manually upload a file (Excel or text) for web authoring, Tableau can't refresh the file automatically. To update your data, select "Edit Connection" to upload a new version of the file.

In Tableau Public, go to your viz and click **Request Update**. You can also keep your data fresh automatically by selecting "Keep this data in sync" in Tableau Desktop Public Edition.

Update file-based published data sources in Tableau Online: If you have a published data source in Tableau Online (published through Tableau Desktop) that uses file-based data, you can keep it fresh using Tableau Bridge. For more information, see [Expand Data Freshness Options by Using Tableau Bridge](#).

Run Initial SQL

Note: Tableau Prep Builder version 2019.2.2 and later supports using Initial SQL, but doesn't yet support all of the same options supported by Tableau Desktop. For information

Tableau Server on Windows Help

about using Initial SQL with Tableau Prep Builder, see [Use Initial SQL to query your connections](#) in the Tableau Prep Builder online help.

When connecting to some databases, you can specify an initial SQL command that will run when a connection is made to the database, for example, when you open the workbook, refresh an extract, sign in to Tableau Server, or publish to Tableau Server. Initial SQL is not run when you refresh your view. Note that this initial SQL is different than a custom SQL connection. A custom SQL connection defines a relation (or table) to issue queries against. For more information, see [Connect to a Custom SQL Query](#).

You can use this command to:

- Set up temporary tables to use during the session.
- Set up a custom data environment.

You have the option to add an initial SQL command in the Server Connection dialog box or on the Data Source page.

Note: If your data source supports running an initial SQL statement, an **Initial SQL** link appears in the lower-left corner of the Server Connection dialog box. For information about your data source, see [Supported Connectors](#).

To use initial SQL

1. In the Server Connection dialog box, click **Initial SQL**. Or, on the Data Source page, select **Data > Initial SQL** or **Data > Query Banding and Initial SQL** depending on the database you connect to.
2. Enter the SQL command into the Initial SQL dialog box. You can use the **Insert** drop-

down menu to pass parameters to your data source.

Note: Tableau does not examine the statement for errors. This SQL statement is simply sent to the database when you connect.

Your software license may restrict you from using initial SQL with your connection. If you publish to Tableau Server, the server must be configured to allow Initial SQL statements. By default, the server software is configured to allow these statements to run when the workbook is loaded in a web browser.

Administrators can configure server to ignore initial SQL statements by using the `tsm configuration set` command:

```
tsm configuration set -k vizqlserver.initialsql.disabled -v true
```

If the server doesn't allow initial SQL statements, the workbook opens, but the initial SQL commands are not sent.

For more information about the `tsm configuration set` command, see the [Tableau Server Help](#).

Parameters in an initial SQL statement

You can pass parameters to your data source in an initial SQL statement. There are several reasons why this is useful:

- You can configure impersonation using the **TableauServerUser** or **Tableau-ServerUserFull** parameters.
- If your data source supports it, you can set up row-level security (for example, for Oracle VPD or SAP Sybase ASE) to make sure that users see only the data that they are authorized to see.
- You can provide more details in logging, for example, the Tableau version or the workbook name.

The following parameters are supported in an initial SQL statement:

Parameter	Description	Example of returned value
TableauServerUser	The user name of the current server user. Use when setting up impersonation on the server. Returns an empty string if the user is not signed in to Tableau Server.	jsmith
TableauServerUserFull	The user name and domain of the current server user. Use when setting up impersonation on the server. Returns an empty string if the user is not signed in to Tableau Server.	domain.lan\jsmith
TableauApp	The name of the Tableau application.	Tableau Desktop Professional Tableau Server
TableauVersion	The version of the Tableau application.	9.3

WorkbookName

The name of the Tableau workbook. Use only in workbooks with an embedded data source.

Financial-Ana-
lysis

Examples

The following examples show different ways you can use parameters in an initial SQL statement.

- This example sets the security context on Microsoft SQL Server:

```
EXECUTE AS USER = [TableauServerUser] WITH NO REVERT;
```

- This example shows how, on a DataStax data source, you can use parameters to add detail to logging or to set up a session variable to keep track of the data:

```
SET TABLEAUVERSION [TableauVersion];
```

- This example can be used to help set up row-level security for Oracle VPD:

```
begin
```

```
  DBMS_SESSION.SET_IDENTIFIER([TableauServerUser]);
```

```
end;
```

Note: Oracle PL/SQL blocks require a trailing semicolon to terminate the block. Consult Oracle documentation for the proper syntax.

Defer execution to the server

You can defer an initial SQL statement so that it is executed only on the server. One reason to defer execution to the server is if you don't have permission to execute the commands that set up impersonation. Use `<ServerOnly></ServerOnly>` tags to enclose the commands to be executed only on the server.

Example:

Tableau Server on Windows Help

```
CREATE TEMP TABLE TempTable(x varchar(25));
INSERT INTO TempTable VALUES (1);
<ServerOnly>INSERT INTO TempTable Values(2);</ServerOnly>
```

Security and impersonation

If you use the **TableauServerUser** or **TableauServerUserFull** parameter in an initial SQL statement, you will create a dedicated connection that can't be shared with other users. This will also restrict cache sharing, which can enhance security, but may also slow performance.

Troubleshoot 'create table' for MySQL and Oracle connections

For MySQL connections, tables are not listed after using initial SQL to create table

When you connect to MySQL, if you run an initial SQL statement like the following, tables might not show because of the way Tableau constructs the query:

```
CREATE TABLE TestV1.testtable77(testID int);
```

To resolve this issue, add `IF NOT EXISTS` to the SQL statement:

```
CREATE TABLE IF NOT EXISTS TestV1.TestTable(testID int);
```

For Oracle connections, using initial SQL to create table causes Tableau to stall

When you connect to Oracle and run an initial SQL statement like the following, Tableau is stalled with a spinning wheel because of the way Tableau constructs the query:

```
CREATE TABLE TEST_TABLE (TESTid int)
```

To resolve this issue, use the following SQL statement:

```
BEGIN
EXECUTE IMMEDIATE 'create table test_table(testID int)';
EXCEPTION
WHEN OTHERS THEN NULL;
END;
```

Create and Interact with Flows on the Web

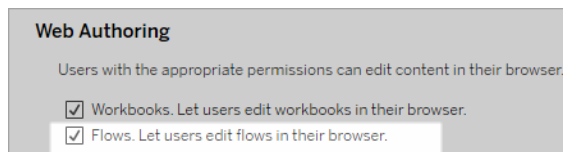

Starting in version 2020.4, you can create and interact with flows on Tableau Server to clean and prepare your data. Connect to your data, build a new flow, or edit an existing flow and your work is automatically saved every few seconds as you go. Create draft flows that are only available to you or publish your flow to make it available for others. Run your individual flows right from the web or run your flows automatically on a schedule using Tableau Prep Conductor if you have the Data Management Add-on. For more information, see [Tableau Prep on the Web](#).

For more information about configuring the Tableau Prep Flow Authoring process on Tableau Server, see [Tableau Prep Flow Authoring](#).

Complete the tasks described in this article to enable web authoring for flows and other flow features on the web.

Turn flow web authoring on or off for a site

1. In a web browser, sign in to the server as an administrator and go to the site in which you want web authoring to be enabled. In that site, click **Settings**.
2. In the **Web Authoring** section, select **Flows. Let users edit flows in their browser.** to enable the functionality.

Clear the check box to turn off web authoring for that site.

3. If you want the change to take effect immediately, restart the server. Otherwise, the change takes effect after server session caching expires or the next time users sign in after signing out.

Enable linked tasks

Supported in Tableau Online and Tableau Server version 2021.3.0 and later.

Enable administrators to configure schedules to be used to run linked tasks. With this option users can schedule up to 20 flows to run one after the other. For more information about linked tasks, see [Schedule linked tasks](#).

If you have multiple sites, you can turn off **Linked Tasks** for individual sites, but the option must first be enabled at the **Server Settings** level. If the setting is turned off after linked tasks are scheduled, any tasks that are running will complete and the scheduled linked tasks are hidden and no longer show on the **Scheduled Tasks** tab.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable **Linked Tasks** for flows. In that site, click **Settings**.
2. In the **Linked Tasks** section, select **Let users schedule linked tasks** to enable administrators to configure schedules to run linked tasks.
3. Select **Let users run linked tasks manually using Run Now** to enable users to run linked flow tasks using **Run Now**.

Enable flow parameters

Enable users to schedule and run flows that include parameters. Parameters enable users to scale their flows by building them once, then changing the parameter values to accommodate different data scenarios.

Parameters can be entered in an input step for file name and path, table name, or when using custom SQL queries, in an output step for file name and path and table name, and in any step type for filters or calculated values.

Flow parameter settings can be applied at the server level to include all sites on Tableau Server. The settings can be disabled at the site level to include only specific sites.

For more information about using parameters in flows, see [Create and Use Parameters in Flows](#) in the Tableau Prep help.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable **Flow Parameters**. In that site, click **Settings**.
2. In the **Flow Parameters** section, select **Let users run and schedule flows that use parameters** to enable the functionality.
3. Select **Allow parameters that can accept any input** to enable anyone running the flow to enter any parameter value in the flow at run time.

Important: Setting this option enables any flow user to enter any value in a parameter, potentially exposing data that the user should not have access to.

If this option is not selected, users can only select from predefined list of parameter values and any flows that include parameters that accept any value cannot be run or scheduled to run.

Flow Parameters

This setting allows flows that include parameters to be scheduled and run on the site, and enables anyone running the flow to set flow parameters at run time or when scheduling a task. [Learn more](#)

Let users run and schedule flows that use parameters

Allow parameters that can accept any input. This can impact security. [Learn more](#)

Enable Tableau Prep Conductor

If the Data Management Add-on is enabled, enable this option to let users schedule and track flows in Tableau Server and Tableau Online. For information about the additional configuration requirements for Tableau Prep Conductor, see [Tableau Prep Conductor](#).

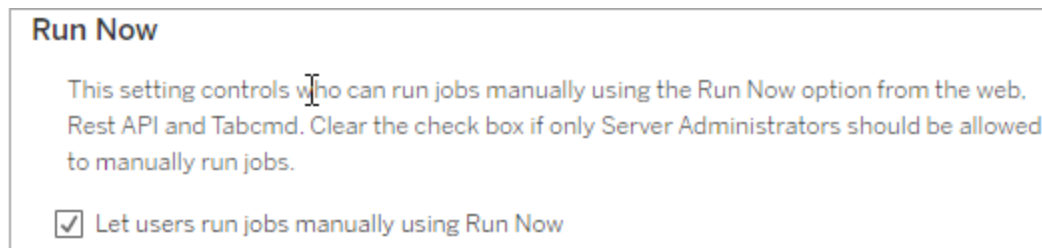

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Tableau Prep Conductor. In that site, click **Settings**.
2. In the **Tableau Prep Conductor** section, select **Let users schedule and monitor flows** to enable the functionality.

Enable Run Now

Control whether users or only administrators can run flows manually using the **Run Now** option. The Data Management Add-on is not required to run flows manually.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Run Now for flows. In that site, click **Settings**.
2. In the **Run Now** section, select **Let users run jobs manually using Run Now** to enable the functionality.

Clear the check box if only Server Administrators can run flows manually.

Flow Subscriptions

Control whether users can receive flows notifications about scheduled tasks for successful flow runs. The Data Management Add-on is required to enable notifications.

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable flow subscriptions. In that site, click **Settings**.
2. In the **Flow Subscriptions** section, select **Let users send or receive emails that include flow output data** to enable the functionality.

Flow Subscriptions

Flow owners can schedule and send emails with flow output data to themselves and others. [Learn more](#)

Let users send or receive emails that include flow output data

Attach .csv and .xlsx flow output files. This option sends data outside of Tableau and is not recommended

Note: The option to attach either a .csv or .xlsx file type to the email is only available for on-premise environments.

Enable Tableau Prep Conductor

If the Data Management Add-on is enabled, enable this option to let users schedule and track flows in Tableau Server and Tableau Online. For information about the additional configuration requirements for Tableau Prep Conductor, see [Tableau Prep Conductor](#).

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Tableau Prep Conductor. In that site, click **Settings**.
2. In the **Tableau Prep Conductor** section, select **Let users schedule and monitor**

flows to enable the functionality.

Enable Tableau Prep Extensions

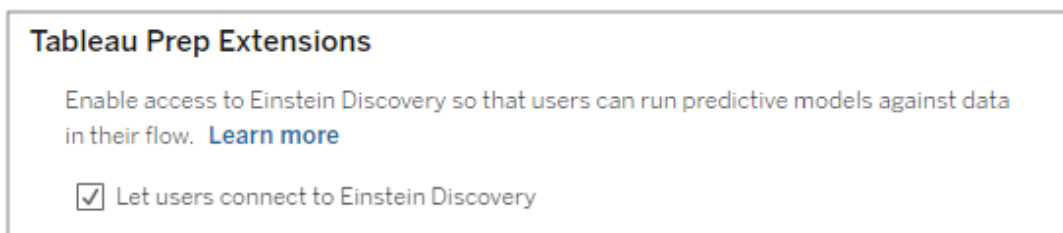

Supported in Tableau Server and Tableau Online starting in version 2021.2.0

Set this option to control whether users can connect to Einstein Discovery to run predictive models against data in their flow.

You can use Einstein Discovery-powered models to bulk score predictions for the data in your flow when authoring flows on the web. Predictions can help you make better informed decisions and take actions to improve your business outcomes.

You'll need to configure additional settings to include predictions in our flow. For more information, see [Add Einstein Discovery Predictions to your flow](#) and [Configure Einstein Discovery Integration](#).

1. In a web browser, sign in to the server as an administrator and go to the site in which you want to enable Tableau Prep Extensions. In that site, click **Settings > Extensions**.
2. In the **Tableau Prep Extensions** section, select **Let users connect to Einstein Discovery** to enable the functionality.

Turn autosave off or on

Enabled by default, this feature automatically saves a user's flow work every few seconds.

While not recommended, administrators can disable autosave on a site using the Tableau Server REST API method "Update Site" and `flowAutoSaveEnabled` setting. For more information, see [Tableau Server REST API Site Methods: Update Site](#). For more information about autosave on the web, see Turn autosave off or on.

For more information about configuring site settings, see [Site Settings Reference](#) in the Tableau Server help.

Tableau Prep on the Web

Internet Explorer 11 on Windows and compatibility mode for Internet Explorer is not supported.

Starting in version 2020.4, Tableau Prep supports web authoring for flows. Now you can create flows to clean and prepare your data using Tableau Prep Builder, Tableau Server, or Tableau Online. You can also manually run flows on the web and the Data Management is not required.

While most of the same Tableau Prep Builder functionality is also supported on the web, there are a few differences when creating and working with your flows.

Important: To create and edit flows on the web you must have a Creator license. The Data Management add-on is only required if you want to run your flows on a schedule using Tableau Prep Conductor. For more information about configuring and using Tableau Prep Conductor, see Tableau Prep Conductor in the [Tableau Server](#) or [Tableau Online](#) help.

Installation and Deployment

To enable users to create and edit flows on the web, you'll need to configure several settings on your server. For more information about each of these settings, see [Create and Interact with Flows on the Web](#).

Tableau Server on Windows Help

- **Web Authoring:** Controls whether users can create and edit flows on Tableau Server or Tableau Online.
- **Run Now:** Controls whether users or only administrators can run flows manually using the **Run Now** option. The Data Management isn't required to run flows manually on the web.
- **Tableau Prep Conductor:** If the Data Management Add-on is enabled, enable this option to let users schedule and track flows.
- **Tableau Prep Extensions** (version 2021.2.0 and later): Controls whether users can connect to Einstein Discovery to apply and run predictive models against data in their flow.
- **Autosave:** Enabled by default, this feature automatically saves a user's flow work every few seconds.

On Tableau Server, administrators can fine-tune the configuration of the Tableau Prep Flow Authoring processes. For more information, see [Tableau Prep Flow Authoring](#).

Sample data and processing limits

To maintain performance while working with flows on the web, limits are applied to the amount of data you can include in a flow.

The following limits apply:

- When connecting to files, the maximum file size is 1GB.
- The data sampling option to include all data is not available. The default sample data limit is 1 million rows.
- The maximum number of rows that a user can select when using large data sets is configured by the administrator. As a user, you can select the number of rows up to that limit. For more information, see [tsm configuration set Options](#).

Available features on the web

When you create and edit flows on the web you may notice a few differences in navigation and the availability of certain features. While most features are available across all platforms, some features are limited or not yet supported in Tableau Server or Tableau Online. The following table identifies features where differences might apply.

Feature area	Tableau Prep	Tableau	Tableau
--------------	--------------	---------	---------

	Builder	Server	Online
Connect to Data*	✓	✓	✓
Build and Organize your Flow	✓	✓	✓
Set your data sample size**	✓	✓	✓
Union files and database tables in the input step***	✓	✓	✓
Clean and Shape Data	✓	✓	✓
Aggregate, Join, or Union Data	✓	✓	✓
Use R and Python Scripts in your Flow****	✓	✓	✗
Create reusable flow steps	✓	✗	✗
Automatically save your flows on the web	Not Applicable	✓	✓
Automatic file recovery	✓	Not Applicable	Not Applicable
View flow output in Tableau Desktop	✓	✗	✗
Create an extract to a file	✓	✗	✗
Create an extract to a Microsoft Excel worksheet	✓	✗	✗
Create a published data source	✓	✓	✓
Save flow output to external databases	✓	✓	✓
Add Einstein Discovery Predictions to your Flow	✓	✓	✓

Tableau Server on Windows Help

* Some connectors may not be supported on the web. Open the Connect pane on your server to see supported connectors.

** In Tableau Server and Tableau Online, the data sample size is subject to limits set by your administrator.

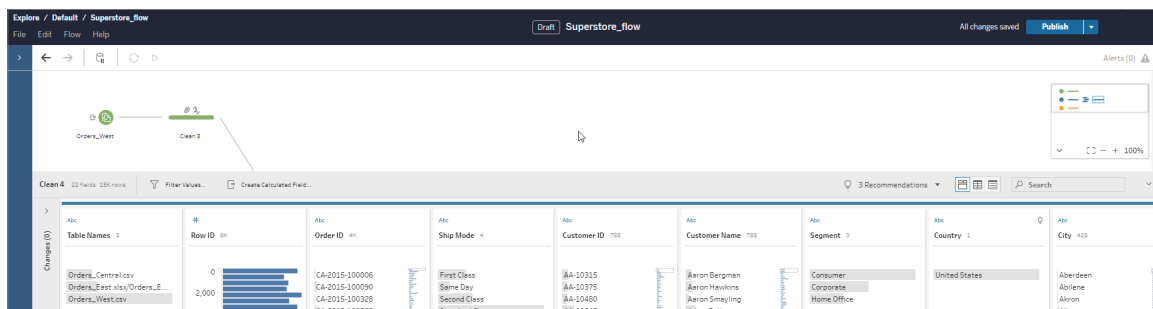

*** Input unions can't be edited or created in Tableau Server or Tableau Online. Only in Tableau Prep Builder.

**** Script steps can't be added when creating or editing a flow in Tableau Online. This is currently supported only in Tableau Prep builder and Tableau Server.

Autosave and working with drafts

When you create or edit flows on the server, your work is automatically saved as a draft every few seconds so that in the event of a crash, or when closing a tab by accident, you don't lose your work.

Drafts are saved to the server and project you are signed into. You can't save or publish a draft to another server, but you can save the flow to another project on that server using the **File > Publish As** menu option.

Draft content can only be seen by you until you publish it. If you publish changes and need to revert them, you can use the **Revision History** dialog to view and revert to a previously published version. For more information about saving flows on the web, see [Automatically save your flows on the web](#).

Publishing flows on the web

Whether you create a flow from scratch on the web or edit an existing flow, before you can run the flow you'll need to publish it.

- You can only publish draft flows to the same server you are signed into.
- You can publish a draft to a different project using the **File** menu and selecting **Publish As**.
- You can embed credentials for your flow's database connections to enable the flow to run without having to manually enter the credentials when the flow runs.

Embed credentials

Embedding credentials only applies to running flows on your server. Currently, you will manually need to enter your credentials when editing a flow connected to a database.

Embedding credentials can only be set at the flow level and not at the server or site level.

Do one of the following:

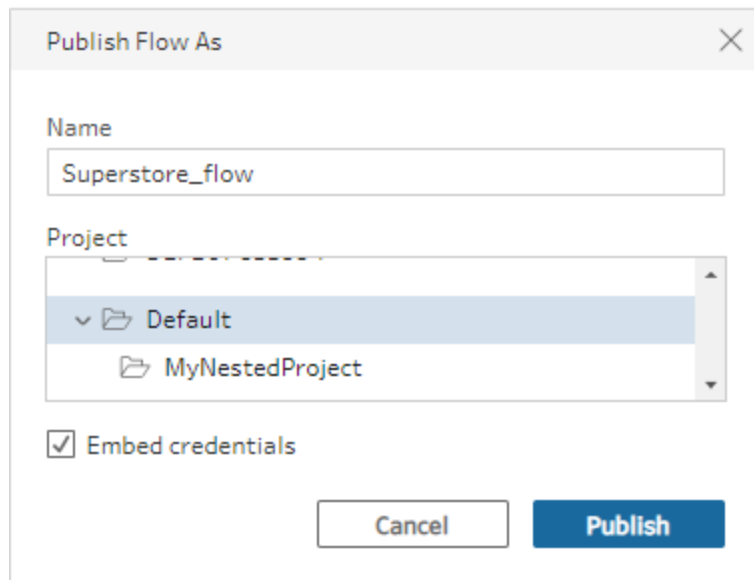

- From the top menu, select **File > Connection Credentials > Embed in Published Flow**.

- When publishing a flow, select the **Embed credentials** check box. This option

Tableau Server on Windows Help

shows when you select **Publish As** to publish the flow to a new project for the first time or when you are editing a flow that was last published by someone else.

Publish a flow

When you publish your flow, it becomes the current version of the flow and can be run and seen by others who have access to your project. Flows that are never published or flow changes that you make to a draft can only be seen by you until you publish the flow. For more information about flow statuses, see [Automatically save your flows on the web](#).

To publish your flow, do one of the following:

- From the top menu, select **File > Publish** or **File > Publish As**

- From the top bar, click the **Publish** button or click the drop arrow to select **Publish As**.

Who can do this

- Server Administrator, Site Administrator Creator, and Creator allow full connecting and publishing access.
- Creator can perform web authoring tasks.
- Explorer (can publish) and Site Administrator Explorer have limited publishing capabilities. For more information, see:
 - Windows: [General capabilities allowed with each site role](#)
 - Linux: [General capabilities allowed with each site role](#)

Create, Interact with, and Embed Views on the Web

You can create and interact with views on Tableau Server. For more information, see the following topics in the Tableau Help for users.

[Using Tableau on the Web](#)

[Tour your Tableau Site](#)

[Edit Views on the Web](#)

[Join your Data](#)

[Create a Dashboard](#)

[Create a Story](#)

[Embed Views and Dashboards in Web Pages](#)

[Make Workbooks Compatible Between Versions](#)

Alerts and subscriptions

[Troubleshoot Subscriptions](#)

[Send Data-Driven Alerts from Tableau Online or Tableau Server](#)

Manage Saved Credentials for Data Connections

Saved credentials enable you to connect to a data source without being prompted for your credentials. The credentials saved for your connection can be OAuth access tokens, or other credentials, such as user name and password.

On Tableau Server, if your server administrator has allowed you to save credentials, you can find and manage them in the **Saved Credentials** section on your Account Settings page.

Note: If you do not see the Saved Credentials section, consult with your server administrator about allowing saving credentials.

Remove saved credentials

To remove Tableau access to data, delete the associated saved credentials for that data from your account.

After you delete the credentials, you will need to sign in to the data the next time you access it. This will create new saved credentials.

Your administrator might choose for all users to use the same shared credentials for connecting to a data source. If this is the case, the saved credential is associated with the data connection for all users, and it does not appear under Saved Credentials on your Account Settings page.

Note: If you're a Tableau Server user and can't delete saved credentials, ask your administrator if they've cleared the **Allow users to save data source access tokens** option in the server settings.

Test connections using saved credentials

If the connector supports test functionality, you can test the connection using saved credentials.

1. While you're signed in to Tableau Server or Tableau Online, display your Account Settings page.
2. In the Saved Credentials section, click the **Test** link next to the stored connection that you want to test.

This test confirms that Tableau Online or Tableau Server can access your account using this corresponding saved credential. If the test succeeds, but you cannot access your data

Tableau Server on Windows Help

through this managed connection, confirm that the credentials you provided for this connection can access your data.

For example, if you accidentally created the connection using your personal Gmail account, but you use a different account to access a Google Analytics database, you will need to delete the saved credentials and sign in to the data using the appropriate Gmail account.

Update saved credentials

To help ensure uninterrupted data access from existing Tableau content after a custom OAuth client has been configured for your site, we encourage you to update your saved credentials. To update saved credentials, you can delete the previous saved credentials for a particular connector and then add it again.

When you add saved credentials again, both new and existing Tableau content will access the data using the custom OAuth client configured by your server administrator. For more information about custom OAuth clients, see FAYE.

1. Sign in to Tableau Server and navigate to your **My Account Settings** page.
2. Under **Saved Credentials for Data Sources**, do the following:
 1. Click **Delete** next to the saved credentials for a connector.
 2. Next to the same connector, click **Add** and follow the prompts to 1) connect to the custom OAuth client that your site admin notified you about and 2) save the latest credentials.

Clear all saved credentials

When you select **Clear All Saved Credentials**, the following items are removed from your user account:

- All saved credentials for connections that are stored in your account.

Caution: If any of these saved credentials are stored with published workbooks or data sources, deleting them also removes access to the data source from those locations. Effectively, this is like "changing the locks" anywhere the affected saved credentials are used.

- Passwords you have used to access published data extracts or workbooks that connect to them.

Create and Edit Private Content in Personal Space

Personal Space is a private location for all Explorers and Creators to save or edit when working in a Tableau Site. Content saved in Personal Space can't be shared with other users, but can be moved to a project when you're ready for others to see it. Within Personal Space, you can create a new workbook or save a workbook to Personal Space as a separate copy. You can also move existing content you own into Personal Space for editing, then move back to a project later. Explorers can download workbooks in Personal Space, including all data included in the workbook.

Privacy in Personal Space

Content saved to your personal space is only visible to you and site administrators. Site administrators can't directly access any user's Personal Space or edit content in someone else's Personal Space, but they can view and manage Personal Space workbooks. Personal Space workbooks appear in administrator search results and as a workbook location on the Explore page. In addition, the permissions menu is unavailable when a workbook is in Personal Space because the workbook is private.

Tableau Server on Windows Help

Tableau Catalog and Personal Space

Starting in 2019.3, Tableau Catalog is available in the Data Management Add-on to Tableau Server and Tableau Online. For more information, see "About Tableau Catalog" in the Tableau Server or Tableau Online Help.

When Tableau Catalog is enabled in your work environment, the information about workbooks you save in your personal space is indexed by Catalog. These workbooks are included in lineage counts, however, only you can see the workbooks. Furthermore, users who browse through the lineage tool see Permissions required instead of information about workbooks in your personal space.

Collaboration tools

When a workbook is in Personal Space, some functionality is disabled, including share, metrics, comments, alerts, and subscriptions. Existing alerts and subscriptions to you will continue running, but alerts and subscriptions to others will fail, since the content is now private. Metrics can't be created in Personal Space, but will continue to work if a connected workbook is moved there.

These limitations are removed when the workbook is moved or saved to another location. For example, if a workbook contains comments and moves to Personal Space, existing comments are hidden. Comments restore when the workbook is moved to another location.

Extract refreshes in Personal Space

To limit resource consumption, existing extract refreshes continue to run if they've been scheduled, but new extract refreshes can't be scheduled while a workbook is in Personal Space.

Find content in Personal Space

You can access Personal Space from the left navigation menu to see all your Personal Space content or create a new workbook, and can save to Personal Space when creating or

editing a workbook anywhere on the site.

You can also see workbooks in Personal Space from the Explore page when All Workbooks is selected, and can filter down to Personal Space content.

Save a workbook to Personal Space

Personal Space works much like a private project for you to save a new or existing workbook from Tableau Online or Tableau Server. Workbooks can't be published directly to Personal Space from Tableau Desktop.

To save a workbook to Personal Space:

Select **File > Save As**.

Under Location, select **Personal Space**.

Note: Explorers can only save workbooks to Personal Space, and may not see a location selection dialog.

Move workbooks to Personal Space

You can move an existing workbook to Personal Space if you are the owner of the workbook and there is room in your Personal Space. Personal Space storage limits are set by administrators.

To move a workbook to Personal Space:

- Select a workbook, then click the Actions drop-down menu.
- Select **Move**
- Under Location, Select **Personal Space**.

Note: Explorers can only save workbooks to Personal Space, and may not see the **Move** action or location selection dialog.

For more information, see [Perform actions](#) in the Manage Web Content help topic.

When you move an existing workbook or data source to Personal Space, tools like share, alerts, and subscriptions become hidden. Existing extract refreshes continue to run if they've been scheduled, but users can't schedule new extract refreshes within their Personal Space.

Existing subscriptions and alerts also continue, but can't be edited from Personal Space and will fail if other users are recipients. Existing connected metrics will continue to refresh, but the connected view will not be visible to other users.

Move workbooks from Personal Space

When you move a workbook out of Personal Space, collaboration tools like share, alerts, and subscriptions become visible, and any existing comments reappear.

Use Relationships for Multi-table Data Analysis

Tables that you drag into this canvas use relationships. Relationships are a flexible way to combine data for multi-table analysis in Tableau.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to](#). Learn more about the basics of creating relationships in this 5-minute video.

Note: The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

Learn more about how relationships work in these Tableau blog posts:

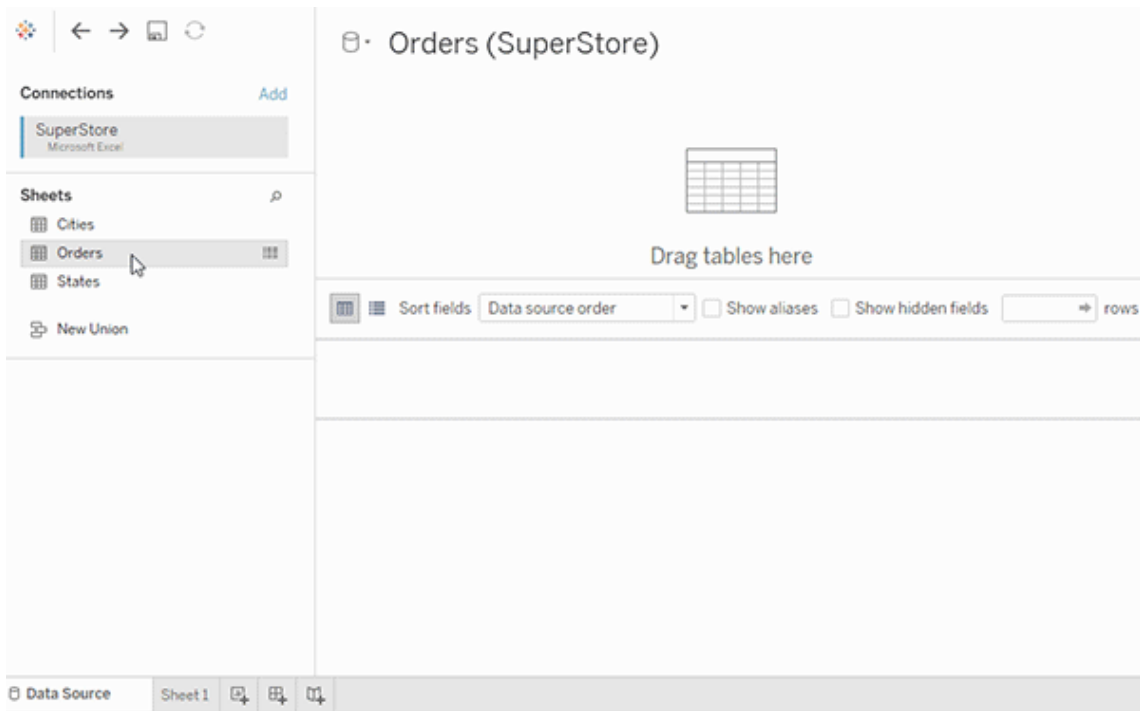

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

Are you building a new data source and workbook?

Drag a table to the Data Source page canvas to start building your data source.

A data source can be made of a single table that contains all of the dimension and measure fields you need for analysis...

Or, you can create a multi-table data source by dragging out more tables and defining their relationships...

Tableau Server on Windows Help

Watch this 1-minute video about getting started with using relationships.

Note: The interface for editing relationships shown in this video differs slightly from the current release but has the same functionality.

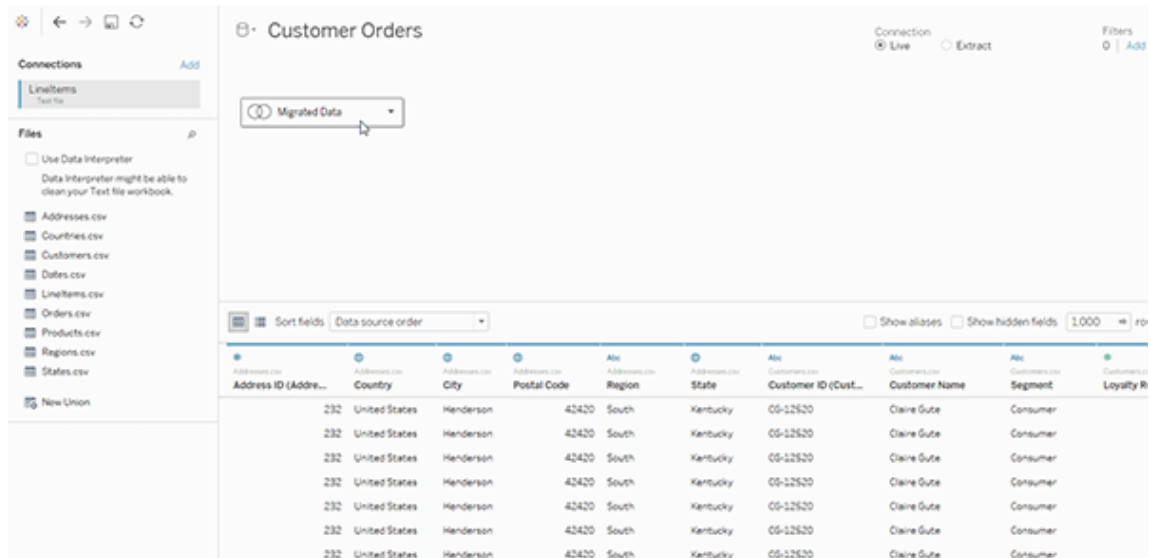

For more information about using relationships, see [Relate Your Data](#), [How Relationships Differ from Joins](#), [The Tableau Data Model](#), and [Create and define relationships](#).

For more information on changes to data sources and analysis in Tableau 2020.2, see [What's Changed with Data Sources and Analysis in 2020.2](#) and [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#).

Are you opening an older workbook or data source?

When you open a pre-2020.2 workbook or data source in 2020.2, your data source will

appear as a single logical table in the canvas, with the name "Migrated Data" or the original table name. Your data is preserved and you can continue to use the workbook as you did before.

To see the physical tables that make up the single logical table, double-click that logical table to open it in the physical layer. You will see its underlying physical tables, including joins and unions.

For more information on changes to data sources and analysis in Tableau 2020.2, see [What's Changed with Data Sources and Analysis in 2020.2](#) and [Questions about Relationships, the Data Model, and Data Sources in 2020.2](#).

The Tableau Data Model

Every data source that you create in Tableau has a data model. You can think of a data model as a diagram that tells Tableau how it should query data in the connected database tables.

The tables that you add to the canvas in the **Data Source** page create the structure of the data model. A data model can be simple, such as a single table. Or it can be more complex, with multiple tables that use different combinations of relationships, joins, and unions.

The data model has two layers:

- The default view that you first see in the Data Source page canvas is the *logical layer* of the data source. You combine data in the logical layer using relationships (or noodles). Think of this layer as the Relationships canvas in the Data Source page. For more information, see [Use Relationships for Multi-table Data Analysis](#).
- The next layer is the *physical layer*. You combine data between tables at the physical layer using joins and unions. Each logical table contains at least one physical table in this layer. Think of the physical layer as the Join/Union canvas in the Data Source page. Double-click a logical table to view or add joins and unions.

Logical Layer

Noodles = Relationships

Physical Layer

Venn diagram = Joins

The top-level view of a data source with multiple, related tables. This is the logical layer. Logical tables can be combined using relationships (noodles). They don't use join types. They act like containers for physical tables.

Double-click a logical table to open it and see its physical tables. Physical tables can be combined using joins or unions. In this example, the Book logical table is made of three, joined physical tables (Book, Award, Info).

Logical Layer	Physical Layer
Relationships canvas in the Data Source page	Join/Union canvas in the Data Source page
Tables that you drag here are called logical tables	Tables that you drag here are called physical tables
Logical tables can be related to other logical tables	Physical tables can be joined or unioned to other physical tables
Logical tables are like containers for physical tables	Double-click a logical table to see its physical tables
Level of detail is at the row level of the logical table	Level of detail is at the row level of merged physical tables
Logical tables remain distinct (normalized), not merged in the data source	Physical tables are merged into a single, flat table that defines the logical table

Layers of the data model

The top-level view that you see of a data source is the **logical layer** of the data model. You can also think of it as the Relationships canvas, because you combine tables here using relationships instead of joins.

When you combine data from multiple tables, each table that you drag to the canvas in the logical layer must have a relationship to another table. You do not need to specify join types for relationships; during analysis Tableau automatically selects the appropriate join types based on the fields and context of analysis in the worksheet.

The **physical layer** of the data model is where you can combine data using joins and unions. You can only use pivots in this canvas. You can think of it as the Join/Union canvas. In previous versions of Tableau, the physical layer was the only layer in the data model. Each logical table can contain one or more physical tables.

Important: You can still create single-table data sources in Tableau that use joins and unions. The behavior of single-table analysis in Tableau has not changed. Your upgraded workbooks will work the same as they did before 2020.2.

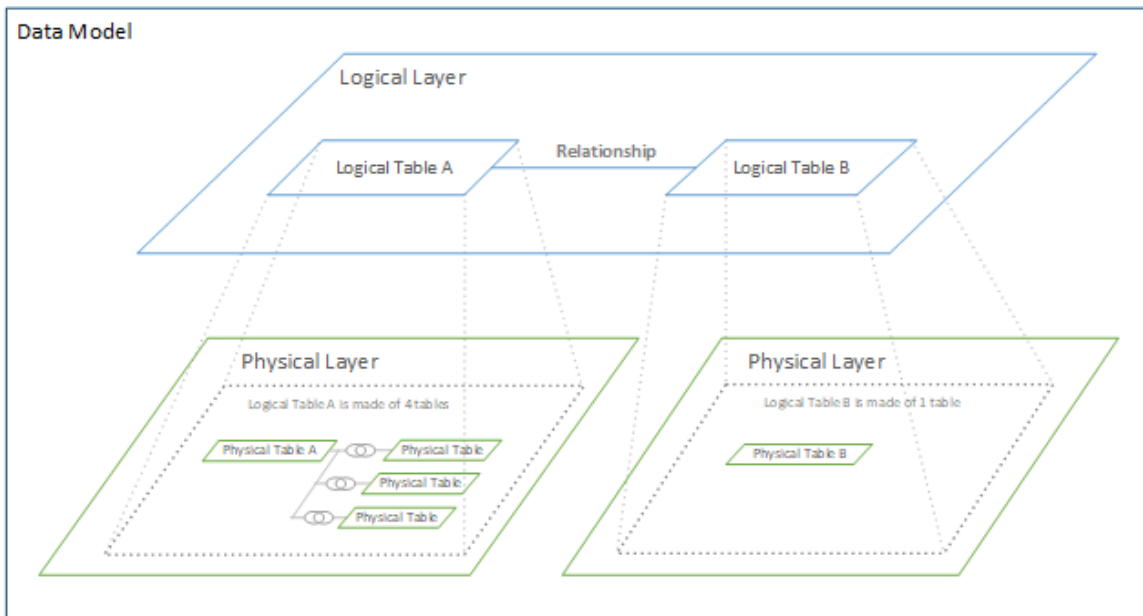

Learn more: For related information on combining data using relationships, also see these topics and blog posts:

- How Relationships Differ from Joins
- Use Relationships for Multi-table Data Analysis
- [Relate Your Data](#)
- [Relationships, part 1: Introducing new data modeling in Tableau](#)

- [Relationships, part 3: Asking questions across multiple related tables](#)

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

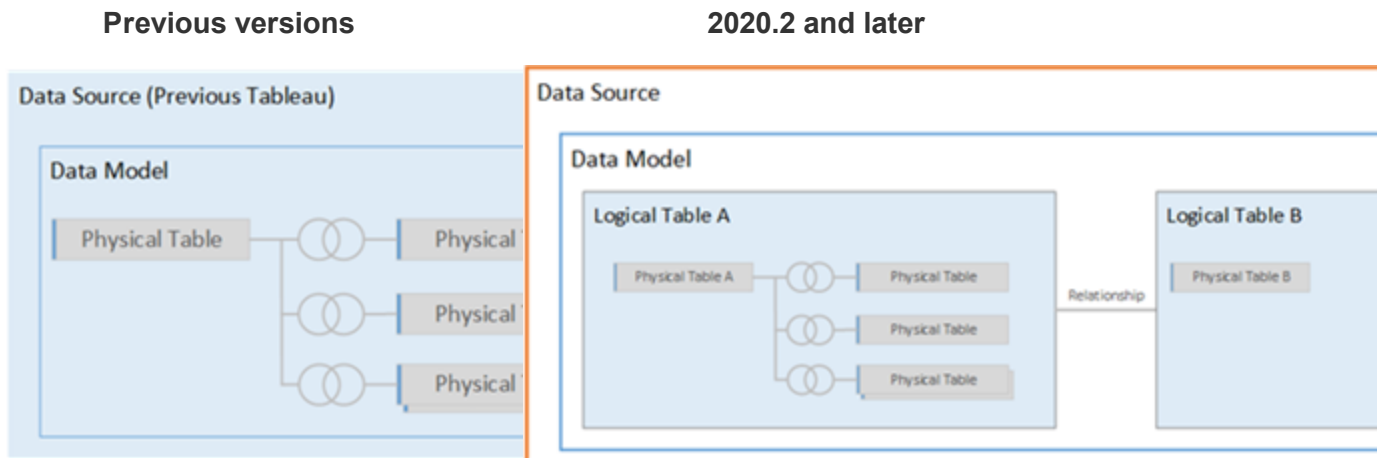

Understanding the data model

In previous versions of Tableau, the data model had only the physical layer. In Tableau 2020.2 and later, the data model has the logical (semantic) layer and a physical layer. This gives you more options for combining data using schemas to fit your analysis.

In Tableau 2020.2 and later, a logical layer has been added in the data source. Each logical table contains physical tables in a physical layer.

In previous versions of Tableau, the data model in your data source consisted of a single, physical layer where you could specify joins and unions. Tables added to the physical layer (joined or unioned) create a single, flattened table (denormalized) for analysis.

In versions of Tableau before 2020.2, the data model has only the physical layer

In 2020.2 and later, the data model has two layers: the logical layer and the physical layer

In Tableau 2020.2, the data model in your data source includes a new semantic layer above the physical layer—called the logical layer—where you can add multiple tables and relate them to each other. Tables at the logical layer are not merged in the data source, they remain distinct (normalized), and maintain their native level of detail.

Logical tables act like containers for merged physical tables. A logical table can contain a single, physical table. Or it can contain multiple physical tables merged together through joins or unions.

Build a new model

When you add one or more tables to the logical layer, you are essentially building the data model for your data source. A data source can be made of a single, logical table, or you can

Tableau Server on Windows Help

drag multiple tables to the canvas to create a more complex model.

- The first table that you drag to the canvas becomes the root table for the data model in your data source.
- After you drag out the root table, you can drag out additional tables in any order. You will need to consider which tables should be related to each other, and the matching field pairs that you define for each relationship.
- If you are creating a star schema, it can be helpful to drag the fact table out first, and then relate dimension tables to that table.
- Deleting a table in the canvas automatically deletes its related descendants as well. If you delete the root table, all other tables in the model are also removed.
- Each relationship must be made of at least one matched pair of fields. Add multiple field pairs to create a compound relationship. Matched pairs must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- Relationships can be based on calculated fields.
- You can specify how fields used in the relationships should be compared by using operators when you define the relationship.

For more information about relationships, see [Create and define relationships in Relate Your Data](#).

Multi-table model

- To create a multi-table model, drag tables to the logical layer of the Data Source page canvas.

Tables that you drag to the logical layer of the Data Source page canvas must be related to each other. When you drag additional tables to the logical layer canvas, Tableau automatically attempts to create the relationship based on existing key constraints and matching fields to define the relationship. If it can't determine the matching fields, you will need to select them.

If no constraints are detected, a **Many-to-many** relationship is created and referential integrity is set to **Some records match**. These default settings are a safe choice and provide the most a lot of flexibility for your data source. The default settings support full outer joins and optimize queries by aggregating table data before forming joins during analysis. All column and row data from each table becomes available for analysis.

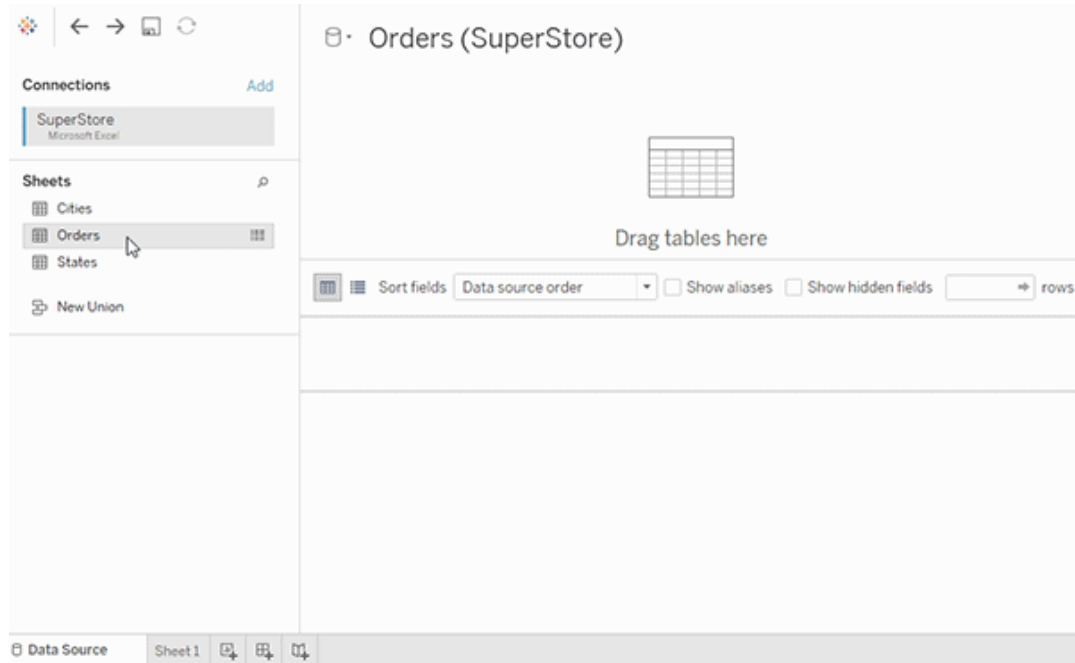

You can add more data inside any logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged in their logical table.

Follow the steps in [Create and define relationships](#) to combine multiple tables.

Tableau Server on Windows Help

Single-table model

- To create a single-table model, drag a table into the logical layer canvas of the Data Source page. You can then use the fields from that table in the Data pane for analysis.

Single-table model that contains other tables

You can add more data inside the single, logical table by double-clicking the table. This opens the physical layer of the Data Source page canvas. If you need to use joins or unions, you can drag the tables you want to join or union into the physical layer canvas. The physical tables are merged in their logical table.

This example shows the Book table in the Relationships canvas (logical layer) of the data source. Double-clicking the Book logical table opens the Join/Union canvas (physical layer).

In this example, the joins merge the Award and Info tables with the Book table. In this case, the join between Book and Award will be one-to-many, at the level of detail of awards. This would duplicate measure values for Book and Info. To avoid duplication, you could relate Award and Info to Book instead of joining them inside of the Book logical table.

Supported data model schemas

The data modeling capabilities introduced to Tableau in 2020.2 are designed to make analysis over common multi-table data scenarios—including star and snowflake data models—easy. The following types of models are supported in Tableau data sources.

Single-table

Analysis over a single logical table that contains a mixture of dimensions and measures works just as in Tableau pre-2020.2. You can build a logical table using a combination of joins, unions, custom SQL, and so on.

Tableau Server on Windows Help

Star and snowflake

In enterprise data warehouses, it is common to have data structured in star or snowflake schemas where measures are contained in a central fact table and dimensions are stored separately in independent dimension tables. This organization of data supports many common analysis flows including rollup and drill down.

These models can be directly represented with relationships in the data modeling capabilities available starting with Tableau 2020.2.

Drag the fact table into the model first and then relate the dimension tables to the fact table (in a star schema) or to other dimension tables (in a snowflake).

Typically, in a well-modeled star or snowflake schema, the relationships between the fact table and the dimension tables will be many-to-one. If this information is encoded in your data warehouse, Tableau will automatically use this to set the relationship's Performance

Options. If not, you can set this information yourself. For more information, see [Optimize Relationship Queries Using Performance Options](#).

In a well-modeled star or snowflake schema, every row in the fact table will have a matching entry in each of the dimension tables. If this is true and captured in your data warehouse integrity constraints, Tableau will automatically use this information to set the referential integrity setting in Performance Options. If some fact table rows do not have a matching row in a dimension table (sometimes called “late-arriving dimensions” or “early-arriving facts”), Tableau will default to retaining all rows when computing measures, but may drop values when showing dimension headers. For more information, see [Optimize Relationship Queries Using Performance Options](#).

Star and snowflake with measures in more than one table

In some star or snowflake schemas, all the measures for your analysis are contained in the fact table. However, it is often true that additional measures of interest may be related to the dimension tables in your analysis. Even if the dimension tables do not contain measures, it is common in analysis to want to count or otherwise aggregate dimension values. In these cases, the distinction between fact tables and dimension tables is less clear. To create clarity when viewing your data model, we recommended adding the finest grain table to the data source canvas first, and then relating all other tables to that first table.

Tableau Server on Windows Help

If you were to join these tables together into a single logical table, the measures in the dimension tables would be replicated, resulting in distorted aggregates unless you took precautions to deduplicate the values using LOD calculations or COUNT DISTINCT. However, if you instead create relationships between these tables, Tableau will aggregate measures before performing joins, avoiding the problem of unnecessary duplication. This relieves you of the need to carefully track the level of detail of your measures.

Multi-fact analysis

Tableau's data modeling capabilities support some forms of multi-fact analysis. Additional fact tables (containing measures) can be added to any of the previously mentioned models as long as they only relate to a single dimension table. For example, you can bring two or more fact tables together to analyze a shared dimension, such as in Customer 360-like analyses. These fact tables can be at a different level of detail than the dimension table, or from each other. They can also have a many-to-many relationship with the dimension table. In these scenarios, Tableau will ensure that values are not replicated before aggregation.

If you don't have a shared dimension table that relates your fact tables, you can sometimes dynamically build one using custom SQL or by using joins or unions of other dimension tables.

Two fact tables can be related directly to each other on a common dimension. This type of analysis works best when one of the fact tables contains a superset of the common dimension.

Unsupported models

- **Multiple fact tables related to multiple shared dimension tables.** In some use cases it is common to have multiple fact tables related to multiple shared dimension tables. For example, you might have two fact tables, Store Sales and Internet Sales, related to two common dimension tables, Date and Customer. Typically, such scenarios would require creating a circular relationship in your data model. Circular relationships are not supported in 2020.2.

You can approximate this type of model by merging some of the tables in the physical layer. For example, you might be able to union Store Sales and Internet Sales into a single table, which can then be related to Date and Customer. Alternatively, you might be able to cross-join Date and Customer to create a single dimension table which can then be related to Store Sales and Internet Sales.

- **Directly relating 3 or more fact tables on shared dimensions.** While it is possible to build this model in the logical layer, you might see unwanted results, unless you only use dimensions from a single table.

Requirements for relationships in a data model

- When relating tables, the fields that define the relationships must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- You can't define relationships based on geographic fields.
- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

Factors that limit the benefits of using related tables

- Dirty data in tables (i.e. tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters will limit Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.
- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

How Relationships Differ from Joins

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. You don't define join types for relationships, so you won't see a Venn diagram when you create them.

Think of a relationship as a contract between two tables. When you are building a viz with fields from these tables, Tableau brings in data from these tables using that contract to build a query with the appropriate joins.

- **No up-front join type.** You only need to select matching fields to define a relationship (no join types). Tableau first attempts to create the relationship based on existing key constraints and matching field names. You can then check to ensure they are the fields you want to use, or add more field pairs to better define how the tables should be related.
- **Automatic and context-aware.** Relationships defer joins to the time and context of analysis. Tableau automatically selects join types based on the fields being used in the visualization. During analysis, Tableau adjusts join types intelligently and preserves the native level of detail in your data. You can see aggregations at the level of detail of the fields in your viz rather than having to think about the underlying joins. You don't need to use LOD expressions such as FIXED to deduplicate data in related tables.
- **Flexible.** Relationships can be many-to-many and support full outer joins. When you combine tables using relationships, it's like creating a custom, flexible data source for every viz, all in a single data source for the workbook. Because Tableau queries only tables that are needed based on fields and filters in a viz, you can build a data source that can be used for a variety of analytic flows.

For more information, see [Relate Your Data](#) and [Don't Be Scared of Relationships](#).

Joins are still available as an option for combining your data. Double-click a logical table to go to the join canvas. For more information, see [Where did joins go?](#)

Watch a video: For an introduction to using relationships in Tableau, see this 5-minute video.

Note: The interface for editing relationships shown in this video might differ slightly from the current release but has the same functionality.

Also see video podcasts on relationships from [Action Analytics](#), such as [Why did Tableau Invent Relationships?](#) Click "Video Podcast" in the [Library](#) to see more.

For related information about how relationship queries work, see these Tableau blog posts:

- [Relationships, part 1: Introducing new data modeling in Tableau](#)
- [Relationships, part 2: Tips and tricks](#)
- [Relationships, part 3: Asking questions across multiple related tables](#)

Characteristics of relationships and joins

Relationships are a dynamic, flexible way to combine data from multiple tables for analysis. We recommend using relationships as your first approach to combining your data because it makes data preparation and analysis easier and more intuitive. [Use joins only when you absolutely need to.](#)

Here are some advantages to using relationships to combine tables:

- Make your data source easier to define, change, and reuse.
- Make it easier to analyze data across multiple tables at the correct level of detail (LOD).
- Do not require the use of LOD expressions or LOD calculations for analysis at different levels of detail.
- Only query data from tables with fields used in the current viz.

Tableau Server on Windows Help

Relationships

- Are displayed as flexible noodles between logical tables
- Require you to select matching fields between two logical tables
- Do not require you to select join types
- Make all row and column data from related tables potentially available in the data source
- Maintain each table's level of detail in the data source and during analysis
- Create independent domains at multiple levels of detail. Tables aren't merged together in the data source.
- During analysis, create the appropriate joins automatically, based on the fields in use.
- Do not duplicate aggregate values (when Performance Options are set to Many-to-Many)
- Keep unmatched measure values (when Performance Options are set to Some Records Match)

Joins

Joins are a more static way to combine data. Joins must be defined between physical tables up front, before analysis, and can't be changed without impacting all sheets using that data source. Joined tables are always merged into a single table. As a result, sometimes joined data is missing unmatched values, or duplicates aggregated values.

- Are displayed with Venn diagram icons between physical tables
- Require you to select join types and join clauses
- Joined physical tables are merged into a single logical table with a fixed combination of data
- May drop unmatched measure values
- May duplicate aggregate values when fields are at different levels of detail
- Support scenarios that require a single table of data, such as extract filters and aggregation

Requirements for using relationships

- When relating tables, the fields that define the relationships must have the same data type. Changing the data type in the Data Source page does not change this requirement. Tableau will still use the data type in the underlying database for queries.
- You can't define relationships based on geographic fields.

- Circular relationships aren't supported in the data model.
- You can't define relationships between published data sources.

Factors that limit the benefits of using related tables

- Dirty data in tables (i.e. tables that weren't created with a well-structured model in mind and contain a mix of measures and dimensions in multiple tables) can make multi-table analysis more complex.
- Using data source filters will limit Tableau's ability to do join culling in the data. Join culling is a term for how Tableau simplifies queries by removing unnecessary joins.
- Tables with a lot of unmatched values across relationships.
- Interrelating multiple fact tables with multiple dimension tables (attempting to model shared or conformed dimensions).

Where did joins go?

You can still specify joins between tables in the physical layer of a data source. Double-click a logical table to go to the Join/Union canvas in the physical layer and add joins or unions.

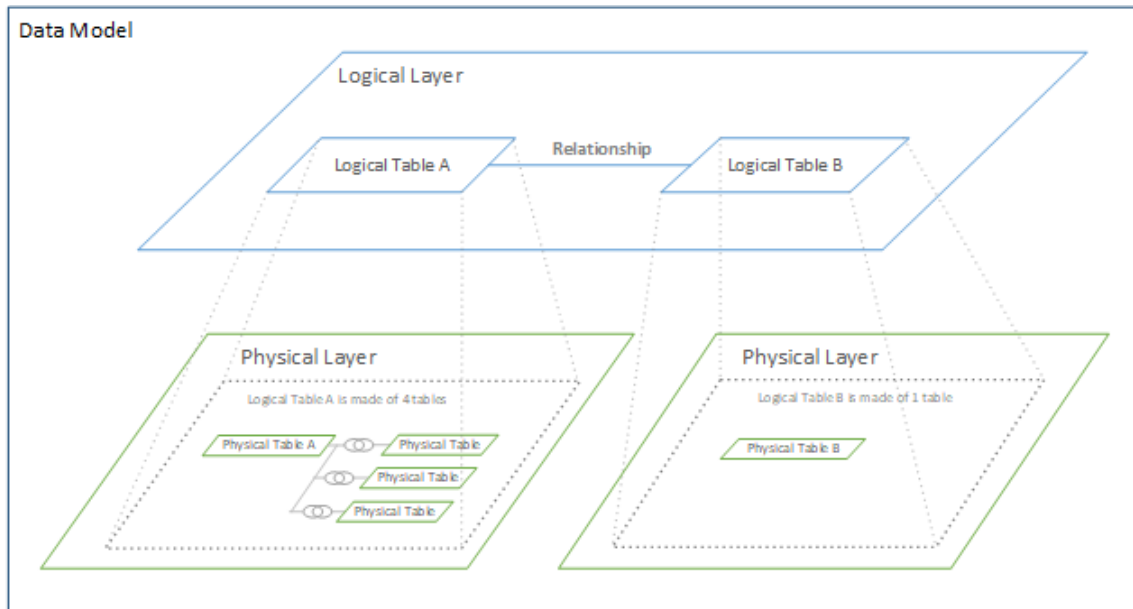

Every top-level, logical table contains at least one physical table. Open a logical table to view, edit, or create joins between its physical tables. Right-click a logical table, and then click **Open**. Or, just double-click the table to open it.

Tableau Server on Windows Help

When you create a data source, it has two layers. The top-level layer is the logical layer of the data source. You combine data between tables in the logical layer using relationships.

The next layer is the physical layer of the data source. You combine data between tables at the physical layer using joins. For more information, see [Logical and physical tables in the data model](#).

Optimize Relationship Queries Using Performance Options

Performance Options are optional settings that define the cardinality (uniqueness) and referential integrity (matching records) between the two tables in a relationship. These settings help Tableau optimize queries during analysis.

- **If you aren't sure what to choose**, use the recommended default settings indicated by Tableau. Using the defaults is safe and will automatically generate correct aggregations and joins during analysis. If you don't know the cardinality or referential integrity, you don't need to change these settings.
- **If you know the shape of your data**, you can optionally change these settings to represent uniqueness and matching between the records in the two tables.

In many analytical scenarios, using the default settings for a relationship will give you all of the data you need for analysis. In some scenarios, you might want to adjust the Performance Options settings to describe your data more accurately. For more details about using relationships to combine and analyze data, see [Relate Your Data](#) and this Tableau blog post: [Relationships, part 1: Introducing new data modeling in Tableau](#).

Tableau Server on Windows Help

What the Cardinality and Referential Integrity settings mean

Cardinality options

Cardinality settings determine if Tableau aggregates table data before or after automatically joining the data during analysis.

- Select **Many** if the field values aren't unique, or you don't know. Tableau will aggregate the relevant data before forming joins during analysis.
- Select **One** if field values are unique. During analysis, the relevant data will be joined before aggregation. Setting this option correctly optimizes queries in the workbook when the field values in the relationship are unique. However, selecting **One** when field values aren't unique can result in duplicate aggregate values being shown in the view.

Note: Selecting **One** treats records as if each key value is unique and there is at most only one row with a null value.

Referential Integrity options

Referential Integrity settings determine the type of join used to get the dimension values for a measure during analysis.

- Select **Some Records Match** if some values in the field don't have a match in the other table, or you don't know. During analysis, Tableau uses outer joins to get dimensions values for a measure. All measure values will be shown in the view, even unmatched measures.
- Select **All Records Match** if values in the field are guaranteed to have a match in the other table. This setting generates fewer and simpler joins during analysis, and optimizes queries. You might see inconsistent results during analysis (unmatched values removed or missing in view) if there are unmatched values in this table.

Notes: Selecting **All Records Match** treats records as if no null values exist in the fields used for the relationship. During analysis, Tableau will use inner joins to get dimension values for a measure. By default, Tableau will never join null keys.

For more information about Cardinality and Referential integrity as concepts, see [Cardinality and Referential Integrity](#).

Where did joins go?

You can still specify joins between tables in the physical layer of a data source. Double-click a logical table to go to the join canvas.

Every top-level, logical table contains at least one physical table. Open a logical table to view, edit, or create joins between its physical tables. Right-click a logical table, and then click **Open**. Or, just double-click the table to open it.

Tableau Server on Windows Help

When you create a data source, it has two layers. The top-level layer is the logical layer of the data source. You combine data between tables in the logical layer using relationships.

The next layer is the physical layer of the data source. You combine data between tables at the physical layer using joins. For more information, see [Logical and physical tables in the data model](#).

Tips on using Performance Options

If you know the shape of your data, you can use the optional settings in Performance Options to establish the cardinality of the tables to each other (one-to-one, one-to-many, many-to-many) and indicate referential integrity (values from one table will always have match in the other table).

Instead of thinking of the settings in Performance Options as “yes” and “no”, think of them as “yes” and “I don’t know”. If you are sure that a table’s values are unique, select **One**. If you are sure that each record in one table matches one or more records in the other table, select **All Records Match**. Otherwise, leave the default settings as they are.

If you aren't sure about the shape of your data, use the default settings. When Tableau can't detect these settings in your data, the default settings are:

- Cardinality: Many-to-Many
- Referential integrity: Some Records Match

If Tableau detects key relationships or referential integrity in your data, those settings will be used and indicated as “detected”.

To reapply the default settings, click **Revert to Default**.

Terms defined

Cardinality refers to the uniqueness of data contained in a field (column) or combination of fields. When the tables you want to analyze contain many rows of data, queries can be slow (and performance of the overall data source is affected) so we recommend choosing a method for combining data based on the cardinality of the related columns between tables.

- Low cardinality: When related columns have a lot of repeated data. For example, a table called Products might contain a Category column that contains three values: Furniture, Office Supplies, and Technology.
- High cardinality: When related columns have highly unique data. For example, a table called Orders might contain an Order ID column that contains a unique value for every order of product.

Referential integrity means that one table will always have a matching row in the other table. For example, a Sales table will always have a matching row in the Product Catalog table.

Automatically Build Views with Ask Data

Ask Data lets you type a question in common language and instantly get a response right in Tableau. Answers come in the form of automatic data visualizations, with no need to manually drag-and-drop fields or understand the nuances of your data's structure.

Ask Data lets you ask sophisticated questions naturally, with support for key analytical concepts like time series and spatial analysis, and an understanding of conversational phrases like "last year", "earliest", and "most popular".

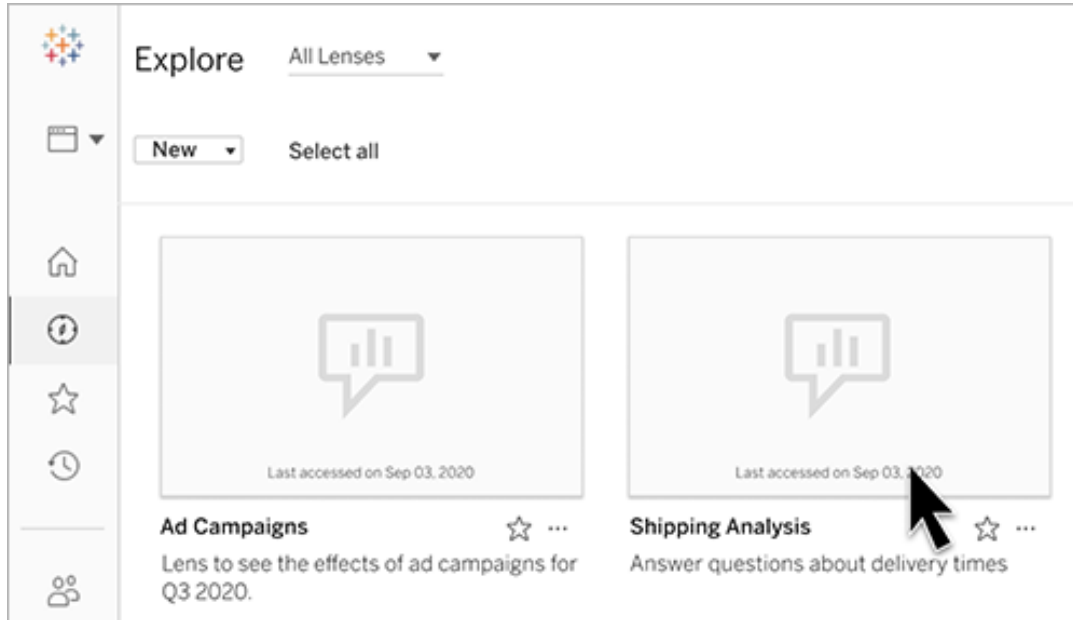

Navigating to Ask Data lenses

Before you can query a data source with Ask Data, **a Tableau author must first create a lens** that specifies the subset of data fields the lens uses.

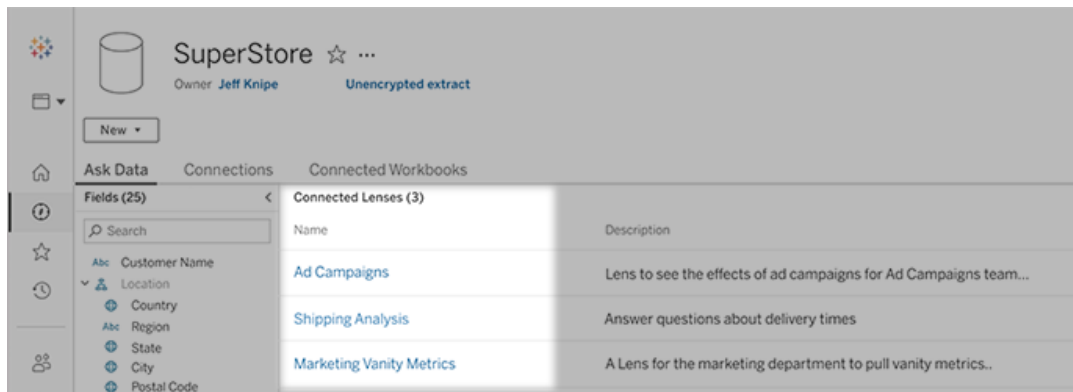

In Tableau, here are all the places where you can access an Ask Data lens:

Tableau Server on Windows Help

- On the All Lenses page at the top level of your Tableau Online or Tableau Server site.

- On the Ask Data tab for a data source for which lenses have been created.

- In an Ask Data object on a dashboard.

Ask Data from a lens page or dashboard object

1. Navigate to a lens via the All Lenses page for your Tableau site, the Ask Data tab for a data source, or an Ask Data object on a dashboard.
2. (Optional) Under **Recommended Visualizations**, click an entry to quickly see visualizations the lens author has created for your organization.

If a recommendation addresses your data analysis needs, you can stop here. Otherwise, continue on to quickly create your own question.

3. (Optional) In the Data pane at left, briefly hover over each field to learn more about the data it contains.

Tableau Server on Windows Help

In a narrower dashboard object, the Data pane may be hidden, but you can see the same information by clicking the **Fields** drop-down menu.

4. In the box reading “**Search fields or values to create a visualization**”, enter your query about the data.

5. As you type, Ask Data searches data fields, functions, and string values and displays results in a drop-down list. Click items in the list to add them to your current entry, shown above the search box. To automatically create a viz using the current entry, press **Enter** at any time.

Modifying a query by searching for fields and analytical functions

A. Current entry B. Current filters C. Search box D. Returned fields E. Returned analytical functions F. Returned field values

Tip: Hover over elements in the text box to see how they're incorporated in the interpretation above. Words that aren't used are grayed out, helping you rephrase your query in a way that's clearer to Ask Data.

Rephrase your question

You can rephrase questions by clicking options, data fields, and filters in the user interface.

Change the viz type

If the default viz doesn't fully reveal your data, click the menu at upper right, and choose from these supported viz types:

- Bar Chart
- Gantt Bar
- Heat Map
- Histogram
- Line Chart
- Map
- Pie Chart
- Scatter
- Stacked Bar Chart
- Text Table
- Treemap

Tableau Server on Windows Help

Note: To automatically create certain viz types, Ask Data sometimes adds fields like “Number of Records” to your entries.

Change fields, filters, and displayed data

Ask Data gives you several ways to fine-tune how field values are displayed.

- To switch the fields used for the vertical and horizontal axes, click the Swap Axes button  to the left of the viz selection menu:

- To change a field or its aggregation or grouping type (for example, from sum to average), click the field name in the text box.

- For categorical filters, click values (like "exclude United States" in the example below) to change specific values or enter wildcard parameters.

- To adjust a numeric range, click words like “high”, “between”, or “cheap”.

- To delete a field or filter, hover over it and click the **X**.

Adjust date filters

To adjust a date filter, click words like “in”, “last”, “previous”, or “between”. Then click one of the following:

- **Specific Dates** to enter a specific time period or date value
- **Relative Dates** to show a date range relative to the present day
- **Range of Dates** to enter specific start and end points

Specific Dates offers some unique options in the **Date Detail** menu:

- **Time Period** options show a single continuous date range
- **Date Value** options show ranges that can repeat in multiple time periods. For example, to see combined sales performance for Q1 across multiple years, under Date Value, you would choose Quarters.

Compare differences over time

Ask Data lets you compare time periods with phrases like “year over year”, “quarter over quarter”, or similar comparisons by month, week, or day. The results appear as difference or percent difference table calculations in workbooks you save from Ask Data.

In the text box, click a difference calculation to choose other fields, aggregation methods, and time periods.

Apply simple calculations

Ask Data supports simple calculations between two measures, which you can apply using these symbols:

- + sums the measures
- produces the difference between them
- * multiplies
- / divides

In workbooks you save from Ask Data, these calculations don't become calculated fields but instead ad hoc calculations on the Columns, Rows, or Marks shelves.

Add sheets with other vizzes

To quickly create multiple different vizzes from a lens, add sheets in Ask Data.

At the bottom of the web page, do any of the following:

- Click the **Add Sheet** icon to the right of named sheets.

- Right-click a sheet name, and choose either **Duplicate** or **Delete**.

(To rename sheets from Ask Data, you need to save them in a new workbook.)

Share Ask Data vizzes via email, Slack, or a link

You can quickly share Ask Data vizzes with anyone who has access to a lens.

Tableau Server on Windows Help

1. In the upper right corner of the browser, click the Share icon.

2. Do either of the following:
 - To share the viz via email or Slack, enter specific user names in the text box. (Email and Slack integration must previously be configured by your Tableau administrator.)
 - To copy a URL you can paste into custom emails and other messages, click **Copy Link**.

Send feedback to the lens owner

If you have questions about the structure of a lens or how best to use it with Ask Data, you can send feedback directly to the author. (This option is enabled by default, but lens authors may disable it.)

1. To the left of the query box for Ask Data, click the "Ask Data tips" icon.

2. At the bottom of the tips dialog, click **Contact the Lens Author**.

Tips for successful queries

As you structure questions for Ask Data, apply these tips to get better results.

- **Use keywords** — For example, instead of “I want to see all the countries that these airports are in”, try “by airport and country”.
- **Use exact wording for field names and values** — For example, if your lens includes Airport Code, Airport Name, and Airport Region fields, specify those by name.
- **See a ranked list** — Ask Data maps terms like “best” and “worst” to Top 1 and Bottom 1, respectively. If you want to see broader rankings, use “high” and “low” instead. For example, enter “houses with low sale prices”.
- **Query table calculations** — In query expressions for table calculation fields, note that you can't filter, limit, or include "year over year difference".
- **Surround unusually long values with quotation marks** — To analyze long field values that contain line returns, tabs, or more than ten words, surround them with quotation marks. To improve performance, Ask Data doesn't index fields of that length, or anything beyond the first 200,000 unique field values.

Create Lenses that Focus Ask Data for Specific Audiences

Most people don't need information from an entire data source but instead want data visualizations relevant to their job function, like sales, marketing, or support. To optimize Ask Data for different audiences like these, Tableau authors create separate *Ask Data lenses*, which query a selected subset of fields. For the selected fields, authors can specify synonyms for field names and values, reflecting terms the lens audience uses in common language (for example, "SF" for "San Francisco"). Lens authors then customize the recommended visualizations that appear below the Ask Data query box, which provide answers to users with a single click.

Note: Ask Data lenses can be created only for data sources published separately to a Tableau site. Lenses can't be created for data sources embedded in workbooks or those with a virtual connection.

Tableau Server on Windows Help

Create or configure a lens page on your Tableau site

On your Tableau site, each lens has a separate page where users can query Ask Data and authors can configure lens fields, synonyms, and suggested questions.

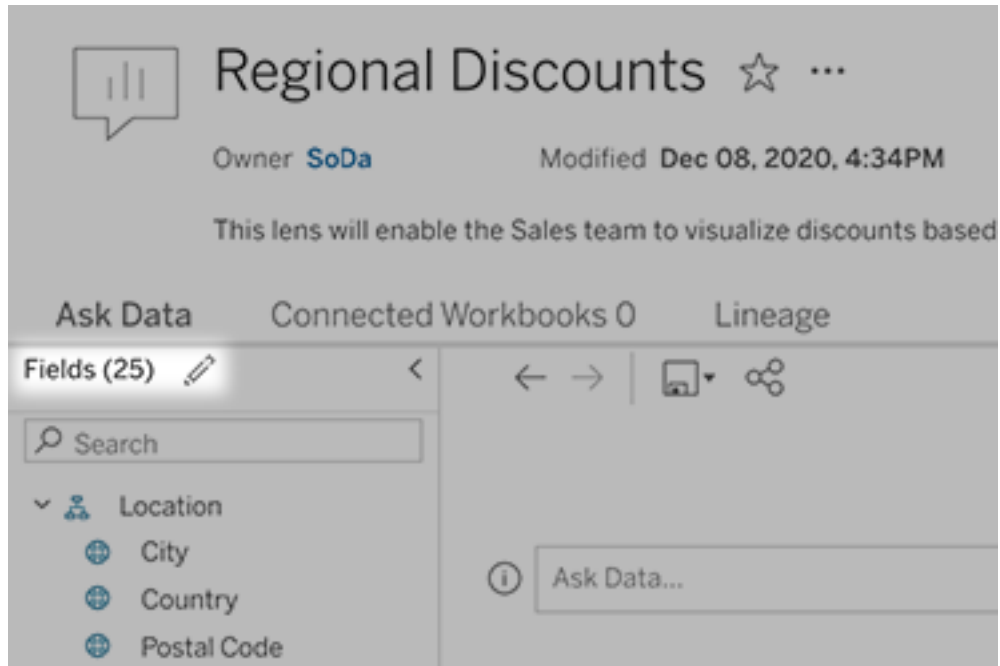

The screenshot shows a Tableau lens page for 'Shipping Analytics'. At the top, there is a title 'Shipping Analytics' with a three-bar icon to its left. Below the title, it shows 'Owner Jared', 'Modified Apr 26, 2021, 2:09 PM', and 'Data Source RetailSample Extract'. A description reads: 'A lens for ad-hoc analytics from the logistics team.' Below this is a section titled 'Ask Data'. On the left, there is a 'Data' pane with a search bar and a list of fields: Address, Brand, CATEGORY, Class, Department, Distributioncenter, District, Division, Geographic Location (expanded to show Region, State, City, Zip). The main area shows 'No fields' and 'No filters' with a search box for 'Search fields or values to create a visualization'. Below this is a 'Recommended Visualizations' section with three options: 'FAQs', 'Prices by category', and 'Shipping Costs over time'.

A lens page on a Tableau site

1. To create a lens page on your Tableau site, go to a data source page, and choose **New > Ask Data Lens**.

To configure an existing lens, go to the lens page on your site. (From an Ask Data object in a dashboard, you can click the pop-up menu in the upper corner and choose **Go to Lens Page**.)

2. If you're creating a new lens, enter a name, description, and project location, and then click **Publish Lens**.
3. At the top of the Fields pane at left, click the pencil icon. Then select the relevant fields for lens users, and click **Save**.

4. At left, hover over individual tables or fields, and click the pencil icon:

Then do any of the following:

- Provide a more representative name by clicking the pencil icon to the right.

Tableau Server on Windows Help

- Add common synonyms for field names and values that lens users may enter in their queries.
- Edit descriptions that appear when users hover over fields.

Change the list of recommended visualizations

To address common queries from lens users, you can customize the recommended visualizations that appear below the query box.

Add or replace a recommended visualization

1. Enter a query into the text box, and press Enter or Return.
2. After the visualization appears, from the pin icon in the toolbar, choose either **Pin to Recommended Visualizations** or **Replace Recommendation**.

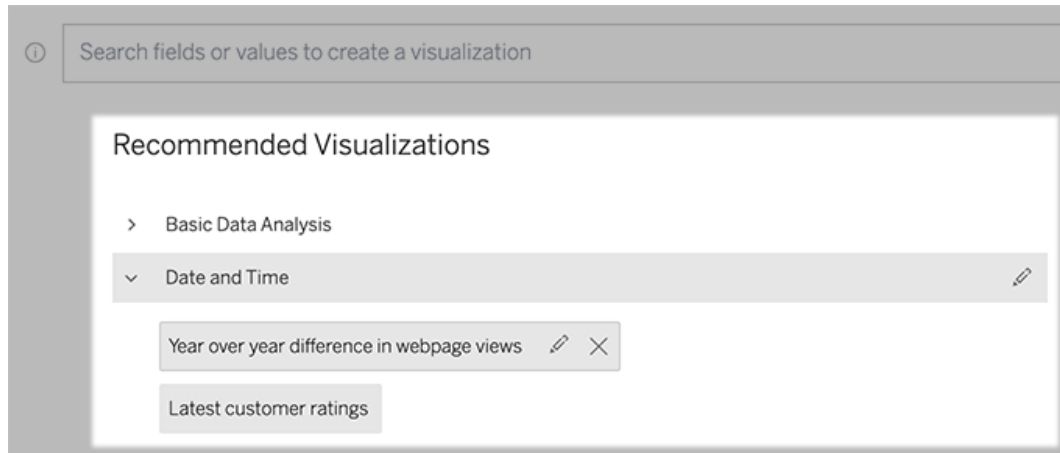

3. For a new recommendation, enter a name, and choose the section in which you want it to appear. For a replacement recommendation, choose the existing one you want to overwrite.

Edit section titles and recommendation names, or delete recommendations

- To edit a section title, click the pencil icon  to the right of the title.
- To change the name of a recommendation, hover over it and click the pencil icon .

To delete a recommendation, click the X.

Add an Ask Data lens to a dashboard

On a dashboard, you can add an Ask Data object that lets users query a published data source via a lens on your Tableau site.

1. While editing a dashboard in Tableau Online, or Tableau Server, drag the Ask Data object to the canvas.

Note: In Tableau Desktop, you can also drag an Ask Data object to the canvas for placement purposes. But to select a lens, you will need publish to Tableau Online or Tableau Server and edit the object there.

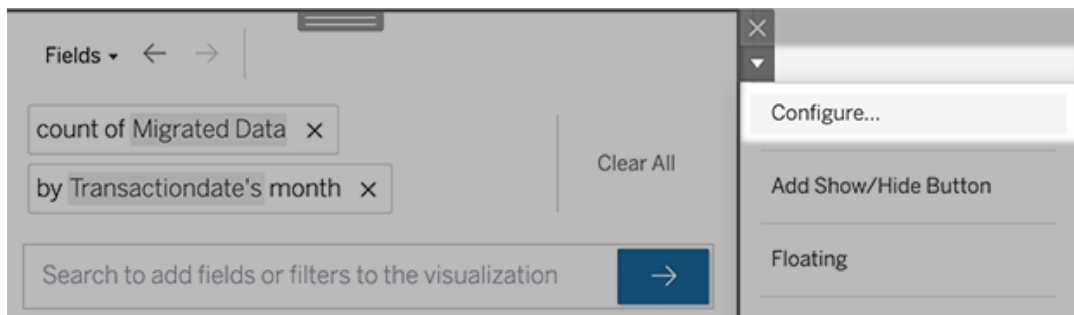

2. Select a published data source previously connected to the workbook.
3. To use an existing lens, select it, and click **Use Lens**. Then skip remaining steps.

Or, to create a new lens, do one of the following:

- If there are no lenses for the data source, click **Go to Data Source Page**.
 - If lenses already exist, click the data source name at the bottom of the dialog.
4. Complete the steps in Create or configure a lens page on your Tableau site.
 5. After you finish creating the lens, return to the Lens object in your dashboard, and click **Refresh**. Then select the new lens, and click **Use Lens**.

Apply a different lens to an Ask Data dashboard object

1. From the pop-up menu at the top of the object, choose **Configure**.

2. Go to Add an Ask Data lens to a dashboard, and repeat steps 2 onward.

Change a lens name, description, or project location

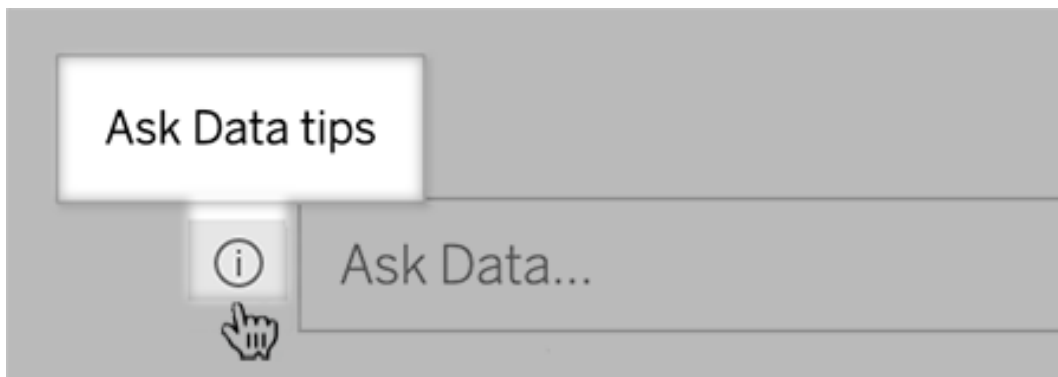

1. Navigate to the lens page on Tableau Online or Tableau Server.
2. To the right of the lens name at the top of the page, click the three dots (...), and choose **Edit Workbook**.
3. Click **Edit Lens Details**.

See how people use Ask Data with a lens

For data source owners and lens authors, Ask Data provides a dashboard that reveals the most popular queries and fields, the number of visualization results that users clicked, and other helpful information. Filters let you narrow data down to specific users and time ranges. These stats help you further optimize a lens to increase the success of your users.

Note: If you use Tableau Server, you can access this data in the Tableau Server Repository to create custom dashboards.

1. In Tableau Server or Tableau Online, navigate to a lens page.
2. To the left of the Ask Data text box, click the "Ask Data tips" icon.

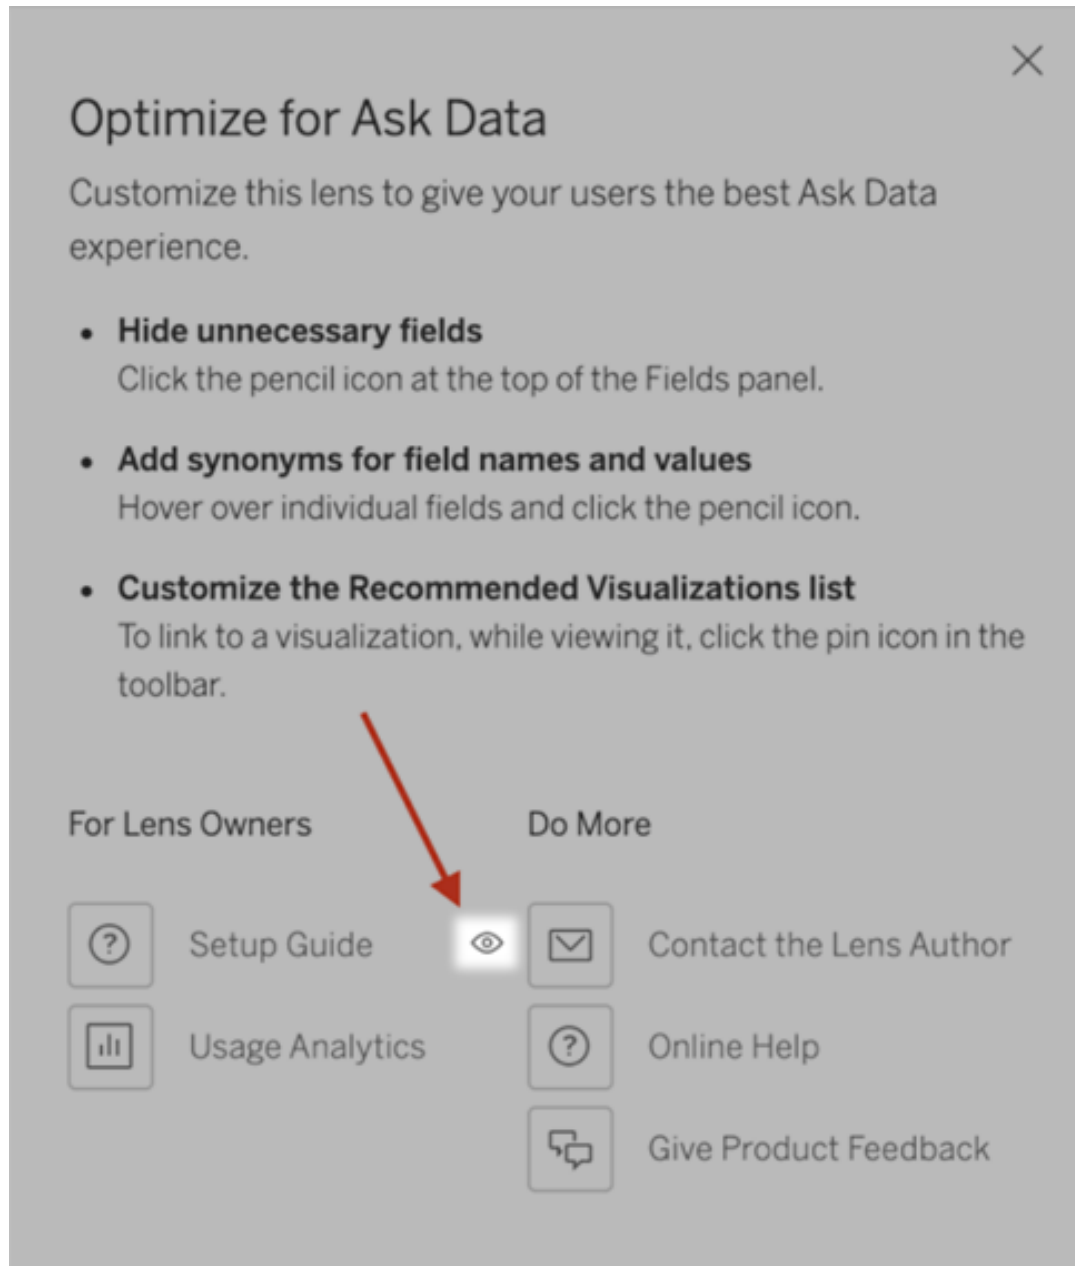

3. In the lower-left corner of the tips dialog, click **Usage Analytics**.

Let users email you questions about a lens

As a lens owner, you can allow users to email you with questions about data structure, expected results, and more. This option is on by default, but you can turn it off using the steps below.

Tableau Server on Windows Help

1. In Tableau Server or Tableau Online, navigate to a lens page.
2. To the left of the Ask Data text box, click the "i" shown above in See how people use Ask Data with a lens.
3. At the bottom of the tips dialog, click the eye icon next to "Contact the Lens Author" to enable or disable feedback.

Permissions for publishing and viewing lenses

For Ask Data objects in dashboards, no change to permissions should be required: by default, existing workbook authors can create lenses, and existing dashboard audiences can view them. But for reference, here's a detailed outline of required lens permissions for both dashboards and direct access via a data source page.

To create and publish a lens, a user needs:

- The Creator or Explorer user role
- Lens Creation permission for the data source (inherited by default from the Connect permission)
- Write permission for the parent project to which the lens is published

To access and interact with a published lens, a user needs:

- The Viewer role or above
- Connect permission for the data source
- View permission for the lens

Note: By default, lens permissions like View reflect a project's permissions for workbooks. If Tableau administrators want to change default lens permissions, they can do so either individually for each project, or in bulk using the permissions API.

Disable or Enable Ask Data for a Site

Ask Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Ask Data** section, choose from these options:

Tableau Server on Windows Help

- **Enabled** enables creation of Ask Data lenses for all published data sources.
- **Disabled** hides Ask Data throughout the site, while preserving information about previously created lenses so they can be restored if Ask Data is re-enabled.

Note: Beginning with version 2019.4.5, Tableau Server administrators can configure whether or not Ask Data is enabled by default.

Optimize Data for Ask Data

If you manage and publish data sources, here are some tips to help make users of Ask Data more successful. By spending a little extra time on this process, you'll open up data analysis to a wider range of people at your organization, helping them independently answer questions and gain deeper insights.

Optimize data in Ask Data

In the Data pane on the left of the Ask Data interface, data source owners can add synonyms for fields and exclude irrelevant values.

Changing settings at the data source or lens level

When changing settings in the Data pane for Ask Data, pay close attention to whether you're at the data source or lens level. (For more information, see [Create Lenses that Focus Ask Data for Specific Audiences.](#))

- At the data source level, you'll see the cylindrical data source icon in the upper left corner. Here, changes you make in the Data pane will apply by default to all subsequently created lenses.

Note: For extracts, two cylinders will appear.

- For an individual lens, you'll see the quotation icon in the upper left corner. Here, changes you make in the Data pane will apply to this lens alone.

Tableau Server on Windows Help

Add synonyms for field names and values

People may not use the same terminology found in your data source, so data source owners and Tableau administrators can **add synonyms for specific data field names and values**. Synonyms you enter are available throughout your organization, making data analysis quicker and easier for everyone.

Exclude values of specific fields from search results

To improve the usability of search results in Ask Data, you can exclude the values of specific fields from indexing. Though Ask Data doesn't add non-indexed values to search results, the values still appear in visualization results when relevant. For example, if you don't index values from a "Product" field because they add unnecessary detail to search results, Ask Data can still display values such as "iPhone 12" in resulting data visualizations. And users can manually add non-indexed values to queries by surrounding them with quotation marks (for example, "Sales for Product containing "iPhone 12"").

Note: This field-level setting is ignored if **the value indexing setting for the data source** is set to Disabled. Field names and related synonyms are always indexed.

1. Go to the Ask Data tab for a data source or individual lens.
2. Hover over a data source field at left, and click the **Edit Field Details** icon (the pencil).

3. Deselect **Index field values**.

Either click the text box that appears to reindex the data source now, or let it reindex based on its regular indexing schedule.

Optimize data sources

To create the best experience for Ask Data users, optimize the original data source.

Note: Ask Data doesn't support multidimensional cube data sources, or non-relational data sources like Google Analytics, or data sources with a virtual connection.

Optimize indexing for Ask Data

Data source owners can change how often field values are indexed for Ask Data, optimizing system performance.

1. At the top of a data source page, click the Details icon:

2. In the Ask Data section, click **Edit**.
3. Choose an indexing option for field values:
 - **Automatic** checks for changes every 24 hours and analyzes the data source if it is live, has had an extract refreshed, or has been republished. Choose this option for a data source frequently used with Ask Data, so it will be ready before users query it.
 - **Manual** analyzes the data source only when Tableau creators manually trigger indexing on the data source page. Choose this option if the data source changes frequently but users query it with Ask Data only occasionally.

Tableau Server on Windows Help

To trigger manual indexing, go to the data source page, click the circled “i” in the Data pane at left, and then click **Reindex Data Source**.

- **Disabled** analyzes only field names, not values.

4. Click **Save**

Use data extracts for faster performance

For improved performance and support for large data sets, use Ask Data with published extracts rather than live data sources. For more information, see [Create an extract](#).

Ensure that users can access the data source

To use Ask Data, users must have permission to connect to the individual data source. If a data source has row-level permissions, those permissions also apply to Ask Data, which won't recognize secure values or make related statistical recommendations.

Be aware of unsupported data source features

Ask Data supports all Tableau data source features except the following. If your data source contains these, Ask Data users won't be able to query related fields.

- Sets
- Combined fields
- Parameters

Anticipate user questions

Anticipate the kinds of questions your users will ask, and then optimize your data source for those questions using these techniques:

- Clean and shape data in [Tableau Prep](#) or a similar tool.
- [Join data](#) to include all fields users may have questions about in one table, improving performance.
- Add [calculated fields](#) that answer common user questions.
- Create [bins with appropriate sizes](#) for quantitative variables that users are likely to want to see as a histogram or another binned form.

Simplify the data

To make data easier to understand by both users and Ask Data, simplify the data source as much as possible during the data prep process.

1. Remove any unnecessary fields to improve performance.
2. Give each field a unique and meaningful name.
 - For example, if there are five field names that start with “Sales ...”, better distinguish them so Ask Data can properly interpret the term “sales”.
 - Rename “Number of records” to something more meaningful. For example, use “Number of earthquakes” in a data source where each record is an earthquake.
 - Avoid field names that are numbers, dates, or boolean (“true” or “false”) values.
 - Avoid names which resemble analytical expressions such as “Sales in 2015” or “Average Products Sold”.
3. Create meaningful [aliases for field values](#), reflecting terms people would use in conversation.

Set appropriate field defaults

To help Ask Data analyze data correctly, ensure that default field settings reflect the content of each field.

- [Set data types](#) for text, time, date, geographic, and other values.
- [Assign the proper data role](#): dimension or measure, continuous or discrete.

Tableau Server on Windows Help

- For each measure, **assign appropriate default settings** in Tableau Desktop, such as color, sort order, number format (percentage, currency, etc.), and aggregation function. For example, SUM may be appropriate for “Sales”, but AVERAGE might be a better default for “Test Score”.

Tip: It's particularly helpful to set a default comment for each field, because these comments appear as informative descriptions when users hover over fields in Ask Data.

Create hierarchies for geographic and categorical fields

For time data, Tableau automatically creates hierarchies, which let users quickly drill up and down in vizzes (for example, from day to week to month). For geographic and categorical data, however, we recommend that you **create custom hierarchies** to help Ask Data produce visualizations that reflect the relationships between fields. Be aware that Ask Data won't show the hierarchies in the data pane.

Ask Data doesn't index hierarchy names, only names of fields within hierarchies. For example, if a geographic hierarchy named “Location” contains “Country” and “City” fields, users should enter “Country” and “City” in their questions for Ask Data.

Discover Insights Faster with Explain Data

Explain Data gives you a new window into your data. Use it to inspect, uncover, and dig deeper into the marks in a viz as you build, explore, and analyze your data. When you select a mark while editing a view and run Explain Data, Tableau builds statistical models and proposes possible explanations for the selected mark, including potentially related data from the data source that isn't used in the current view.

For information on running Explain Data and exploring explanations, see [Get Started with Explain Data](#).

Note: This topic describes how Explain Data works in Tableau 2021.2 and later versions. If you have a previous version of Tableau, read this topic in [version 2021.1 of Explain Data help](#).

Select a mark and run Explain Data from the tooltip menu. The Explain Data pane opens with possible explanations

As you build different views, use Explain Data as a jumping-off point to help you explore your data more deeply and ask better questions. For more information, see [How Explain Data helps to augment your analysis](#). For information on what characteristics make a data source more interesting for use with Explain Data, see [Requirements and Considerations for Using Explain Data](#).

Access to Explain Data

Explain Data is enabled by default at the site level. Server administrators (Tableau Server) and site administrators (Tableau Online) can control whether Explain Data is available for a site. For more information, [Disable or Enable Explain Data for a Site](#).

Authors who can edit workbooks and have the Run Explain Data permission capability for a workbook can run Explain Data in editing mode.

Authors can use Explain Data Settings to control whether Explain Data is available in viewing mode in published workbooks and which explanation types are displayed in the Explain Data pane.

When Explain Data is enabled by the author of a published workbook, all users with the Run Explain Data capability can run Explain Data on a mark in viewing mode.

For information on controlling access to Explain Data, explanation types, and fields, see [Control Access to Explain Data](#).

How Explain Data helps to augment your analysis

Explain Data is a tool that uncovers and describes relationships in your data. It can't tell you what is causing the relationships or how to interpret the data. **You are the expert on your data.** Your domain knowledge and intuition are key in helping you decide what characteristics might be interesting to explore further using different views. For related information, see [How Explain Data Works and Requirements and Considerations for Using Explain Data](#).

For more information on how Explain Data works and how to use Explain Data to augment your analysis, see these Tableau Conference presentations:

- [From Analyst to Statistician: Explain Data in Practice \(1 hour\)](#)
- [Leveraging Explain Data \(45 minutes\)](#)
- [Explain Data Internals: Automated Bayesian Modeling \(35 minutes\)](#)

Get Started with Explain Data

Use Explain Data in your flow of analysis as you are exploring the marks in a viz. The best way to get started with Explain Data is to select a mark, run Explain Data, and start exploring explanations.

Use Explain Data

- Run Explain Data on a mark
- Drill into explanations
- View analyzed fields
- Why am I seeing a Reselect button?
- Terms and concepts in explanations
- [Explanation Types](#)

Author Workbooks and Control

Access

- [Requirements and Considerations for Using Explain Data](#)
- [Change Explain Data Settings \(Authors-only\)](#)
- Control Access to Explain Data
- Disable or Enable Explain Data for a Site
- How Explain Data Works

Run Explain Data on a mark

The basic steps to run Explain Data are:

1. Select a mark in a viz.
2. Hover the cursor over the mark, and then click **Explain Data** in the tooltip menu.

The Explain Data pane opens with possible explanations for the value of the analyzed mark. Click different explanation names to expand the details and start exploring.

Tableau Server on Windows Help

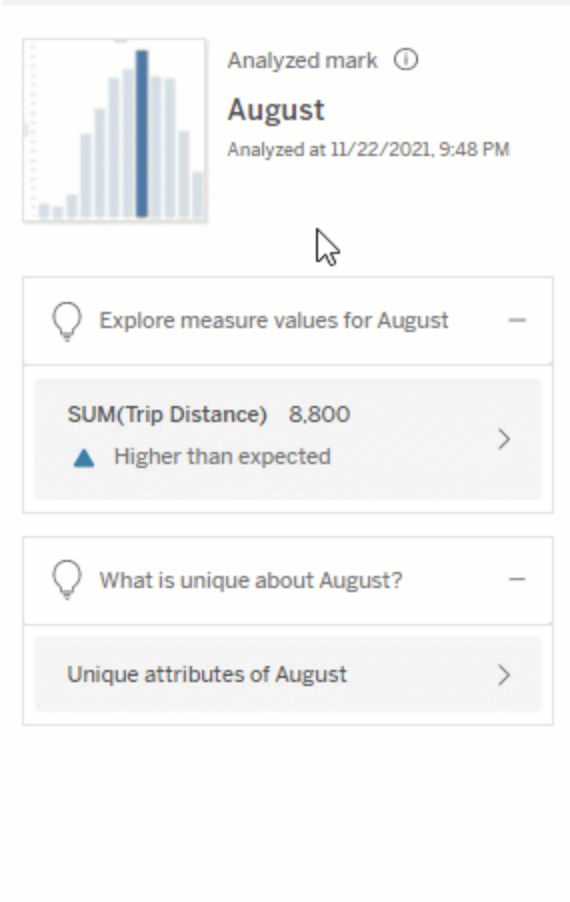

Tips for using Explain Data

- You must select a single mark—only one mark can be explained at a time.
- The view must contain marks that are aggregated using SUM, AVG, COUNT, COUNTD, or AGG (a calculated field).
- If Explain Data cannot analyze the type of mark selected, the Explain Data icon and context menu command will not be available. For more information, see [Situations where Explain Data is not available](#).
- The data you analyze must be drawn from a single, primary data source. Explain Data does not work with blended or cube data sources.
- For information on what characteristics make a data source more interesting for use with Explain Data, see Requirements and Considerations for Using Explain Data.

Drill into explanations

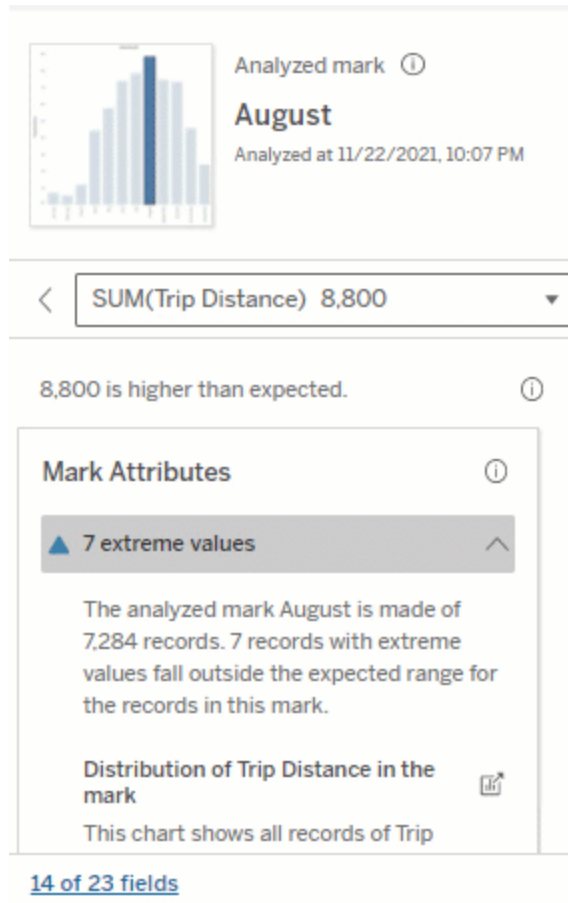

1. In the Explain Data pane, click an explanation name to see more details.

Click the arrows to expand or contract explanations.

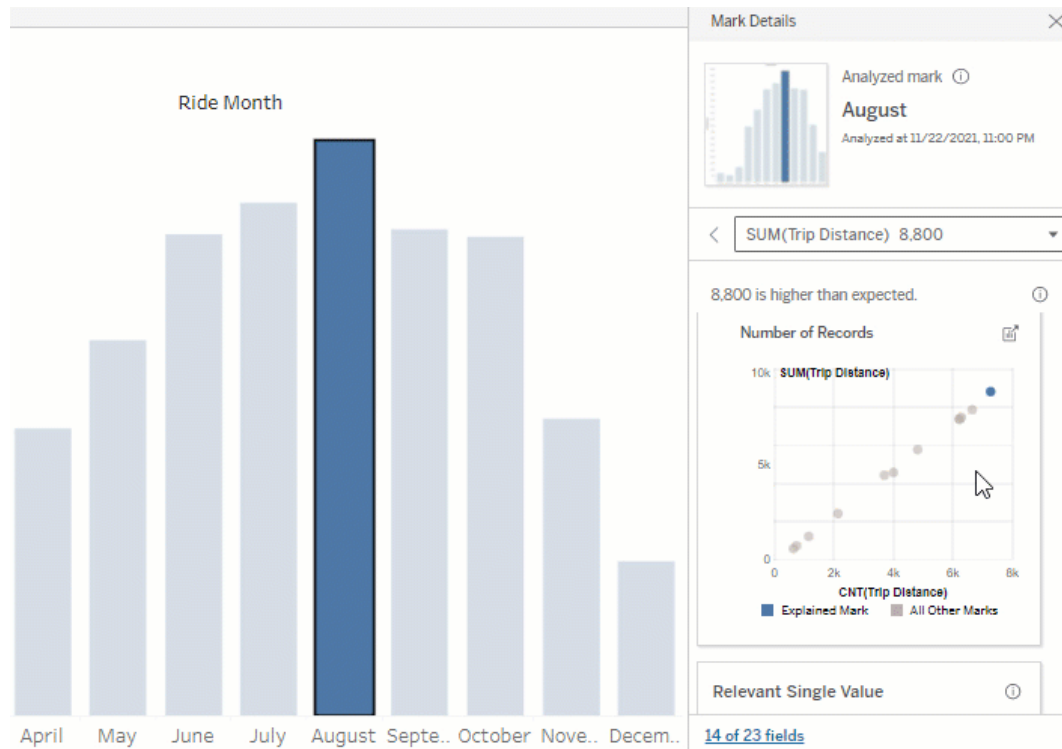

2. Scroll to see explanation details.

Tableau Server on Windows Help

Some explanations offer different layers of details for further exploration

3. Hover over charts in the explanations to see more detail. Click the **Open** ⓘ icon to see a larger version of the visualization.

Creators or Explorers who open the view for editing can click the **Open**  icon to open the visualization as a new worksheet and explore the data further.

Note: Creators and Explorers who have editing permissions can also control Explain Data Settings. For more information, see [Control Access to Explain Data](#).

4. Hover over a Help icon  to see tooltip help for an explanation. Click the Help icon  to keep the tooltip open. Click a **Learn More** link to open the related help topic.

Why am I seeing a Reselect button?

When you run Explain Data, the explanations that are presented in the Explain Data pane specifically apply to the mark you selected. If you click a different mark, deselect the analyzed mark, or navigate to a different sheet in the workbook, a Reselect button appears in the view thumbnail image at the top of the Explain Data pane.

If you click **Reselect**, Tableau returns you to the original view and worksheet, and reselects the analyzed mark. Click **Update** to run Explain Data again.

To explore a new mark, click another mark, and then click **Run** in the Explain Data pane.

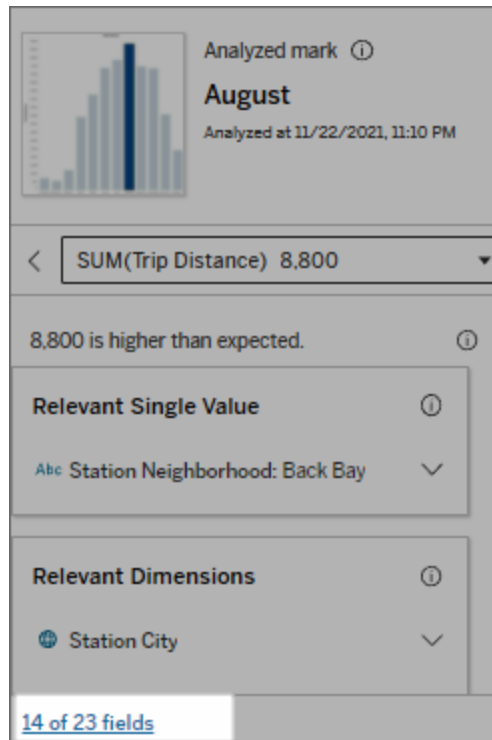

Explain Data might also display messages to indicate the view has changed (such new fields or filters added or removed from the view), if the data source has changed, or if Explain Data settings have changed.

View analyzed fields

1. Run Explain Data on a mark.
2. In the Explain Data pane, under **Explore measure values for**, click a measure name.

3. Click the *number-of-fields* link at the bottom of the pane.

Authors have the option to open Explain Data Settings to control which fields are included in the analysis. For more information, see [Change fields used for statistical analysis](#).

Terms and concepts in explanations

The following terms and concepts appear frequently in explanations. You may find it helpful to become acquainted with their meaning in the context of using Explain Data.

What is a mark?

A mark is a selectable data point that summarizes some underlying record values in your data. A mark can be made of a single record or multiple records aggregated together. Marks in Tableau can be displayed in many different ways such as lines, shapes, bars, and cell text.

Tableau gets the records that make up the mark based on the intersection of the fields in the view.

The **analyzed mark** refers to a mark that you selected in the view that was analyzed by Explain Data.

For more information on marks, see [Marks](#).

What does expected mean?

The expected value for a mark is the median value in the expected range of values in the underlying data in your viz. The expected range is the range of values between the 15th and 85th percentile that the statistical model predicts for the analyzed mark. Tableau determines the expected range each time it runs a statistical analysis on a selected mark.

If an expected value summary says the mark is *lower than expected* or *higher than expected*, it means the aggregated mark value is outside the range of values that a statistical model is predicting for the mark. If an expected value summary says the mark is *slightly lower* or *slightly higher* than expected or *within the range of natural variation*, it means the aggregated mark value is within the range of predicted mark values, but is lower or higher than the median.

For more information, see [What is an expected range?](#)

What are dimensions and measures?

Each column name in a database is a field. For example, Product Name and Sales are each fields. In Tableau, fields like Product Name that categorize data are called dimensions; fields with quantifiable data like Sales are called measures. Tableau aggregates measures by default when you drag them into a view.

Some explanations describe how the underlying record values and the aggregations of those values may be contributing to the value of the analyzed mark. Other explanations may mention the distribution of values across a dimension for the analyzed mark.

When you run Explain Data on mark, the analysis considers dimensions and measures in the data source that aren't represented in the view. These fields are referred to as unvisualized dimensions and unvisualized measures.

For more information on dimensions and measures, see [Dimensions and Measures](#).

What is an aggregate or aggregation?

An aggregate is a value that is a summary or total. Tableau automatically applies aggregations such as SUM or AVG whenever you drag a measure onto Rows, Columns, a Marks card option, or the view. For example, measures are displayed as SUM(Sales) or AVG(Sales) to indicate how the measure is being aggregated.

To use Explain Data, your visualization must use a measure that is aggregated with SUM, AVG, COUNT, COUNTD, or AGG.

For more information about aggregation, see [Data Aggregation in Tableau](#).

What is a record value?

A record is a row in a database table. A row contains values that correspond to each field. In this example, Category, Product Name, and Sales are fields (or columns). Furniture, Floor Lamp, and \$96 are the values.

Category	Product Name	Sales
Furniture	Floor Lamp	\$96.00

What is a distribution?

A distribution is a list of all the possible values (or intervals) of the data. It also indicates how often each value occurs (frequency of occurrence).

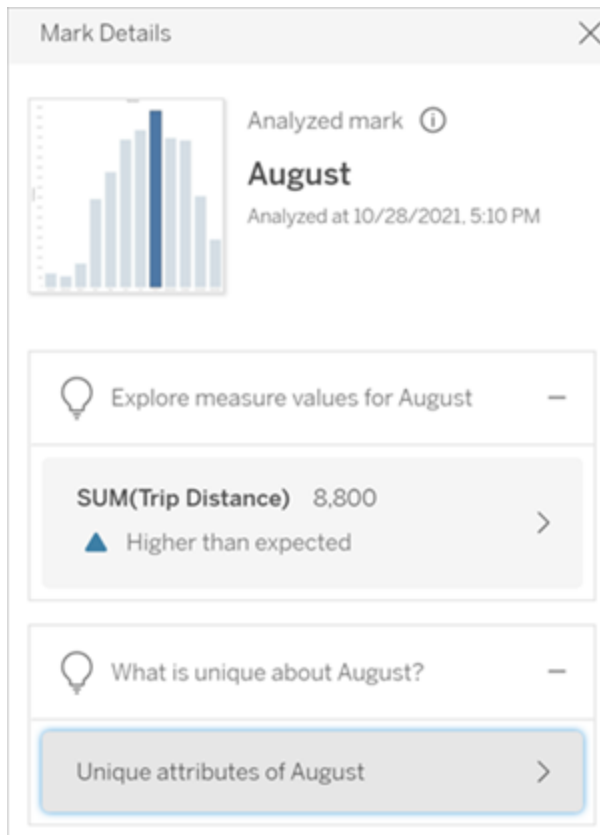

Explanation Types in Explain Data

Each time you select a new mark in a viz or dashboard and run Explain Data, Tableau runs a new statistical analysis considering that mark and the underlying data in the workbook. Possible explanations are displayed in expandable sections for the Explain Data pane. For information about how Explain Data analyzes and evaluates explanations, see [How Explain Data Works](#).

Explore measure values

The **Explore measure values** section of the Explain Data pane lists explanations for each measure that can be explained (referred to as *target measures*). Each explanation listed here describes a relationship with the values of the target measure that are tested on the analyzed mark. Use your real-world, practical understanding of the data to determine if the relationships found by Explain Data are meaningful and worth exploring.

Tableau Server on Windows Help

In this example, Trip Distance is the target measure

Mark Attributes

These explanations describe how underlying records of the marks in the view may be contributing to the aggregated value of the measure being explained. Mark attributes can include **Extreme Values**, **Null Values**, **Number of Records**, or the **Average Value** of the mark.

Note: For definitions of common terms used in explanations, see Terms and concepts in explanations.

Extreme Values

This explanation type indicates if one or more records have values that are significantly higher or lower than most records. If the explanation is supported by a model, it indicates the extreme value is affecting the target measure of the analyzed mark.

When a mark has extreme values, it doesn't automatically mean it has outliers or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an extreme value in the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 dollars instead of 10 cents. Or, it could reveal that a particular sales person had a great quarter.

Note: This explanation must be enabled by the author to be visible in viewing mode for a published workbook. For more information, see [Control Access to Explain Data](#).

This explanation shows:

- The number of underlying records in the analyzed mark.
- The extreme value or values contributing to the value of the target measure.
- The distribution of values in the mark.
- The record details that correspond to each distribution value.

Exploration options:

- Hover over a circle in the chart to see its corresponding value.
- Click the left or right arrow below the details list to scroll through record details.
- If available, click **View Full Data**, and then click the **Full Data** tab to see all records in a table.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- If the number of records is low, examine these values compared to the extreme value.
- If the extreme value is significantly higher or lower than the other record values, exclude it and consider how it changes the value of the analyzed mark.
- When considering the data with and without the extreme value, use this as an opportunity to apply your practical

In this example, a single extreme value of 463 hours rented is contributing to the higher than expected sum of Total Time Rented of 613 hours.

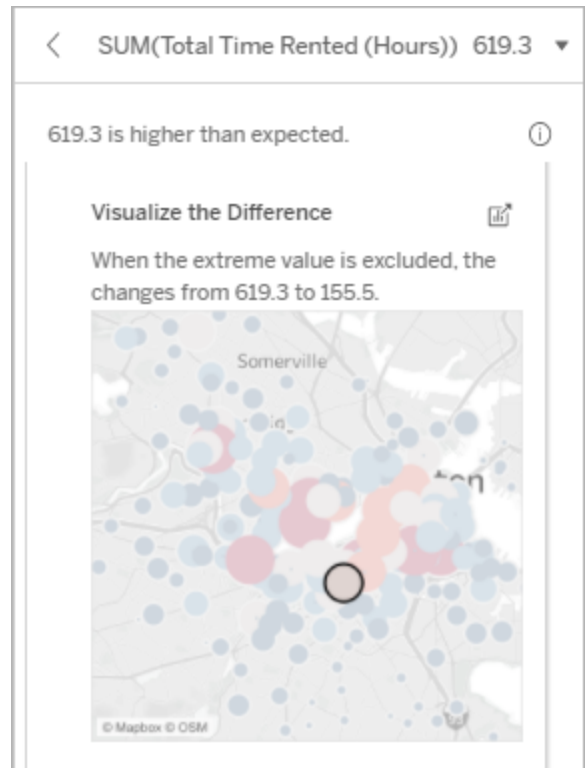

A likely reason for this high value could be that someone forgot to dock the bike when they returned it. In this case, the author might want to exclude this value for future analysis.

knowledge about the data.

Visualize the Difference

This section shows:

- How the analyzed mark value changes when the extreme value is excluded.

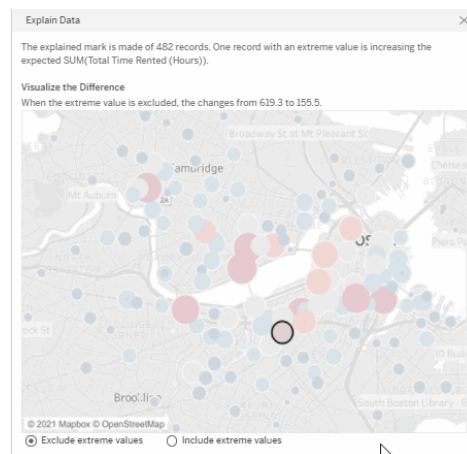

Exploration options:

- Click the **Open** icon to see a larger version of the visualization.
- Explore the difference with and without the extreme value (or values).
- Authors can open the view as a new sheet and apply a filter to exclude the extreme value.

Next steps for analysis:

- If the extreme value is significantly higher or lower than the other record

In this example, when the extreme value of 483 is excluded, the ana-

Tableau Server on Windows Help

values, exclude it and see how it changes the value of the analyzed mark.

- When considering the data with and without the extreme value, use this as an opportunity to apply your practical knowledge about the data.

lyzed mark is no longer high compared to other marks in the view. Other marks now stand out. The author might want to explore the other marks to consider why these other locations have higher hours for bike rentals.

Null Values

The Null Values explanation type calls out situations where there is a higher than expected amount of missing data in a mark. It indicates the fraction of target measure values that are null and how the null values might be contributing to the aggregate value of that measure.

This explanation shows:

- The percent of values that are null in the target measure for the analyzed mark (blue circle).

Exploration options:

- Hover over each circle in the scatter plot to see its details.
- Scroll to see more of the chart.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Optionally exclude null values in the mark for further analysis.

In this example, the percent of null values in the target measure is shown as a blue circle.

Number of Records

This explanation type describes when the count of the underlying records is correlated to the sum. The analysis found a relationship between the number of records that are being aggregated in a mark and the mark's actual value.

While this might seem obvious, this explanation type helps you explore whether the mark's value is being affected by the magnitude of the values in its records or simply because of the number of records in the analyzed mark.

This explanation shows:

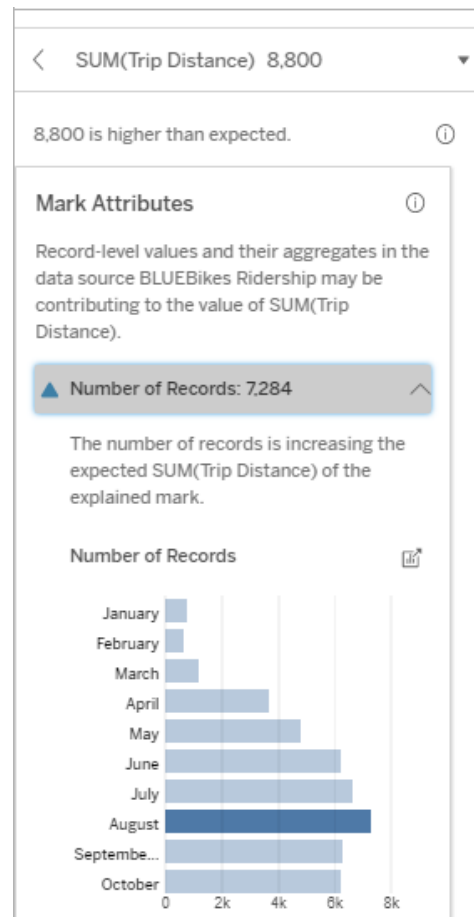

- The number of records in the target measure for the analyzed mark (dark blue bar).
- The number of records in the target measure for other marks in the source visualization (light blue bar).

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Compare whether the individual values of records are low or high, or the number of records in the analyzed mark is low or high.
- Authors, if you are surprised by a high number of records, you might need to normalize the data.

In this example, the number of records for Trip Distance is listed for each value of Ride Month, which is a

dimension in the original visualization. August has the highest total trip distance value.

You might explore whether August has the highest value for trip distance because more rides occurred in August, or if it has the highest trip distance because some rides were longer.

Average Value of Mark

This explanation type describes when the average of a measure is correlated to the sum. Compare whether the average value is low or high, or the number of records is low or high.

This explanation shows:

- The average of the target measure for each value of a dimension used in the source visualization.

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Compare whether the average value is low or high, or the number of records is low or high. For example, are profits high because you sold a lot of items or because you sold expensive items?
- Try to figure out why the analyzed mark has a significantly higher or lower average value.

In this example, the average trip distance for August is not significantly higher or lower than most months. This suggests that trip distance is higher for August because there were more rides in August, rather than from people taking longer rides.

Relevant Single Value

Use this explanation to understand the composition of the record values that make up the analyzed mark.

Tableau Server on Windows Help

This explanation type identifies when a single value in an unvisualized dimension may be contributing to the aggregate value of the analyzed mark. An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view.

This explanation indicates when every underlying record of a dimension has the same value, or when a dimension value stands out because either many or few of the records have the same single value for the analyzed mark.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#).

This explanation shows:

- The percent of the number of records for a single value of a dimension for the analyzed mark (blue bar) versus all marks (gray bar) in the source visualization.
- The percent of the number of records for all other values of a dimension for the analyzed mark (blue bar) versus all marks (gray bar) in the source visualization.
- The average of the target measure for the single value of a dimension in the analyzed mark (blue bar) versus all marks (gray bar).
- The average of the target measure for all other values of a dimension for the analyzed mark (blue bar) versus all marks (gray bar) in the source visualization.

Exploration options:

- Hover over each bar to see its details.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analyzed mark.
- Authors might want to create a new visualization to explore any unvisualized dimension surfaced in this

In this example, the statistical analysis has exposed that many of the rides come from the station neighborhood of Back Bay. Note that Station Neighborhood is an unvisualized dimension that has some relationship to Trip Distance in the underlying data for the source visualization.

explanation.

Relevant Dimensions

Use this explanation to understand the composition of the record values that make up the analyzed mark.

This explanation type shows that the distribution of an unvisualized dimension may be contributing to the aggregate value of the analyzed mark. This type of explanation is used for target measure sums, counts, and averages. An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#).

This explanation shows:

- The percent of the number of records for all values of a dimension for the analyzed mark (blue bar) versus all values of a dimension for all marks (gray bar) in the source visualization.
- The average of the target measure for all values of a dimension for the analyzed mark (blue bar) all values of a dimension for all marks (gray bar).

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analyzed mark.
- Authors might want to create a new visualization to explore any unvisualized dimensions surfaced in this explanation.

In this example, the statistical analysis has exposed that more rides were taken from Boylston stations and fewer rides were taken from MIT and Kendall, compared to rides taken for marks overall.

Note that Station Name is an unvisualized dimension that has some relationship to Trip Distance in the underlying data for the source visualization.

Relevant Measures

This explanation type shows that the average of an unvisualized measure may be contributing to the aggregate value of the analyzed mark. An unvisualized measure is a measure that exists in the data source, but isn't currently being used in the view.

This explanation can reveal a linear or quadratic relationship between the unvisualized measure and the target measure.

Note: For definitions of common terms used in explanations, see Terms and concepts in explanations.

This explanation shows:

- The relationship between the sum of the target measure and the average of an unvisualized measure for the analyzed mark (blue circle) and all marks (gray circles) in the view.
- If the sum of the target measure is high or low because the average value of the unvisualized measure is high or low.

Exploration options:

- Hover over each circle to see its details.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Authors might want to create a new visualization to explore any unvisualized measures surfaced in this explanation.

What is unique about the mark?

The **What is unique** section of the Explain Data pane shows possible reasons why the analyzed mark is unique or unusual. These explanations:

- Do not explain why the value of this mark is what it is.
- Are not related in any way to the value of the measures in the source visualization.
- Do not take any target measures into account.

In this example, one possible reason why trip distance is high is because the average total time rented is also high.

Relevant Single Value

The explanation type indicates when all records in the analyzed mark have the same single value in the unvisualized dimension, which is unusual compared to the distribution of values for all other marks in the view.

An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view

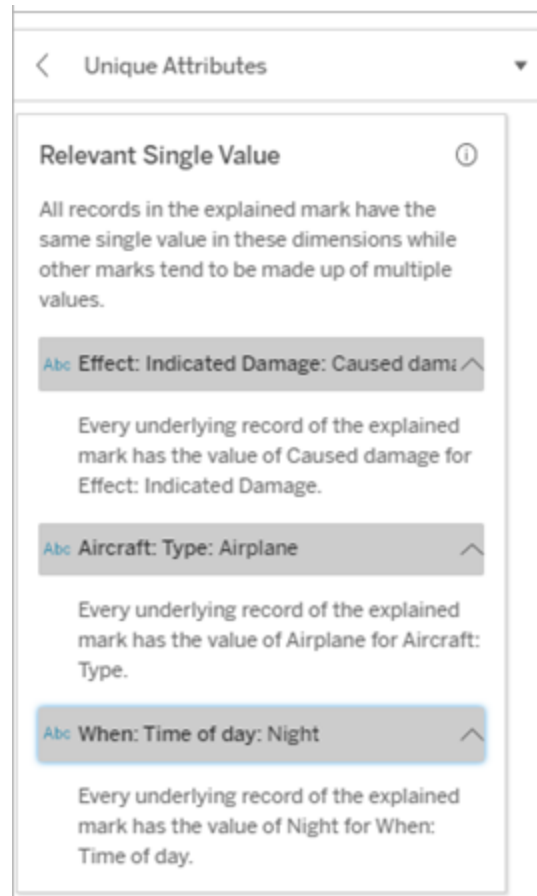

Note: For definitions of common terms used in explanations, see Terms and concepts in explanations.

This explanation shows:

- When every underlying record has the same single value for a dimension.

Next steps for analysis:

- If all records in the analyzed mark have the same single value, you might want to check the number of records in that mark.
- You might check if the unvisualized dimension is a proxy for a dimension that is being used in the source visualization.

This example shows an explanation

for data about incidents related to birds and other wildlife colliding with aircraft. In the unfortunate case of a wapiti (elk), three underlying dimensions each had underlying records with single values: Aircraft, Indicated Damage, and Time of Day.

Relevant Dimensions

Use this explanation to understand the composition of the record values that make up the analyzed mark.

The distribution of an unvisualized dimension in the analyzed mark is unusual compared to the distribution of values for all other marks in the view. An unvisualized dimension is a dimension that exists in the data source, but isn't currently being used in the view.

Note: For definitions of common terms used in explanations, see [Terms and concepts in explanations](#).

This explanation shows:

- The percent of the number of records for all values of a dimension for the analyzed mark (blue bar) versus all values of a dimension for all marks (gray bar) in the source visualization.

Exploration options:

- Hover over each bar to see its details.
- Scroll to see more of the chart.
- Click the **Open**  icon to see a larger version of the visualization.

Next steps for analysis:

- Use this explanation to understand the composition of the record values that make up the analyzed mark.
- Authors might want to create a new visualization to explore any unvisualized dimensions surfaced in this explanation.

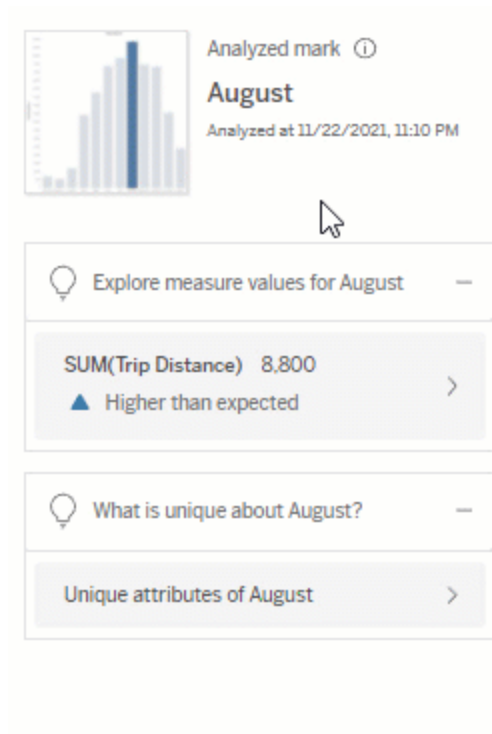

In this example, a high percentage of records are associated with overcast weather. Because the data is about bike rentals in Boston, and the analyzed mark is Trip Distance for August, we can assume that the weather is typically warm and humid. People might have rented bikes more often on overcast days to avoid the heat. It's also possible there were more overcast days in August.

Analyzed Fields in Explain Data

When you run Explain Data on a mark, a statistical analysis is run on the aggregated mark, and then on potentially related fields from the data source that aren't represented in the current view.

Explain Data might not include every column from the data source in the analysis. In many cases, certain types of fields will be automatically excluded from the analysis. For more information, see [Fields excluded by default](#).

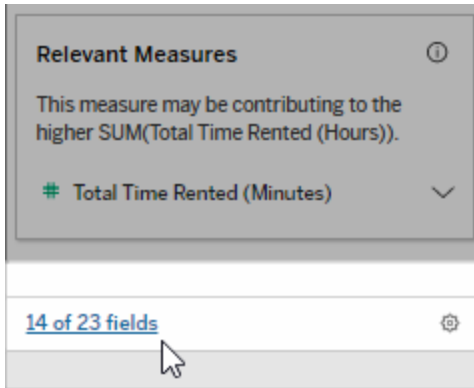

Note: Dimensions with more than 500 unique values won't be considered for analysis (unless allowed by the author in Explain Data Settings).

All users can view information on which fields are included or excluded in the current analysis. Creators and Explorers who have editing permissions can edit the fields used by Explain Data for statistical analysis.

Tableau Server on Windows Help

View fields analyzed by Explain Data

When you expand an explanation for a measure that is contributing to the value of the mark, a link that indicates the number of fields considered in the analysis is displayed at the bottom of the Explain Data pane.

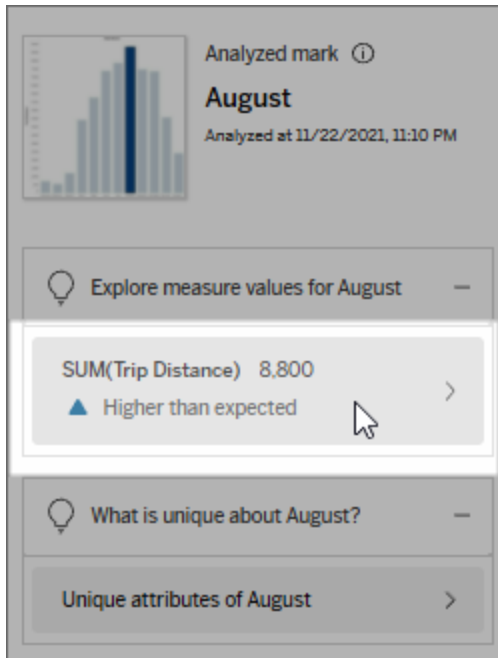

Click the link to see the list of fields included in or excluded from the current statistical analysis.

When a data source contains more than 1000 unvisualized dimensions or measures, you might see an alert asking if you want Explain Data to consider more fields. Click **Explain All** to run an analysis that includes more fields. The analysis may take longer to complete.

To view fields used by Explain Data for statistical analysis

1. [Run Explain Data on a mark.](#)
2. In the Explain Data pane, under **Contributing to the value of**, click a measure name.

3. Click the *number-of-fields* link at the bottom of the pane.

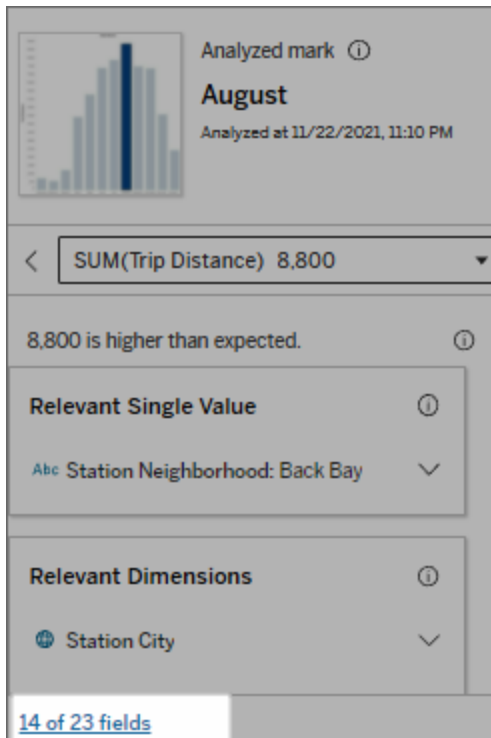

Tableau Server on Windows Help

Change fields used for statistical analysis

Creators and Explorers who have editing permissions can select fields to be included or excluded from the statistical analysis in the Fields tab of the Explain Data Settings dialog box.

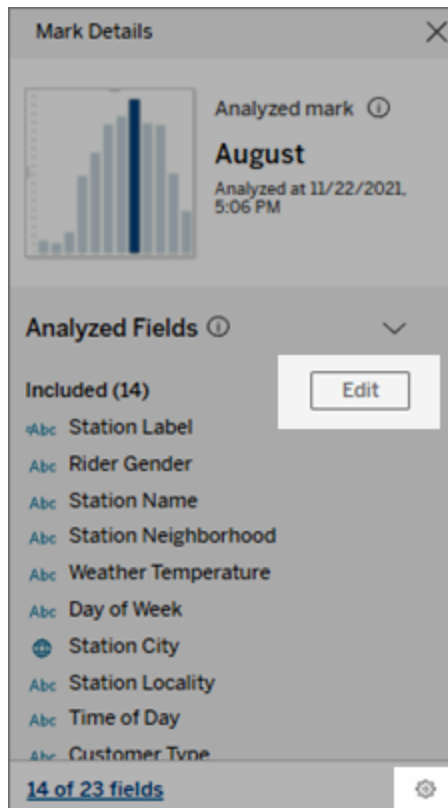

When a data source contains dimensions with a large number of unique values (up to 500), those fields won't be considered for analysis.

To edit the fields used by Explain Data for statistical analysis

Settings for analyzed fields are applied at the data source level.

1. Run Explain Data on a mark when editing a view.
2. In the Explain Data pane, click the settings icon at the bottom of the Explain Data pane.
Or, click the **Edit** button in the Analyzed Fields view ([how to open analyzed fields](#)).

3. In the Explain Data Settings dialog box, click the **Fields** tab.
4. Click a drop-down arrow next to a field name, select **Automatic** or **Never Include**, and then click **OK**.

Note that fields must have less than 500 unique values to be included in the analysis.

Fields excluded by default

Fields excluded by default

All unvisualized measures when there are more than 1,000 measures in the data source.

All unvisualized dimensions when there are more than 1,000 dimensions in the data source.

Reasons for exclusion

Computing explanations for more than 1000 unvisualized measures or dimensions can take longer to compute, sometimes several minutes. These fields are excluded by default for initial analysis, but you can choose to include them for further analysis.

In this situation, you might see an alert asking if you want Explain Data to consider more fields. Click the alert link to get more information. Click **Explain All** to run an analysis that includes more fields.

Fields excluded by default	Reasons for exclusion
Fields that use geometry, latitude, or longitude	Geometry, latitude, or longitude by themselves can never be explanations. It is highly likely that an explanation that calls out the latitude or the longitude as an explanation is due to a spurious correlation and not a probable explanation.
Dimensions with high cardinality (dimensions with > 500 members)	High cardinality dimensions take longer to compute. Dimensions with more than 500 unique values will not be considered for analysis.
Groups, bins, or sets	Not currently supported.
Table calculations	Table calculations cannot be analyzed when table calculations are at a different level of detail than the view.
Unvisualized measures that can't be averaged	Unvisualized measures that can't be averaged include measures that are calculated fields where the calculation expression includes aggregations (display as AGG() fields when added to the sheet).
Discrete measures and continuous dimensions	Not currently supported.
Hidden fields	Not available.
Calculated fields with errors	No values present to analyze.

Requirements and Considerations for Using Explain Data

Explain Data is always available to authors in Tableau Desktop.

For Tableau Online and Tableau Server: When Explain Data is enabled for a site, Creators and Explorers with the appropriate permissions can run Explain Data when editing a work-

book. Authors can allow any user to run Explain Data in viewing mode in published workbooks. For more information, see [Control Access to Explain Data](#).

What makes a viz a good candidate for Explain Data

Explain Data works best on visualizations that require deeper exploration and analysis, rather than infographic-style, descriptive vizzes that communicate summarized data.

- Row-level data is necessary for Explain Data to create models of your data and generate explanations. Vizzes with underlying, row-level data, where relationships might exist in unvisualized fields are good candidates for running Explain Data.
- Vizzes based on pre-aggregated data without access to row-level data are not ideal for the statistical analysis performed by Explain Data.

What data works best for Explain Data

When you are using Explain Data in a worksheet, remember that Explain Data works with:

- **Single marks only**—Explain Data must be run on a single mark. Multiple mark analysis is not supported.
- **Aggregated data**—The view must contain one or more measures that are aggregated using SUM, AVG, COUNT, or COUNTD. At least one dimension must also be present in the view.
- **Single data sources only**—The data must be drawn from a single, primary data source. Explain Data does not work with blended or cube data sources.

When preparing a data source for a workbook, keep the following considerations in mind if you plan to use Explain Data during analysis.

- Use a data source with underlying data that is sufficiently wide. An ideal data set has at least 10-20 columns in addition to one (or more) aggregated measures to be explained.
- Give columns (fields) names that are easy to understand.
- Eliminate redundant columns and data prep artifacts. For more information, see [Change fields used for statistical analysis](#).

- Don't discard unvisualized columns in the data source. Explain Data considers fields in the underlying data when it analyzes a mark.
- Low cardinality dimensions work better. The explanation of a categorical dimension is easier to interpret if its cardinality is not too high (< 20 categories). Dimensions with more than 500 unique values will not be considered for analysis.
- Don't pre-aggregate data as a general rule. But if the data source is massive, consider pre-aggregating the data to an appropriate level of detail.
- Use extracts over live data sources. Extracts run faster than live data sources. With live data sources, the process of creating explanations can create many queries (roughly one query per each candidate explanation), which can result in explanations taking longer to be generated.

Situations where Explain Data is not available

Sometimes Explain Data will not be available for a selected mark, depending on the characteristics of the data source or the view. If Explain Data cannot analyze the selected mark, the Explain Data icon and context menu command will not be available.

Explain Data can't be run in views that use:

- Map coordinate filters
- Blended data sources
- Data sources with parameters
- Data sources that don't support COUNTD or COUNT(DISTINCT ...) syntax, such as Access.
- Filters on aggregate measures
- Disaggregated measures

Explain Data can't be run if you select:

- Multiple marks
- Axis
- Legend
- Grand total
- Trend line or reference line
- A mark in a view that contains a very low number of marks

Explain Data can't be run when the measure to be used for an

- Isn't aggregated using SUM, AVG, COUNT, COUNTD

Tableau Server on Windows Help

explanation:

- Is a table calculation
- Is used in measure values

Explain Data can't offer explanations for a dimension when it is:

- A calculated field
- A parameter
- Used in Measure Names and Measure Values
- A field with more than 500 unique values. Dimensions with more than 500 unique values will not be considered for analysis.

Control Access to Explain Data

Your access to Explain Data will vary depending on your site role and content permissions. Explain Data is always available to authors in Tableau Desktop. Authors with appropriate permissions can run Explain Data in editing mode in Tableau Online and Tableau Server.

Authors can also control whether Explain Data is available in viewing mode in published workbooks and which explanation types are displayed in the Explain Data pane.

Be aware that Explain Data can surface values from dimensions and measures in the data source that aren't represented in the view. As an author, you should run Explain Data and test the resulting explanations to make sure that sensitive data isn't being exposed in your published workbooks.

Who can access Explain Data

Explain Data is enabled by default at the site level. Server administrators (Tableau Server) and site administrators (Tableau Online) can control whether Explain Data is available for a site. For more information, [Disable or Enable Explain Data for a Site](#).

Mode	Who Can Access
Viewing mode	When an author makes Explain Data available in viewing mode in a published workbook, Tableau Viewers , Explorers , and Creators who have the Run Explain Data permission

Mode	Who Can Access
	<p>capability can run and explore Explain Data explanations in viewing mode.</p>
Editing mode	<p>Tableau Creators can run Explain Data when editing a view in Tableau Desktop, Tableau Online, or Tableau Server.</p> <p>Explorers who have the Run Explain Data permission capability and editing permissions can run Explain Data when editing a workbook in Tableau Online or Tableau Server.</p> <p>Creators and Explorers who have editing permissions can open new worksheets for further analysis.</p> <p>They also can use Explain Data Settings to control who can use Explain Data and what they can see.</p>

Control who can use Explain Data and what they can see

A combination of settings must be enabled to make Explain Data available in editing mode and viewing mode in Tableau Online and Tableau Server.

Editing mode

Requirements for authors to run Explain Data or edit Explain Data settings in editing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer (can publish)
- Permissions: **Run Explain Data** capability set to **Allowed**. Allowed by default.

Note: The **Download Full Data** capability for a Creator or Explorer (can publish) controls whether they see the View Full Data option in Extreme Values explanations. Viewers are always denied the Download Full Data capability. However, all users can see record-level details when the Extreme Values explanation type is enabled in Explain Data settings.

Tableau Server on Windows Help

Viewing mode

Requirements for all users to run Explain Data in viewing mode:

- Site setting: **Availability of Explain Data** set to **Enable**. Enabled by default.
- Site role: Creator, Explorer, or Viewer
- Permissions: **Run Explain Data** capability set to **Allowed**. Allowed by default.
- Workbook setting: **Allow Explain Data to be used in this workbook when viewed online** selected in the Explain Data Settings dialog box. Not allowed by default.

Important: To allow all users (including Viewer site role) to run Explain Data in viewing mode, the workbook author must select the option **Allow Explain Data to be used in this workbook when viewed online** in the Explain Data Settings dialog box. For more information, see [Enable Explain Data in viewing mode in published workbooks and dashboards](#).

Creators and Explorers with editing permissions and the Run Explain Data permission capability can access **Explain Data Settings**, which provide options for controlling:

- Whether all users, including Viewers, are allowed to run Explain Data and [see explanations while viewing published workbooks](#) and dashboards. This option is not enabled by default, so authors need to explicitly allow it.
- The [explanation types that are displayed](#) in the Explain Data pane.
- The [fields that are included in, or excluded from](#) statistical analysis.

These options are set for the entire workbook and can only be set in the Explain Data Settings dialog box.

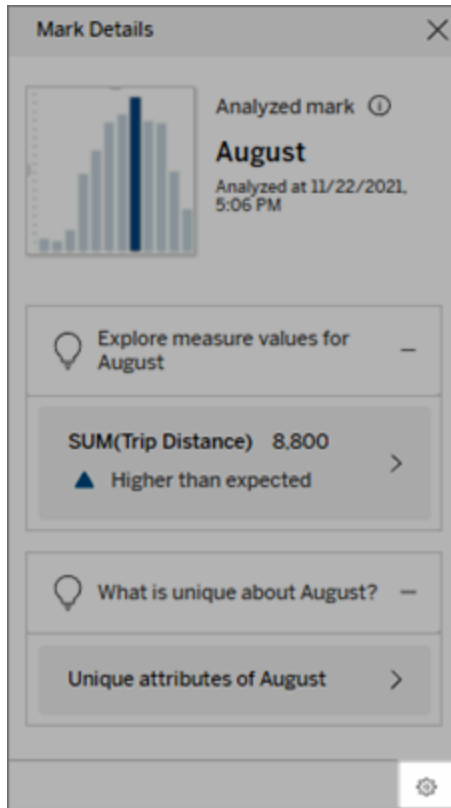

Open the Explain Data Settings dialog box

1. From the **Data** menu, select *data-source-name* > **Explain Data Settings**. For example:

Or, in the Explain Data pane, click the settings icon (bottom right).

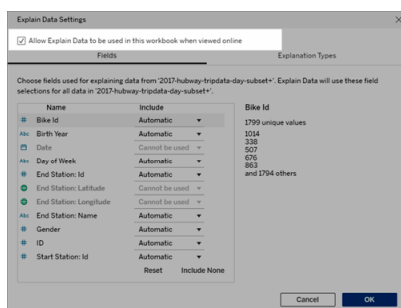

Tableau Server on Windows Help

Enable Explain Data in viewing mode in published workbooks and dashboards

By default, Explain Data is not available in viewing mode. To turn Explain Data on for viewing mode, authors must do the following:

1. In the **Explain Data Settings** dialog box, click the **Explanation Types** tab.
2. Select **Allow Explain Data to be used in this workbook when viewed online**.

Alternatively, leave this option unchecked to return to the default setting and make

Explain Data unavailable in viewing mode. Creators and Explorers who have editing permissions and the Run Explain Data permission capability will still be able to run Explain Data when editing a workbook.

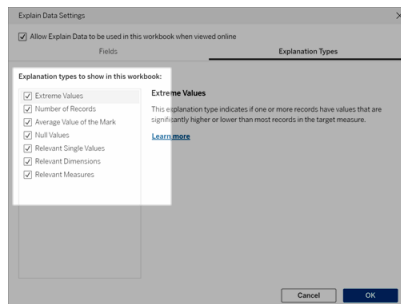

3. Click **OK**.

Test the setting by saving and closing the published workbook, and then open a view from the workbook in viewing mode. Select a mark, and then run Explain Data to check the explanation results.

Include or exclude explanation types displayed by Explain Data

Creators and Explorers who have editing permissions can choose to exclude (or include) explanation types displayed for all workbook users.

1. In the **Explain Data Settings** dialog box, click the **Explanation Types** tab.

2. In the list of explanation types, select or clear an explanation type.
3. Click **OK**.

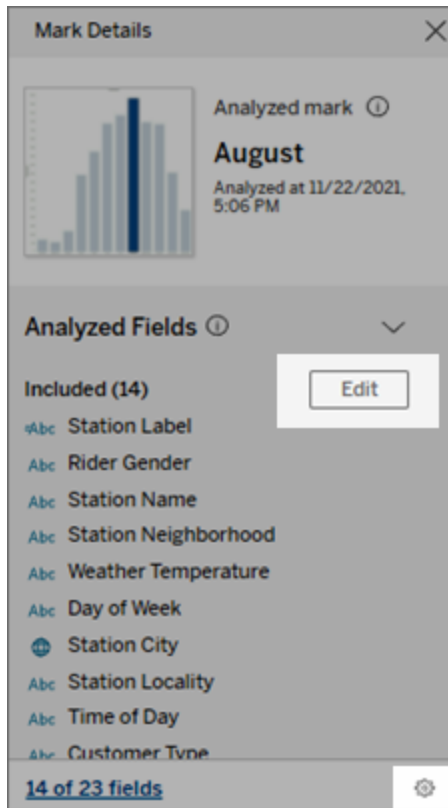

Test the setting by saving and closing the published workbook, and then opening a view from the workbook in viewing mode. Select a mark that typically has Extreme Value explanations, and then run Explain Data to check the explanation results.

Include or exclude fields used for statistical analysis

Creators or Explorers who have editing permissions can choose to exclude (or include) fields that are eligible for analysis.

Tableau Server on Windows Help

1. In the Explain Data pane (bottom right), click the settings icon. Or, click the **Edit** button in the **Analyzed Fields view**.

2. In the **Explain Data Settings** dialog box, click the **Fields** tab.
3. In the list of fields under **Include**, click the drop-down arrow and select **Automatic** to include an eligible field every time Explain Data runs for that workbook.

Note that fields must have less than 500 unique values to be included in the analysis.

Select **Never Include** to explicitly exclude the field.

Select **Include None** to run a statistical analysis on the data without considering fields.

Select **Reset** to return to the default settings.

4. Click **OK**.

Test the setting by saving the published workbook. Select a mark, and then run Explain Data to check the explanation results.

How Explain Data Works

Use Explain Data as an incremental, jumping-off point for further exploration of your data. The possible explanations that it generates help you to see the different values that make up or relate to a selected mark in a view. It can tell you about the characteristics of the data points in the data source, and how the data might be related (correlations) using statistical modeling. These explanations give you another tool for inspecting your data and finding

interesting clues about what to explore next.

Note: Explain Data is a tool that uncovers and describes relationships in your data. It can't tell you what is causing the relationships or how to interpret the data. **You are the expert on your data.** Your domain knowledge and intuition is key in helping you decide what characteristics might be interesting to explore further using different views.

For related information on how Explain Data works, and how to use Explain Data to augment your analysis, see these Tableau Conference presentations:

- [From Analyst to Statistician: Explain Data in Practice \(1 hour\)](#)
- [Leveraging Explain Data \(45 minutes\)](#)
- [Explain Data Internals: Automated Bayesian Modeling \(35 minutes\)](#)

What Explain Data is (and isn't)

Explain Data is:

- A tool and a workflow that leverages your domain expertise.
- A tool that surfaces relationships in your data and recommends where to look next.
- A tool and a workflow that helps expedite data analysis and make data analysis more accessible to a broader range of users.

Explain Data is not:

- A statistical testing tool.
- A tool to prove or disprove hypotheses.
- A tool that is giving you an answer or telling you anything about causality in your data.

When running Explain Data on marks, keep the following points in mind:

- **Consider the shape, size, and cardinality of your data.** While Explain Data can be used with smaller data sets, it requires data that is sufficiently wide and contains enough marks (granularity) to be able to create a model.
- **Don't assume causality.** Correlation is not causation. Explanations are based on models of the data, but are not causal explanations.

A correlation means that a relationship exists between some data variables, say A and B. You can't tell just from seeing that relationship in the data that A is causing B, or B is causing A, or if something more complicated is actually going on. The data patterns are exactly the same in each of those cases and an algorithm can't tell the difference between each case. Just because two variables seem to change together doesn't necessarily mean that one causes the other to change. A third factor could be causing them both to change, or it may be a coincidence and there might not be any causal relationship at all.

However, you might have outside knowledge that is not in the data that helps you to identify what's going on. A common type of outside knowledge would be a situation where the data was gathered in an experiment. If you know that B was chosen by flipping a coin, any consistent pattern of difference in A (that isn't just random noise) must be caused by B. For a longer, more in-depth description of these concepts, see the article [Causal inference in economics and marketing](#) by Hal Varian.

How explanations are analyzed and evaluated

When you run Explain Data on a mark, a statistical analysis is run on the aggregated mark and then on possibly related data points from the data source that aren't represented in the current view.

Explain Data first predicts the value of a mark using only the data that is present in the visualization. Next, data that is in the data source (but not in the current view) is considered and added to the model. The model determines the range of predicted mark values, which is within one standard deviation of the predicted value.

What is an expected range?

The expected value for a mark is the median value in the expected range of values in the underlying data in your viz. The expected range is the range of values between the 15th and 85th percentile that the statistical model predicts for the analyzed mark. Tableau determines the expected range each time it runs a statistical analysis on a selected mark.

Possible explanations are evaluated on their explanatory power using statistical modeling. For each explanation, Tableau compares the expected value with the actual value.

value	Description
Higher than expected / Lower than expected	If an expected value summary says the mark is <i>lower than expected</i> or <i>higher than expected</i> , it means the aggregated mark value is outside the range of values that a statistical model is predicting for the mark. If an expected value summary says the mark is <i>slightly lower</i> or <i>slightly higher</i> than expected, or <i>within the range of natural variation</i> , it means the aggregated mark value is within the range of predicted mark values, but is lower or higher than the median.
Expected Value	If a mark has an expected value, it means its value falls within the expected range of values that a statistical model is predicting for the mark.
Random Variation	When the analyzed mark has a low number of records, there may not be enough data available for Explain Data to form a statistically significant explanation. If the mark's value is outside the expected range, Explain Data can't determine whether this unexpected value is being caused by random variation or by a meaningful difference in the underlying records.
No Explanation	When the analyzed mark value is outside of the expected range and it does not fit a statistical model used for Explain Data, no explanations are generated.

Models used for analysis

Explain Data builds models of the data in a view to predict the value of a mark and then determines whether a mark is higher or lower than expected given the model. Next, it considers additional information, like adding additional columns from the data source to the view, or flagging record-level outliers, as potential explanations. For each potential explanation, Explain Data fits a new model, and evaluates how unexpected the mark is given the new

information. Explanations are scored by trading off complexity (how much information is added from the data source) against the amount of variability that needs to be explained. Better explanations are simpler than the variation they explain.

Explanation type	Evaluation
Extreme values	<p>Extreme values are aggregated marks that are outliers, based on a model of the visualized marks. The selected mark is considered to contain an extreme value if a record value is in the tails of the distribution of the expected values for the data.</p> <p>An extreme value is determined by comparing the aggregate mark with and without the extreme value. If the mark becomes less surprising by removing a value, then it receives a higher score.</p> <p>When a mark has extreme values, it doesn't automatically mean it has outliers, or that you should exclude those records from the view. That choice is up to you depending on your analysis. The explanation is simply pointing out an interesting extreme value in the mark. For example, it could reveal a mistyped value in a record where a banana cost 10 dollars instead of 10 cents. Or, it could reveal that a particular sales person had a great quarter.</p>
Number of records	<p>The number of records explanation models the aggregate sum in terms of the aggregate count; average value of records models it in terms of the aggregate average. The better the model explains the sum, the higher the score.</p> <p>This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p>

Explanation type	Evaluation
Average value of the mark	<p>This type of explanation is used for aggregate marks that are sums. It explains whether the mark is consistent with the other marks because in terms of its aggregate count or average, noting the relation $SUM(X) = COUNT(X) * AVG(X)$.</p> <p>This explanation describes whether the sum is interesting because the count is high or low, or because the average is high or low.</p>
Relevant Dimensions	<p>This explanation models the target measure of the analyzed mark in terms of the breakdown among categories of the unvisualized dimension. The analysis balances the complexity of the model with how well the mark is explained.</p> <p><i>An unvisualized dimension</i> is a dimension that exists in the data source, but isn't currently being used in the view. This type of explanation is used for sums, counts and averages.</p> <p>The model for unvisualized dimensions is created by splitting out marks according to the categorical values of the explaining column, and then building a model with the value that includes all of the data points in the source visualization. For each row, the model attempts to recover each of the individual components that made each mark. The analysis indicates whether the model predicts the mark better when components corresponding to the unvisualized dimension are modeled and then added up, versus using a model where the values of the unvisualized dimension are not known.</p> <p>Aggregate dimension explanations explore how well mark values can be explained without any conditioning. Then, the model conditions on values for each column that is a potential explanation. Conditioning on the distribution of an explanatory column should</p>

Explanation type	Evaluation
Relevant Measures	<p>result in a better prediction.</p> <p>This explanation models the mark in terms of this unvisualized measure, aggregated to its mean across the visualized dimensions. An <i>unvisualized measure</i> is a measure that exists in the data source, but isn't currently being used in the view.</p> <p>A Relevant Measures explanation can reveal a linear or quadratic relationship between the unvisualized measure and the target measure.</p>

Disable or Enable Explain Data for a Site

Explain Data is enabled for sites by default, but Tableau administrators may disable it.

1. Go to the **General** site settings.
2. (Tableau Server only) In the **Web Authoring** section, select **Let users edit workbooks in their browser**.
3. In the **Availability of Explain Data** section, select from these options:
 - **Enable Explain Data** lets Creators and Explorers with the appropriate permissions run Explain Data in editing mode. Lets all users with appropriate permissions run Explain Data when it is enabled for viewing mode.
 - **Disable Explain Data** prevents all users from running Explain Data or accessing Explain Data settings in workbooks.

Use Dashboard Extensions

Extensions let you add unique features to dashboards or directly integrate them with applications outside Tableau. Adding extensions is easy; you incorporate them into dashboard layouts just like other dashboard objects.

Tableau Server on Windows Help

Extensions expand dashboard functionality with the help of web applications created by third-party developers. If you're a developer and want to create your own extensions, see the [Tableau Extensions API documentation](#) on GitHub.

Note: Tableau administrators can turn off dashboard extensions for [Tableau Desktop](#), [Tableau Server](#), and [Tableau Online](#).

Add an extension to a dashboard

1. In a Tableau workbook, open a dashboard sheet.
2. From the **Objects** section, drag **Extension** to the dashboard.

3. In the “Add an Extension” dialog box, do either of the following:
 - Search for and select an extension.
 - Click **Access Local Extensions**, and navigate to a .trex file you previously downloaded.
4. If prompted, allow or deny the dashboard extension access to data in the workbook. For more information, see [Data security](#), [Network-enabled](#), and [Sandboxed extensions](#).

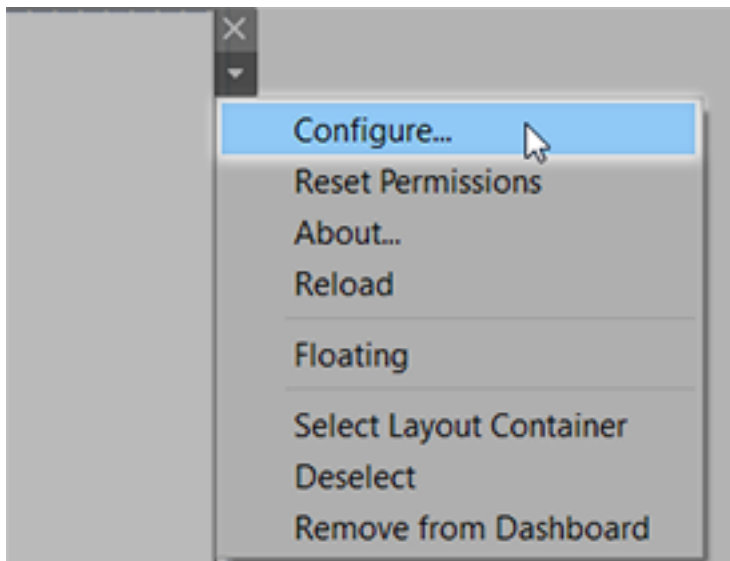

If you allow access, follow any on screen instructions for configuring the extension.

Note: If you're using Tableau Server or Tableau Online, Extension objects will appear blank in prints, PDFs, and images of dashboards (including images in subscription emails).

Configure a dashboard extension

Some dashboard extensions provide configuration options that let you customize features.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Configure**.
2. Follow the on-screen instructions to configure the extension.

Reload a dashboard extension

If a dashboard extension becomes unresponsive, you might need to reload it, which is similar to refreshing a web page in a browser.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reload**.

The dashboard extension is refreshed and set to its original state.

2. If reloading the extension fails to return it to a useable state, try removing it from the dashboard and adding it again.

Data security, Network-enabled, and Sandboxed extensions

Dashboard extensions are web applications that come in two forms:

- *Network-enabled extensions* run on web servers located outside of your local network.
- *Sandboxed extensions* run in a protected environment without access to any other resource or service on the web.

Before adding a Network-enabled extension or viewing a dashboard with one, be certain that you trust the website that hosts it. By default, dashboard extensions use the HTTPS protocol, which guarantees an encrypted channel for sending and receiving data, and ensures some privacy and security.

For more information about data security when using dashboard extensions, see [Extension Security - Best Practices for Deployment](#).

Allow or deny data access to a Network-enabled extension

Depending on how an extension is designed, it can access either visible data in a view, or full underlying data, table and field names from data sources, and information about data source connections. When you add an extension, or view a dashboard with one, you're given an opportunity to allow or deny the extension to run and access this data.

If you're viewing a dashboard with an extension that requires full data access, and that access has been denied, a message appears in place of the extension. If you trust the extension and want to use it, you can reset permissions and allow the extension to run.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **Reset Permissions**.
2. Click either **Allow** to let the extension run and access data, or **Deny** to prevent the extension from running.

Ensure that JavaScript is enabled in Tableau Desktop

Dashboard extensions interact with data using the Tableau Extensions API library, a JavaScript library. If you want to use extensions, be sure that JavaScript is enabled in the dashboard security settings:

Choose **Help > Settings and Performance > Set Dashboard Web View Security > Enable JavaScript**.

Ensure that extensions run on Tableau Online or Tableau Server

You can add extensions to workbooks you publish from Tableau Desktop or directly in the web-authoring mode of Tableau Online and Tableau Server. A Tableau administrator must allow extensions to run on a site and add Network-enabled extensions to a safe list. Administrators should only allow extensions that you have tested and trust.

Tableau Server on Windows Help

If you want to use a dashboard extension on Tableau Online or Tableau Server, direct your administrator to [Manage Dashboard Extensions in Tableau Online](#) or [Manage Dashboard Extensions in Tableau Server](#).

Supported web browsers for Sandboxed extensions

Sandboxed extensions run in all browsers supported [Tableau Server](#) and [Tableau Online](#) except Internet Explorer 11.

Supported versions of Tableau Server for Sandboxed extensions

You can use Sandboxed extensions in Tableau Server 2019.4 and later.

Get support for dashboard extensions

To get help for an extension, you'll need to contact the developer or company who created it.

1. Select the extension in the dashboard, and from the drop-down menu in the upper-right corner, choose **About**.
2. Click **Get Support** to go to the support page of the extension developer.

Note: Tableau doesn't provide support for extensions or for other programs that interface with the Extensions API. However, you can submit questions and ask for help in the [Tableau developer community](#).

Format Animations

Animate visualizations to better highlight changing patterns in your data, reveal spikes and outliers, and see how data points cluster and separate.

Animations visually transition between filter, sort, and zoom settings, different pages, and changes to filter, parameter, and set actions. As visualizations animate in response to these changes, viewers can more clearly see how data differs, helping them make better informed decisions.

Understanding simultaneous and sequential animations

When you author animations, you can choose between two different styles: simultaneous or sequential. Here are examples of each type.

Simultaneous animations

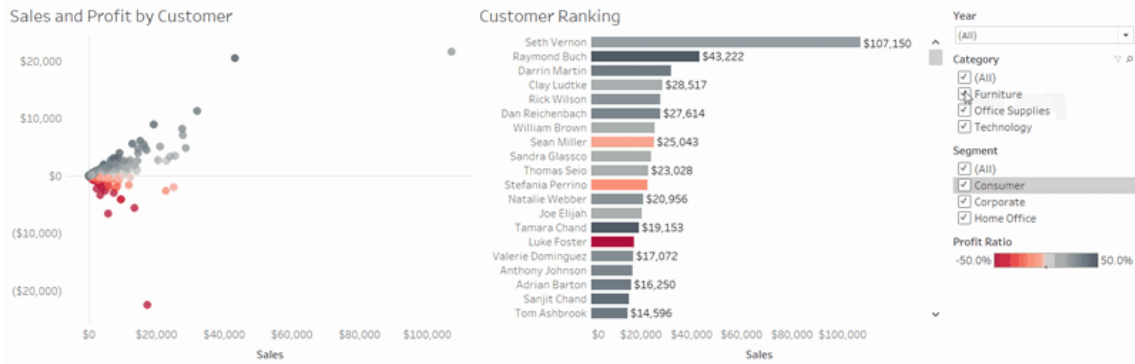

The default simultaneous animations are faster and work well when showing value changes in simpler charts and dashboards.

Click the image above to replay the animation.

Sequential animations

Sequential animations take more time but make complex changes clearer by presenting them step-by-step.

Click the image above to replay the animation.

Animate visualizations in a workbook

When you create a new workbook, Tableau enables animations for your viz by default. You can turn animations on or off at the user and workbook level.

1. Choose **Format > Animations**.
2. If you want to animate every sheet, under **Workbook Default**, click **On**. Then do the following:
 - For **Duration**, choose a preset, or specify a custom duration of up to 10 seconds.
 - For **Style**, choose **Simultaneous** to play all animations at once or **Sequential** to fade out marks, move and sort them, and then fade them in.
3. To override workbook defaults for a particular sheet, change the settings under **Selected Sheet**.

Note: In the Selected Sheet section, “(Default)” indicates a setting that auto-

atically reflects the related Workbook Default setting.

Sequential ▼

Tableau Server on Windows Help

To replay an animation, click the **Replay** button in the toolbar. From the **Replay** button, you can also choose the speed at which the animation replays: actual speed, 2x speed, or 1/2 speed.

Reset animation settings for a workbook

You can reset animations to return an entire workbook to the default animation settings. Be aware that this turns animations off by default.

1. Choose **Format > Animations**.
2. In the middle of the **Animations** pane, click **Reset All Sheets**.

Completely disable all animations

When you create a new workbook, animations are enabled by default. If you find animations distracting while viewing vizs, you can completely disable them so they never play. (This isn't a system-wide setting; each user needs to apply it separately.)

- In Tableau Desktop, choose **Help > Settings and Performance**, and deselect **Enable Animations**.
- In Tableau Online or Tableau Server, click your profile image or initials in the top right corner of the browser, and choose **My Account Settings**. Then scroll down to the bottom of the page, deselect **Enable animations**, and click **Save Changes**.

Note: When animations are disabled, you can still choose **Format > Animations** in authoring mode and adjust settings—but they will have no effect.

Format decimals for axes animations

If the number of decimal places for a measure is set to the default, then the number of decimals shown during the axis animation might fluctuate during the axes animation. To avoid this, format the number of decimal places displayed for a measure. For more information, see [Format Numbers and Null Values](#).

Why animations won't play

Server rendering

Animations won't play if a viz is server-rendered. To ensure that vizzes render on a client computer or mobile device, use these techniques:

- If you're a viz author, [reduce viz complexity](#).
- If you're a Tableau Server administrator, [increase the complexity threshold for client-side rendering](#).

Note: On computers with lower processing power, animations may appear choppy, but users can continue to interact with vizzes without any delays in responsiveness.

Unsupported browsers and features

Animations are supported by all web browsers except Internet Explorer.

The following Tableau features don't animate:

- Maps, polygons, and density marks in web browsers
- Pie and text marks
- Headers
- Forecasts, trends, and reference lines

Tableau Server on Windows Help

- Page history trails (If a viz includes these, turn off animations to avoid unexpected behavior.)

URL Actions

A URL action is a hyperlink that points to a web page, file, or other web-based resource outside of Tableau. You can use URL actions to create an email or link to additional information about your data. To customize links based on your data, you can automatically enter field values as parameters in URLs.

Tip: URL actions can also point to a web page object in a dashboard. See [Actions and Dashboards](#) to learn more.

A URL action run from a tooltip menu. The link reflects the action name, not the target URL.

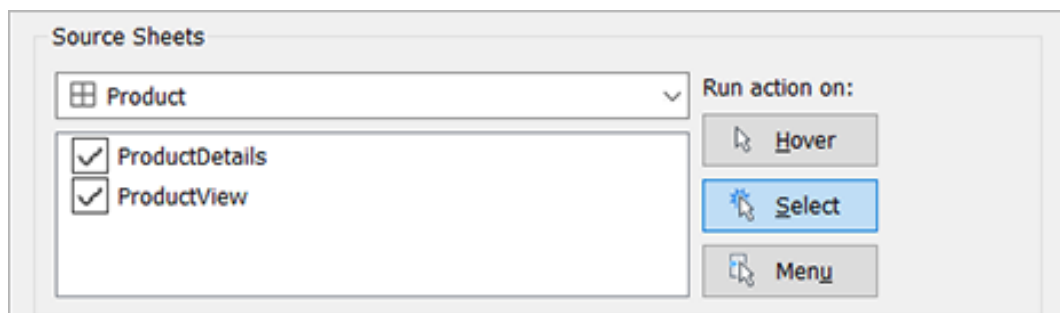

Open a web page with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action** and then select **Go to URL**.

- In the next dialog box, enter a name for the action. To enter field variables in the name, click the **Insert** menu to the right of the **Name** box.

Note: Give the action a descriptive name, because in tooltip menus the link reflects that name, not the URL. For example, when linking to more product details, a good name could be “Show More Details”.

- Use the drop-down list to select a source sheet or data source. If you select a data source or dashboard you can select individual sheets within it.

- Select how users will run the action.

If you choose this option...

Hover	The action is run when the user...
Hover	Mouses over a mark in the view. This option works best for highlight and filter actions within a dashboard.
Select	Clicks a mark in the view. This option works well for all types of actions.
Menu	Right-clicks (control-clicks on Mac) a selected mark in the view, then clicks an option in a tooltip menu. This option works particularly well for URL actions.

- For URL Target, specify where the link will open:

Tableau Server on Windows Help

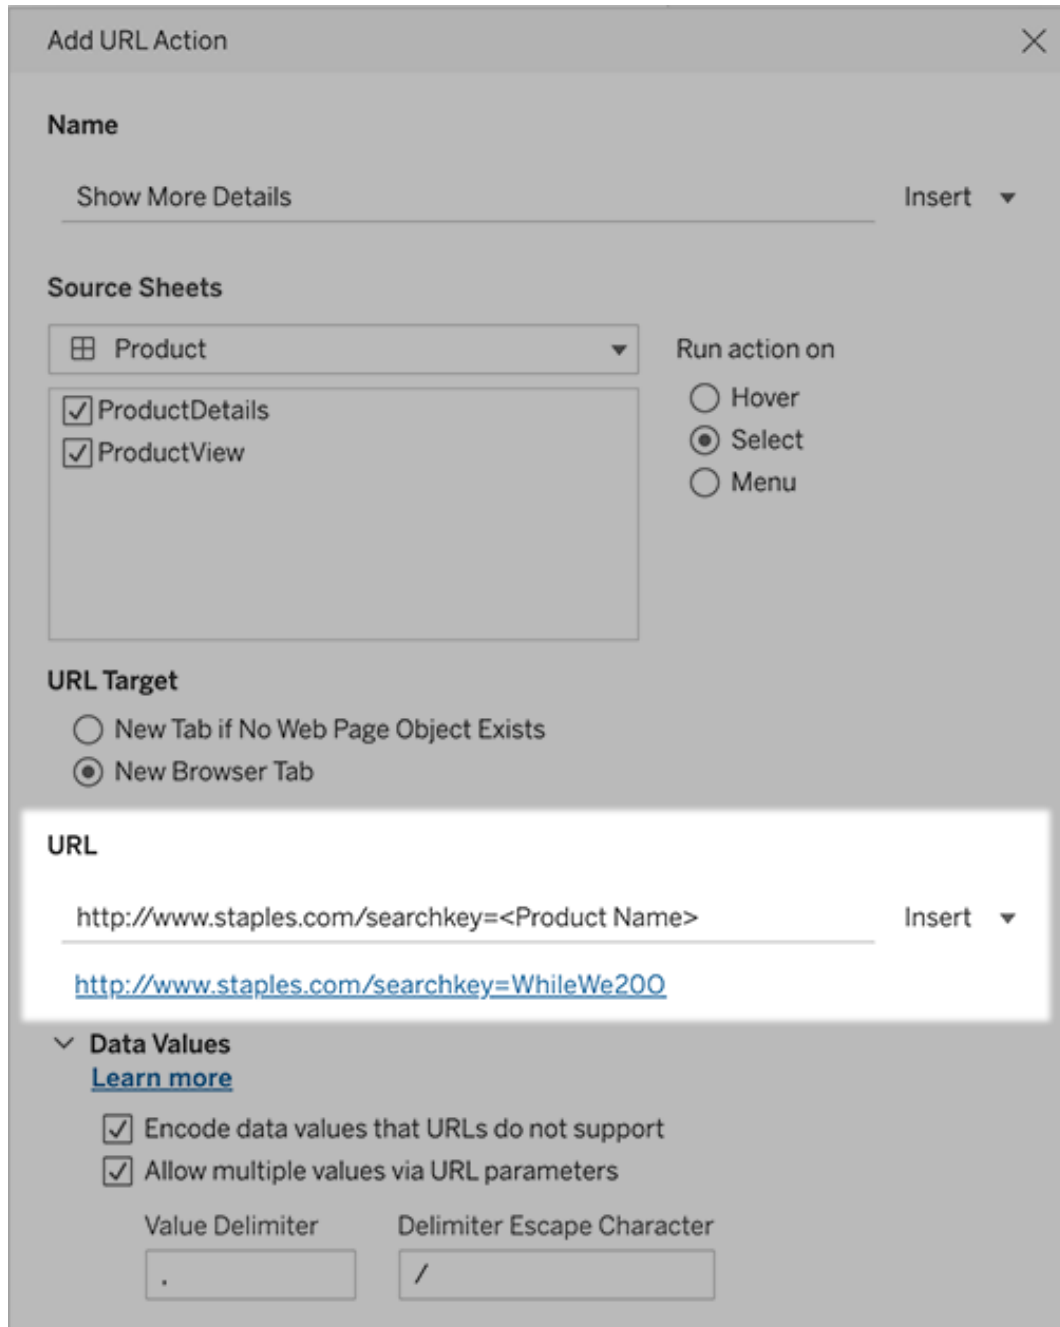

- **New Tab if No Web Page Object Exists** — Ensures that the URL opens in a browser on sheets that lack web page objects. This is a good choice when Source Sheets is set to All or a data source.
- **New Browser Tab** — Opens in the default browser.
- **Web Page Object** — (Available only for dashboards with Web Page objects) Opens in the web page object you select.

7. Enter a URL with one of the following prefixes:

- `http, https, ftp, mailto, news, gopher, tsc, tsl, sms, tel, file`
- Tableau Desktop also supports local paths like `C:\Example folder-\example.txt`

To enter field and filter values as parameters in the URL, click the **Insert** menu to the right of the URL. Be aware that any referenced fields must be present in the view, not just a related data source. For details, see [Using field and filter values in URLs](#).

Note: On a dashboard, you can specify an ftp address only if the dashboard doesn't contain a web object. If a web object exists, the ftp address won't load.

▼ **Data Values**

[Learn more](#)

- Encode data values that URLs do not support
- Allow multiple values via URL parameters

Value Delimiter: .

Delimiter Escape Character: /

Below the URL you enter is a hyperlinked example you can click for testing.

8. (Optional) In the Data Values section, select any of the following options:

- **Encode Data Values that URLs Do Not Support** — Select this option if your data contains values with characters that browsers don't allow in URLs. For example, if one of your data values contains an ampersand, such as “Sales & Finance,” the ampersand must be translated into characters that your browser understands.
- **Allow Multiple Values via URL Parameters** — Select this option if you are linking to a web page that can receive lists of values via parameters in the URL. For example, say you select several products in a view and you want to see each product's details hosted on a webpage. If the server can load multiple product details based on a list of identifiers (product ID or product name), you could use multi-select to send the list of identifiers as parameters.

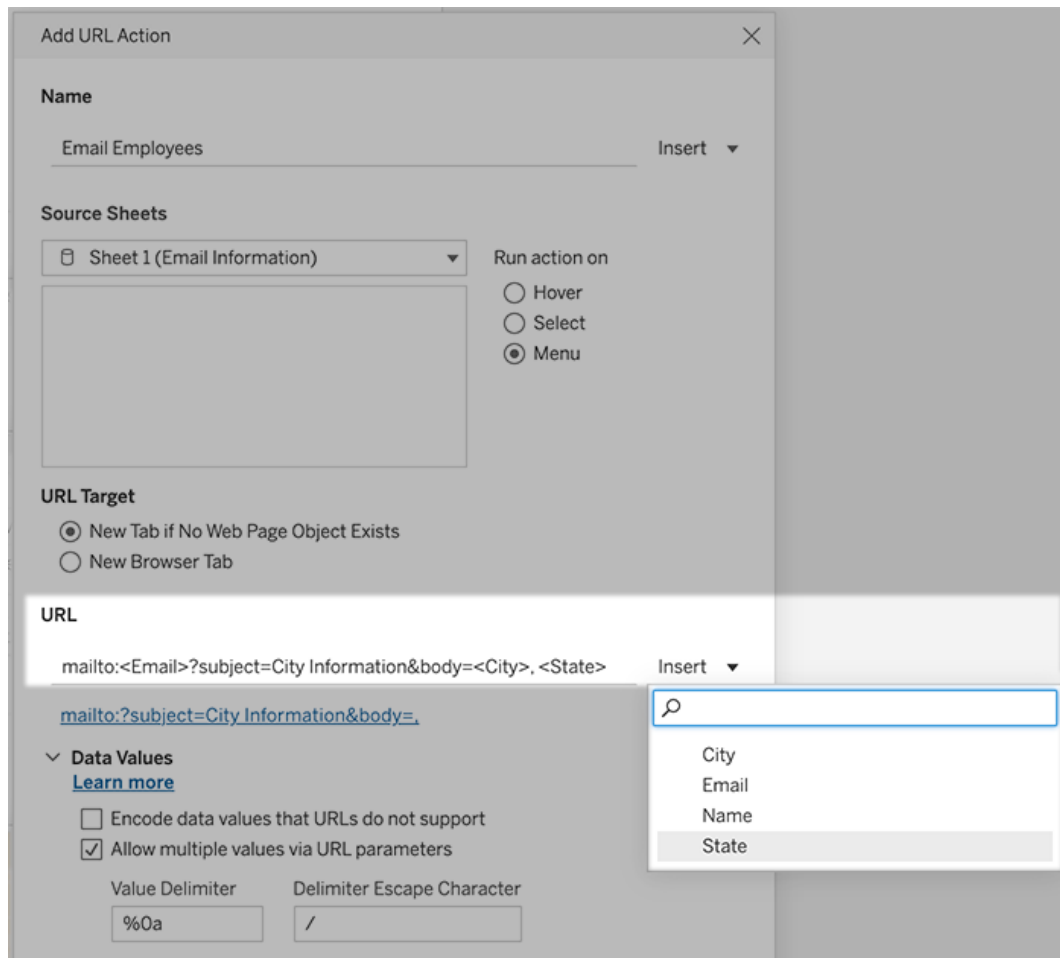

When you allow multiple values, you must also define the delimiter escape character, which is the character that separates each item in the list (for example, a comma). You must also define the Delimiter Escape, which is used if the delimiter character is used in a data value.

Create an email with a URL action

1. On a worksheet, select **Worksheet > Actions**. From a dashboard, select **Dashboard > Actions**.
2. In the Actions dialog box, click **Add Action**, and select **Go to URL**.
3. In the Source Sheets drop-down list, select the sheet that contains the field with the email addresses you want to send to.
4. In the URL box, do the following:
 - Type **mailto:**, and click the **Insert** menu at right to select the data field that contains email addresses.
 - Type **?subject=**, and enter text for the Subject line.

- Type **&body=**, and click the **Insert** menu at right to select the fields of information that you want to include in the body of the email.

In the example below, the “Email” field contains the email addresses, the subject is “City Information”, and the body text of the email consists of the city and state data that is associated with the email address.

:

5. (Optional) Display data from your workbook in the body of your email as a vertical list instead of the default horizontal list. For example, suppose you have a horizontal list of cities, such as Chicago, Paris, Barcelona, which you would rather display

Tableau Server on Windows Help

vertically, like this:

Chicago

Paris

Barcelona

To make the list vertical, in the Data Values section, do the following:

- Deselect **Encode Data Values that URLs Do Not Support**
- Select **Allow Multiple Values via URL Parameters**.
- Type **%0a** in the **Value Delimiter** text box to add line breaks between each item in the list. (These are the URL-encoded characters for a line break.)

Using field and filter values in URLs

When users trigger URL actions from selected marks, Tableau can send field, filter, and parameter values as variables in the URL. For example, if a URL action links to a mapping website, you could insert the address field to automatically open the currently selected address on the website.

1. In the Edit URL Action dialog box, begin typing the URL for the link.
2. Place the cursor where you want to insert a field, parameter, or filter value.
3. Click the **Insert** menu to the right of the text box and select the field, parameter, or filter you want to insert. The variable appears within angle brackets. You can continue adding as many variables as you need.

Note: Any referenced fields must be present in the view, not just a related data source. Otherwise, the link won't display in the viz, even if it functions when you

click Test Link.

Including aggregated fields

The list of available fields includes only non-aggregated fields. To use aggregated field values as link parameters, first create a related calculated field, and add that field to the view. (If you don't need the calculated field in the visualization, drag it to Detail on the Marks card.)

Inserting parameter values

When inserting parameter values, URL actions send the Display As value by default. To instead send the actual value, add the characters `~na` after the parameter name.

For example, say you have a parameter that includes IP addresses, with Actual Value strings such as 10.1.1.195 and Display As strings with more friendly values such as

Computer A (10.1.1.195). To send the actual value, you'd revise the parameter in the URL to look like this: `http://<IPAddress~na>/page.htm`.

Create a Subscription to a View or Workbook

Subscriptions email you an image or PDF snapshot of a view or workbook at regular intervals—without requiring you to sign in to Tableau Server or Tableau Online.

Note: In Tableau Server, administrators determine whether subscriptions are turned on for a site.

If Tableau Catalog is turned on for a site, administrators can also determine whether subscription emails include relevant upstream data quality warnings.

Tableau Catalog is available in the Data Management Add-on to Tableau Server and Tableau Online. For more information, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Online](#) Help.

Set up a subscription for yourself or others

When you open a view in Tableau Server or Tableau Online, if you see a subscription icon (✉+) in the toolbar, you can subscribe to that view or to the entire workbook. You can subscribe other users who have permission to view the content if you own a workbook, if you are a project leader with an appropriate site role, or if you are an administrator.

1. From the Explore section of your site, select **All Workbooks** or **All Views**, or open the project that contains the view you want to subscribe to.

2. Open a view either directly, or after opening the containing workbook.
3. In the toolbar above the view, click **Subscribe**.

4. Add the Tableau users or groups you want to receive the subscription. To receive a subscription, users must have the **View** and **Download Image/PDF** permissions. If they use Tableau Server, their accounts must also have email addresses.

Note: When you subscribe a group, each user is added individually at the time the subscription is created. If more users are added to the group later, you must re-subscribe the group for those new users to receive the subscription. Likewise,

Tableau Server on Windows Help

users later removed from the group will not have their subscriptions removed automatically unless their permissions to the subscribed view are removed.

5. Choose whether subscription emails include the current view or the entire workbook.
6. Choose the format for your snapshot: as a PNG image, a PDF attachment, or both.
 - If PDFs, choose the paper size and orientation you'd like to receive.

7. When the workbook uses one data extract on a published connection, you can pick a frequency:
 - **When Data Refreshes:** sends only when data in the view or workbook is refreshed by running refresh schedules.
 - **On Selected Schedule:** Pick a schedule for the subscription.
8. If frequency is not set to When Data Refreshes, pick a schedule:
 - For Tableau Server, choose from subscription schedules established by your administrator.
 - For Tableau Online and Tableau Server with **custom schedules enabled**, click the drop-down arrow to the right of the current settings.

Then specify a custom schedule that sends subscription emails whenever you wish. (The precise delivery time may vary if server load is high.)

The screenshot shows a configuration form for a subscription schedule. It includes the following fields and options:

- Repeats:** A dropdown menu set to "Hourly".
- Every:** A dropdown menu set to "Hour".
- From:** A dropdown menu set to "09:00".
- To:** A dropdown menu set to "17:00".
- Time Zone:** A link labeled "(UTC-08:00) America/Los Angeles".
- On:** A row of seven checkboxes for days of the week: S, M, T, W, Th, F, S. The "M", "T", "W", and "Th" checkboxes are selected.

To change the time zone, click the Time Zone link it to go to your account settings page.

9. To clarify subscription emails, customize the subject line, and add a message.
10. If the view contains data only when high-priority information exists, select **Don't send if view is empty**.
11. If you own the workbook, select **Subscribe me**.
12. Click **Subscribe**.

When you receive a subscription email, you can select the image (or the link in the message body for PDF subscriptions) to be taken to the view or workbook in Tableau Online or Tableau Server.

Update or unsubscribe from a subscription

You can unsubscribe from an existing subscription, or make changes to a subscription's format, schedule, subject, or empty view mode.

1. Access your Tableau Server or Tableau Online account settings by doing one of the following:
 - Click **Manage my subscriptions** at the bottom of a subscription email.

- Sign in to Tableau Server or Tableau Online. At the top of the page, select your

user icon, and then select **My Content**.

2. Click **Subscriptions**.
3. Select the check box next to the view you want to unsubscribe from, click **Actions**, and then click **Unsubscribe**, or select the subscription option you'd like to change.

Resume or delete suspended subscriptions

Sometimes, subscriptions fail because of an issue with the workbook or a problem loading the view. If a subscription fails more than five times, you'll receive a notification email that your subscription has been suspended. There are a few ways to resume a suspended subscription if you're a subscription owner or administrator:

- From the My Content area of Tableau web pages, an icon appears in the Last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.
- From the Subscriptions tab of the affected workbook, an icon appears in the last update column to indicate that the subscription is suspended. Select ... > **Resume Subscription** to resume.

You'll receive an email notification when the subscription is working again.

Interact with Data in Tableau

This tutorial walks you through some of the basics of viewing and interacting with data visualizations, or views, in Tableau Server.

Tableau is a tool that lets you interact with published visualizations to explore insights, ask questions, and stay on top of your data. Here's how to get started.

Go ahead. It's safe to click around

Tableau is built for interaction. What you do to a visualization changes how it looks for you, just for now.

Others will still see the visualization as it originally appeared. And the data used to build it stays the same, too.

1: What is a Tableau Site?

A Tableau Site is a place for your team to share data and data visualizations with each other. You can explore what they've published and made available to you.

When you sign in to your Tableau site, you'll land on the home page.

2: Search for a viz

Tableau calls visualizations on a site Views. Use search to find views or workbooks (a package of views in a single file).

Search results will show all the different content types relevant to your query.

Tableau Server on Windows Help

You can select See All for all search results if the views in the quick search aren't what you were looking for, or use the Explore page to browse. There you'll see all the different types of content a Tableau site can host.

3: Interact with Content

A published view is a canvas for you to interact and understand your data. Remember, you won't hurt or change the underlying data, or change what others see.

Here are some of the tools in your toolbox to find data insights.

See Details and Sort Data

Now that you know you can click on the data, let's check it out.

As you move the mouse across a view, you might see tooltips that reveal details about each data point, or mark. You can also select multiple marks.

Sort tables alphabetically or numerically by hovering over a column header and clicking the sort icon.

Tableau Server on Windows Help

Filter Data

Trim or limit the visible data to a specific area, date, or category.

Undo/Revert

Maybe you didn't mean to exclude everything but one area. Click Undo to remove the last change, or use Revert to undo all your selections.

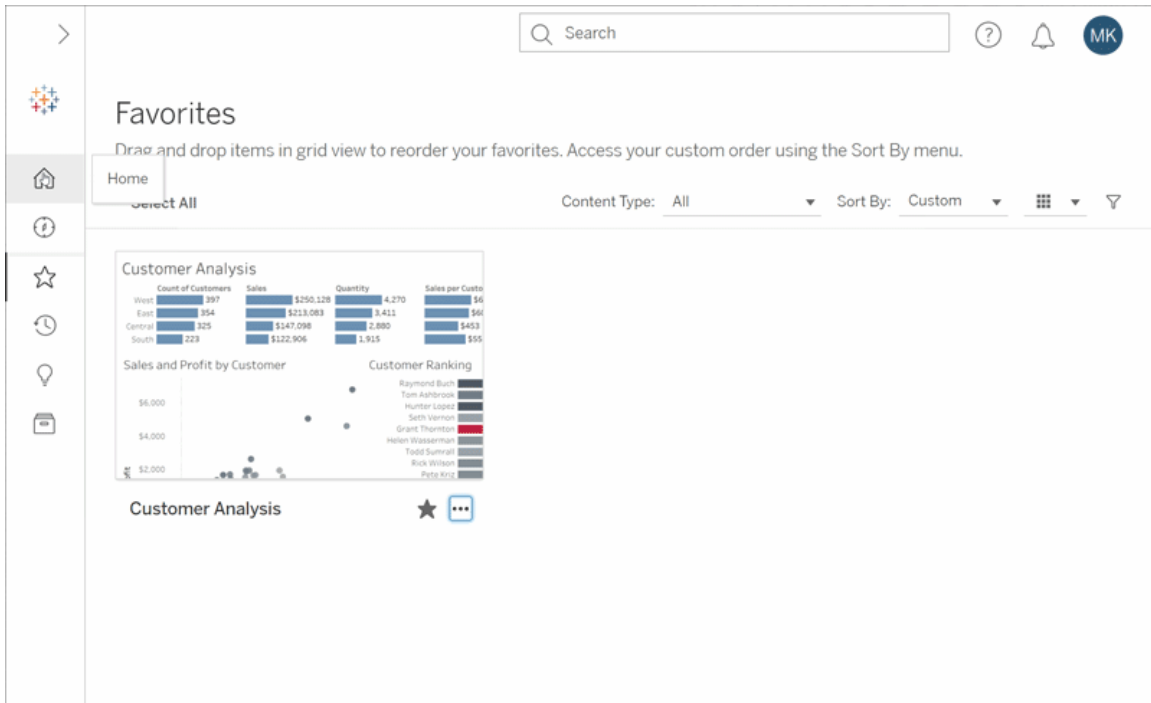

4: Keep up

This view can automatically update with new data, so you don't need to go searching for new charts to get the latest information. Keep it handy by clicking the star icon to add it to your favorites.

All favorites are added to the Favorites page in the navigation panel. And any recent dashboard or view you explored also appears in the Home page, waiting for you next time.

Tableau Server on Windows Help

There's a lot you can do in Tableau Server, and this just explored some of the basics. For more information, see [What Can I Do with a Tableau Web View?](#)

Happy exploring!

Select Background Maps

Tableau comes with a set of online and offline background maps that you can access to create map views.

By default, Tableau connects to an online map provider.

The three background maps that come with Tableau are described below. They can be found in the **Maps > Background Maps** menu. If the workbook author has added a WMS server or Mapbox map to the workbook, they will be listed using the name the author gave them in the **Maps > Background Maps** menu as well.

None Displays data between latitude and longitude axes.

- Offline** This background map stores the images that make up the map in a cache on your machine for improved performance and offline access. For more information, see the offline maps section [below](#).
- Tableau** Connects to the Tableau background map. By default, all map views connect to this background map, unless you specify otherwise.

To select a new background map:

- In Tableau Desktop, Tableau Server, or Tableau Online, select **Map > Background Maps** and then select the background map you want to use.

Note: In Tableau Server, your administrator can restrict you to using only Offline maps. The specific server commands to configure this behavior can be found [here](#).

Set a default background map in Tableau Desktop

By default, all map views connect to the Tableau background map. In Tableau Desktop, if you do not want maps views to automatically be created with the Tableau background map, you can specify a different background map as the default.

To specify a default background map:

1. In Tableau Desktop, select **Map > Background Maps**, and then select the background map that you want to make the default.
2. Select **Map > Background Maps > Set as Default** to set the selected background map to the default.

The background map is automatically saved as a Tableau Map Source (.tms) and placed in the Mapsources folder of your My Tableau Repository. It is now the default background map for all new worksheets.

Use the Offline background map in Tableau Desktop, Online, or Server

You can create and inspect data in a map view offline using the offline background map that comes with Tableau Desktop.

To use the offline background map:

- In Tableau, select **Map > Background Maps > Offline**

Note: The offline background map uses map images stored on your machine. You can find these images in the following locations:

- **On Windows:** `C:\Program Files\Tableau\<Tableau Version>\Local\Maps`
- **On Mac:** `//Applications/<Tableau Version>.app/Contents/install/local/maps`

There are several actions, however, that require Tableau to retrieve a map image that may not be stored. If the new map image is not stored on your machine, you won't be able to load the map until you reconnect to the online map that comes with Tableau.

You may need to reconnect to the online map if you would like to do one or more of the following:

- **Turn layers on or off** - if you decide to turn on a layer that isn't stored in the cache, Tableau will need to connect to retrieve the necessary information.
- **Zoom in or out** - zooming in or out on a map requires different map images. If the images at the specified zoom level don't exist in the cache, Tableau will need to retrieve the updated maps.
- **Pan** - panning sometimes requires new map images. If you are working offline and don't have the necessary map images and legends stored in the cache, the new images and legends will not load.

To reconnect to the Tableau online map:

- On Tableau Desktop, select **Map > Background Maps > Tableau**

Note: If you set a map to Offline and then publish the workbook, the published workbook will still use the Offline, stored maps, with all of the functionality and limitations of Offline maps noted above.

About the Tableau background map

The Tableau background map includes updated map and demographic data, as well as stylistic improvements. It has taken the place of the Tableau classic background map. Any map view created with an earlier version of Tableau Desktop, and with a connection to the Tableau classic background map, will automatically connect to the Tableau background map when opened in Tableau Desktop version 9.0 or later.

Note: If you create a map view with data layers in Tableau Desktop version 8.3 or earlier using the Tableau classic background map, and then open that view in Tableau Desktop 9.0 or later, the color of the data layers may appear differently due to data layering and color ramp (color palette) improvements made to the Tableau background map.

Create and Troubleshoot Metrics

Metrics provide a fast way to stay informed about your data. Because metrics update automatically and display their current value in the grid and list view of your content, you can check all the key numbers you care about in seconds.

Tableau Server on Windows Help

At their most basic level, metrics show the value of an aggregate measure, like the sum of sales. More complex metrics can include timelines, comparisons, and statuses that provide an easy to understand indicator of how you're performing relative to a prior point in time or a value you have defined.

If you have a set of dashboards that you regularly check, create metrics for the numbers that you want to monitor, then track them in one place by adding them to your favorites or a collection, or by creating them in the same project. That way, you don't need to load and filter the dashboards unless you want to dig deeper into your data.

Find metrics on your site

There are a few ways to find metrics on your Tableau site. To browse all the metrics that you have permission to view, navigate to the Explore page, then select **All Metrics** from the content type menu.

If you're looking for metrics related to a particular view or workbook, check the connected metrics for that content. To see connected metrics for a view, open the view, then click the **Metrics** button in the view toolbar. The metrics displayed are ordered from the newest creation date to the oldest.

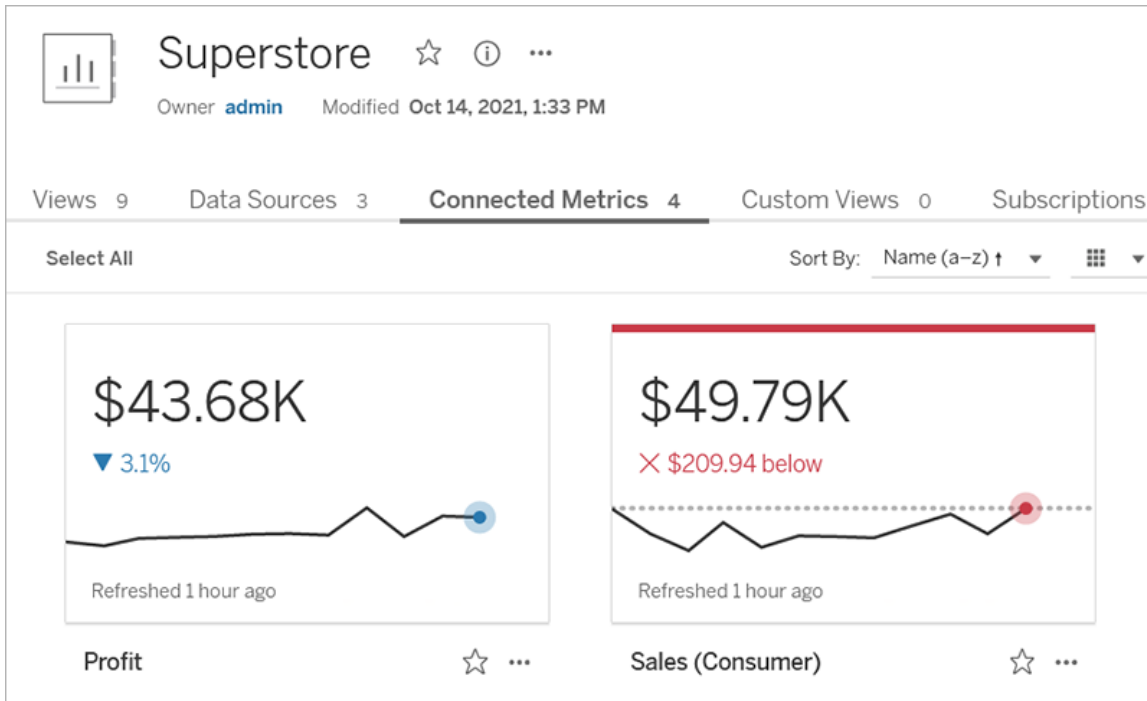

The screenshot shows the Tableau interface with the 'Metrics' tab selected. The left sidebar lists 'Segment, Forecast indicator' with the following items:

- Consumer, Actual
- Consumer, Estimate
- Corporate, Actual
- Corporate, Estimate
- Home Office, Actual
- Home Office, Estimate

The main area displays a 'Metrics' panel with a 'Create' button and the text 'Metrics created from this view'. A card shows the following data:

- Value: \$44.64K
- Status: ✓ \$4.64K above
- Refreshed: 3 minutes ago
- Label: Sales (Corporate)

To see connected metrics for all the views in a workbook, navigate to the workbook, then click the **Connected Metrics** tab. You can sort these metrics using the Sort By menu.

Components of a metric

The only data required to define a metric is an aggregate measure. Metrics are created from a mark in a view, and the measure associated with that mark defines the metric. The measure must be aggregated, because an unaggregated mark will not change over time. For information about dimensions and measures in Tableau, see [Dimensions and Measures, Blue and Green](#).

A metric can optionally be defined by a date dimension, and you can configure a comparison and a status for your metric. Each of these components will add context to the data presented on the metric card.

Metrics that have only a measure defining them will appear as a single number. This number will update when the data updates, but there will be no timeline on the card.

Timeline

When you select a mark to define a metric, if the mark has a date dimension associated with it, that dimension becomes part of the metric definition. Metrics with a date dimension show a timeline, and you can configure the historical comparison for the metric. By default, the historical comparison is to the previous mark.

When you open a metric's details page, the timeline shows the value of the measure based on the granularity of the date dimension, for example, daily sales or monthly users. Hover over the points on the timeline to see historical values.

Comparison

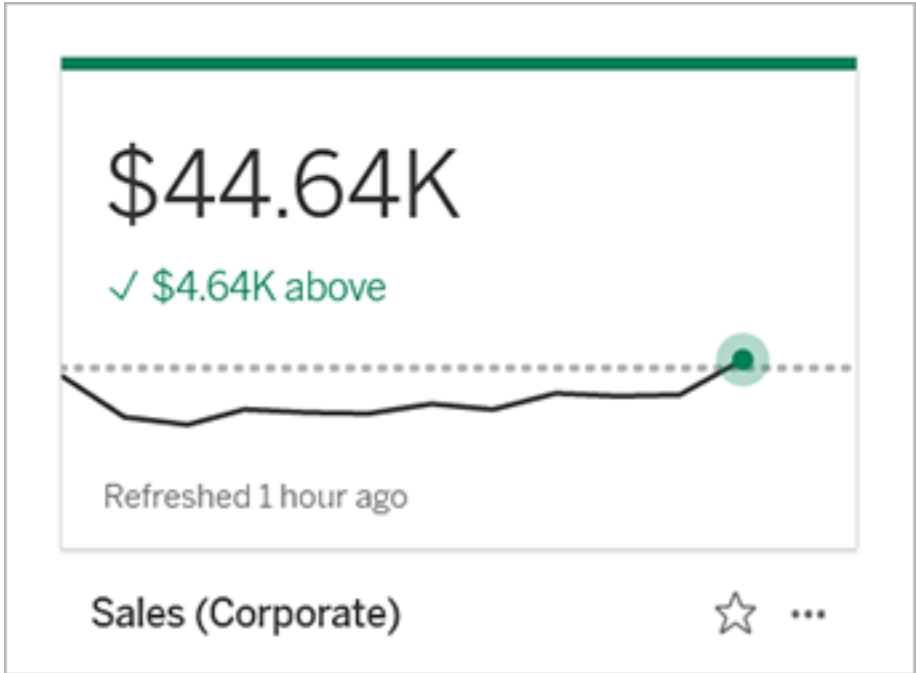

There are two types of comparisons that you can configure for metrics: historical comparisons and constant comparisons. You can configure a historical comparison only if a metric has a date dimension associated with it, but constant comparisons can be added for any type of metric.

A historical comparison is a relative comparison between the current value and a specified number of hours, days, or other unit of time previous. For example, you could set a comparison between the current value for monthly sales and the value from 12 months ago.

Every time data is added to a metric, the historical comparison will adjust relative to the date or time of the new data.

Constant comparisons are to a single value that doesn't change as new data is added. You might set a comparison to represent a threshold to stay above, for example, if you need to maintain a 90% on-time delivery rate. Or you might define a cumulative goal you are working toward, for example, a monthly sales target.

Status

For metrics with a constant comparison, you can define whether being above, below, or at the comparison value is good, bad, or neutral. A metric with a “good” status will display a check mark next to the comparison value, and the metric card will have a green band at the top. A metric with a “bad” status will display an X next to the comparison value, and the metric card will have a red band at the top. Metrics with a “neutral” status appear the same as metrics without a status indicator; there is no icon or color applied to the card.

Create a metric from a view

If you have a site role of Creator or Explorer (can publish), and you have the Create/Refresh Metric capability on the relevant workbook, you can create metrics on Tableau Online or Tableau Server.

Before you create a metric, check the connected metrics for the view to make sure that the metric you are planning to create doesn't already exist. Instead of creating a duplicate metric, open the existing metric and add it as a favorite.

Select the mark to define your metric

1. Navigate to the view that you want to create a metric from.
2. On the view toolbar, select the **Metrics** button.

The metrics pane opens.

3. If the pane shows connected metrics, select the **Create** button to enter authoring mode.
4. Select a mark. If you encounter an error, see [When you can't create a metric](#).

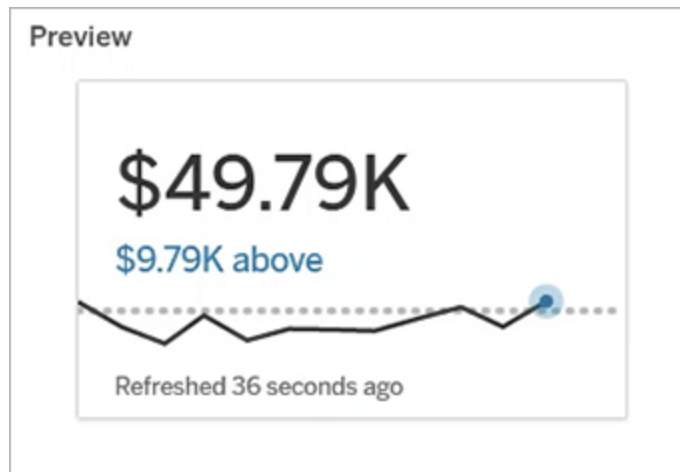

Tableau Server on Windows Help

The measure associated with this mark defines your metric. Any filters you apply to the mark are applied to your metric. If this mark has a date dimension associated with it, that date dimension also defines your metric, and your metric will display a timeline.

The metrics pane shows a preview of your metric. The value in the preview is the most recent value for the metric, which may differ from the value of the mark you selected if it was not the most recent in the time series. The preview updates as you try different configurations.

Describe and configure your metric

The options available to configure your metric depend on the mark you select and on the type of comparison you choose.

1. The **Name** field is pre-populated based on the mark you select. You can give the metric a different name. A metric must have a unique name within the project it belongs to.
2. Under **Description**, enter an optional message to help others understand your metric. For example, describe filters applied to the metric or indicate the data source used by the metric.
3. For the **Date Range** (only for metrics with a date dimension), select one of the default options, or set a custom range. If your metric has a large number of marks, limiting the

date range can make it easier to read the timeline.

4. Select the **Comparison Type** for the metric: historical or constant.
5. For **Historical** comparisons:
 - Enter how far prior you want to compare against. The unit of time for the comparison is the same as the granularity of your data, such as hours or months.
 - Select **Show Comparison Line** to include a second line for the comparison period on the timeline.
6. For **Constant** comparisons:
 - Enter the value to compare against. Don't include commas or symbols in this field. To enter a percentage, simply type the number without the percent sign, for example, enter 25 instead of 0.25 for a target of 25%. When you enter a valid target value, the preview updates to show how far above or below the target the current value is.
 - Set the **Status** for the comparison to indicate whether being above, at, or below the value is good, bad, or neutral. By default, the status is set to neutral. Check the metric preview to see how different statuses affect your metric.
7. Under **Definition > Measure**, select the measure to use for your definition from the drop-down. This option appears only if the mark you select has more than one measure associated with it.

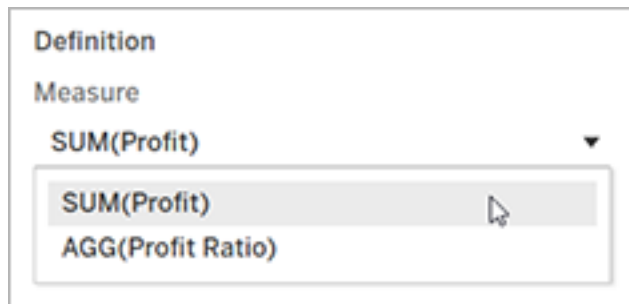

Tableau Server on Windows Help

Finalize your metric

1. Under **Project**, select **Change Location** to choose a different project for the metric. By default, your metric will be added to the same project that the view belongs to.

Every metric in a project must have a unique name. Because a metric's name and project are initially set based on the mark you select, you might run into a conflict when you try to save your metric, if another user has already created a metric from that mark. Either choose a different project or name for your metric or, if you want to overwrite the existing metric, see [Overwrite a metric](#).

2. Click the **Create** button.

A message appears with a link to the metric in the project you added it to.

Success: Metric "Profit" created in project "Metrics". [Go to Metric](#) X

3. Verify that the permissions for your metric are correct, following the guidance in [Set permissions](#).

By default, a metric inherits the permissions of the project it is created in. Anyone with access to your metric will be able to see the metric's data, even if they don't have permission to access the connected view or data source.

Now that you've created a metric, you can manage the metric the same way you manage other independent pieces of content on your Tableau site. Though metrics are created from a view, they exist independently of that view, unlike data driven alerts or subscriptions. You can move the metric to a different project without moving the connected view. For information about managing content on your Tableau site, see [Manage Web Content](#).

Overwrite a metric

Once a metric is created, you can change the name and description of the metric, but you can't change how the metric is defined or configured. If you want to change the data that the

metric uses, you must overwrite it. In order to overwrite a metric, you need to be the metric owner or be granted the correct permission capability.

1. To overwrite a metric, create a metric with the same name in the same project as the metric you want to overwrite.

The Overwrite Metric dialog appears.

2. Click the **Overwrite** button.

When you overwrite a metric, the metric continues to appear for those who have added it to their favorites, and any changes made to permissions for the previous metric will apply to the new metric.

When you can't create a metric

If you select a mark on a chart that doesn't support metrics, you'll get an error message explaining why you can't create a metric. The table below summarizes these scenarios.

Reason	Scenarios
You don't have the correct permissions.	<ul style="list-style-type: none"> • The workbook owner or an administrator has denied the Create/Refresh Metric capability. For more information, see Permissions.
You can't access the complete data.	<ul style="list-style-type: none"> • Row level security or user filters limit the data you can see. For more information, see Restrict Access at the Data Row Level. • The workbook uses a virtual connection to connect to the data. For more information, see About Virtual Connections and Data Policies.
The password for the workbook's data source is not embedded or is no longer valid.	<ul style="list-style-type: none"> • The workbook prompts for a password. For more information, see Set Credentials for Accessing Your Published Data.

Reason	Scenarios
The data isn't at the correct level of granularity.	<ul style="list-style-type: none">• The data in the chart isn't aggregated. Metrics use aggregations, such as sum or average. For more information, see Data Aggregation in Tableau.• There are multiple values per cell of data—a result of data blending. For more information, see Troubleshoot Data Blending.
The date dimension is not supported.	<ul style="list-style-type: none">• The chart includes both date parts and date values. For more information, see Change Date Levels.• The date dimension uses the ISO 8601 calendar rather than the standard Gregorian calendar. For more information, see ISO-8601 Week-Based Calendar.• The date dimension is aggregated at the custom level of Month / Year or Month / Day / Year. For more information, see Custom Dates.

How metrics refresh

When a metric refreshes, it checks the connected view (the view the metric was created from) for new data. A refresh doesn't necessarily update the value of a metric, because there may be no changes to the data.

Metrics refresh at a frequency either based on an extract's refresh schedule or, for live data, every 60 minutes. The time of the last refresh is displayed on the metric.

Fix failing refreshes

If a metric isn't able to access the connected view or its underlying data, the refresh will fail. If the refresh for your metric fails, you'll receive a notification, which notes the time of the failure and the affected metric.

Metric refreshes may fail for one of the following reasons.

- The connected view was deleted or modified.
- Permissions changed for the connected view.
- The password for the data source is no longer embedded or is no longer valid.
- The metric owner doesn't have the required site role to refresh the metric. A site role of Creator or Explorer (can publish) is required.
- There was a temporary connectivity issue, which will resolve itself.

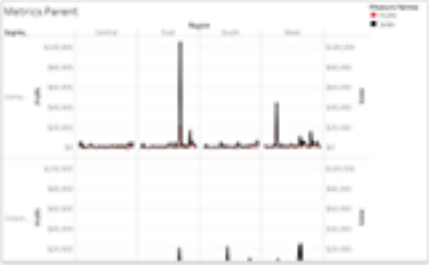

To identify the cause of the failure, look at the metric details. Make sure that the metric owner has the required site role to refresh the metric. Then inspect the **Connected View**.

Metric Details

Owner
Jane Johnson

Connected View

The metric has been created from this view:

Weekly Sales and Profit

Definition

Measure	SUM(Profit)
Date Dimension	WEEK(Order Date)

If the connected view is still listed

Open the view to investigate the cause of the failure.

Tableau Server on Windows Help

If the view loads, check that the measure and (optional) date dimension that define the metric are still present in the view.

- If the view appears to be unchanged, you might no longer have permission to refresh metrics from it. The content owner or a Tableau administrator can change the Create/Refresh Metric permission capability. For more information, see [Permissions](#).
- If the measure is no longer present, the view has been modified so the metric can't connect to the data needed to refresh. The content owner or a Tableau administrator can check the revision history and restore previous versions. For more information, see [View Revision History](#).

If the view doesn't load, but instead prompts for a password or displays an error when connecting to the data source, the password for the data source is not embedded or is no longer valid. The content owner or a Tableau administrator can edit the data source connection to embed the password. For more information, see [Edit Connections](#).

If there is no connected view listed

The view was deleted or you no longer have permission to access the view. Contact your Tableau administrator for assistance.

Resume suspended refreshes

If a refresh fails enough times, the refresh is suspended. You'll receive a notification if the refresh for your metric is suspended.

When a metric refresh is suspended, Tableau no longer attempts to get new data for the metric. Metrics with suspended refreshes continue to present historical data.

If the cause of the failure is fixed, you can resume the refresh.

1. Open the affected metric.
2. On the warning message, click **Resume refresh**.

Tableau attempts to perform the refresh. If this attempt succeeds, you'll receive a notification, and the refresh will resume on schedule. If the attempt doesn't succeed, your refresh remains suspended.

Try overwriting the metric if the connected view is still available. For more information, see [Overwrite a metric](#). Otherwise, you can keep the metric to reference past data or delete the metric.

Note: If the metric refresh is suspended because you don't have the required site role for it to refresh, you won't be able to resume the refresh or delete the metric.

Metrics appear in Tableau Catalog

Starting in 2019.3, Tableau Catalog is available in the Data Management Add-on to Tableau Online and Tableau Server. When the Tableau Catalog is enabled in your environment, you can see metrics in the Catalog lineage tool, and metrics affected by data quality warnings display those warnings. For more information about Tableau Catalog, see "About Tableau Catalog" in the [Tableau Server](#) or [Tableau Online](#) Help.

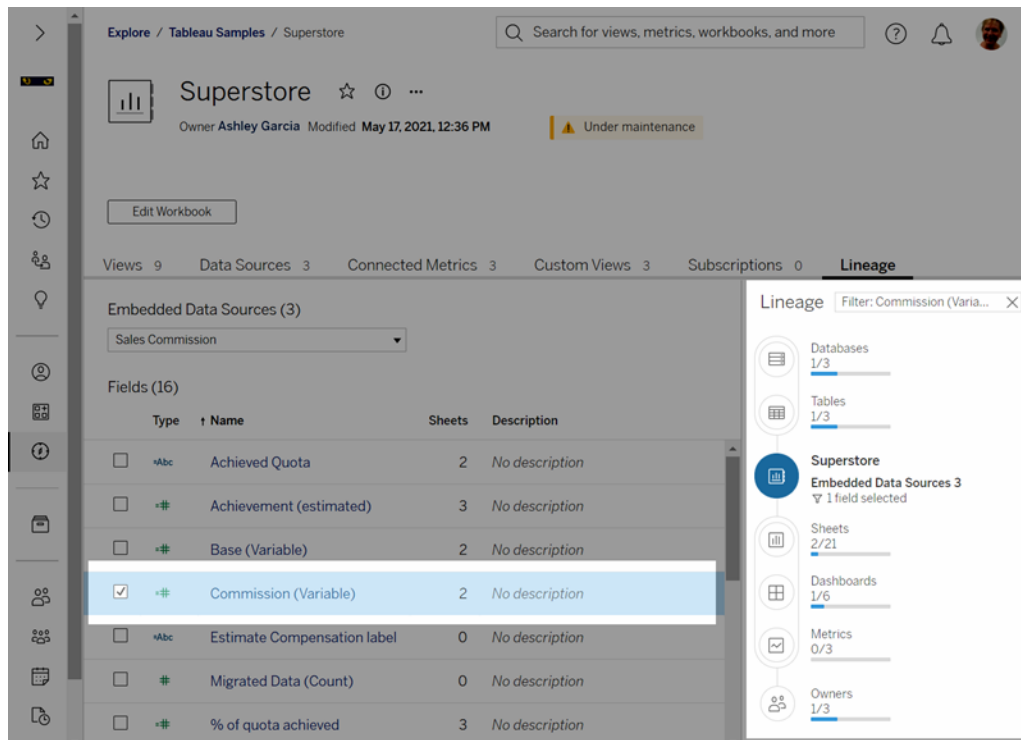

When you have metrics defined for the numbers you want to monitor, it's important to know if the data that the metrics rely on are impacted in any way. You can use Catalog in a couple of ways to know this. First, data quality warnings set on the data your metric is based on show on the metric. These warnings appear when you open a metric in Tableau Mobile, and in Tableau Server and Tableau Online when you hover over a metric in grid view and on the metric details page, as shown below:

Tableau Server on Windows Help

For more information, see "Set a Data Quality Warning" in the [Tableau Server](#) or [Tableau Online](#) Help.

You can also use the lineage tool in Tableau Catalog to see the upstream sources that your metric relies on. When doing an impact analysis, you can see which metrics are affected if a certain column or a table is changed or deprecated, or if certain workbooks are removed. Including metrics in the lineage means that Catalog gives a full picture of the impact changes can have on the assets in your environment.

For more information, see "Use Lineage for Impact Analysis" in the [Tableau Server](#) or [Tableau Online](#) Help.

Set Credentials for Accessing Your Published Data

When you publish a workbook to Tableau Online or Tableau Server, you can publish the data source it connects to as part of the workbook (*embedded* into the workbook), or as a separate, standalone data source. In addition, if the data source you're publishing requires authentication, you can customize how credentials are obtained.

The type of authentication to your data source is independent of how people sign in to your Tableau Online or Tableau Server site. For example, to give people direct access to the data in a workbook, you would embed a database user's credentials into the data source's connection. But anyone viewing the workbook would still need to be able to sign in to the site on Tableau Online or Tableau Server to open your workbook.

This topic describes how to set authentication on data connections as part of the publishing process.

Note: This topic does not apply to connections that do not require authentication, such as text files or Excel files.

Set the authentication type

For many types of connection you can embed a database user's name and password, or use single sign on (SSO). Specific exceptions are described later in this topic.

The following steps describe how to set authentication as part of publishing a data source or workbook. You can do this for each connection in the data source.

1. In the Publish Workbook dialog box, go to the **Data Sources** area, which lists the workbook's connections, and select **Edit**.
2. In the **Manage Data Sources** popup, after you decide whether to publish the data source separately or as part of the workbook, select an authentication type for each connection in the data source.

The available authentication types depend on the connection type, and they can include one or more of the following:

- **Prompt user:** Users must enter their own database credentials to access the published data when the view or workbook loads.
- **Embedded password:** The credentials you used to connect to the data will be saved with the connection and used by everyone who accesses the data source or workbook you publish.
- **Server run as account:** A single Kerberos service account will be used to authenticate the user. On Windows this is the account that Tableau Server runs as. On Linux it can be any Kerberos account.

- **Viewer credentials:** The viewer's credentials are passed through to the database using SSO (usually Kerberos).
- **Impersonate with embedded account or Impersonate with server Run As service account:** Impersonation using embedded credentials connects with the embedded credentials and then switches to the viewer's identity (only for databases that support this). Impersonation using the Run As service account is similar but first, connects with the Kerberos service account before switching to the viewer's identity.
- **Refresh not enabled or Allow refresh access:** These options appear when you publish an extract of cloud data such as from Salesforce, and database credentials are needed to access the underlying data. **Allow refresh access** embeds the credentials in the connection, so that you can set up refreshes of that extract on a regular schedule. Setting **Refresh not enabled** prompts users when they open the workbook.

Important: How you want to keep extracted data fresh is also a factor:

- If you want to set up an automatic refresh schedule, you must embed the password in the connection.
- If you're publishing a cloud data connection to Tableau Online, the publishing steps will alert you if you need to add Tableau Online to the data provider's authorized list.
- You can't publish an extract that's created from a Kerberos-delegated, row-level-secure data source.

Dropbox, OneDrive connections

For Dropbox and OneDrive, when you publish a data source or workbook and select **Embedded password**, Tableau creates a saved credential and embeds it in the data source or workbook.

Workbook connections to Tableau data sources

When you publish a workbook that connects to a Tableau Online or Tableau Server data source, rather than setting the credentials to access the underlying data, you set whether

Tableau Server on Windows Help

the workbook can access the published data source it connects to. Regardless of the original data type, the choice for server data sources is always **Embedded password** or **Prompt users**.

If you select to prompt users, a user who opens the workbook must have **View** and **Connect** permissions on the data source to see the data. If you select embed password, users can see the information in the workbook even if they don't have View or Connect permissions.

- If you publish to Tableau Server, see [Edit Connections](#) in the Tableau Server Help.
- If you publish to Tableau Online and the workbook connects to Salesforce, Google Analytics, Google Sheets, Google BigQuery, OneDrive, Dropbox, and QuickBooks Online data, see [Refresh Data Using Saved Credentials](#) in the Tableau Online Help.
- If you are a Tableau Server administrator looking for more information about authentication, see the Tableau Server help topics, "Authentication" ([Windows](#) | [Linux](#)) and "Data Connection Authentication" ([Windows](#) | [Linux](#)).

Set a Data Freshness Policy

Understand data performance and freshness

You've built your workbook, and your team loves it. But sometimes people need to click the Refresh button for the most up-to-date data to appear in the viz. You built the workbook using a live connection, so why does the data need to be refreshed? The answer is performance.

To improve performance, Tableau caches data so subsequent visits can reuse and return that cached data faster. You can click the Refresh button to retrieve updated data, but this can add to potential performance costs.

To balance data performance and freshness, set a data freshness policy for your workbook. When you set a data freshness policy, your data is refreshed at the time you specify. Tableau won't visualize cached data that doesn't meet the freshness policy you've set.

Choose what's best for your workbook

Some people might not want caching so that they always have the freshest data, while other people might want large caches to reduce overhead and improve workbook performance. The first step in setting a data freshness policy is to decide what's right for your business.

Tableau Online refreshes cached data every 12 hours by default, and workbook owners can set data freshness policies at the workbook level.

In Tableau Server, server administrators can [set a default caching policy for all sites on the server](#), and workbook owners can set data freshness policies at the workbook level.

Note: Data freshness policies aren't available in Tableau Desktop or for workbooks that use file-based data sources.

Edit a workbook data freshness policy

To edit a workbook data freshness policy, you must be the workbook owner, and the workbook must have a live connection to the data source.

1. Sign in to a site on Tableau Online or Tableau Server.
2. From the Home or Explore page, navigate to the workbook you want to set a policy for.
3. Click the details icon .
4. From the Workbook Details dialog, click **Edit Data Freshness Policy**.
5. Choose one of the following options:
 - Site default (12 hours)
 - Always live (Tableau will always get the latest data)
 - Ensure data is fresh every

Tableau Server on Windows Help

Ensure data is fresh at

6. Click **OK**.

Personal Space / Regional Sales

<input type="checkbox"/> ☆	Regional Sales	...	26

Site default refreshes your data every 12 hours, which is a great option if your audience regularly uses your dashboard, but doesn't need up-to-the-minute data freshness.

Always live provides the freshest data at all times, which can increase loading time.

Ensure data is fresh every... allows you to specify how often data is refreshed with the granularity of minutes, hours, days, or weeks.

Ensure data is fresh at... allows you to schedule the time and day for data refreshes. If you have an important meeting every Monday, Wednesday, and Friday at 09:00 AM Pacific time,

then you can set your data refresh to occur at 08:45 AM every Monday, Wednesday, and Friday, so you have the freshest data when your meeting starts.

Manage Server

After installing Tableau Server, you can customize and manage your server. For example, you can manage security, licenses, sites, subscriptions and data-driven alerts, and more.

Security

As a part of managing Tableau Server, you can configure authentication, data security, and network security.

Authentication

Authentication verifies a user's identity. Everyone who needs to access Tableau Server—whether to manage the server, or to publish, browse, or administer content—must be represented as a user in the Tableau Server repository. The method of authentication may be performed by Tableau Server (“local authentication”), or authentication may be performed by an external process. In the latter case, you must configure Tableau Server for external authentication technologies such as Kerberos, SSPI, SAML, or OpenID. In all cases, whether authentication takes place locally or is external, each user identity must be represented in the Tableau Server repository. The repository manages authorization meta data

for user identities.

Looking for Tableau Server on Linux? See [Authentication](#).

Although all user identities are ultimately represented and stored in the Tableau Server repository, you must manage user accounts for Tableau Server in an identity store. There are two, mutually exclusive, identity store options: LDAP and local. Tableau Server supports arbitrary LDAP directories, but it's been optimized for Active Directory LDAP implementation. Alternatively, if you are not running an LDAP directory, you can use the Tableau Server local identity store. For more information see [Identity Store](#).

As shown in the following table, the type of identity store you implement, in part, will determine your authentication options.

Identity Store	Authentication Mechanism							
	Basic	SAML	Site SAML	Kerberos	(Windows only) Automatic Login Windows (SSPI)	OpenID Connect	Trusted Auth	Mutual SSL
Local	X	X	X			X	X	X
Active Directory	X	X		X	X		X	X

Tableau Server on Windows Help

LDAP	X	X					X	X
------	---	---	--	--	--	--	---	---

Access and management permissions are implemented through site roles. Site roles define which users are administrators, and which users are content consumers and publishers on the server. For more information about administrators, site roles, groups, Guest User, and user-related administrative tasks, see [Users](#) and [Site Roles for Users](#).

Note: In the context of authentication, it's important to understand that users are not authorized to access external data sources through Tableau Server by virtue of having an account on the server. In other words, in the default configuration, Tableau Server does not act as a proxy to external data sources. Such access requires additional configuration of the data source on Tableau Server or authentication at the data source when the user connects from Tableau Desktop.

Add-on authentication compatibility

Some authentication methods can be used together. The following table shows authentication methods that can be combined. Cells marked with an "X" indicate a compatible authentication set. Blank cells indicate incompatible authentication sets.

	Trusted Authentication	Server-wide SAML	Site SAML	Kerberos	(Windows only) Automatic Login Windows (SSPI)	Mutual SSL	OpenID Connect
Trusted Authentication	N/A	X	X	X		X	X

ation							
Server-wide SAML	X	N/A	X				
Site SAML	X	X	N/A				
Kerberos	X			N/A			
Automatic Login Windows (SSPI)					N/A		
Mutual SSL	X					N/A	
OpenID Connect	X						N/A

Client authentication compatibility

Clients	Authentication Mechanism							
	Basic	SAML	Site SAML	Kerberos	(Windows only) Automatic Login Windows (SSPI)	OpenID Connect	Trusted Auth	Mutual SSL
Tableau Desktop	X	X	X	X	X	X		X
Tableau	X	X	X	X	X	X		X

Tableau Server on Windows Help

Prep								
Tableau Mobile	X	X	X	X (iOS only)	X *	X		X
Tabcmd	X							
Web Browser-s	X	X	X	X	X	X	X	X

* SSPI is not compatible with the Workspace ONE version of the Tableau Mobile app.

Local authentication

If the server is configured to use local authentication, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, tabcmd, API, or web client, Tableau Server verifies the credentials.

To enable this scenario, you must first create an identity for each user. To create an identity, you specify a username and a password. To access or interact with content on the server, users must also be assigned a site role. User identities can be added to Tableau Server in the server UI, using [tabcmd Commands](#), or using the [REST API](#).

You can also create groups in Tableau Server to help manage and assign roles to large sets of related user groups (e.g., "Marketing").

When you configure Tableau Server for local authentication, you can set password policies and account lockout on failed password attempts. See [Local Authentication](#).

Note: Tableau with multi-factor (MFA) authentication is available for Tableau Online only.

External authentication solutions

Tableau Server can be configured to work with a number of external authentication solutions.

NTLM and SSPI

If you configure Tableau Server to use Active Directory during installation, then NTLM will be the default user authentication method.

When a user logs onto Tableau Server from Tableau Desktop or a web client, the credentials are passed through to Active Directory, which then verifies them and sends an access token to Tableau Server. Tableau Server will then manage user access to Tableau resources based on the site roles stored in the repository.

If Tableau Server is installed on a Windows computer in Active Directory, then you may optionally enable automatic logon. In this scenario, Tableau Server will use Microsoft SSPI to automatically sign in your users based on their Windows username and password. This creates an experience similar to single sign-on (SSO).

Do not enable SSPI if you plan to configure Tableau Server for SAML, trusted authentication, a load balancer, or for a proxy server. SSPI is not supported in these scenarios. See `tsm authentication sspi <commands>`.

Kerberos

You can configure Tableau Server to use Kerberos for Active Directory. See Kerberos.

SAML

You can configure Tableau Server to use SAML (security assertion markup language) authentication. With SAML, an external identity provider (IdP) authenticates the user's credentials, and then sends a security assertion to Tableau Server that provides information about the user's identity.

For more information, see SAML.

Tableau Server on Windows Help

OpenID Connect

OpenID Connect is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server. To use OpenID Connect (OIDC) on Tableau Server, the server must be configured to use the local identity store. Active Directory or LDAP identity stores are not supported with OIDC. For more information, see [OpenID Connect](#).

Mutual SSL

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection. For more information, see [Configure Mutual SSL Authentication](#).

Trusted authentication

Trusted authentication (also referred to as "Trusted tickets") lets you set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from a trusted web server, it assumes that the web server has already handled whatever authentication is necessary. Tableau Server receives the request with a redeemable token or ticket and presents the user with a personalized view which takes into consideration the user's role and permissions. For more information, see [Trusted Authentication](#).

LDAP

You can also configure Tableau Server to use LDAP for user authentication. Users are authenticated by submitting their credentials to Tableau Server, which will then attempt to bind to the LDAP instance using the user credentials. If the bind works then the credentials are valid and Tableau Server grants the user a session.

“Binding” is the handshake/authentication step that happens when a client tries to access an LDAP server. Tableau Server does this for itself when it makes various non-authentication related queries (such as importing users and groups).

You can configure the type of bind you want Tableau Server to use when verifying user credentials. Tableau Server supports GSSAPI and simple bind. Simple bind passes credentials directly to the LDAP instance. We recommend that you configure SSL to encrypt the bind communication. Authentication in this scenario may be provided by the native LDAP solution, or with an external process, like SAML.

For more information about planning for and configuring LDAP, see [Identity Store and External Identity Store Configuration Reference](#).

Other authentication scenarios

- REST API: [Signing In and Out \(Authentication\)](#)
- Mobile device authentication: [Single sign-on for Tableau Mobile](#)
- Certificate trust for TSM clients: [Connecting TSM clients](#)

Data access and source authentication

You can configure Tableau Server to support a number of different authentication protocols to various different data sources. Data connection authentication may be independent of Tableau Server authentication.

For example, you may configure user authentication to Tableau Server with local authentication, while configuring Kerberos delegation, OAuth, or SAML authentication to specific data sources. See [Data Connection Authentication](#).

Local Authentication

If the server is configured to use local identity store, then Tableau Server authenticates users. When users sign-in and enter their credentials, either through Tableau Desktop, tabcmd, API, or web client, Tableau Server verifies the credentials. Tableau user names

Tableau Server on Windows Help

stored in the identity store are associated with rights and permissions for Tableau Server. After authentication is verified, Tableau Server manages user access (authorization) for Tableau resources.

To use local authentication, you must configure Tableau Server with a local identity store during Setup. You cannot use local authentication if your Tableau Server has been configured with an external identity store (LDAP, Active Directory, etc).

Password storage

When local authentication is used, the user's salted and hashed password is stored in the repository. Passwords are never stored directly, rather, the result of salting and hashing the password is stored. Server uses the PBKDF2 derivation function with the HMAC SHA512 hashing function.

Configure password settings

After you install Tableau Server with local authentication, you can use Tableau Server Manager (TSM) to configure a number of password-related settings:

- Password policies: these policies define the requirement for password structure, such as length, character types, and other requirements.
- Password expiration: enable and specify password expiry.
- Login rate limit: Tableau Server throttles the time between sign-in attempts after users enter 5 incorrect passwords. Users will need to wait a few seconds before attempting another sign-in. If users continue to enter incorrect passwords, then they must wait for exponentially longer periods of time in between sign-in attempts. By default, the maximum time between sign-in attempts is 60 minutes.

Lock out account access after too many failed attempts. You can specify how many failed attempts users are allowed to enter before they are locked out. For information on how to unlock access to a locked account, see [View and manage users on a site](#) .

- User password reset: Enable users to reset passwords. Enabling password reset will

configure Tableau Server to display a link on the sign-in page. Users who forget passwords or want to reset a password can click the link to initiate a reset-password workflow. Password reset must be configured using TSM CLI, as described below.

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click on **User Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Select Local authentication from the drop-down menu to display the password settings.
4. Configure the password settings and then click **Save Pending Changes**.
5. Click **Pending Changes** at the top of the page:

6. Click **Apply Changes and Restart**.

Use the TSM CLI

For the initial configuration of password policies, we recommend that you use the configuration file template below to create a json file. You can also set any single configuration key listed below with the syntax described in [tsm configuration set](#).

1. Copy the following json template to a file. Fill in the key values with your password policy configuration. See the reference section that follows for more information about key options.

```
{
```

Tableau Server on Windows Help

```
"configKeys": {  
  "wgserver.localauth.policies.mustcontainletters.enabled":  
  false,  
  "wgserv-  
er.localauth.policies.mustcontainuppercase.enabled": false,  
  "wgserver.localauth.policies.mustcontainnumbers.enabled":  
  false,  
  "wgserver.localauth.policies.mustcontainsymbols.enabled":  
  false,  
  "wgserv-  
er.localauth.policies.minimumpasswordlength.enabled":  
  false,  
  "wgserv-  
er.localauth.policies.minimumpasswordlength.value": 8,  
  "wgserv-  
er.localauth.policies.maximumpasswordlength.enabled":  
  false,  
  "wgserv-  
er.localauth.policies.maximumpasswordlength.value": 255,  
  "wgserver.localauth.passwordexpiration.enabled": false,  
  "wgserver.localauth.passwordexpiration.days": 90,  
  "wgserver.localauth.ratelimiting.maxbackoff.minutes": 60,  
  "wgserver.localauth.ratelimiting.maxattempts.enabled":  
  false,  
  "wgserver.localauth.ratelimiting.maxattempts.value": 5,  
  "features.PasswordReset": false  
}
```

```
}
```

2. Run the `tsm settings import -f file.json` to pass the json file with the appropriate values to Tableau Services Manager to configure Tableau Server.
3. Run the `tsm pending-changes apply` command to apply the changes. See `tsm pending-changes apply`.

Configuration file reference

This section lists all of the options that can be used to configure password policies.

```
wgserver.localauth.policies.mustcontainletters.enabled
```

Default value: `false`

Require at least one letter in passwords.

```
wgserver.localauth.policies.mustcontainuppercase.enabled
```

Default value: `false`

Require at least one upper-case letter in passwords.

```
wgserver.localauth.policies.mustcontainnumbers.enabled
```

Default value: `false`

Require at least one number letter in passwords.

```
wgserver.localauth.policies.mustcontainsymbols.enabled
```

Default value: `false`

Require at least one special character in passwords.

```
wgserver.localauth.policies.minimumpasswordlength.enabled
```

Default value: `false`

Tableau Server on Windows Help

Enforce minimum-length passwords.

`wgserver.localauth.policies.minimumpasswordlength.value`

Default value: 8

The minimum number of characters passwords must have. Enter a value between 4 and 255, inclusive. You must set `wgserver.localauth.policies.minimumpasswordlength.enabled` to `true` to enforce this value.

`wgserver.localauth.policies.maximumpasswordlength.enabled`

Default value: `false`

Enforce maximum-length passwords.

`wgserver.localauth.policies.maximumpasswordlength.value`

Default value: 255

The maximum number of characters passwords may have. Enter a value between 8 and 225, inclusive. You must set `wgserver.localauth.policies.maximumpasswordlength.enabled` to `true` to enforce this value.

`wgserver.localauth.passwordexpiration.enabled`

Default value: `false`

Enforce password expiry.

`wgserver.localauth.passwordexpiration.days`

Default value: 90

The number of days before a password expires. Enter a value between 1 and 365, inclusive. You must set `wgserver.localauth.passwordexpiration.enabled` to `true` to enforce this value.

`wgserver.localauth.ratelimiting.maxbackoff.minutes`

Default value: 60

Maximum time between sign-in attempts after a user enters multiple incorrect passwords. Enter a value between 5 and 1440, inclusive.

`wgserver.localauth.ratelimiting.maxattempts.enabled`

Default value: `false`

Enforce account lock out after 5 incorrect passwords are entered. To change the number of incorrect passwords that will trigger account lock out, you set `wgserver.localauth.ratelimiting.maxattempts.value`.

`wgserver.localauth.ratelimiting.maxattempts.value`

Default value: 5

The number of incorrect passwords that a user may enter to trigger account lock out. Enter a value between 5 and 100, inclusive. You must set `wgserver.localauth.ratelimiting.maxattempts.enabled` to `true` to enforce this value.

`features.PasswordReset`

Default value: `false`

Enable users to reset passwords. Tableau Server must be configured to send email for this feature to operate. See [Configure SMTP Setup](#).

SAML

SAML (Security Assertion Markup Language) is an XML standard that allows secure web domains to exchange user authentication and authorization data. You can configure Tableau Server to use an external identity provider (IdP) to authenticate users over SAML 2.0. No user credentials are stored with Tableau Server, and using SAML enables you to add Tableau to your organization's single sign-on environment.

You can use SAML server wide, or you can configure sites individually. Here's an overview of those options:

- **Server-wide SAML authentication.** A single SAML IdP application handles authentication for all Tableau Server users. Use this option if your server has only the Default site, as it is unnecessary to configure site specific SAML in this case. You may also use Server-wide SAML in multisite environments, but users are limited to a single IdP to across all sites.
- **Server-wide local authentication and site-specific SAML authentication.** In a multi-site environment, users who are not enabled for SAML authentication at the site level can sign in using local authentication.
- **Server-wide SAML authentication and site-specific SAML authentication.** In a multi-site environment, all users authenticate through a SAML IdP configured at the site level, and you specify a server-wide default SAML IdP for users that belong to multiple sites.

If you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites. Server-side SAML does not need to be enabled for site-specific SAML to function, but it must be configured.

User authentication through SAML does not apply to permissions and authorization for Tableau Server content, such as data sources and workbooks. It also does not control access to underlying data that workbooks and data sources connect to.

Note: Tableau Server supports both service provider initiated and IdP initiated SAML in browsers and in the Tableau Mobile app. SAML connections from Tableau Desktop must be service provider initiated.

The following image shows the steps to authenticate a user with single sign-on in a typical service provider initiated flow:

1. User navigates to the Tableau Server sign-in page or clicks a published workbook URL.
2. Tableau Server starts the authentication process by redirecting the client to the configured IdP.
3. The IdP requests the user's username and password from the user. After the user submits valid credentials, the IdP authenticates the user.
4. The IdP returns the successful authentication in the form of a SAML Response to the

client. The client passes the SAML Response to Tableau Server.

5. Tableau Server verifies that the username in the SAML Response matches a licensed user stored in the Tableau Server Repository. If a match is verified, then Tableau Server responds to the client with the requested content.

SAML Requirements

Before you configure SAML on Tableau Server, make sure your environment meets the requirements.

Important: SAML configurations, both with the IdP and on Tableau Server, are case sensitive. For example, URLs configured with the IdP and on Tableau Server must match exactly.

Certificate and identity provider (IdP) requirements

To configure Tableau Server for SAML, you need the following:

- **Certificate file.** A PEM-encoded x509 certificate file with a **.crt** extension. This file is used by Tableau Server, not the IdP. If you have an SSL certificate, it is possible in some circumstances to use the same certificate with SAML. For more information, see [Using SSL certificate and key files for SAML](#) later in this article.

Tableau Server requires a certificate-key pair to sign the request that is sent to the IdP. This reduces the threat of a man-in-the-middle attack given the difficulty of spoofing a signed request. Additionally, Tableau Server verifies that the AuthNResponse it receives from the trusted IdP. Tableau Server verifies the AuthNResponse by using the signature produced by the IdP. The IdP certificate metadata is provided to Tableau Server as part of the initial SAML configuration process.

Signed requests are not always necessary for all IdPs. By default, Tableau Server requires signed requests. We recommend this configuration to ensure a more secure communication transmission with the IdP. Work with your IdP team to understand if disabling signed requests is necessary. To disable signed requests see `samlSettings` Entity.

- **Signature algorithm.** The certificate must use a secure signature algorithm, for

example SHA-256. If you attempt to configure Tableau Server for SAML with a certificate that uses SHA-1 signature hash, Tableau Server will reject the certificate. You can configure Tableau Server to accept the less-secure SHA-1 hash by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.

- **RSA key and ECDSA curve sizes.** The Tableau Server certificate must have an RSA key strength of 2048, and the IdP certificate must have either an RSA key strength of 2048 or ECDSA curve size of 256.

You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys, `wgserver.saml.min_allowed.rsa_key_size` and `wgserver.saml.min_allowed.elliptic_curve_size`.

- **Certificate key file.** An RSA or DSA private key file that has the **.key** extension. RSA keys must be in in PKCS#1 or PKCS#8 format.

Password protection requirements are as follows:

- The PKCS#1 RSA key file cannot be password protected.
- To use a password-protected key file, you must configure SAML with a RSA PKCS#8 file. **Note:** A PKCS#8 file with a null password is not supported.
- Password-protected key files are not supported in site-specific SAML deployments.

Summary of support

Key file format	Server-Wide SAML Support	Site-Level SAML Support
PKCS#8 RSA	Yes	No
PKCS#8 (no/null password)	No	No

Key file format	Server-Wide SAML Support	Site-Level SAML Support
PKCS#1 RSA	Yes	Yes
PKCS#1 RSA (password)	No	No
PKCS#1 DSA (password)	No	No

- **IdP must sign SAML assertions with a secure signature algorithm.** By default, Tableau Server will reject SAML assertions signed with the SHA-1 algorithm. You can configure Tableau Server to accept assertions signed with the less-secure SHA-1 hash by setting the `tsm wgserver.saml.blocklisted_digest_algorithms` configuration key.
- **IdP account that supports SAML 2.0 or later.** You need an account with an external identity provider. Some examples are PingFederate, SiteMinder, and Open AM.
- **IdP provider that supports import and export of XML metadata.** Although a manually created metadata file might work, Tableau Technical Support cannot assist with generating the file or troubleshooting it.

SSL off-loading

If your organization terminates SSL connections from the IdP at a proxy server before sending the authentication request to Tableau Server, then you may need to make a proxy configuration. In this scenario, SSL is "off-loaded" at the proxy server, which means the https request is terminated at the proxy server and then forwarded to Tableau Server over http.

Tableau Server validates the SAML response message returned from the IdP. Since SSL is off-loaded at the proxy, Tableau Server will validate with the protocol that it receives (http), but the IdP response is formatted with https, so validation will fail unless your proxy server

includes the X-Forwarded-Proto header set to `https`. See [Configure Tableau Server to work with a reverse proxy server](#).

Using SSL certificate and key files for SAML

If you are using a PEM-encoded x509 certificate file for SSL, you can use the same file for SAML. For SSL, the certificate file is used to encrypt traffic. For SAML, the certificate is used for authentication.

In addition to the requirements listed in [Certificate and identity provider \(IdP\) requirements](#) above, to use the same certificate for both SSL and SAML, the certificate must also meet the following condition to work for SAML:

- Confirm that the certificate includes only the certificate that applies to Tableau Server and not any other certificates or keys.

To do this, you can create a backup copy of the certificate file, and then open the copy in a text editor to review its contents.

User management requirements

When you enable SAML, user authentication is performed outside of Tableau, by the IdP. However, user management is performed by an identity store: either an external identity store (Active Directory or LDAP) or by Tableau Server in a local identity store. For more information about planning for user management with Tableau Server, see [Identity Store](#).

When you configure the identity store during Setup, you must select the option that reflects how you want to use SAML. If you want to use site-specific SAML, you must configure server-wide SAML before you configure individual sites.

- **For site-specific SAML:** If you have multiple sites on Tableau Server and want to set up each site for a particular IdP or IdP application (or configure some sites not to use SAML), configure Tableau Server to manage user with a local identity store. For site-specific SAML, Tableau Server relies on the IdP for authentication and does not use passwords.

- **For server-wide SAML:** If you configure server-wide SAML with a single IdP, you can configure Tableau Server to use the local identity store or an external identity store. If you are using Active Directory, you must disable the **Enable automatic logon** option.
- **Server-wide SAML authentication and site-specific SAML authentication.** In a multi-site environment, all users authenticate through a SAML IdP configured at the site level. In this scenario, you specify a server-wide default SAML IdP for users who belong to multiple sites. To configure this scenario, Tableau Server must be configured with a local identity store.

Note: The **REST API** and **tabcmd** do not support SAML single-sign (SSO). To sign in, you must specify the name and password of a user who has been created on the server. The user may be managed by the local identity store or an external identity store, depending on how you have configured Tableau Server. For Tableau Online, you can specify the TableauID credentials of the user. REST API or tabcmd calls will have the permissions of the user you sign in as.

SAML compatibility notes and requirements

- **Matching usernames:** The user name stored in Tableau Server must match the configured user name attribute sent by the IdP in the SAML assertion. By default, Tableau Server expects the incoming assertion to contain an attribute called "username" with that user's information. For example, if the user name for Jane Smith is stored in PingFederate as **jsmith**, it must also be stored in Tableau Server as **jsmith**.

When configuring SAML during authentication

If you are configuring SAML as part of the initial Tableau Server setup, make sure the account you plan to use exists in your IdP before you run setup. During Tableau Server setup you create the server administrator account.

When running multiple domains

If you use an Active Directory or LDAP external identity store and you are running in multiple domains (that is, users belong to multiple domains, or your Tableau Server installation includes multiple domains), the IdP must send both the user name *and* domain attributes for a user in the SAML assertion. Both these user name and domain attributes must match exactly the user name and domain stored in Tableau Server. Use the `domain\username` format for the user attribute and the fully qualified domain name (FQDN) for the domain attribute. If the domain attribute isn't included, the domain of the Tableau Server computer, also referred to as the default domain, will be used for all users. If users are not in the same domain as the Tableau Server computer, the exclusion of the domain attribute will cause sign in errors.

For more information, see Support for multiple domains and the "Match Assertions" section in the **Use TSM CLI** tab of Configure Server-Wide SAML.

- **Signature algorithm:** Tableau Server uses SHA256 signature algorithm.
- **Single Log Out (SLO):** Tableau Server supports both service provider (SP)-initiated SLO and identity provider (IdP)-initiated SLO for both server-wide SAML and site-specific SAML.
- **External authentication types:** Tableau Server supports using one external authentication type at a time.
- **Mutual SSL:** Tableau Server does not support mutual SSL (two-way SSL) and SAML together. If you want to use mutual SSL, you can configure it on the IdP.
- **Assertions encoding:** Assertions must be UTF-8 encoded.
- **Encryption and SAML assertions:** When configured for server-wide SAML, Tableau Server supports encrypted assertions from the IdP. Encryption assertions are enabled by the certificate that you upload as part of the initial configuration for server-wide SAML.

Tableau Server on Windows Help

When configured for site-specific SAML, Tableau Server does not support encrypted assertions from the IdP. However, all SAML requests and responses are sent over HTTPS.

- **User identity in Tableau Server for tabcmd users:** As described in User management requirements section above, to use tabcmd, you must sign in as a user defined on the server. You cannot use SAML accounts with **tabcmd**.
- **Using SAML SSO with Tableau Desktop:** By default, Tableau Desktop allows SP-initiated SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau Desktop using the following command:

```
tsm authentication saml configure --desktop-access disable
```

For more information, see `tsm authentication saml <commands>`.

- **Distributed installations:** TSM versions of Tableau Server (2018.2 and newer) use the Client File Service to share files in a multi node cluster. After you have configured SAML on the initial node in your cluster, the Client File Service will distribute certificate and key files to the other nodes.
- **Login URL:** For users to be able to sign in, your IdP must be configured with SAML Login endpoint that sends a POST request to the following URL:

```
https://<tableauserver>/wg/saml/SSO/index.html.
```

- **Logout URL:** To enable users to sign out after signing in with SAML (single logout, or SLO), your IdP must be configured with a SAML Logout endpoint that sends a POST request to the following URL:

```
https://<tableauserver>/wg/saml/SingleLogout/index.html.
```

Note: Tableau Server supports both service provider (SP)-initiated SLO and identity provider (IdP)-initiated SLO for both server-wide SAML and site-specific SAML.

- **Post-logout redirect URL:** By default, when a user signs out of Tableau Server, the sign-in page is displayed.

To display a different page after sign-out, use the `tsm authentication saml configure` command with the `-su` or `--signout-url` option.

- To specify an absolute URL, use a fully-qualified URL starting with `http://` or `https://`, as in this example:

```
tsm authentication saml configure -su https://example.com
```

- To specify a URL relative to the Tableau Server host, use a page starting with a `/` (slash):

```
tsm authentication saml configure -su /our-logoutpage.html
```

- **Active Directory Federation Service (AD FS):** You must configure AD FS to return additional attributes for Tableau authentication with SAML. The **Name ID** and **username** attributes can be mapped to the same AD attribute: **SAM-Account-Name**.

For configuration information, see [Configure SAML with AD FS on Tableau Server](#).

- **AuthNContextClassRef :** `AuthNContextClassRef` is an optional SAML attribute that enforces validation of certain authentication "contexts" in IdP initiated flows. You can set comma-separated values for this attribute with TSM. When this attribute is set, Tableau Server validates that the SAML response contains at least one of the values listed. If the SAML response does not contain one of the configured values, authentication will be rejected, even if the user has successfully authenticated with the IdP.

Tableau Server on Windows Help

Leaving this optional attribute blank will result in default behavior: any successfully authenticated SAML response will result in a user being granted a session within Tableau Server.

This value is only evaluated for server-wide SAML. If site-SAML is configured, the `AuthNContextClassRef` attribute will be ignored.

To set this value with TSM web interface, see [Configure Server-Wide SAML](#).

To set this value with tsm configuration set, use the key, `wgserver.saml.authcontexts`, to set a comma-separated list of values.

To set this value with a JSON configuration file, see [samlSettings Entity](#).

Using SAML SSO with Tableau client applications

Tableau Server users with SAML credentials can sign in to the server from Tableau Desktop or the Tableau Mobile app. For full compatibility, we recommend that the Tableau client application version matches that of the server. To connect using site-specific SAML, users must run version 10.0 or later of the Tableau client application.

Connecting to Tableau Server from Tableau Desktop or Tableau Mobile uses a service provider (SP) initiated connection.

Redirecting authenticated users back to Tableau clients

When a user signs in to Tableau Server, Tableau Server sends a SAML request (`AuthnRequest`) to the IdP, which includes the Tableau application's **RelayState** value. If the user has signed in to Tableau Server from a Tableau client such as Tableau Desktop or Tableau Mobile, it's important that the RelayState value is returned within the IdP's SAML response back to Tableau.

When the RelayState value is not returned properly in this scenario, the user is taken to their Tableau Server home page in the web browser, rather than being redirected back to the application they signed in from.

Work with your Identity Provider and internal IT team to confirm that this value will be included as part of the IdP's SAML response, and then preserved by any network appliance (such as a proxy or load balancer) that resides between your IdP and Tableau Server.

XML data requirements

As part of SAML configuration, you exchange XML metadata between Tableau Server and the IdP. This XML metadata is used to verify a user's authentication information when the user initiates the Tableau Server sign-in process.

Tableau Server and the IdP each generates its own metadata. Each set of metadata must contain the information described in the following list. If either set is missing information, errors can occur when you configure SAML or when users try to sign in.

- **HTTP POST:** Tableau Server only supports HTTP POST requests for SAML communications. HTTP Redirect is not supported.
- With the `Binding` attribute set to `HTTP-POST`, the SAML metadata that Tableau Server and the IdP each export must contain the following elements.
 - The element that specifies the URL that the IdP redirects to after successful authentication. This is required in the Service Provider metadata, not the Identity Provider metadata.

```
<md:AssertionConsumerService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
  Location="https://<tableau-server-
>/wg/saml/SSO/index.html index="0" isDefault="true"/>
```

For Site SAML, the `Location` endpoint is `/samlservice/public/sp/metadata?alias=<site alias>`.

- The logout endpoint element appears in Tableau Server metadata and specifies the URL that the IdP will use for Tableau Server's logout endpoint. If this

Tableau Server on Windows Help

element is not in the IdP metadata, Tableau Server cannot negotiate a logout endpoint with the IdP and the SAML Logout feature will not be available within Tableau Server:

```
<md:SingleLogoutService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"  
Location="https://SERVER-NAME:9031/idp/slo">
```

Note: SP-initiated SLO is supported for both server-wide and site-specific SAML. However, IdP-initiated SLO is not supported.

- Verify that the metadata XML from the IdP includes a **SingleSignOnService** element, in which the binding is set to HTTP-POST, as in the following example:

```
<md:SingleSignOnService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"  
Location="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

- This element should appear in IdP metadata and specifies the URL that Tableau Server will use for the IdP's logout endpoint.

```
<md:SingleLogoutService Bind-  
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"  
Location="https://SERVER-NAME:9031/idp/slo"/>
```

- **Attribute named *username*:** You must configure the IdP to return an assertion that includes the `username` attribute in the `saml:AttributeStatement` element. The assertion's attribute type must be `xs:string` (it should *not* be typed as `xs:any`).

The following example shows what this might look like.

```
<saml:Assertion assertion-element-attributes>  
  <saml:Issuer>issuer-information</saml:Issuer>
```

```

<Signature xmlns="http://www.w3.org/2000/09/xmldsig#">
  ...
</Signature>
<saml:Subject>
  ...
</saml:Subject>
<saml:Conditions condition-attributes >
  ...
</saml:Conditions>
<saml:AuthnStatement authn-statement-attributes >
  ...
</saml:AuthnStatement>

<saml:AttributeStatement>
  <saml:Attribute Name="username" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
    <saml:AttributeValue xmlns:xs="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">
      user-name
    </saml:AttributeValue>
  </saml:Attribute>
</saml:AttributeStatement>
</saml:Assertion>

```

By default, Tableau Server will read the `username` attribute in the `AuthNResponse` returned from the Idp. However, some IdPs may return a different attribute that is intended to identify the user.

To change the SAML attribute that passes the `username` value, run the following TSM command:

Tableau Server on Windows Help

```
tsm authentication saml map-assertions --user-name <USER-NAME>.
```

See `tsm authentication`.

Configure Server-Wide SAML

Configure server-wide SAML when you want all single sign-on (SSO) users on Tableau Server to authenticate through a single SAML identity provider (IdP), or as the first step to configuring site-specific SAML in a multi-site environment.

If you have configured server-wide SAML and are ready to configure a site, see [Configure Site-Specific SAML](#).

The SAML configuration steps we provide make the following assumptions:

- You are familiar with the options for configuring SAML authentication on Tableau Server, as described in the [SAML](#) topic.
- You have verified that your environment meets the [SAML Requirements](#), and obtained the SAML certificate files described in those requirements.

Before you begin

Gather the certificate files and place them on the Tableau Server.

In the Tableau Server folder, create a new folder named SAML, and place copies of the SAML certificate files in that folder. For example:

```
C:\Program Files\Tableau\Tableau Server\SAML
```

This is the recommended location because the user account that runs Tableau Server has the necessary permissions to access this folder.

As part of your disaster recovery plan, we recommend keeping a backup of certificate and IdP files in a safe location off of the Tableau Server. The SAML asset files that you upload to Tableau Server will be stored and distributed to other nodes by the Client File Service.

However, these files are not stored in a recoverable format. See Tableau Server Client File Service.

Note: If you use the same certificate files for SSL, you could alternatively use the existing certificate location for configuring SAML, and add the IdP metadata file to that directory when you download it later in this procedure. For more information, see Using SSL certificate and key files for SAML in the SAML requirements.

If you are running Tableau Server in a cluster, then the SAML certificates, keys, and metadata file will be automatically distributed across the nodes when you enable SAML.

Use the TSM web interface

This procedure requires that you upload the SAML certificates to TSM so that they are properly stored and distributed in the server configuration. The SAML files must be available to the browser on the local computer where you are running the TSM web interface in this procedure.

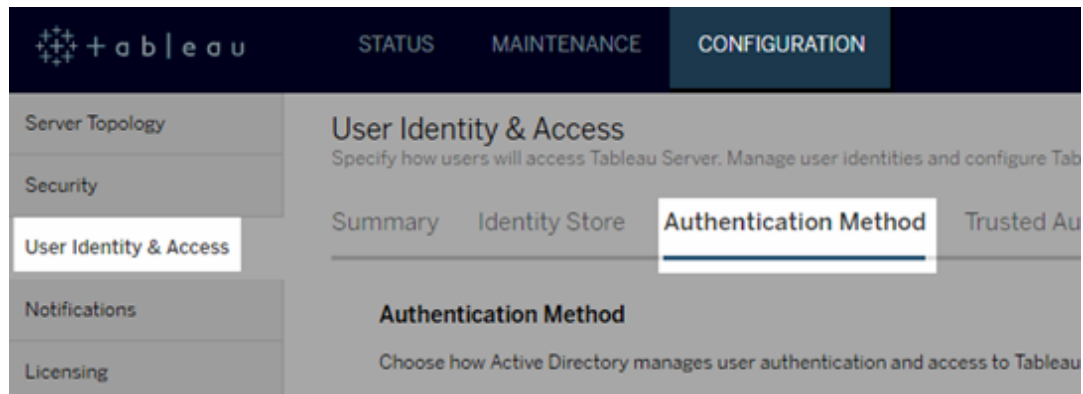

If you have gathered and saved the SAML files to the Tableau Server as recommended in the previous section, then run the TSM web interface from the Tableau Server computer where you copied the files.

If you are running the TSM web interface from a different computer, then you will need to copy all SAML files locally before proceeding. As you follow the procedure below, browse to the files on the local computer to upload them to TSM.

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.

2. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

3. For **Authentication Method**, select **SAML**.
4. In the SAML section that appears, complete Step 1 in the GUI, entering the following settings (do not yet select the check box to enable SAML for the server):

- **Tableau Server return URL**—The URL that Tableau Server users will access, such as `https://tableau-server`.

Using `https://localhost` or a URL with a trailing slash (for example, `http://tableau_server/`) is not supported.

- **SAML entity ID**—The entity ID uniquely identifies your Tableau Server installation to the IdP.

You can enter your Tableau Server URL again here. If you plan to enable site-specific SAML later, this URL also serves as the base for each site's unique ID.

- **SAML certificate and key files**— Click **Select File** to upload each of these files.

If you are using a PKCS#8 passphrase-protected key file, you must enter the passphrase with TSM CLI:

```
tsm configuration set -k wgserver.saml.key.passphrase  
-v <passphrase>
```

After you provide the information required in Step 1 in the GUI, the **Download XML Metadata File** button in Step 2 in the GUI becomes available.

5. Now select the **Enable SAML authentication for the server** check box above Step 1 in the GUI.
6. Complete the remaining SAML settings.
 - a. For Steps 2 and 3 in the GUI, exchange metadata between Tableau Server and the IdP. (Here's where you might need to check in with the IdP's documentation.)

Select **Download XML Metadata File**, and specify the file location.

If you are configuring SAML with AD FS, you can return to Step 3: Configure AD FS to accept sign-in requests from Tableau Server of "Configure SAML with AD FS on Tableau Server."

For other IdPs, go to your IdP account to add Tableau Server to its applications (as a service provider), providing the Tableau metadata as appropriate.

Follow the instructions in the IdP's website or documentation to download the IdP's metadata. Save the .xml file to the same location that holds your SAML certificate and key files. For example:

```
C:\Program Files\Tableau\Tableau Server\SAML\idp-  
metadata.xml
```

- b. Return to the TSM web UI. For Step 4 in the GUI, enter the path to the IdP metadata file, and then click **Select File**.

Tableau Server on Windows Help

- c. For Step 5 in the GUI: In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

Tip: “Assertions” are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that “heading” name, rather than an example of a value that might appear in that column.

- d. For Step 6 in the GUI, select the Tableau applications in which you want to give users a single sign-on experience.

Note: The option to disable mobile access is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.

- e. For the SAML sign-out redirect, if your IdP supports single logout (SLO), enter the page you want to redirect users to after they sign out, relative to the path you entered for the Tableau Server return URL.
- f. For Step 7 in the GUI, optionally add a comma-separated value for the

`AuthNContextClassRef` attribute. For more information about how this attribute is used, see SAML compatibility notes and requirements.

7. Click **Save Pending Changes** after you've entered your configuration information.
8. Click **Pending Changes** at the top of the page:

9. Click **Apply Changes and Restart**.

Use the TSM CLI

Before you begin

Go to your IdP's website or application, and export the IdP's metadata XML file.

Confirm that the metadata XML from the IdP includes a **SingleSignOnService** element, in which the binding is set to `HTTP-POST`, as in the following example:

```
<md:SingleSignOnService Bind-
ing="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST" Loca-
tion="https://SERVER-NAME:9031/idp/SSO.saml2"/>
```

Step 1: Configure return URL, SAML entity ID, and specify certificate and key files

1. Open the command prompt shell and configure the SAML settings for the server (replacing placeholder values with your environment path and file names).

```
tsm authentication saml configure --idp-entity-id
https://tableau-server --idp-metadata "C:\Program Files\T-
ableau\Tableau Server\SAML\<metadata-file.xml>" --idp-
return-url https://tableau-server --cert-file "C:\Program
```

Tableau Server on Windows Help

```
Files\Tableau\Tableau Server\SAML\<>file.crt>" --key-file  
"C:\Program Files\Tableau\Tableau Server\SAML\<>file.key>"
```

For more information, see `tsm authentication saml configure`.

2. If you are using a PKCS#8 key that is protected with a passphrase, enter the passphrase as follows:

```
tsm configuration set -k wgserver.saml.key.passphrase -v  
<passphrase>
```

3. If SAML is not already enabled on Tableau Server; for example, you're configuring it for the first time, or you have disabled it, enable it now:

```
tsm authentication saml enable
```

4. Apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Step 2: Generate Tableau Server metadata and configure the IdP

1. Run the following command to generate the required XML metadata file for Tableau server.

```
tsm authentication saml export-metadata -f <file-name.xml>
```

You can specify a file name, or omit the `-f` parameter to create a default file named `samlmetadata.xml`.

2. On your IdP's website or in its application:

- Add Tableau Server as a Service Provider.

Refer to your IdP's documentation for information about how to do this. As part of the process of configuring Tableau Server as a Service Provider, you will import the Tableau Server metadata file you generated from the `export-metadata` command.

- Confirm that your IdP uses **username** as the attribute to verify users.

Step 3: Match assertions

In some cases, you may need to change the assertion values in the Tableau Server configuration to match the assertion names that are passed by your IdP.

You can find assertion names in the IdP's SAML configuration. If different assertion names are passed from your IdP, then you must update Tableau Server to use the same assertion value.

Tip: "Assertions" are a key SAML component, and the concept of mapping assertions can be tricky at first. It might help to put this in a tabular-data context, in which the assertion (attribute) name is equivalent to a column heading in the table. You enter that "heading" name, rather than an example of a value that might appear in that column.

The following table shows the default assertion values and the configuration key that stores the value.

Assertion	Default value	Key
Username	username	wgserver.saml.idpattribute.username
Display name	displayName	Tableau does not support this attribute type.

Tableau Server on Windows Help

Email	email	Tableau does not support this attribute type.
Domain	(not mapped by default)	wgserver.saml.idpattribute.domain

To change a given value, run the `tsm configuration set` command with the appropriate key:value pair.

For example, to change the `username` assertion to the value, `name`, run the following commands:

```
tsm configuration set -k wgserver.saml.idpattribute.username -v name
```

```
tsm pending-changes apply
```

Alternatively, you can use the `tsm authentication saml map-assertions` command to change a given value.

For example, to set the domain assertion to a value called `domain` and specify its value as "example.myco.com," run the following commands:

```
tsm authentication saml map-assertions --domain example.myco.com
```

```
tsm pending-changes apply
```

Optional: Disable client types from using SAML

By default, both Tableau Desktop and the Tableau Mobile app allow SAML authentication.

If your IdP does not support this functionality, you can disable SAML sign-in for Tableau clients using the following commands:

```
tsm authentication saml configure --desktop-access disable
```

```
tsm authentication saml configure --mobile-access disable
```

Note: The `--mobile-access disable` option is ignored by devices running Tableau Mobile app version 19.225.1731 and higher. To disable SAML for devices running these versions you must disable SAML as a client login option on Tableau Server.

```
tsm pending-changes apply
```

Optional: Add AuthNContextClassRef value

Add a comma-separated value for the `AuthNContextClassRef` attribute. For more information about how this attribute is used, see SAML compatibility notes and requirements.

To set this attribute run the following commands:

```
tsm configuration set -k wgserversaml.authcontexts -v <value>
```

```
tsm pending-changes apply
```

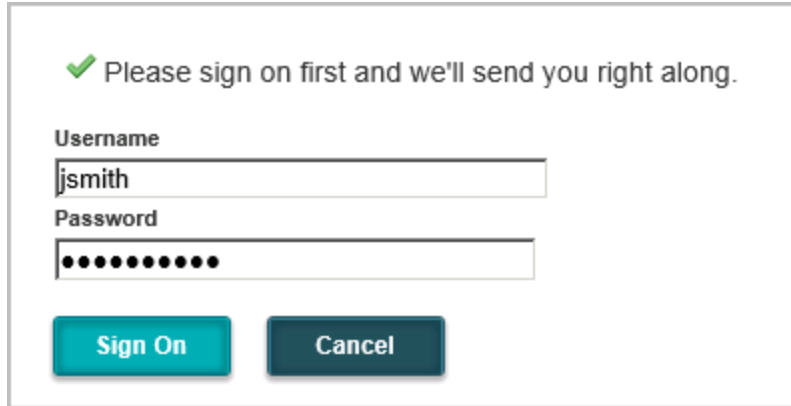

Test the configuration

1. In your web browser, open a new page or tab, and enter the Tableau Server URL.

The browser redirects you to the IdP's sign-in form.

2. Enter your single sign-on user name and password.

✓ Please sign on first and we'll send you right along.

The IdP verifies your credentials and redirects you back to your Tableau Server start page.

Configure SAML with Salesforce IdP on Tableau Server

This topic provides road-map steps that describe how to configure SAML on Tableau Server with the Salesforce IdP.

This topic also explains how to enable Lightning Web Component (LWC). The LWC allows Salesforce administrators to embed a Tableau visualization within a Lightning page. When SSO is configured for Tableau Viz LWC on Tableau Server, the user experience is seamless: after the user signs into Salesforce, embedded Tableau views will work without further authentication to Tableau Server.

Enable Salesforce as a SAML Identity Provider

If you have not yet configured Salesforce as an IdP, then follow the procedure, [Enable Salesforce as a SAML Identity Provider](#), on the Salesforce Help site.

During the process to enable Salesforce as a SAML IdP, you will either specify a certificate or Salesforce will generate a self-signed certificate for use with SAML. Download this certificate (.crt file) and the associated provider metadata file (.xml). You will need these assets in the next step.

Configure SAML on Tableau Server

Using the certificate and metadata files that you downloaded in the previous step, follow the procedure in [Configure Server-Wide SAML](#).

As part of the configuration process, you will generate a SAML Entity ID and a return URL (also referred to as the “ACS”) for Tableau Server. You will need these assets for the next step.

(Optional) After you have configured server-wide SAML, you can configure site-specific SAML on Tableau Server. See [Configure Site-Specific SAML](#).

Add Tableau Server as a Connected App in Salesforce

Follow the procedure, [Integrate Service Providers as Connected Apps with SAML 2.0](#), on the Salesforce Help site.

In this process, you will create a new connected app (Tableau Server). Some important details follow:

- Select "Enable SAML"
- Enter the Entity ID and the ACS (return URL) that you generated when configuring Tableau in the previous section.
- For the IdP certificate, be sure to select the same certificate that you specified or generated when you enabled Salesforce as a SAML provider.
- To allow users to sign in to Tableau Server from your org, manage access to your connected app by assigning the appropriate profiles or permission sets.

Enable Lightning Web Component

To enable LWC for SAML SSO on Tableau Server, you must enable in-frame authentication. Before you enable LWC, upgrade to the latest maintenance release of Tableau Server. Two additional version details are important:

- If you are not running the latest maintenance release, and your users are running Chrome browsers to access Salesforce Lightning, then review the Tableau KB article, [Embedded Views Fail to Load After Updating to Chrome 80](#).

Tableau Server on Windows Help

- If you are using LWC with site-specific SAML on Tableau Server, then you must be running the Tableau Server 2020.4 or later.

After you have configured SAML on Tableau Server, run the following TSM commands to enable in-frame authentication:

```
tsm configuration set -k wgserver.saml.iframe_idp.enabled -v true
```

```
tsm pending-changes apply
```

Embed Tableau Views into Salesforce

After you have configured Tableau Server for SSO, you can then install the LWC in your Salesforce org and embed Tableau views. See [Embed Tableau Views into Salesforce](#).

Configure SAML for Tableau Viz Lightning Web Component

Tableau provides a Lightning Web Component (LWC) for embedding a Tableau visualization within a Salesforce Lightning page.

This topic describes how to enable a SSO experience for embedded Tableau visualizations in a Salesforce Lightning page. SSO for the Tableau Viz LWC scenario requires SAML configuration. The SAML IdP used for Tableau authentication must be either the Salesforce IdP or same IdP that is used for your Salesforce instance.

In this scenario, Salesforce administrators can drag-and-drop Tableau Viz LWC into the Lightning page to embed a visualization. Any view that is available to them on Tableau Server can be displayed in the dashboard by entering the embedded URL to the view.

When single sign-on (SSO) is configured for Tableau Viz LWC on Tableau Server, the user experience is seamless: after the user signs into Salesforce, embedded Tableau views will work without further authentication to Tableau Server.

When SSO is not configured, then users will need to reauthenticate with Tableau Server to view embedded visualizations from Tableau Server.

Requirements

- The SAML IdP used for Tableau authentication must be either the Salesforce IdP or same IdP that is used for your Salesforce instance. See [Configure SAML with Salesforce IdP on Tableau Server](#).
- SAML must be configured on Tableau Server. See [Configure Server-Wide SAML](#), or [Configure Site-Specific SAML](#).
- SAML must be configured for Salesforce.
- Install the Tableau Viz Lightning Web Component. See [Embed Tableau Views into Salesforce](#).

Configuring the authentication workflow

You may need to make additional configurations to optimize the sign-in experience for users who access Lightning with embedded Tableau views.

If a seamless authentication user experience is important, then you will need to make some additional configurations. In this context, “seamless” means that users who access the Salesforce Lightning page where Tableau Viz LWC SSO has been enabled, will not be required to perform any action to view the embedded Tableau view. In the seamless scenario, if the user is logged into Salesforce, then embedded Tableau views will be displayed with no additional user action. This scenario is enabled by *in-frame authentication*.

For a seamless user experience you will need to enable in-frame authentication on Tableau Server and at your IdP. The sections below describe how to configure in-frame authentication.

On the other hand, there are scenarios where users are interacting with the Lightning page that will require them to click a “Sign in” button to view the embedded Tableau view. This scenario, where a user must take another action to view the embedded Tableau view, is called pop-up authentication.

Pop-up authentication is the default user experience if you do not enable in-frame authentication.

Tableau Server on Windows Help

Enable in-frame authentication on Tableau Server

Before you enable in-frame authentication on Tableau Server, you must have already configured and enabled SAML on Tableau Server.

Run the following TSM commands to enable in-frame authentication:

```
tsm configuration set -k wgserver.saml.iframe_idp.enabled -v true
```

```
tsm pending-changes apply
```

Note: Clickjack protection is enabled by default on Tableau Server. When you enable in-frame authentication, clickjack protection is temporarily disabled for the in-frame authentication session. You should evaluate the risk of disabling clickjack protection. See [Clickjack Protection](#).

Tableau Server Versioning

For the best user experience, run the latest maintenance release of Tableau Server.

If you are not running the latest maintenance release, and your users are running Chrome browsers to access Salesforce Lightning, then review the Tableau KB article, [Embedded Views Fail to Load After Updating to Chrome 80](#).

Enable in-frame authentication with your SAML IdP

As described above, a seamless authentication user experience with Salesforce Mobile requires IdP support for in-frame authentication. This functionality may also be referred to as “iframe embedding” or “framing protection” at IdPs.

Salesforce safelist domains

In some cases, IdPs only allow enabling in-frame authentication by domain. In those cases, set the following Salesforce wildcard domains when you enable in-frame authentication:

*.force

*.visualforce

Salesforce IdP

Salesforce IdP supports in-frame authentication by default. You do not need to enable or configure in-frame authentication in the Salesforce configuration. However, you must run the TSM command on Tableau Server as described above.

Okta IdP

See *Embed Okta in an iframe*, in the Okta Help Center topic, [General customization options](#).

Ping IdP

See the Ping support topic, [How to Disable the "X-Frame-Options=SAMEORIGIN" Header in PingFederate](#).

OneLogin IdP

See *Framing protection*, in the OneLogin Knowledge Base article, [Account Settings for Account Owners](#).

ADFS and Azure AD IdP

Microsoft has blocked all in-frame authentication and it cannot be enabled. Instead, Microsoft only supports pop-up authentication in a second window. As a result, pop up behavior can be blocked by some browsers, which will require users to accept pop ups for the `force.com` and `visualforce.com` sites.

Tableau Server on Windows Help

Salesforce Mobile App

If your users primarily interact with Lightning on the Salesforce Mobile App, then you should be aware of the following scenarios:

- The Salesforce Mobile App requires that you configure SSO/SAML to view embedded Tableau.
- The Salesforce Mobile App requires in-frame authentication. Pop-up authentication does not work. Instead, users on the Salesforce Mobile App will see the Tableau sign-in button but will not be able to sign to Tableau.
- Mobile App will not work on ADFS and Azure AD IdP.
- The Mobile App uses OAuth tokens to enable SSO. There are scenarios where the OAuth token refreshes and logs users out, requiring users to log back in. To learn more, see the Tableau KB article, [Tableau Viz Lightning Web Component On Salesforce Mobile App Prompts for Sign-in](#).
- The SSO behavior differs according to the version of Salesforce Mobile App (iOS vs Android) and the the IdP:

IdP	Mobile OS	SSO behavior
Salesforce IdP	Android	SSO works initially, but users will need to sign-in after some time.
	iOS	
External IdP	Android	SSO does not work. Users will need to manually sign-in. (SSO must still be configured to enable users access to embedded Tableau views).
	iOS	SSO works initially, but users will need to sign-in after some time.

Configure SAML with Azure AD IdP on Tableau Server

You can configure Azure AD as a SAML identity provider (IdP), and add Tableau Server to your supported single sign-on applications. When you integrate Azure AD with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

Before you begin: Prerequisites

Before you can configure Tableau Server and SAML with Azure AD, your environment must have the following:

- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
 - SSL certificate requirements
 - SAML Certificate and identity provider (IdP) requirements
- If your users are signing in from a domain that's not the default domain, review SAML Requirements and User Management in Deployments with External Identity Stores to ensure the domain attribute value is set and defined to avoid any sign in issues later on.

Step 1: Verify SSL connection to Azure AD

Azure AD requires an SSL connection. If you haven't done so yet, complete the steps in [Configure SSL for External HTTP Traffic to and from Tableau Server](#), using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you do not need to configure external SSL.

If your organization uses Azure AD App proxy, see the section below, [Azure AD App Proxy](#).

Step 2: Configure SAML on Tableau Server

Complete the steps in [Configure Server-Wide SAML](#) through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

Step 3: Configure Azure AD claim rules

The mapping is case sensitive and requires exact spelling, so double-check your entries. The table here shows common attributes and claim mappings. You should verify attributes

Tableau Server on Windows Help

with your specific Azure AD configuration.

LDAP Attribute	Outgoing Claim Type
onpremisesamaccountname	username
Given-Name	firstName Note: This is optional.
Surname	lastName Note: This is optional.
netbiosname	domain Note: This is only required if you have users signing in from a domain that's not the default domain.

In some organizations, Azure AD as a SAML IdP is used in with Active Directory as the identity store for Tableau Server. In this case, `username` is usually the `sAMAccountName` name. See Microsoft's documentation for identifying the `sAMAccountName` attribute within Azure AD to map to the `username` attribute.

Step 4: Provide Azure AD metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.
2. In Step 4 of the SAML configuration window, enter the location of the XML file you exported from Azure AD, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in [Configure Server-Wide SAML](#). Save and apply changes.
4. Stop Tableau Server, open TSM CLI, and run the following commands.

The first command assures that Azure AD can properly redirect to Tableau Server after it accepts users' SAML credentials. The second command configures Tableau Server with the same "Refresh Token Max Inactive Time" that is the default on Azure AD and Azure AD Azure AD. Setting the maximum inactive time to match Azure AD avoids a common error state as described in [Tableau Knowledge Base article, Intermittent Error "Unable to Sign In" with SAML SSO on Tableau Server](#).

```
tsm configuration set -k wgserver.saml.sha256 -v true  
  
tsm authentication saml configure -a 7776000
```

5. Apply the changes:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Azure AD App Proxy

If you are running Azure AD App Proxy in front of Tableau Server and SAML is enabled, then you will need to make an additional configuration to Azure AD App Proxy.

Tableau Server can only accept traffic from one URL when SAML is enabled. However, by default, Azure AD App Proxy sets an external URL and an internal URL.

You must set both of these values to the same URL in your custom domain. For more information, see the Microsoft documentation, [Configure custom domains with Azure AD Application Proxy](#).

Troubleshooting

Azure AD App Proxy

In some cases, links to views render internally but fail externally when traffic is crossing an Azure AD App Proxy. The issue arises when there is a pound sign (#) in the URL and users are accessing the link with a browser. The Tableau Mobile app is able to access URLs with a pound sign.

User session timeouts appear to be ignored

When Tableau Server is configured for SAML, users might experience sign in errors because the IdP maximum authentication age setting is set to a value greater than Tableau's maximum authentication age setting. To resolve this issue, you can use the tsm configuration set option `wgserver.saml.forceauthn` to require the IdP to re-authenticate the user each time Tableau redirects the authentication request, even if the IdP session for the user is still active.

For example, when the Azure AD setting `maxInactiveTime` is greater than Tableau Server's setting `maxAuthenticationAge`, Tableau redirects the authentication request to the IdP who subsequently sends Tableau an assertion that the user is already authenticated. However, because the user was authenticated outside of Tableau Server's `maxAuthenticationAge`, Tableau rejects the user authentication. In cases like this, you can do one or both of the following:

- Enable the `wgserver.saml.forceauthn` option to require the IdP to re-authenticate the user every time Tableau redirects the authentication request. For more information, see `wgserver.saml.forceauthn`.
- Increase Tableau Server's `maxAuthenticationAge` setting. For more information, see “a, --max-auth-age <max-auth-age>” in the tsm authentication topic.

Configure SAML with AD FS on Tableau Server

You can configure Active Directory Federation Services (AD FS) as a SAML identity provider, and add Tableau Server to your supported single sign-on applications. When you integrate AD FS with SAML and Tableau Server, your users can sign in to Tableau Server using their standard network credentials.

Prerequisites

Before you can configure Tableau Server and SAML with AD FS, your environment must have the following:

- A server running Microsoft Windows Server 2008 R2 (or later) with AD FS 2.0 (or later) and IIS installed.
- We recommend that you secure your AD FS server (for example, using a reverse proxy). When your AD FS server is accessible from outside your firewall, Tableau Server can redirect users to the sign in page hosted by AD FS.
- SSL certificate encrypted using SHA-2 (256 or 512 bit) encryption, and that meets the additional requirements listed in the following sections:
 - SSL certificate requirements
 - SAML Certificate and identity provider (IdP) requirements

Step 1: Verify SSL connection to AD FS

AD FS requires an SSL connection. If you haven't done so yet, complete the steps in [Configure SSL for External HTTP Traffic to and from Tableau Server](#), using a certificate that meets the requirements as specified above.

Alternatively, if Tableau Server is configured to work with a reverse proxy or load balancer where SSL is being terminated (commonly referred to as SSL off-loading), then you do not need to configure external SSL.

Tableau Server on Windows Help

Step 2: Configure SAML on Tableau Server

Complete the steps in Configure Server-Wide SAML through downloading the Tableau Server metadata to an XML file. At that point, return here and continue to the next section.

Step 3: Configure AD FS to accept sign-in requests from Tableau Server

Note: These steps reflect a third-party application and are subject to change without our knowledge.

Configuring AD FS to accept Tableau Server sign-in requests is a multi-step process, starting with importing the Tableau Server XML metadata file to AD FS.

1. Do one of the following to open the **Add Relying Party Trust Wizard**:

Windows Server 2008 R2:

- a. Select **Start menu > to Administrative Tools > AD FS 2.0**.
- b. In **AD FS 2.0**, under **Trust Relationships**, right-click the **Relying Party Trusts** folder, and then click **Add Relying Party Trust**.

Windows Server 2012 R2:

- a. Open **Server Manager**, and then on the **Tools** menu, click **AD FS Management**.
 - b. In **AD FS Management**, on the **Action** menu, click **Add Relying Party Trust**.
2. In the **Add Relying Party Trust Wizard**, click **Start**.
 3. On the **Select Data Source** page, select **Import data about the relying party from a file**, and then click **Browse** to locate your Tableau Server XML metadata file. By default, this file is named **samlspmetadata.xml**.
 4. Click **Next**, and on the **Specify Display Name** page, type a name and description for

the relying party trust in the **Display name** and **Notes** boxes.

5. Click Next to skip the **Configure Multi-factor Authentication Now** page.
6. Click Next to skip the **Choose Issuance Authorization Rules** page.
7. Click Next to skip the **Ready to Add Trust** page.
8. On the **Finish** page, select the **Open the Edit Claim Rules dialog for this relying party trust when the wizard closes** check box, and then click **Close**.

Next, you'll work in the **Edit Claim Rules** dialog, to add a rule that makes sure the assertions sent by AD FS match the assertions Tableau Server expects. At a minimum, Tableau Server needs an email address. However, including first and last names in addition to email will ensure the user names displayed in Tableau Server are the same as those in your AD account.

1. In the **Edit Claim Rules** dialog box, click **Add Rule**.
2. On the **Choose Rule Type** page, for **Claim rule template**, select **Send LDAP Attributes as Claims**, and then click **Next**.
3. On the **Configure Claim Rule** page, for **Claim rule name**, enter a name for the rule that makes sense to you.
4. For **Attribute store**, select **Active Directory**, complete the mapping as shown below, and then click **Finish**.

The mapping is case sensitive and requires exact spelling, so double-check your entries. The table here shows common attributes and claim mappings. Verify attributes with your specific Active Directory configuration.

LDAP Attribute	Outgoing Claim Type
SAM-Account-Name	Name ID
SAM-Account-Name	username

Tableau Server on Windows Help

Given-Name	firstName
Surname	lastName

If you are running AD FS 2016 or later, then you must add a rule to pass through all claim values. If you are running an older version of AD FS, skip to the next procedure to export AD FS metadata.

1. Click **Add Rule**.
2. Under **Claim rule template**, choose **Pass Through or Filter an Incoming Claim**.
3. Under **Claim rule name**, enter Windows.
4. On the **Edit Rule - Windows** pop-up:
 - Under **Incoming claim type**, select **Windows account name**.
 - Select **Pass through all claim values**.
 - Click **OK**.

Now you will export AD FS metadata that you'll import to Tableau Server later. You will also make sure the metadata is configured and encoded properly for Tableau Server, and verify other AD FS requirements for your SAML configuration.

1. Export AD FS Federation metadata to an XML file, and then download the file from **<https://<adfs server name>/FederationMetadata/2007-06/FederationMetadata.xml>**.
2. Open the metadata file in a text editor like Sublime Text or Notepad++, and verify that it is correctly encoded as UTF-8 without BOM.

If the file shows some other encoding type, save it from the text editor with the correct encoding.

3. Verify that AD FS uses forms-based authentication. Sign-ins are performed in a browser window, so you need AD FS to default to this type of authentication.

Edit **c:\inetpub\adfs\ls\web.config**, search for the tag , and move the line so it appears first in the list. Save the file so that IIS can automatically reload it.

Note: If you don't see the `c:\inetpub\adfs\ls\web.config` file, IIS is not installed and configured on your AD FS server.

4. (Optional) This step is required only if AD FS is configured as an IDP for site-specific SAML. This step is not required if AD FS is configured as the IDP for server-wide SAML.

Configure an additional AD FS relying party identifier. This allows your system to work around any AD FS issues with SAML logout.

Do one of the following:

Windows Server 2008 R2:

- a. In **AD FS 2.0**, right-click on the relying party you created for Tableau Server earlier, and click **Properties**.
- b. On the **Identifiers** tab, in the **Relying party identifier** box, enter `https://<tableauservername>/public/sp/metadata` and then click **Add**.

Windows Server 2012 R2:

- a. In **AD FS Management**, in the **Relying Party Trusts** list, right-click on the relying party you created for Tableau Server earlier, and click **Properties**.
- b. On the **Identifiers** tab, in the **Relying party identifier** box, enter `https://<tableauservername>/public/sp/metadata` and then click **Add**.

Note: AD FS can be used with Tableau Server for a single relying party to the same instance. AD FS cannot be used for multiple relying parties to the same instance, for example, multiple site-SAML sites or server-wide and site SAML configurations.

Tableau Server on Windows Help

Step 4: Provide AD FS metadata to Tableau Server

1. Return to the TSM web UI, and navigate to **Configuration > User Identity & Access > Authentication Method** tab.
2. In Step 4 of the SAML configuration window, enter the location of the XML file you exported from AD FS, and select **Upload**.

3. Complete the remaining steps (matching assertions and specifying client type access) as specified in Configure Server-Wide SAML. Save and apply changes.
4. Stop Tableau Server, open TSM CLI, and run the following commands.

The first command assures that AD FS can properly redirect to Tableau Server after it accepts users' SAML credentials. The second command configures Tableau Server with the same "Refresh Token Max Inactive Time" that is the default on AD FS and Azure AD FS. Setting the maximum inactive time to match AD FS avoids a common error state as described in Tableau Knowledge Base article, [Intermittent Error "Unable to Sign In" with SAML SSO on Tableau Server](#).

```
tsm configuration set -k wgserver.saml.sha256 -v true
```

```
tsm authentication saml configure -a 7776000
```

5. Apply the changes:

```
tsm pending-changes apply
```

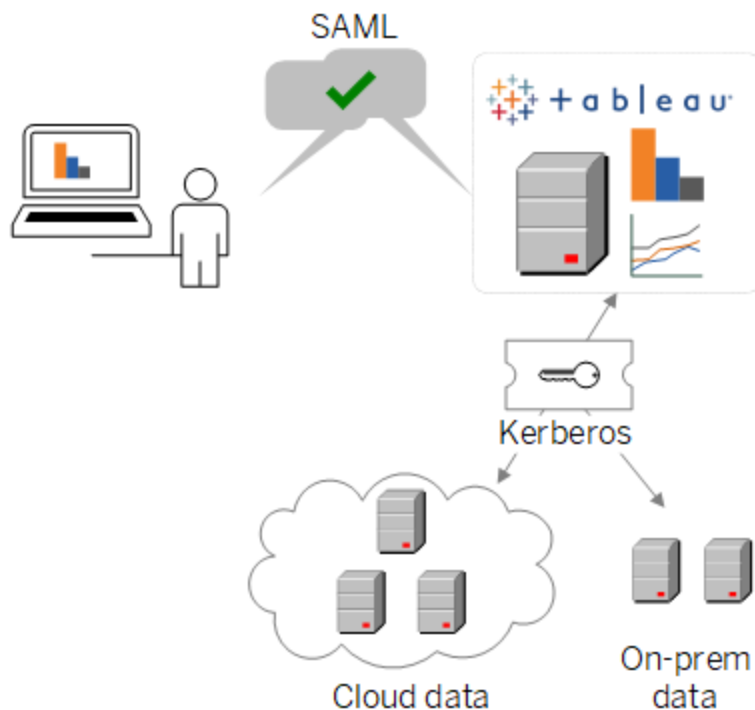

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can

suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Use SAML SSO with Kerberos Database Delegation

In a Windows Active Directory (AD) environment, you can enable SAML single sign-on (SSO) to Tableau Server, along with Kerberos database delegation. This provides authorized users direct access to Tableau Server, as well as to the underlying data defined in their published workbooks and data sources.

Overview of the process

In a typical scenario:

1. One of your Tableau analysts publishes a dashboard to Tableau Server. That dashboard contains a connection to a Hadoop cluster, for example, that is configured to

Tableau Server on Windows Help

accept Kerberos credentials.

Then the workbook publisher sends a link to colleagues for review.

2. When a colleague clicks the link, Tableau Server authenticates the user through the SAML SSO process. Then it looks at the user's authorization scheme, and if allowed, uses the Tableau Server keytab to access the underlying database on behalf of the user. This populates the dashboard with the Hadoop data that the user is authorized to see.

Configure Tableau Server for SAML with Kerberos

Using SAML with Kerberos works inherently when you complete the processes to enable each separately:

1. Configure Tableau Server for SAML, as described in [Configure Server-Wide SAML](#).
2. Configure Tableau Server and your underlying databases to accept Kerberos credentials, as described in [Enable Kerberos Delegation](#) and related articles.

Configure Site-Specific SAML

Use site-specific SAML in a multi-site environment when you want to enable single sign-on, and you also use multiple SAML identity providers (IdPs) or IdP applications. When you enable site SAML, you can specify the IdP or IdP application for each site, or configure some sites to use SAML and the others to use the default server-wide authentication method.

If you want all server users to use SAML and sign in through the same IdP application, see [Configure Server-Wide SAML](#).

Prerequisites for enabling site-specific SAML

Before you can enable SAML single sign-on at the site level, complete the following requirements:

- The Tableau Server identity store must be configured for local identity store.

You cannot configure site-specific SAML if Tableau Server is configured with an external identity store such as Active Directory or OpenLDAP.

- Make sure your environment and your IdP meet the general SAML Requirements.

Some features are supported only in server-wide SAML deployments, including but not limited to:

- Password-protected key files, which are not supported in site-specific SAML deployments.
- You must configure server-wide SAML before you configure site-specific SAML. You do not need to enable server-wide SAML, but site-specific SAML requires the server-wide configuration. See [Configure Server-Wide SAML](#).
- Note the location of the SAML certificate files. You will provide this when you Configure the server to support site-specific SAML.

For more information, see [Put metadata and certificate files in place](#) in the topic on configuring server-wide SAML.

- Add Tableau Server as a service provider to your IdP. You can find this information in the documentation the IdP provides.
- Confirm that the system clocks of the computer hosting the site-SAML IdP and the computer hosting Tableau Server are within 59 seconds of each other. Tableau Server does not have a configuration option to adjust the response skew (time difference) between the Tableau Server computer and the IdP.

Server-wide settings related to site-specific SAML

In the settings for configuring site-specific SAML, Tableau provides a site-specific return URL and entity ID based on these settings. The site-specific return URL and entity ID cannot be modified. These configurations are set by TSM as described in [Configure Server-Wide SAML](#).

Tableau Server on Windows Help

Server-wide settings, maximum authentication age and response skew, do not apply to site-specific SAML. These configurations are hard-coded:

- The maximum authentication age refers to how long an authentication token from the IdP is valid after it is issued. The hard-coded maximum authentication age site-specific SAML is 24 days.
- The response skew is the maximum number of seconds difference between Tableau Server time and the time of the assertion creation (based on the IdP server time) that still allows the message to be processed. The hard-coded site-specific value for this is 59 seconds.

Configure the server to support site-specific SAML

After you complete the prerequisites listed above, you can run the following commands to configure the server to support site-specific SAML.

1. Configure Server-Wide SAML. At a minimum, you must run the following TSM command (if you have already configured server-wide SAML, skip to Step 2):

```
tsm authentication saml configure --idp-entity-id <tableau-server-entity-id> --idp-return-url <tableau-server-return-url> --cert-file <path-to-saml-certificate.crt> --key-file <path-to-saml-keyfile.key>
```

2. Enable site SAML. Run the following commands:

```
tsm authentication sitesaml enable

tsm pending-changes apply
```

About the commands

The `sitesaml enable` command exposes the **Authentication** tab on each site's **Settings** page in the Tableau Server web UI. After you configure the server to support site SAML, you can continue to Configure SAML for a site to work through the settings on the **Authentication** tab.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

If you want to review the commands and settings that will be carried out when you run `pending-changes apply`, you can run the following command first:

```
tsm pending-changes list --config-only
```

Configure SAML for a site

This section takes you through the configuration steps that appear on the **Authentication** page in the Tableau Server web UI. In a self-hosted Tableau Server installation, this page appears only when support for site-specific SAML is enabled at the server level. It is enabled by default in Tableau Online.

Note: To complete this process, you will also need the documentation your IdP provides. Look for topics that refer to configuring or defining a service provider for a SAML connection, or adding an application.

Step 1: Export metadata from Tableau

To create the SAML connection between Tableau Server and your IdP, you need to exchange required metadata between the two services. To get metadata from Tableau Server, do either of the following steps. See the IdP's SAML configuration documentation to confirm the correct option.

- Select **Export metadata** to download an XML file that contains the Tableau Server SAML entity ID, Assertion Consumer Service (ACS) URL, and X.509 certificate.

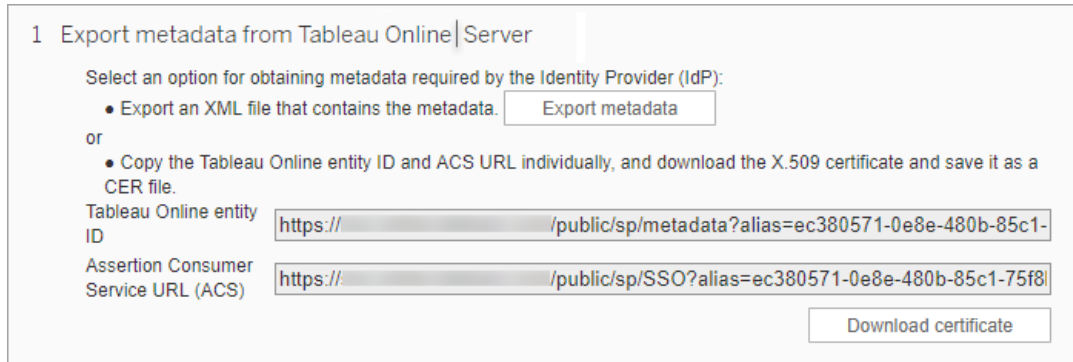

The entity ID is site-specific, and based on the server-wide entity ID that you specified when you enabled site SAML on the server. For example, if you specified `https://tableau_server`, you might see the following entity ID for the site:

```
https://tableau_server-  
/samlservice/public/sp/metadata?alias=48957410-9396-430a-  
967c-75bdb6e002a0
```

You cannot modify the site-specific entity ID or ACS URL that Tableau generates.

- Select **Download signing and encryption certificate** if your IdP expects the required information in a different way. For example, if it wants you to enter the Tableau Server entity ID, ACS URL, and X.509 certificate in separate locations.

The following image has been edited to show that these settings are the same in Tableau Online and Tableau Server.

Steps 2 and 3: External steps

For Step 2, to import the metadata you exported in step 1, sign in to your IdP account, and use the instructions provided by the IdP's documentation to submit the Tableau Server

metadata.

For Step 3, the IdP's documentation will guide you also in how to provide metadata to a service provider. It will instruct you to download a metadata file, or it will display XML code. If it displays XML code, copy and paste the code into a new text file, and save the file with a .xml extension.

Step 4: Import IdP metadata to the Tableau site

On the **Authentication** page in Tableau Server, import the metadata file that you downloaded from the IdP or configured manually from XML it provided.

Step 5: Match attributes

Attributes contain authentication, authorization, and other information about a user. In the **Identity Provider (IdP) Assertion Name** column, provide the attributes that contain the information Tableau Server requires.

- **Username or Email:** (Required) Enter the name of the attribute that stores user names or email addresses.
- **Display name:** (Optional but recommended) Some IdPs use separate attributes for first and last names, and others store the full name in one attribute.

Select the button that corresponds to the way your IdP stores the names. For example, if the IdP combines first and last name in one attribute, select **Display**

name, and then enter the attribute name.

5 Match attributes

Match the attribute names (assertions) in the IdP's SAML configuration to the corresponding attribute names on Tableau Server. Click Test Connection to fetch available attributes.

Tableau Server Attribute	Identity Provider (IdP) Assertion Name
<p>Username or Email</p> <p>Enter the username or email address attribute that the IdP sends during the authentication process. This must match the attribute name in Tableau</p>	<input type="text" value="NameID"/>
<p>Display Name</p> <p>Enter an assertion name for either the first name and last name, or for the full name, depending on how the IdP stores this information. Tableau Server uses these attributes to set the display name.</p>	
<input checked="" type="radio"/> First name	<input type="text" value="firstName"/>
<input type="radio"/> Last name	<input type="text" value="lastName"/>
<input type="radio"/> Full name	<input type="text" value="FullName"/>

Apply

Step 6: Manage users

Select existing Tableau Server users, or add new users you want to approve for single sign-on.

When you add or import users, you also specify their authentication type. On the Users page, you can change users' authentication type any time after adding them.

For more information, see [Add Users to a Site or Import Users and Set the User Authentication Type for SAML](#).

Important: Users that authenticate with site-specific SAML can belong only to one site. If a user needs to access multiple sites, set their authentication type to the server default. Depending on how site-specific SAML was configured by the server administrator, the server default is either local authentication or server-wide SAML.

Step 7: Troubleshooting

Start with the troubleshooting steps suggested on the Authentication page. If those steps do not resolve the issues, see Troubleshoot SAML.

Update SAML Certificate

After you have configured SAML authentication, you may need to periodically update the certificate. In some cases, you may need to change the certificate for operational changes in your IT environment. In either case, you must use TSM or the Site Authentication page to update the SAML certificate that has already been configured.

Below are the steps to update the certificate and key files for server-wide and site-specific SAML implementations.

Update certificate for server-wide SAML

To change or update the certificate (and the corresponding key file if required) for server-wide SAML, follow the steps below:

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see Sign in to Tableau Services Manager Web UI.

2. Stop Tableau Server.

Tableau Server on Windows Help

You can do this either from the TSM web UI, by clicking **Tableau Server is running**, and selecting **Stop Tableau Server**, or from the command line, using the `tsm stop` command.

3. On the **Configuration** tab, select **User Identity & Access**, and then select the **Authentication Method** tab.

4. For **Authentication Method**, select **SAML**.
5. Complete Step 1 - Step 4 in the GUI to update the SAML certificate file and exchange metadata between Tableau Server and your IdP.

Step 1: Provide the location for the following SAML attributes and files.

Tableau Server return URL	<input type="text" value="Required"/>
SAML entity ID	<input type="text" value="Required"/>
SAML certificate file	<input type="button" value="Select File"/>
SAML key file	<input type="button" value="Select File"/>

Step 2: Download XML metadata file, and register it with your IdP.

Step 3: Go to your IdP's website or application and add Tableau Server as a Service Provider. Then export your IdP's metadata XML file.

Step 4: Upload your IdP's metadata XML file

SAML IdP metadata file	<input type="button" value="Select File"/>
------------------------	--

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

After you change the certificate, you must run `tsm pending-changes apply` to restart Tableau Server services. We also recommend restarting any other services on the computer that use the SAML certificate. If you are changing a root certificate on the operating system, you must reboot the computer.

Update certificate for site-specific SAML

The certificate used for Tableau site metadata is provided by Tableau and not configurable. To update the certificate for site-specific SAML, you must upload a new certificate to your IdP and re-exchange the metadata with Tableau Server.

1. Sign in to the site as a server or site administrator, and select **Settings > Authentication**.
2. Under Authentication types, select **Edit connection** to expand the Authentication GUI.
3. Open a new tab or window, and sign in to your IdP account.
4. Use the instructions provided by the IdP's documentation to upload a new SAML certificate.
5. Download the new XML metadata file to provide to Tableau Server.
6. Return to the **Authentication** page in Tableau Server, and in Step 4 of the GUI, import the metadata file that you downloaded from the IdP.
7. Click **Save** after you've updated your configuration information.

Troubleshoot SAML

This topic provides information about resolving issues that can occur when you configure SAML authentication.

Tableau Server on Windows Help

SAML and Enable Automatic Logon

If you are using SAML and if Tableau Server is also configured to use Active Directory, do not also select **Enable automatic logon**. **Enable automatic logon** and SAML cannot both be used on the same server installation.

HTTP Status 500 error when configuring SAML

Under some circumstances you might get an HTTP status 500 error and see the following error after enabling SAML and navigating to the Tableau Server URL in a browser:

```
org.opensaml.saml2.metadata.provider.MetadataProviderException:  
User specified binding is not supported by the Identity Provider  
using profile urn:oasis:names:tc:SAML:2.0:profiles:SSO:browser
```

To help resolve this error, make sure of the following:

- The IdP URL for the SSO profile specified in the SAML tab is correct.
- The IdP URL for the SSO profile provided while creating the service provider in the IdP is correct.
- The IdP is configured to use `HTTP-POST` requests. (Redirect and SOAP are not supported.)

If any of these settings were not correct, make appropriate updates and then perform the SAML configuration steps again, starting with generating and exporting the XML metadata document from Tableau Server.

If these settings are correct, but you still see the error, examine the metadata XML that is produced by Tableau Server and by the IdP, as described in [SAML Requirements](#).

Signing In from the Command Line

SAML is not used for authentication when you sign in to Tableau Server using `tabcmd` or the [Tableau Data Extract command line utility](#) (provided with Tableau Desktop), even if Tableau

Server is configured to use SAML. These tools require the authentication configured when Tableau Server was originally installed (either local authentication or AD).

Login fails: failed to find the user

Login fails with the following message:

```
>Login failure: Identity Provider authentication successful for user <username from IdP>. Failed to find the user in Tableau Server.
```

This error typically means that there is a mismatch between the usernames stored in Tableau Server and provided by the IdP. To fix this, make sure that they match. For example, if Jane Smith's username is stored in the IdP as `jsmith` it must be stored in Tableau Server as `jsmith`.

Login fails: SSL offloading

Logon fails with the following message:

```
Unable to Sign In - Invalid username or password.
```

Additionally, the vizportal logs (set to debug mode) contain the following message:

```
DEBUG com.tableau.core.util.RemoteIP - Found header null in X-FORWARDED-PROTO
```

Note: To log SAML-related events, `vizportal.log.level` must be set to debug. For more information, see [Change Logging Levels](#).

This combination of messages indicates a misconfiguration of an external proxy server that is offloading SSL for the connection to Tableau Server. To resolve this issue, see the KB article, ["Unable to Sign In" and "Invalid username or password" Error With SAML After Upgrading](#).

Tableau Server on Windows Help

SAML Error Log

SAML authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, login attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see [Log File Snapshots \(Archive Logs\)](#).

Note: To log SAML-related events, `vizportal.log.level` must be set to `debug`. For more information, see [Change Logging Levels](#).

Check for SAML errors in the following files in the unzipped log file snapshot:

```
\vizportal\vizportal-<n>.log
```

In Tableau Server 9.0 and later, the application process (`vizportal.exe`) handles authentication, so SAML responses are logged by that process.

Trailing Slash

On the SAML tab, confirm that the **Tableau Server return URL** does not end with a trailing slash

Correct: **`http://tableau_server`**

Incorrect: `http://tableau_server/`

Confirm Connectivity

Confirm that the Tableau Server you are configuring has either a routeable IP address or a NAT at the firewall that allows two-way traffic directly to the server.

You can test your connectivity by running `telnet` on Tableau Server and attempting to connect with the SAML IdP. For example: `C:\telnet 12.360.325.10 80`

The above test should connect you to the HTTP port (80) on the IdP and you should receive an HTTP header.

Kerberos

Kerberos is a three-way authentication protocol that relies on the use of a trusted third-party network service called the Key Distribution Center (KDC) to verify the identity of computers and provide for secure connections between the computers through the exchange of *tickets*. These tickets provide mutual authentication between computers or services, verifying that one has permission to access the other.

Tableau Server supports Kerberos authentication in an Active Directory Kerberos environment, with authentication to Tableau Server being handled by Kerberos.

Note: The Kerberos support in Tableau Server is for user authentication. It does not handle internal permissions and authorization related to Tableau Server content, such as workbooks.

How Kerberos works

When you configure Tableau Server for Kerberos in an Active Directory (AD) environment, the AD domain controller also serves as the Kerberos Key Distribution Center (KDC) and issues Ticket Granting Tickets to the other nodes in the domain. Users authenticated by the KDC do not have to authenticate further when connecting to Tableau Server.

The following is a diagram of the authentication workflow.

- 1 User logs into their Active Directory domain.
- 2 The Kerberos KDC authenticates the user and sends a Ticket Granting Ticket (TGT) to the user's computer.
- 3 The user connects to Tableau Server in Tableau Desktop or in a web browser.
- 4 Tableau Server authenticates the user.

Kerberos Requirements

You can configure Kerberos authentication for Tableau Server running in Active Directory environments.

General requirements

- External Load Balancer/Proxy Server: If you are going to use Tableau Server with Kerberos in an environment that has external load balancers (ELBs) or proxy server, you need to set these up before you configure Kerberos in the Tableau Server Configuration utility. See [Configuring Proxies for Tableau Server](#).
- iOS Browser Support: An iOS user can use Kerberos authentication with mobile

Safari if a Configuration Profile specifying the user's Kerberos identity is installed.

See [Configuring an iOS Device for Kerberos Support](#) in the Tableau Mobile Help.

For more information about browser support for Kerberos SSO, see Tableau Client Support for Kerberos SSO.

- Tableau Server supports constrained delegation for authentication to datasources. In this scenario, the Tableau data access account is specifically granted rights to the target database SPNs. Unconstrained delegation is not supported.
- The supported data sources (SQL Server, MSAS, PostgreSQL, Hive/Impala, and Teradata) must be configured for Kerberos authentication.
- A keytab file that is configured with the service provider name for the Tableau Server for user authentication. For more information, see [Understanding Keytab Requirements](#).

Active Directory requirements

You must meet the following requirements to run Tableau Server with Kerberos in an Active Directory environment:

- Tableau Server must use Active Directory (AD) for authentication.
- The domain must be an AD 2003 or later domain for Kerberos connections to Tableau Server.
- Smart Card Support: Smart cards are supported when users sign into their workstations with a smartcard and this results in a Kerberos TGT being granted to the user from Active Directory.
- Single-Sign On (SSO): Users must be granted a Kerberos Ticket Granting Ticket (TGT) from Active Directory when they sign into their computers. This is standard behavior for domain-joined Windows computers and standard for Mac computers that use AD as their network account server. For more information on using Mac com-

puters and Active Directory, see [Join your Mac to a network account server](#) in the Apple Knowledge Base.

Kerberos delegation

For Kerberos delegation scenarios the following are required:

- If the domain is AD 2003 or later, single domain Kerberos delegation is supported. The users, Tableau Server, and backend database must be on the same domain.
- If the domain is AD 2008, there is limited cross domain support. Users from other domains can be delegated if the following conditions are met. Tableau Server and the backend database must be on the same domain, and a two way trust is required between the domain where Tableau Server resides and the user's domain.
- If the domain is 2012 or later, full cross-domain delegation is supported. AD 2012 R2 is preferred because it has a dialog for configuring constrained delegation, while 2012 non-R2 requires manual configuration.

Understanding Keytab Requirements

Kerberos authentication relies on credentials that are stored in specially formatted files called keytab files. You may need to generate keytab files for your Tableau Server deployment. This topic describes the keytab files that Tableau Server uses to access various services in a typical organization. You may need to generate keytabs for Tableau Server to integrate into the following services:

- User authentication (SSO) in Windows Active Directory
- Datasource delegation
- Operating system
- Directory service

If your organization includes IT professionals who handle identity, authentication, and/or security, then you should work with them to create a plan for generating appropriate keytabs for your Tableau Server deployment.

User authentication (SSO) in Windows Active Directory

If you will be using Active Directory as the identity store for Tableau Server, and you want users to authenticate with Kerberos SSO, then you will need to generate a keytab file for Tableau Server.

Tableau is running on...	Need to manually generate a keytab?
Windows in Active Directory domain	Yes
Linux in Active Directory domain	Yes
Windows or Linux in non-Active Directory environment	Kerberos SSO is not a supported scenario.

Follow these recommendations (for Windows and Linux versions of Tableau Server):

- Create a service account in your directory for Tableau Server.
- Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate. You may use the same keytab for Kerberos SSO as you use for the directory authentication in the scenario above.
- You must create service principal names (SPN) in Active Directory for the Tableau Server service.
- Use the batch file in the next section to create the SPNs and the keytab file.
- After you have created the SPNs, upload the keytab file as described in Configure Kerberos.

Batch file: Set SPN and create keytab in Active Directory

You can use a batch file to set the service principal names (SPN) and create a keytab file. These operations are a part of the process to enable Kerberos SSO for Tableau Server (on

Tableau Server on Windows Help

Windows or Linux) running in Active Directory.

In previous versions of Tableau Server (before 2018.2), the configuration script was generated from the Tableau Server Configuration utility.

To generate a configuration script, copy and paste the following batch file contents into a text file. The batch file creates service principal names (SPN) for Tableau Server and will create a keytab file for the user you specify in the file.

Follow the directions in the file contents. After you have finished customizing the file, save it as a .bat file.

This file must be run in an Active Directory domain by a Domain admin, who will be prompted for the service account password of the account you specify in the file.

The batch file uses the Windows [set](#), [setspn](#), and [ktpass](#) commands.

Note: The batch file below is self-documented. However, if you do not have experience with Kerberos and generating keytab files, we recommend that you read the Microsoft blog post, [All you need to know about Keytab files](#), before proceeding. Environmental details in your organization may require additional configuration of the ktpass command. For example, you must determine what to set for the `/crypto` parameter. We recommend specifying a single `/crypto` value that is required by your KDC. See the Microsoft article, [ktpass](#) for the full list of supported values for the `/crypto` parameter.

SPN and keytab batch file contents

```
@echo off
setlocal EnableDelayedExpansion

REM *****

REM This script generates the Service Principal Names (SPNs) and
```

```
keytab files required for
REM Kerberos SSO with Apache.
REM This script executes set, setspn, and ktpass commands
included in any Windows Server
REM Operating System from 2003 on.
REM Before running this script you must enter configuration
information for the setspn and
REM ktpass commands.
REM Elements that require your configuration information are
enclosed in as such:
REM ! -- and --!.
REM After you customize this file, save it as a .bat file, and
run on a domain-joined
REM computer.
REM This script must be run by a Domain admin.

REM *****

REM The following set command will prompt the domain admin for
credentials of the
REM Tableau Server service account.
REM This account must be a valid domain user account.
REM If the password contains a literal \" (backslash - double
quote), all backslashes
REM immediately before the double quote must be
REM duplicated when typed for the password to work, e.g. if
password contains
REM \" replace with \\\", if passwords contains \"\" replace
with \\\"

set /p adpass= "Enter password for the Tableau Server service
account."
set adpass=!adpass:"=\!"
```

Tableau Server on Windows Help

```
REM *****

REM The following setspn commands create the SPN in the domain.
REM More information on setspn can be found here:
REM http://technet.microsoft.com/en-us/library/cc731241
  (WS.10).aspx
REM Enter the canonical FQDN and the host names for Tableau
  Server followed by the
REM Tableau Server service account name.
REM Use this syntax: HTTP/hostname domain\service_account_name.
REM The example below shows syntax for a computer named
  "tableau01" in the "example.lan"
REM domain, with service account, "tab-serv-account":
REM setspn -s HTTP/tableau01 example\tab-serv-account
REM setspn -s HTTP/tableau01.example.lan example\tab-serv-
  account
REM DNS and AD are not case sensitive, but the keytab files are.
  Verify that host names
REM match letter case as stored in DNS.
REM Use Windows Server's DNS Manager utility to verify host name
  case.

REM *****

echo Creating SPNs...
setspn -s HTTP/!--replace with canonical host name and service
  account --!
setspn -s HTTP/!--replace with canonical FQDN and service
  account --!

REM The following commands create the keytab file in the same
  directory where the
```

```

REM bat file is run. More information on ktpass can be found
here:
REM https://docs.microsoft.com/en-us/windows-server-
/administration/windows-commands/ktpass
REM Note: keytab files are case-sensitive.
REM The realm following the FQDN should be all uppercase.
REM Syntax is:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass
!adpass!
REM /ptype KRB5_NT_PRINCIPAL /crypto !--cipher--! /out keyt-
abs\kerberos.keytab
REM Best practice: specify the /crypto value that is required
by your KDC.
REM Options for /crypto = {DES-CBC-CRC|DES-CBC-MD5|RC4-HMAC-
NT|AES256-SHA1|AES128-SHA1|All}
REM Specifying /crypto All will result in passwords stored with
RC4 cipher, which is
REM no longer considered secure.
REM When using AES256-SHA1 OR AES128-SHA1, the /mapuser option
must be included
REM in the ktpass command to ensure the keytab file is mapped
properly to the user. For example:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass
!adpass! /ptype KRB5_NT_PRINCIPAL /mapuser <domain\username>
/crypto AES256-SHA1 /out keytabs\kerberos.keytab
REM The following example shows the ktpass syntax with the
example.lan configuration from above:
REM ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass
!adpass! /ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out keyt-
abs\kerberos.keytab

REM *****

echo Creating Keytab files in %CD%\keytabs

```

Tableau Server on Windows Help

```
mkdir keytabs
ktpass /princ HTTP/!--FQDN--!@!--Kerberos_Realm--! /pass !ad-
pass! /ptype KRB5_NT_PRINCIPAL /crypto DES-CBC-CRC /out keyt-
abs\kerberos.keytab
```

Operating system

If your organization uses Kerberos for authentication, then the computer where Tableau Server is running must be authenticated with the Kerberos realm in which it's running.

Tableau is running on...	Need to manually generate a keytab?
Windows in Active Directory domain	No
Linux in Active Directory domain	Yes
Windows or Linux in non-Active Directory environment	Yes

If you are running Tableau Server on Windows, and the computer is joined to the Active Directory, then you do not need to manage or generate a keytab file for the operating system.

If you are running Tableau Server on Linux in a Kerberos realm (MIT KDC or Active Directory), then you will need to generate a keytab file specifically for the computer operating system. The keytab you create for the computer should be specifically for OS authentication. Do not use the same keytab file for OS authentication that you will be using for the other services described later in this topic.

Directory service

If your organization uses a directory service, such as LDAP or Active Directory, to manage user identity, then Tableau Server requires read-only access to the directory.

Alternatively, you can configure Tableau Server to manage all accounts by installing with a local identity store. In this case, you do not need a keytab.

The following table summarizes keytab requirements:

Tableau is running on...	Directory service	Need to manually generate a keytab?
Windows in AD domain	Active Directory	No
Windows	LDAP (GSSAPI bind)	Yes
Linux	Active Directory or LDAP (GSSAPI bind)	Yes
Windows or Linux	Active Directory or LDAP (Simple bind)	No
Windows or Linux	Local identity store	No keytab required.

If you need to manually generate a keytab for this scenario, then you will use it for GSSAPI bind to the directory. Follow these recommendations:

- Create a service account in your directory for Tableau Server.
- Create a keytab specifically for the Tableau Server service account. Do not reuse the keytab file that the computer account/OS uses to authenticate.
- Upload the keytab file as part of the json configuration of the Tableau Server identity store. See `identityStore Entity`.

As part of your disaster recovery plan, we recommend keeping a backup of the keytab and conf files in a safe location off of the Tableau Server. The keytab and conf files that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the files are not stored in a recoverable format. See `Tableau Server Client File Service`.

Datasource delegation

You can also use Kerberos delegation to access data sources in an Active Directory. In this scenario, users can be authenticated to Tableau Server with any supported authentication

Tableau Server on Windows Help

mechanism (SAML, local authentication, Kerberos, etc), but can access datasources that are enabled by Kerberos.

Follow these recommendations:

- The computer account for Tableau Server (Windows or Linux) must be in Active Directory domain.
- The keytab file that you use for Kerberos delegation can be the same keytab that you use for Kerberos user authentication (SSO).
- The keytab must be mapped to the service principal for Kerberos delegation in Active Directory.
- You may use the same keytab for multiple data sources.

For more information, see the following configuration topics:

- Tableau Server on Linux: [Enable Kerberos Delegation](#)
- Tableau Server on Windows: [Enabling Kerberos Delegation](#)

Configure Kerberos

You can configure Tableau Server to use Kerberos. This allows you to provide a single sign-on (SSO) experience across all the applications in your organization. Before you configure Tableau Server for Kerberos make sure your environment meets the Kerberos Requirements.

Note: Kerberos constrained delegation for SSO to Tableau Server is not supported. (Constrained delegation for data sources is supported.) For more information, see Single-Sign On (SSO) in Kerberos Requirements.

To configure Kerberos, you must first enable Kerberos, and then specify a keytab file for user authentication. The keytab file you specify must be configured with the service provider name for the Tableau Server for user authentication. If you are using Kerberos

authentication for data sources, those credentials should be included in the single keytab file that you will specify during Kerberos configuration on Tableau Server.

As part of your disaster recovery plan, we recommend keeping a backup of the keytab file in a safe location off of the Tableau Server. The keytab file that you add to Tableau Server will be stored and distributed to other nodes by the Client File Service. However, the file is not stored in a recoverable format. See [Tableau Server Client File Service](#).

Use the TSM web interface

1. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).

2. Click User **Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Under **Authentication Method**, select **Kerberos** in the drop-down menu.
4. Under Kerberos, select **Enable Kerberos for single sign-on (SSO)**.
5. To copy the keytab file to the server, click **Select File**, and then browse to the file on your computer.

Authentication Method

Specify how Active Directory manages user authentication and access to Tableau Server.

Kerberos

Kerberos

Use Kerberos to provide a single sign-on experience across all applications in your organization. Enable Kerberos on Tableau Server and upload the keytab file. [Learn more](#)

Enable Kerberos for single sign-on (SSO)

Copy the .keytab file to Tableau Server.

Keytab file

6. Click **Save Pending Changes** after you've entered your configuration information.

7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

Use the TSM CLI

1. If you are running Tableau Server on in a distributed cluster deployment, then you will need to manually distribute the keytab file to each node and then set the permissions. Copy the keytab file to the same directory on each node in the cluster. After you have copied the keytab file to each node and set permissions on the file, then run the following TSM commands on one node. The configuration will propagate to each node.
2. Type the following command to specify the location and name of the keytab file:

```
tsm authentication kerberos configure --keytab-file <path-to-keytab_file>
```

3. Type the following command to enable Kerberos:

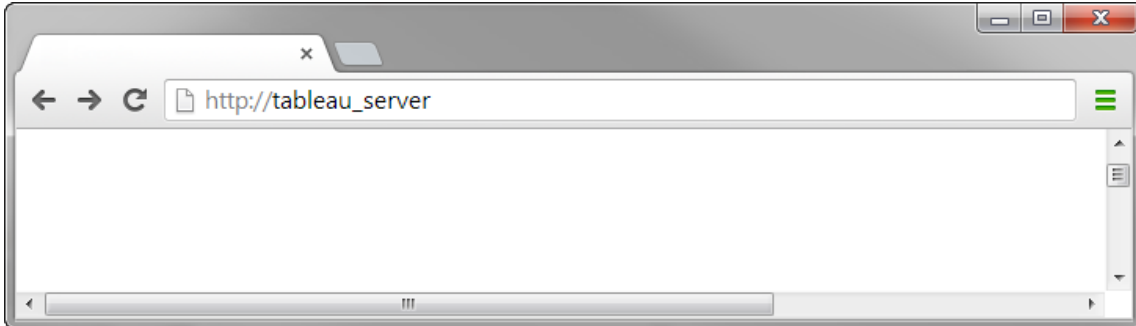

```
tsm authentication kerberos enable
```

4. Run `tsm pending-changes apply` to apply changes.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Confirm your SSO configuration

Once Tableau Server has restarted, test your Kerberos configuration from a web browser on a different computer by typing the Tableau Server name in the URL window:

You should be automatically authenticated to Tableau Server.

Tableau Client Support for Kerberos SSO

This article describes some requirements for and nuances with using Kerberos single sign-on (SSO) with Tableau Server, depending on the particular Tableau client and operating system. Tableau clients covered in this article include common web browsers, Tableau Desktop, and the Tableau Mobile app.

General browser client support

To use browser-based Kerberos Single Sign-on (SSO), the following must be true:

- Kerberos must be enabled on Tableau Server.
- The user must have a user name and password to sign in to Tableau Server.

Note: If Kerberos SSO fails, users can fall back on their user name and passwords credentials.

- The user must be authenticated to Active Directory through Kerberos on the client computer or mobile device. Specifically, this means that they have a Kerberos Ticket Granting Ticket (TGT).

Tableau Server on Windows Help

Tableau Desktop and browser clients

On Windows or the Mac, you can use Kerberos SSO to sign in to Tableau Server from the following versions of Tableau Desktop or browser. Where noted, additional configuration is required.

Windows

- Tableau Desktop 10.3 or later supported.
- Internet Explorer - supported, may require configuration - see [Note 1](#)
- Chrome - supported, may require configuration - see [Note 1](#)
- Firefox - requires configuration - see [Note 2](#)
- Safari - not supported

Mac OS X

- Tableau Desktop 10.3 or newer
- Safari - supported
- Chrome - see [Note 3](#)
- Firefox - see [Note 2](#)
- Internet Explorer - not supported

Tableau Mobile app clients

On a iOS or Android device, you can use the following Tableau Mobile or mobile browser versions to use Kerberos authentication to Tableau Server:

iOS

- Tableau Mobile app- see [Note 4](#)
- Safari - see [Note 4](#)
- Chrome - not supported

Android - see [Note 5](#)

- Tableau Mobile app
- Chrome

Operating system and browser-specific notes

The following notes describe configuration requirements or issues with specific operating system and client combinations.

Note 1: Internet Explorer or Chrome on Windows desktop

Kerberos SSO is supported in both Internet Explorer and Chrome, but it requires configuration in **Windows Internet Options**:

1. Enable **Integrated Windows Authentication**.
2. Verify that Tableau Server URL is in the local intranet zone.

Internet Explorer can sometimes detect intranet zones and configure this setting. If it has not detected and configured the Tableau Server URL, you must manually add the URL to the local intranet zone.

To enable Integrated Windows Authentication:

1. In Windows Control Panel, open **Internet Options**.
2. On the **Advanced** tab scroll down to the **Security** section.
3. Select **Enable Integrated Windows Authentication**.
4. Click **Apply**.

To verify or add the Tableau Server URL to the local intranet zone:

1. In Windows Control Panel, open **Internet Options**.
2. On the **Security** tab, select **Local intranet**, and then click **Sites**.
3. On the **Local intranet** dialog box, click **Advanced**.

In the **Websites** field, look for the internal Tableau Server URL.

Tableau Server on Windows Help

In some organizations, IT administrators will use a wildcard (*) to specify internal URLs. For example, the following URL includes all servers in the internal `example.lan` namespace in the local intranet zone:

```
https://*.example.lan
```

The following image shows a specific URL of `https://tableau.example.lan`.

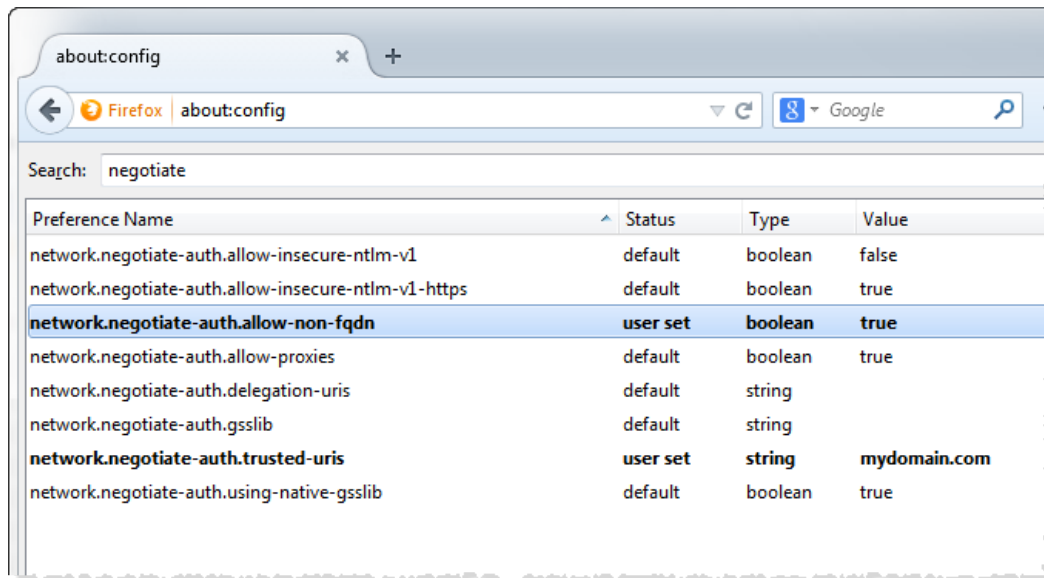

4. If the Tableau Server URL or a wildcard URL is not specified in the **Websites** field, enter the Tableau Server URL in the **Add the website to the zone** field, click **Add**, and then click **OK**.

If the Tableau Server URL is already listed in **Websites**, you can simply close the dialog.

Note 2: Firefox on Windows or Mac OS X desktop

You can use Firefox with Kerberos SSO on either Windows or Mac to sign in to Tableau Server. To do this, you must complete the following steps to configure Firefox to support Kerberos:

1. In Firefox, enter `about:config` in the address bar.
2. Click **I'll be careful, I promise** when warned about changing advanced settings.
3. Enter `negotiate` in the **Search** box.

4. Double-click **`network.negotiate-auth.allow-non-fqdn`**, and then set the value to **true**.
5. Double-click **`network.negotiate-auth.trusted-uris`** and enter the Tableau Server fully qualified domain name (FQDN). For example, `tableau.example.com`.

Note 3: Chrome on Mac OS X desktop

According to Chrome documentation, Kerberos SSO works on a Mac when you launch Chrome from a terminal window with the following command:

```
open -a "Google Chrome.app" --args --auth-server-whitel-
ist="tableauserver.example.com"
```

where `tableauserver.example.com` is the URL for Tableau Server in your environment.

Tableau Server on Windows Help

However, we have found inconsistent results in our testing. Therefore, if you want to use Kerberos SSO on a Mac, we recommend that you use Safari or Firefox. For more information, see the *Integrated Authentication* section at [HTTP authentication](#) on The Chromium Projects site.

Note: Users can still use Chrome on Mac OS X to sign in to Tableau Server, but they might be prompted to enter their user name and password (single sign-on may not work).

Note 4: Mobile Safari or Tableau Mobile on iOS

Kerberos SSO is supported if iOS is configured for Kerberos. The iOS device must have a Kerberos authentication configuration profile installed. This is usually done by an enterprise IT group. Tableau Support cannot assist with configuring iOS devices for Kerberos. See the [authentication topic](#) in the *Tableau Mobile Deployment Guide*.

Note 5: Android platform

Kerberos SSO is not supported on the Tableau Mobile app on the Android operating system. You can still use your Android device and the Tableau Mobile app or a supported mobile browser to connect to Tableau Server. In this scenario, rather than authenticating with Kerberos, users will be prompted to enter their credentials when accessing Tableau Server.

More information

- *Tableau Mobile Deployment Guide: [Control authentication and access for Tableau Mobile](#)*
- See *Web Browsers* under [Tableau Server Tech Specs](#)

Troubleshoot Kerberos

The troubleshooting suggestions in this topic are divided into issues related to single sign-on (SSO) on the server and issues with the delegated data sources.

Single sign-on to Tableau Server

In a Kerberos SSO environment, a user signing in to Tableau Server from a web browser or Tableau Desktop might see a message indicating that Tableau Server can't sign them in automatically (using single sign-on). It suggests that they provide a Tableau Server user name and password instead.

Troubleshooting sign-in errors on the client computer

- **Enter the user name and password**—To check the user's general access to Tableau Server, sign in by entering the user's name and password.

If these credentials fail, the user might not be a user on Tableau Server. For Kerberos SSO to work, the user must be able to access Tableau Server, and they must be granted a Ticket Granting Ticket (TGT) by Active Directory (as described in the **TGT** item later in this list).

- **Check other users' SSO credentials**—Try to connect with SSO to Tableau Server using other user accounts. If all users are affected, the problem might be in

Tableau Server on Windows Help

the Kerberos configuration.

- **Use a computer other than the server computer**—Kerberos SSO does not work when you sign in to Tableau Server on localhost. Clients must connect from a computer other than the Tableau Server computer.
- **Use a server name, not IP address**—Kerberos SSO does not work if you enter an IP address as the Tableau Server name. In addition, the server name you use to access Tableau Server must match the name used in the Kerberos configuration (see [Key table entry](#), below).
- **Confirm that the client has TGT**—The client computer must have a TGT (Ticket Granting Ticket) from the Active Directory domain. Constrained delegation, with the proxy granting a ticket, is not supported.

To confirm the client computer has a TGT, do the following:

- On Windows, open a command prompt and type the following: `klist tgt`
- On the Mac, open a terminal window and type the following: `klist`

The output should show a TGT for the user/domain trying to authenticate to Tableau Server.

The client computer might not have a TGT in the following circumstances:

- The client computer is using a VPN connection.
 - The client computer is not joined to the domain (for example, it is a non-work computer being used at work).
 - The user signed in to the computer with a local (non-domain) account.
 - The computer is a Mac that is not using Active Directory as a network account server.
- **Confirm browser version and settings**—For web browser sign-in, make sure the

browser is supported for Kerberos and, if necessary, is configured correctly.

- Internet Explorer (IE) and Chrome work “out of the box” on Windows.
- Safari works “out of the box” on the Mac.
- Firefox requires additional configuration.

For more information, see Tableau Client Support for Kerberos SSO.

Troubleshooting sign-in errors on the server

If you cannot solve the problem from the client computer, your next steps are to troubleshoot on the computer running Tableau Server. The administrator can use the request ID to locate the sign-in attempt in the Apache logs on Tableau Server.

- **Log files**—Check the Apache error.log for an error with the exact time/date of the failed sign-in attempt.
 - In a ziplog archive, these logs are in the \httpd folder.
 - On Tableau Server, these logs are in the \data\tabsvc\logs\httpd\ folder.
- **Key table entry**—If the error.log entry includes the message, “No key table entry matching HTTP/<servername>.<domain>.<org>@”, for example:

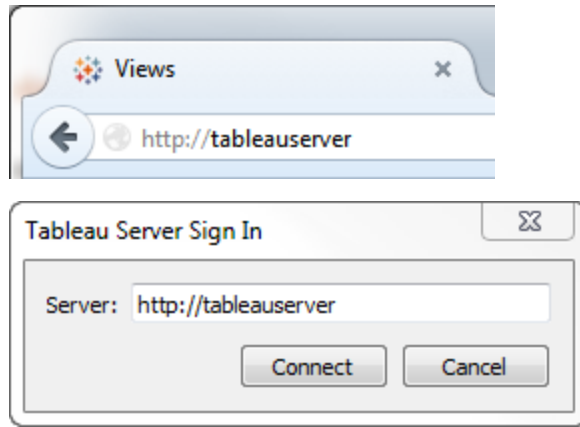

```
[Fri Oct 24 10:58:46.087683 2014] [:error] [pid 2104:tid
4776] [client 10.10.1.62:56789] gss_acquire_cred() failed:
Unspecified GSS failure. Minor code may provide more
information (, No key table entry found matching
HTTP/servername.domain.com@)
```

This error is a result of a mismatch of any of the following:

- **Tableau Server URL** - The URL used by the client computer to access the server.

Tableau Server on Windows Help

This is the name that you type into Tableau Desktop or a browser address bar. It could be a shortname (`http://servername`) or a fully-qualified domain name (`http://servername.domain.com`)

- **DNS reverse lookup** for the server IP address.

This looks up a DNS name using an IP address.

At a command prompt type:

```
ping servername
```

with the IP address returned by pinging the server, do a reverse DNS lookup type:

```
nslookup <ip address>
```

The nslookup command will return network information for the IP address. In the *Non-authoritative answer* portion of the response, verify that the fully qualified domain name (FQDN) matches the following configured values:

- The Kerberos .keytab file
- Service Principal Name (SPN) for the server

For more information about configuring these values, see [Understanding Keytab Requirements](#).

Verify Kerberos configuration script

You may need to modify the `ktpass` command that you used to generate the keytab file for environmental variables. Review the troubleshooting steps in the Knowledge Base article, [Unable to Generate Kerberos Script Configuration for Tableau Server](#).

Data source SSO

Delegated data source access failures

Check the `vizqlserver` log files for "workgroup-auth-mode."

- In a ziplog archive, these logs are in the `\vizqlserver\Logs` folder
- On the Tableau Server, these logs are in the `\data\tabsvc\vizqlserver\Logs` folder

Look for "workgroup-auth-mode" in the log files. It should say "kerberos-impersonate" not "as-is".

Kerberos delegation multi-domain configuration

Tableau Server can delegate users from other Active Directory domains. If your database uses MIT Kerberos, you may need to adjust your Kerberos principal to database user mapping. Specifically, you will need to update `krb5.conf` with rules for each Kerberos realm that users will connect from. Use the `auth_to_local` tag in the `[realms]` section to map principal names to local user names.

For example, consider a user, `EXAMPLE\jsmith`, whose Kerberos Principal is `jsmith@EXAMPLE.LAN`. In this case, Tableau Server will specify a delegated user, `jsmith@EXAMPLE`. Tableau Server will use the Active Directory legacy domain alias as the Kerberos Realm.

Tableau Server on Windows Help

The target database may already have a rule such as the following to map the user, `jsmith@EXAMPLE.LAN` to the database user, `jsmith`.

```
EXAMPLE.LAN = {  
    RULE:[1:$1@$0] (. *@EXAMPLE.LAN) s/@.*//  
    DEFAULT  
}
```

To support delegation, you must add another rule to map `jsmith@EXAMPLE` to a database user:

```
EXAMPLE.LAN = {  
    RULE:[1:$1@$0] (. *@EXAMPLE.LAN) s/@.*//  
    RULE:[1:$1@$0] (. *@EXAMPLE) s/@.*//  
    DEFAULT  
}
```

See the MIT Kerberos Documentation topic, [krb5.conf](#), for more information.

Cross-domain constrained delegation

In some cross-domain scenarios where the KDC is running on a Windows Server prior to Windows 2012, delegation may fail. Errors you may see include:

- SQL Server Network Interfaces: The system cannot contact a domain controller to service the authentication request. Please try again later.
- SQL Server Native Client: Cannot generate SSPI context.
- The Domain Controller returns: `KRB-ERR-POLICY` error with a status `STATUS_CROSSREALM_DELEGATION_FAILURE (0xc000040b)`.

Cross-domain refers to a scenario where Tableau Server is running in a different domain than the data source with different service accounts. For example:

- Tableau Server runs on DomainA with DomainA service account.
- SQL Server runs on DomainB with DomainB service account.

Traditional constrained delegation only works if both servers are in the same domain. The user can come from other domains.

If you are seeing the errors noted above, then to enable this scenario, your Active Directory administrator should remove any traditional constrained delegation which is configured on the delegating account. Removing delegation can be achieved with Active Directory management tools or by removing the values associated with the Active Directory property, `msDS-AllowedToDelegateTo`.

If you want to preserve an existing single domain delegation alongside cross-domain delegation, you must configure both using resource-based constrained delegation.

For more information about Kerberos and constrained delegation, see the Microsoft topic, [Kerberos Constrained Delegation Overview](#).

Web authoring

There are two web authoring scenarios that do not support Kerberos delegation: "Connect to data on the web" and "Create datasource on the web." feature does not support delegation yet. Specifically, if you create a datasource that uses Kerberos on the with web authoring, the data source will use Run As service account authentication. If you want to use Kerberos delegation to create a datasource, then you must publish with Tableau Desktop. For more information on Run As service account, see [Data Access with the Run As Service Account](#).

Configure Mutual SSL Authentication

Using mutual SSL, you can provide users of Tableau Desktop, Tableau Mobile, and other approved Tableau clients a secure, direct-access experience to Tableau Server. With mutual SSL, when a client with a valid SSL certificate connects to Tableau Server, Tableau Server confirms the existence of the client certificate and authenticates the user, based on the user name in the client certificate. If the client does not have a valid SSL certificate, Tableau Server can refuse the connection.

Tableau Server on Windows Help

You can also configure Tableau Server to fall back to username/password authentication if mutual SSL fails. Additionally, a user can log in using the REST API with a username and password (if one exists) whether or not fallback authentication is configured.

User authentication session time limits

When users log in with mutual SSL, the authentication session is governed by the same method that governs the Tableau Server global authentication session configuration.

For clients that connect to Tableau Server using a web browser, configuration of the global authentication session is described in the *Security Hardening Checklist*, see 10. Verify session lifetime configuration.

Sessions for connected clients (Tableau Desktop, Tableau Mobile, Tableau Prep Builder, and Bridge) use OAuth tokens to keep users logged in by re-establishing a session. By default, OAuth client tokens reset after a year. If a client token has not been used in 14 days, then it will expire. You can change these values by setting the `refresh_token.absolute_expiry_in_seconds` and `refresh_token.idle_expiry_in_seconds` options. See `tsm configuration set Options`.

Certificate usage

Before you enable and configure mutual SSL, you must configure external SSL. External SSL authenticates Tableau Server to the client and encrypts the session using the certificate and key that is required when you configure external SSL.

For mutual SSL, an additional certificate file is required. The file is a concatenation of CA certificate files. The file type must be `.crt`. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.

As part of your disaster recovery plan, we recommend keeping a backup of the certificate and revocation (if applicable) files in a safe location off of the Tableau Server. The certificate and revocation files that you add to Tableau Server will be stored and distributed to other

nodes by the Client File Service. However, the files are not stored in a recoverable format. See Tableau Server Client File Service.

RSA key and ECDSA curve sizes

The CA certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

.You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See `tsm configuration set Options`.

Client certificate requirements

Users authenticating to Tableau Server with mutual SSL must present a client certificate that meets minimum security requirements.

Signing algorithm

Client certificates must use a SHA-256 or greater signing algorithm.

Tableau Server configured for mutual SSL authentication will block authentication of users with client certificates that use the SHA-1 signing algorithm.

Users who attempt to log in with SHA-1 client certificates encounter an "Unable to sign in" error, and the following error will be visible in the VizPortal logs:

```
Unsupported client certificate signature detected: [certificate  
Signature Algorithm name]
```

You can configure Tableau Server to accept the less secure SHA-1 signing algorithm by setting the `ssl.client_certificate_login.blocklisted_signature_algorithms` `tsm configuration` option.

RSA key and ECDSA curve sizes

Tableau Server on Windows Help

The client certificate used for mutual SSL must either have an RSA key strength of 2048, or ECDSA curve size of 256.

Tableau Server will fail mutual authentication requests from client certificates that do not meet these requirements. You can configure Tableau Server to accept the less-secure sizes by setting the respective configuration keys:

- `ssl.client_certificate_login.min_allowed.rsa_key_size`
- `ssl.client_certificate_login.min_allowed.elliptic_curve_size`

See [tsm configuration set Options](#).

Use the TSM web interface

1. Configure SSL for External HTTP Traffic to and from Tableau Server.
2. Open TSM in a browser:

`https://<tsm-computer-name>:8850`. For more information, see [Sign in to Tableau Services Manager Web UI](#).
3. On the **Configuration** tab, select **User Identity & Access > Authentication Method**.
4. Under **Authentication Method**, select **Mutual SSL** in the drop-down menu.
5. Under Mutual SSL, select **Use mutual SSL and automatic sign in with client certificates**.
6. Click **Select File** and upload your certificate authority (CA) certificate file to the server.

The file (.crt) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.
7. Enter remaining SSL configuration information for your organization.

Username format: When Tableau Server is configured for mutual SSL, the server gets the user name from the client certificate, so it can establish a direct sign-in for the client user. The name that Tableau Server uses depends on how Tableau Server is configured for user authentication:

- Local Authentication—Tableau Server uses the UPN (User Principal Name) from the certificate.
- Active Directory (AD)—Tableau Server uses LDAP (Lightweight Directory Access Protocol) to get the user name.

Alternatively, you can set Tableau Server to use the CN (Common Name) from the client certificate.

Authentication Method

Specify how Active Directory manages user authentication and access to Tableau Server.

Mutual SSL

Mutual SSL

Use mutual SSL for secure communication between Tableau Server and web clients and for automatic sign-in across all Tableau Server components. [Learn more](#)

Use mutual SSL and automatic sign in with client certificates

SSL CA certificate file

Use username and password if SSL authentication fails

Specify a method for retrieving the username from the certificate.

Username retrieval method

LDAP (Lightweight Directory Access Protocol)

UPN (User Principal Name)

CN (Common Name)

8. Click **Save Pending Changes** after you've entered your configuration information.

9. Click **Pending Changes** at the top of the page:

10. Click **Apply Changes and Restart**.

Tableau Server on Windows Help

Use the TSM CLI

Step 1: Require SSL for external server communication

To configure Tableau Server to use SSL for external communication between Tableau Server and web clients, run the `external-ssl enable` command as follows, providing the names for the server certificate's `.crt` and `.key` files:

```
tsm security external-ssl enable --cert-file <file.crt> --key-file <file.key>
```

- For `--cert-file` and `--key-file`, specify the location and file name where you saved the server's CA-issued SSL certificate (`.crt`) and key (`.key`) files.
- The above command assumes the you are signed in as a user that has the **Server Administrator** site role on Tableau Server. You can instead use the `-u` and `-p` parameters to specify an administrator user and password.
- If the certificate key file requires a passphrase, include the `--passphrase` parameter and value.

Step 2: Configure and enable mutual SSL

Add mutual authentication between the server and each client, and allow for Tableau client users to be authenticated directly after the first time they provide their credentials.

1. Run the following command:

```
tsm authentication mutual-ssl configure --cert-file <file.crt>
```

For `--cert-file`, specify the location and file name of the certificate authority (CA) certificate file.

The file (`.crt`) is an all-in-one file that includes certificates of CAs that are used for client authentication. The file you upload must be a concatenation of the various PEM-encoded certificate files, in order of preference.

2. Run the following commands to enable mutual SSL and apply the changes:

```
tsm authentication mutual-ssl enable
```

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Additional options for mutual SSL

You can use `tsm mutual-ssl configure` to configure Tableau Server to support the following options.

For more information, see [tsm authentication mutual-ssl <commands>](#).

Fallback authentication

When Tableau Server is configured for mutual SSL, authentication is automatic and clients must have a valid certificate. You can configure Tableau Server to allow a fallback option, to accept user name and password authentication.

```
tsm authentication mutual-ssl configure -fb true
```

Tableau Server accepts username and password authentication from REST API clients, even if the above option is set to `false`.

User name mapping

When Tableau Server is configured for mutual SSL, the server authenticates the user directly by getting the user name from their client certificate. The name that Tableau Server uses depends on how the server is configured for user authentication:

Tableau Server on Windows Help

- **Local Authentication**—uses the UPN (User Principal Name) from the certificate.
- **Active Directory (AD)**—uses LDAP (Lightweight Directory Access Protocol) to get the user name.

You can override either of these defaults to set Tableau Server to use the common name.

```
tsm authentication mutual-ssl configure -m cn
```

For more information, see [Mapping a Client Certificate to a User During Mutual Authentication](#)

Certificate Revocation List (CRL)

You might need to specify a CRL if you suspect that a private key has been compromised, or if a certificate authority (CA) did not issue a certificate properly.

```
tsm authentication mutual-ssl configure -rf <revoke-file.pem>
```

How Mutual SSL Authentication Works

Mutual (or two-way) SSL authentication provides a combination of an encrypted data stream, mutual authentication of both server and client, and direct access convenience. To use mutual SSL with Tableau Server, you need the following:

- External SSL configured on Tableau Server.
- A trusted CA-issued SSL certificate for Tableau Server. The file is a concatenation of CA certificate files. A "CA" is a *certificate authority* that issues certificates to the client computers that will connect to Tableau Server. The action of uploading the CA certificate file establishes a trust, which enables Tableau Server to authenticate the individual certificates that are presented by the client computers.
- A certificate on each client that will connect to Tableau Server.
- A Tableau Server configured to use mutual SSL.

Tableau Server and the client verify that each other has a valid certificate, and Tableau Server authenticates the user, based on the user name in the client certificate.

The following image shows a little more detail about the sequence of events that occurs with mutual SSL.

1. The user navigates to Tableau Server.
2. Tableau Server sends its SSL certificate to the client computer.
3. The client computer verifies the Tableau Server certificate.
4. The client computer sends its certificate to Tableau Server.
5. Tableau Server verifies the client certificate.
6. Tableau Server references the user name in the client certificate to authenticate the user.

Mapping a Client Certificate to a User During Mutual Authentication

When you use mutual (two-way) SSL authentication, the client presents its certificate to Tableau Server as part of the authentication process. Tableau Server then maps user information in the client certificate to a known user identity. The strategy that Tableau

Tableau Server on Windows Help

Server uses to perform client mapping depends on the content of your organization's client certificates.

This topic discusses the ways information in a client certificate can map to a user identity and how to change the way Tableau Server performs that mapping. To understand how the mapping happens and whether you need to change it, you must know how client certificates are structured in your organization.

- [User-name mapping options](#)
- [Change the certificate mapping](#)
- [Address user-name ambiguity in multi-domain organizations](#)

User-name mapping options

Tableau Server uses one of the following approaches to map a client certificate to a user identity:

- **Active Directory.** If Tableau Server is configured to use Active Directory for user authentication, when Tableau Server receives a client certificate, it passes the certificate to Active Directory, which maps the certificate to an Active Directory identity. Any explicit user name information in the certificate is ignored.

Note: This approach requires client certificates to be published for the user accounts in Active Directory.

- **User principal name (UPN).** A client certificate can be configured to store the user name in the user principal name field. Tableau Server reads the UPN value and maps it to a user in Active Directory or to a local user.
- **Common name (CN).** A client certificate can be configured to store the user name in the common name field of the certificate. Tableau Server reads the CN value and maps it to a user in Active Directory or to a local user.

If you configure the server for Active Directory authentication and UPN or CN user-name mapping, put the user name in one of the following formats:

```
username, domain/username, or username@domain.
```

For example: `jsmith`, `example.org/jsmith`, or `jsmith@example.org`.

If the server uses local authentication, the format of the name in the UPN or CN fields is not predetermined, but the name in the field must match a user name on the server.

Change the certificate mapping

You use the `tsm authentication mutual-ssl <commands>` commands to map a client certificate to a user identity in Tableau Server:

```
tsm authentication mutual-ssl configure -m <value>
```

Possible values are `ldap` for Active Directory mapping, `upn` for UPN mapping, or `cn` for CN mapping.

When you first install and configure Tableau Server, the server sets the default user-name mapping to match the server's authentication type:

- If the server is configured to use Active Directory, it also uses Active Directory for mapping the certificate to the user identity.
- If the server is configured to use local authentication, the server gets the user-name value from the UPN field in the certificate.

If the default behavior for how Tableau Server maps a user name to an identity is not correct for your server configuration, run the following set of commands to change the mapping to use the CN value:

```
tsm authentication mutual-ssl configure -m cn
```

```
tsm pending-changes apply
```

Tableau Server on Windows Help

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Address user-name mapping ambiguity in multi-domain organizations

Under some circumstances, the user name in a certificate's UPN or CN field can be ambiguous. This ambiguity can lead to unexpected results when the user name is mapped to a user identity on the server.

For example, if Tableau Server is presented with a user name that does not include a domain, the server maps the user name to an identity using the default domain. This can cause an incorrect user-name mapping, potentially assigning a user a different user's identity and permissions.

This can occur particularly in environments where the following conditions apply:

- Your organization supports multiple Active Directory domains.
- The server is configured to use Active Directory authentication.
- The server is configured to use UPN or CN mapping.
- Some users have the same user name but different domains. For example, `jsmith@example.org` and `jsmith@example.com`.
- The user name in the certificate's UPN or CN fields does not include the domain as part of the user name—for example, it shows `jsmith`.

To avoid incorrect user-name mapping, make sure the client certificates include fully qualified user names with the domain, using the format `jsmith@example.org` or `example.org/jsmith`.

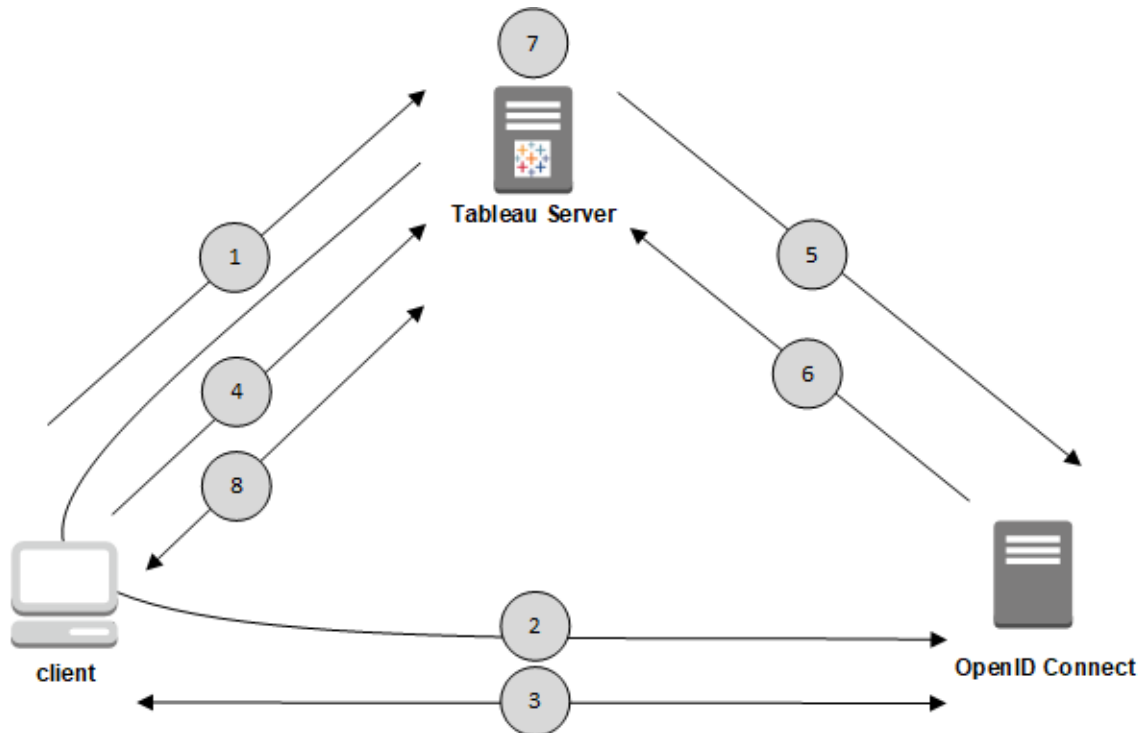

OpenID Connect

You can configure Tableau Server to support OpenID Connect for single sign-in (SSO). OpenID Connect is a standard authentication protocol that lets users sign in to an identity provider (IdP) such as Google. After they've successfully signed in to their IdP, they are automatically signed in to Tableau Server.

Configuring OpenID Connect involves several steps. The topics in this section provide general information about using Tableau Server with OpenID Connect, and provide a sequence for configuring the IdP and Tableau Server.

Authentication overview

This section describes the OpenID Connect authentication process with Tableau Server.

Step 1: A user attempts to log in to Tableau Server from a client computer.

Step 2: Tableau Server redirects the request for authentication to the IdP gateway.

Step 3: The user is prompted for credentials and successfully authenticates to the IdP. The IdP responds with a redirect URL back to Tableau Server. The redirect URL includes an authorization code for the user.

Step 4: The client is redirected to Tableau Server and presents the authorization code.

Step 5: Tableau Server presents the client's authorization code to the IdP along with its own client credentials. Tableau Server is also client of the IdP. This step is intended to prevent spoofing or man-in-the-middle attacks.

Step 6: The IdP returns an access token and an ID token to Tableau Server.

- JSON Web Token (JWT) validation: By default Tableau Server performs a validation of the IdP JWT. During discovery, Tableau Server retrieves the public keys specified by the `jwtks_uri` in the IdP configuration discovery document. Tableau Server validates the ID token for expiry and then verifies the JSON web signature (JWS), the issuer (IdP), and the client ID. You can learn more about the JWT process in the OpenID documentation, [10. Signatures and Encryption](#), and the IETF proposed standard, [JSON Web Token](#). We recommend leaving JWT validation enabled, unless your Idp does not support it.
- The ID token is a set of attribute key-pairs for the user. The key-pairs are called *claims*. Here is an example IdP claim for a user:

```
"sub" :
"7gYhRR3HiRRCaRcgvY50ubrtjGQBMJW4rXbpPFp-
g2cptHP62m2sqowM7G1LwjN5"
"email" : "alice@tableau.com",
"email_verified" : true,
"name" : "Alice Adams",
"given_name" : "Alice",
"family_name" : "Adams",
"phone_number" : "+359 (99) 100200305",
```

```
"profile" : "https://tableau.com/users/alice"
```

Step 7: Tableau Server identifies the user from the IdP claims and completes the authentication request from Step 1. Tableau Server searches for the user's account record stored in the repository by matching the "sub" (subject identifier) to identify the correct user account. If no user account is stored with the sub claim value, then Tableau Server searches for a username in the repository that matches the "email" claim from the IdP. When a username match succeeds, Tableau Server will store the corresponding sub claim to the user's record in the repository. Tableau Server can be configured to use different claims for this process. See Requirements for Using OpenID Connect.

Step 8: Tableau Server authorizes the user.

How Tableau Server Works with OpenID Connect

OpenID Connect is a flexible protocol that supports many options for the information that's exchanged between a service provider (here, Tableau Server) and an IdP. The following list provides details about the Tableau Server implementation of OpenID Connect. These details can help you understand what types of information Tableau Server sends and expects, and how to configure an IdP.

- Tableau Server supports only the OpenID Authorization Code Flow as described in the [OpenID Connect final specification](#).
- Tableau Server relies on using discovery or a provider URL to retrieve the OpenID Provider metadata. Alternatively, you can host a static discovery document on Tableau Server. For more information see [Configure Tableau Server for OpenID Connect](#).
- Tableau Server supports only the `client_secret_jwt` Client Authentication method specified in the OpenID Connect specification. In addition, Tableau Server supports only RSA Asymmetric Encryption for handling the JWT. However, you can turn off JWT validation. See `tsm authentication openid <commands>`.
- Tableau Server expects a `kid` value in the `id_token` attribute's JOSE Header.

Tableau Server on Windows Help

This value is matched with one of the keys found in the JWK Set document, whose URI is specified by the `jwtks_uri` value in the OpenID discovery document. A `kid` value must be present even if there is only one key in the JWK Set document.

- Tableau Server does include OpenID support for the JWK `x5c` parameter or for using X.509 certificates.
- By default, Tableau Server ignores proxy settings and sends all OpenID requests directly to the IdP.

If Tableau Server is configured to use a forward proxy to connect to the internet, then you must make additional changes as described in [Configure Tableau Server for OpenID Connect](#).

Requirements for Using OpenID Connect

This topic describes the requirements to use OpenID Connect with Tableau Server.

IdP account

You must have access to an identity provider (IdP) that supports the OpenID Connect (OIDC) protocol. You must also have an account with the IdP. OpenID Connect is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical. As you configure Tableau Server for OIDC, work with your IdP.

The Google IdP implementation has been extensively tested with Tableau Server and is the model IdP for the configuration documented in these topics.

Local identity store

To use OpenID Connect on Tableau Server, the server must be configured to use local identity store. The server must be configured so that you explicitly create users on the Tableau Server, rather than importing them from an external directory such as Active Directory. Managing users with an external identity store is not supported with OpenID.

IdP claims: mapping users

To sign in successfully to Tableau Server, a given user must be provisioned in OpenID and then mapped to a user account on Tableau Server. OpenID uses a method that relies on *claims* to share user account attributes with other applications. Claims include user account attributes such as email, phone number, given name, etc. To understand how Tableau Server maps IdP claims to user accounts, see [Authentication overview](#).

Tableau Server relies on the IdP claims to map user accounts from the IdP to those hosted on Tableau Server. By default, Tableau Server expects the IdP to pass the email claim. Depending on your IdP, you may need to configure Tableau Server to use a different IdP claim.

If you are using Google as an IdP, then use the default, `email` claim to map IdP identities to Tableau Server user accounts. If you are not using Google as an IdP, then work with your IdP to determine the claim for which you should configure Tableau Server.

Default: using email claim to map users

By default, the user's user name in Tableau Server must match the `email` claim in the IdP ID token. Therefore, in the default configuration, you must use email addresses (also referred to as UPN) as the username in Tableau Server. If you use Google as the IdP, the user name in Tableau Server must be the user's Gmail address (`alice@gmail.com`). Using a complete email address helps to guarantee the uniqueness of the user name in Tableau Server, even when two users have the same email but are on different email hosts.

Note: When you create a user identity in Tableau Server, you specify a user name, password, and optionally an email address. For using OpenID Connect in the default configuration, the user name (expressed as an email address) is the value that must match the user's name in the IdP. The optional email address in the Tableau Server user identity is not used for OpenID authentication.

Ignoring the domain name

You can configure Tableau to ignore the domain portion of an email address when matching the IdP `email` claim to a user account on Tableau Server. In this scenario, the `email` claim in the IdP might be `alice@example.com`, but this will match a user named `alice` in Tableau Server. Ignoring the domain name might be useful if you already have users defined in Tableau Server that match the user names portion of the `email` claim, but not the domain portions.

Important: We do not recommend ignoring the user domain name without taking precautions. Specifically, verify that user names are unique across the configured domains that you've created in your IdP.

Setting Tableau Server to ignore the user domain name has the potential to result in unintended user log on. Consider the case where your IdP has been configured for multiple domains (`example.com` and `tableau.com`). If two users with the same first name, but different user accounts (`alice@tableau.com` and `alice@example.com`) are in your organization, then the first one to complete the OpenID provisioning sequence will claim the `sub` mapping in the IdP. If the wrong user is mapped, then the other user will be unable to log on until the associated `sub` value is reset.

To configure Tableau Server to ignore domain names in user names from the IdP, set `tsm authentication openid configure --ignore-domain` to `true`. For more information, see `tsm authentication openid <commands>`.

When you change the `tsm authentication openid configure --ignore-domain` option to ignore the domain in user names, all user names in Tableau Server must have a domain name.

Using custom claims to map users

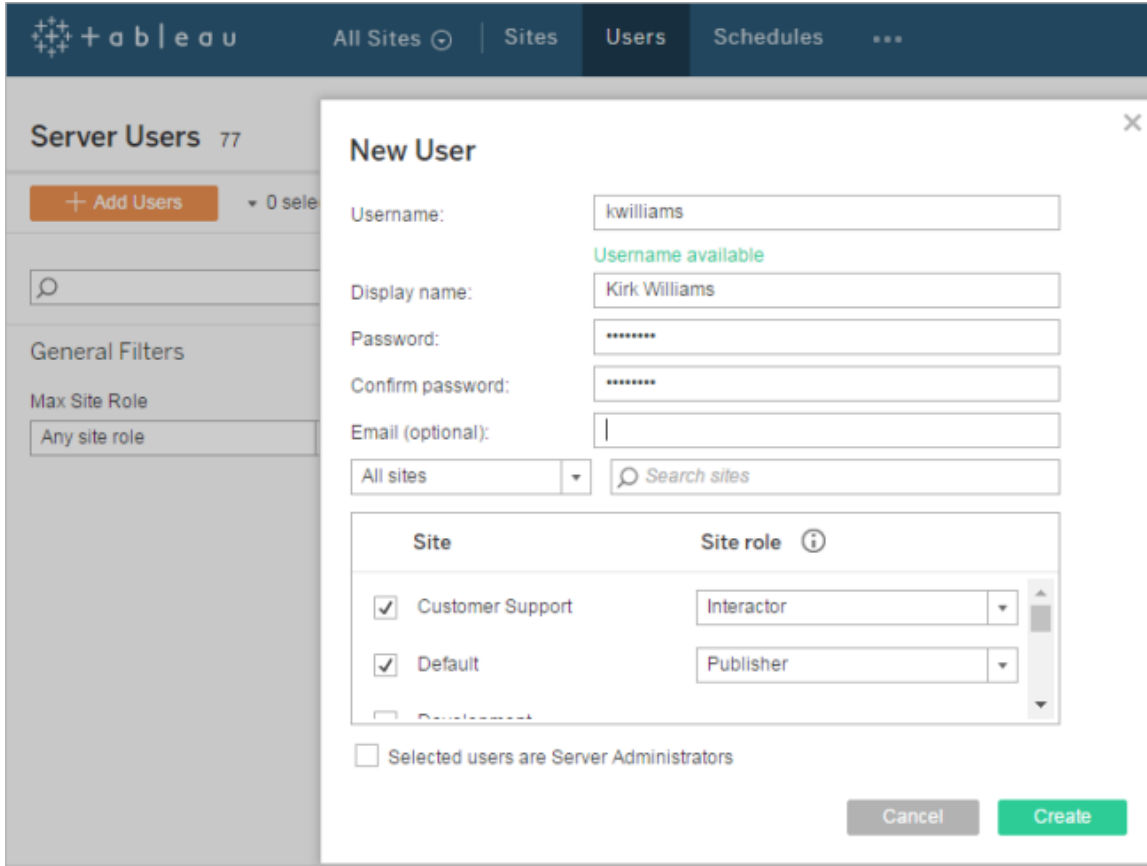

As referenced in Authentication overview, the `sub` claim is often included in IdP claims. Typically, the `sub` claim is a unique string that identifies a given user account. The benefit of

using a `sub` claim is that it will not change, even if you or another admin updates other user attributes or IdP claims (email, phone number, etc) associated with that account. By default, Tableau Server identifies and verifies OpenID users according to the `sub` claim in the IdP ID token.

The OpenID `sub` claim value must be mapped to the corresponding user in Tableau Server. Since the `sub` claim is an arbitrary string, a different claim is used to associate accounts during the first sign-in session. The first time a user signs in to Tableau Server with OpenID, Tableau will match the OpenID user account to a corresponding user account on Tableau. By default, Tableau will use the IdP claim, `email`, to identify the Tableau user. Tableau will then update that user's record with the `sub` claim from OpenID. Since the ID token always includes the `sub` claim along with other claims, on subsequent sessions, Tableau will identify that user with the `sub` claim only.

For some organizations, mapping user names with the email address is not reliable or not supported by the IdP. Beginning with Tableau Server 10.2, you can map user accounts from any arbitrary IdP claim to the Tableau Server username.

The IdP claim you are using must map exactly to a corresponding Tableau Server username. In the example below, the username is `kwilliams`.

To change the IdP claim that is used to map identity on Tableau Server, use the `tsm authentication openid map-claims --user-name` command. For more information, see `tsm authentication openid <commands>`.

Changing the `sub` claim

As described above, the `sub` claim is the identifier that Tableau Server uses to identify users after the initial mapping session. The `sub` claim is written to the corresponding user account in Tableau Server. If your IdP does not provide a `sub` claim, then you can specify an arbitrary claim to use instead. Like `sub`, the claim value you specify must be unique and should not change when other user claims are updated.

To specify a different IdP claim for default sub claim, use the use the `tsm authentication openid map-claims --id` command. For more information, see `tsm authentication openid <commands>`.

Where `arbitraryClaim` is the name of the IdP claim that you want to use as the replacement for the `sub` claim.

Authentication context

If your OpenID Connect IdP requires a specific authentication context, you can specify a list of essential and voluntary ACR values using the `vizportal.openid.essential_acr_values` and `vizportal.openid.voluntary_acr_values` configuration keys. For more information, see `tsm configuration set Options`.

Configure the Identity Provider for OpenID Connect

This topic provides information about configuring an identity provider (IdP) to use OpenID Connect with Tableau Server. This is one step in a multi-step process. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect (you are here)
- Configure Tableau Server for OpenID Connect
- Signing In to Tableau Server Using OpenID Connect

Configure the IdP

Before you can use OpenID Connect with Tableau Server, you must have an account with an identity provider (IdP) and a project or application with the IdP. When you configure Tableau Server, you will need to be able to provide the following information:

- Provider client ID. This is the identifier that the IdP assigned to your application.
- Provider client secret. This is a token that is used by Tableau to verify the authenticity

of the response from the IdP. This value is a secret and should be kept securely.

- Provider configuration URL. This is the URL at the provider's site that Tableau Server should send authentication requests to.

Redirect URL

Some IdPs will require a redirect URL for your Tableau Server. You can manually construct your URL for the IdP using the following syntax:

```
<protocol>://<host>/vizportal/api/web/v1/auth/openIdLogin
```

For example, `https://tableau.example.com/vizportal/api/web/v1/auth/openIdLogin`.

Example IdP process

The following procedure provides an outline of the steps that you follow with the provider. As an example, the procedure discusses using Google as a provider. However, each provider has a somewhat different flow, so the specifics of the steps (and their order) might vary depending on your provider.

1. Register at the provider's developer site and sign in. For example, for Google, you can go to the Developers Console at this URL: <https://console.developers.google.com>
2. Create a new project, application, or relying party account.
3. In the developer dashboard, follow the steps for getting an OAuth 2.0 client ID and client secret. Record these values for later.

Note: Keep the client secret in a secure place.

4. On the developer site, find the URL of the endpoint that the IdP uses for OpenID Connect discovery. For example, Google uses the URL <https://accounts.google.com/.well-known/openid-configuration>. Record this URL for later.

Alternatively, if your IdP has provided you with a static discovery document, copy that file to a local directory on the Tableau Server for later.

Configure Tableau Server for OpenID Connect

This topic describes how to configure Tableau Server to use OpenID Connect for single-sign on (SSO). This is one step in a multi-step process. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

- OpenID Connect
- Configure the Identity Provider for OpenID Connect
- Configure Tableau Server for OpenID Connect (you are here)
- Signing In to Tableau Server Using OpenID Connect

Note: Before you perform the steps described here, you must configure the OpenID identity provider (IdP) as described in [Configure the Identity Provider for OpenID Connect](#).

Use the TSM web interface

1. Open TSM in a browser:

https://<tsm-computer-name>:8850. For more information, see [Sign in to Tableau Services Manager Web UI](#).
2. Click User **Identity & Access** on the **Configuration** tab and then click **Authentication Method**.
3. Under **Authentication Method**, select **OpenID Connect** in the drop-down menu.
4. Under OpenID Connect, select **Enable OpenID authentication for the server**.
5. Enter the OpenID configuration information for your organization:

Tableau Server on Windows Help

Authentication Method

Specify how the identity store manages user authentication and access to Tableau Server.

OpenID Connect

OpenID Connect

Use OpenID when you want users on Tableau Server to authenticate with an external OpenID Connect Identity Provider. Follow the steps below to configure OpenID.

Enable OpenID authentication for the server

Step 1: Create the OpenID configuration by providing the client id, secret, and discovery URL provided by your OpenID Connect Identity Provider.

Provider client ID

Provider client secret

Provider configuration URL

Step 2: Provide the hostname and protocol of the return URL your OpenID Connect Identity Provider will use to redirect users back to Tableau Server.

Tableau Server external URL

Step 3: Copy the URL below and configure your OpenID Connect Identity Provider to redirect users to this endpoint after authenticating.

Note: If your provider relies on a configuration file hosted on the local computer (rather than a file hosted at a public URL), you can specify the file with the `tsm authentication openid <commands>`. Use the `--metadata-file <file_path>` option to specify a local IdP configuration file.

6. Click **Save Pending Changes** after you've entered your configuration information.
7. Click **Pending Changes** at the top of the page:

8. Click **Apply Changes and Restart**.

Use the TSM CLI

The procedure in this section describes how to use TSM command line interface to configure OpenID Connect. You can also use a configuration file for the initial configuration of OpenID

Connect. See openIDSettings Entity.

1. Use the `configure` command of `tsm authentication openid <commands>` to set the following required options:

`--client-id <id>`: Specifies the provider client ID that your IdP has assigned to your application. For example, "laakjwdlnaoiloadjkwaha".

`--client-secret <secret>`: Specifies the provider client secret. This is a token that is used by Tableau to verify the authenticity of the response from the IdP. This value is a secret and should be kept securely. For example, "fwahfkjaw72123=".

`--config-url <url>` or `--metadata-file <file_path>`: Specifies location of provider configuration json file. If the provider hosts a public json discovery file, then use `--config-url`. Otherwise, specify a path on the local computer and file name for `--metadata-file` instead.

`--return-url <url>`: The URL of your server. This is typically is the public name of your server, such as "http://example.tableau.com".

For example, run the command:

```
tsm authentication openid configure --client-id
"laakjwdlnaoiloadjkwaha" --client-secret "fwahfkjaw72123="
--config-url "https://example.com/openid-configuration" --
return-url "http://tableau.example.com"
```

There are additional, optional configurations that you can set for Open ID Connect using either openIDSettings Entity or `tsm authentication openid <commands>`. In addition, if you need to configure IdP claim mapping, see Options for openid map-claims.

2. Type the following command to enable Open ID Connect:

```
tsm authentication openid enable
```

Tableau Server on Windows Help

3. Run `tsm pending-changes apply` to apply changes.

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Configure OpenID to work with a forward proxy

By default, Tableau Server ignores proxy settings and sends all OpenID requests directly to the IdP.

Beginning with Tableau Server 2021.2.2 and newer, if Tableau is configured to use a forward proxy to connect to the internet, then you may configure Tableau Server to use the proxy host and port settings to contact the OpenID IdP.

How you configure Tableau Server is different depending on how you have implemented forward proxy in your organization:

- Forward proxy is configured on the Windows computer where Tableau Server is running.
- Tableau Server sends all outbound traffic directly to a forward proxy server running in your organization.

Windows system proxy configuration

If your organization has configured forward proxy on each Windows computer use this method to use the system proxy configuration for OpenID on Tableau Server. Run the following commands:

```
tsm configuration set -k tomcat.useSystemProxies -v true
tsm pending-changes apply
```

Forward proxy server

Use the command, `tsm configuration set`, to make the changes.

- For HTTPS proxy hosts, use the following key-value pairs:

```
-k tomcat.https.proxyHost -v host.domain  
  
-k tomcat.https.proxyPort -v port_number
```

For example, if your proxy server is at `https://proxy.example.lan:8443`, then run the following commands:

```
tsm configuration set -k tomcat.https.proxyHost -v  
proxy.example.lan  
  
tsm configuration set -k tomcat.https.proxyPort -v 8443  
  
tsm pending-changes apply
```

- For HTTP proxy hosts, use the following key-value pairs:

```
-k tomcat.http.proxyHost -v host.domain  
  
-k tomcat.http.proxyPort -v port_number
```

After you have set these keys, run `tsm pending-changes apply`.

Signing In to Tableau Server Using OpenID Connect

This topic provides information about signing in to Tableau Server using OpenID Connect. The following topics provide information about configuring and using OpenID Connect with Tableau Server.

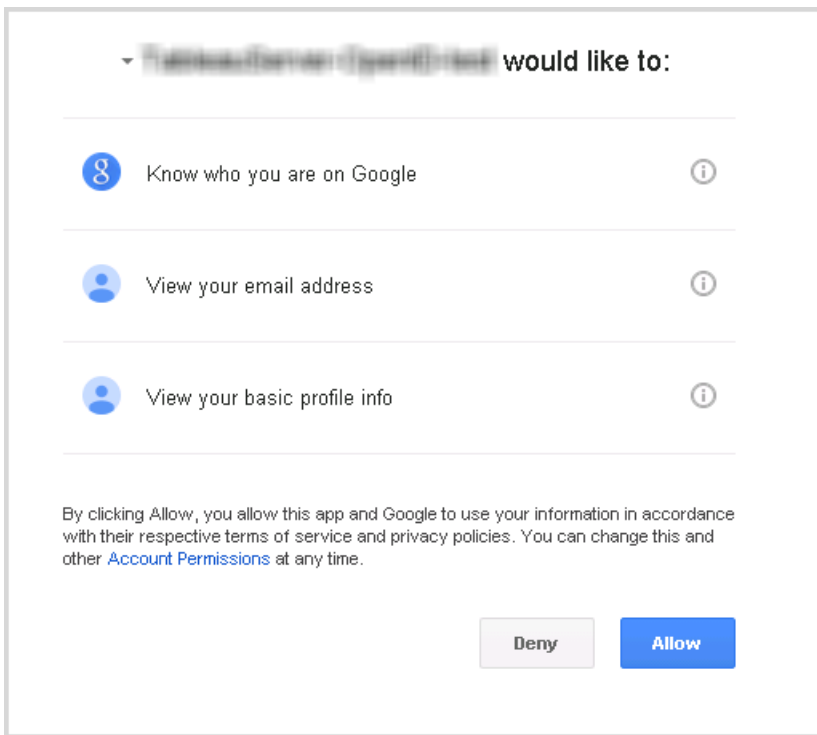

- OpenID Connect
- Configure the Identity Provider for OpenID Connect

Tableau Server on Windows Help

- Configure Tableau Server for OpenID Connect
- Signing In to Tableau Server Using OpenID Connect (you are here)

Signing in using OpenID Connect

After Tableau Server has been configured to use OpenID Connect, users who access the server and aren't already signed in are redirected to the IdP site, where they are prompted to sign in. Users enter the credentials that they have with the IdP. In many cases, the user is also asked to authorize the IdP to share information with Tableau Server, as in the following example:

When a user signs in using OpenID Connect, the IdP sends a unique user identifier (known in OpenID as the sub value) as part of the information that's redirected to Tableau Server. This sub value is associated with the user's Tableau user identity.

Restricting sign-in to server administrators for command-line tools

Command-line tools for working with Tableau Server (`tabcmd`, TSM, and `tableau.com`) do not support sign-in using OpenID Connect. When OpenID Connect is enabled for the server, these tools still require sign-in using a Tableau Server username and password.

Even if users normally authenticate using OpenID Connect, each user has a Tableau Server username and password. This means that users could use command-line tools like `tabcmd`. As a security measure, you can make sure that *only* server administrators can use command-line tools. To do this, use `tsm configuration set to set wgserver.authentication.restricted to true`. When this setting is `true`, only server administrators can sign in to Tableau Server using a username and password; all other users *must* sign in to the server using a single sign-on (SSO) option like OpenID Connect. The effect is that users who are not administrators also cannot then use command-line tools. To make this change, run the following sequence of TSM commands:

```
tsm configuration set -k wgserver.authentication.restricted -v true
```

```
tsm pending-changes apply
```

OpenID Connect Authentication Request Parameters

The OpenID authentication request sent from Tableau Server passes information using a limited set of parameters, as listed in this topic. If your OpenID IdP requires parameters that are not in the following list, it is not compatible for use with Tableau Server.

- `scope`. This value specifies a profile that tells the IdP what user information claims to return. This value can be configured by a Tableau Server administrator. The default value is "openid email profile". For more information, see [Configure the scope value](#) later in this document.
- `response_type`. OpenID Connect supports multiple flows. This value tells the IdP which flow Tableau Server expects. Tableau supports only the authorization code flow, and the value is always set to "code".
- `client_id`. This value specifies the server's ID (**Provider client ID** in the Tableau

Tableau Server on Windows Help

Server Configuration dialog box), which lets the IdP know where the request came from. It is provided by the IdP when the service is registered. The value is configurable by a Tableau Server administrator.

- `redirect_uri`. This value specifies the URL that the IdP redirects to after the user has authenticated using OpenID Connect. The URL must include the host and protocol (for example, `http://example.tableau.com`), but Tableau provides the URL endpoint.
- `nonce`. Tableau Server generates a nonce value to verify that the client that it redirected to matches the entity that comes back from the IdP.

Configure the scope value

The `scope` value indicates to the IdP the information that Tableau Server requests about the user. By default, Tableau Server sends the value "openid profile email". This indicates that Tableau uses OpenID to authenticate (this part of the `scope` attribute value must always be included) and that Tableau Server is requesting the user profile and email information during the exchange of the user authorization code.

If this default scope is not appropriate for your scenario, you can have Tableau Server request custom information about the user. To do so, you configure the IdP with a custom profile (for example, something like "tableau-scope"). You can then configure Tableau Server to send the scope request using the name of the custom profile.

To change the scope value that Tableau Server requests, use the following TSM CLI command:

```
tsm authentication openid configure --custom-scope-name custom-scope-name
```

Note: Tableau Server always includes "openid" as part of the scope value (even if you don't include it in the `custom_scope` setting).

Changing IdPs in Tableau Server for OpenID Connect

This topic provides information about changing an identity provider (IdP) if you have configured Tableau Server to use OpenID Connect.

Changing providers

You might decide to change the IdP that Tableau Server is configured to use. To do so, you follow the procedure that you used to configure the first IdP: establish an account, get a customer ID and secret, configure Tableau Server with that information, and provide the IdP with the redirect URL for Tableau Server. For more information, see [Configure Tableau Server for OpenID Connect](#).

However, you also need to perform an additional step: you must clear any user identifiers (`sub` values) that have already been associated with Tableau Server users. The new IdP will have different `sub` values for each user, and you must clear the existing ones so that Tableau Server can store a new `sub` value when the user signs in using the new IdP.

To clear `sub` values for users, use the `tabcmd reset_openid_sub` command. You can reset (that is, clear) `sub` values for an individual user, as in the following example:

```
tabcmd reset_openid_sub --target-username jsmith
```

You can also clear the `sub` value for all users using this command:

```
tabcmd reset_openid_sub --all
```

Troubleshoot OpenID Connect

Use the following topics to troubleshoot OpenID Connect (OIDC) issues in Tableau Server.

OpenID Connect protocol is supported by many identity providers. The OIDC protocol is an open and flexible standard, and as such, not all implementations of the standard are identical. Most issues that administrators encounter when configuring Tableau Server for OIDC are the result of how different identity providers implement OIDC. If you encounter errors as you set up OIDC with Tableau Server, we recommend that you work with your IdP to resolve them.

Tableau Server on Windows Help

Enabling enhanced OpenID logging

To efficiently troubleshoot OpenID Connect issues in Tableau Server, enable enhanced logging by setting the logging level to debug, and full logging for OpenID using the `vizportal.openid.full_server_request_logging_enabled` configuration key to `true` using these TSM commands:

```
tsm configuration set -k vizportal.log.level -v debug
```

```
tsm configuration set -k vizportal.openid.full_server_request_logging_enabled -v true
```

```
tsm pending-changes apply
```

After completing your troubleshooting, we recommend setting the values of both configuration keys back to their defaults to limit the information collected in logs and to reduce log file sizes. For details on resetting configuration keys to defaults, see [Resetting a configuration key to default](#).

Signing In from the Command Line

Even if Tableau Server is configured to use OpenID, it is not used if you sign in to Tableau Server using `tabcmd`, the [REST API](#), or the [Tableau Data Extract command line utility](#) (provided with Tableau Desktop).

Login Failed

Login can fail with the following message:

```
Login failure: Identity Provider authentication successful for user <username from IdP>. Failed to find the user in Tableau Server.
```

This error typically means that there is a mismatch between a username stored in Tableau Server and the username provided by the IdP. To fix this, make sure that they match. For

example, if Jane Smith's username is stored in the IdP as `j.smith` it must be stored in Tableau Server as `j.smith` as well.

Error 69: "Unable to Sign In"

An error 69 may be returned when you attempt to sign in to Tableau Server with a web browser and receive an error, "Unable to Sign In. Sign in failed. Contact your Tableau Server administrator." The URL that returns this message is `https://example.com/#/error/signin/69?redirectPath=%2`.

If you receive this error, check with your IDP provider to verify if the IdP is expecting `client_secret_post` instead of `client_secret_basic` (the Tableau default).

If the IdP is expecting `client_secret_post`, then you must set the `vizportal.openid.client_authentication` parameter to `client_secret_post`.

For example; If you receive this error and you have configured OIDC for the Salesforce IdP, then you must set the `vizportal.openid.client_authentication` parameter.

See `tsm configuration set Options` for more information.

OpenID Error Log

OpenID authentication takes place outside Tableau Server, so troubleshooting authentication issues can be difficult. However, sign-in attempts are logged by Tableau Server. You can create a snapshot of log files and use them to troubleshoot problems. For more information, see [Tableau Server Logs and Log File Locations](#).

Note: To log OpenID-related events, `vizportal.log.level` must be set to `debug` with `tsm configuration set Options`.

Check for OpenID errors in the following files in the unzipped log file snapshot:

```
\vizportal\vizportal-<n>.log
```

Trusted Authentication

When you embed Tableau Server views into web pages, everyone who visits the page must be a licensed user on Tableau Server. When users visit the page they are prompted to sign in to Tableau Server before they can see the view. If you already have a way of authenticating users on the webpage or within your web application, you can avoid this prompt and save your users from having to sign in twice by setting up trusted authentication.

Trusted authentication simply means that you have set up a trusted relationship between Tableau Server and one or more web servers. When Tableau Server receives requests from these trusted web servers it assumes that your web server has handled whatever authentication is necessary.

If your web server uses SSPI (Security Support Provider Interface), you do not need to set up trusted authentication. You can embed views and your users will have secure access to them as long as they are licensed Tableau Server users and members of your Active Directory.

Note: Client browsers must be configured to [allow third-party cookies](#) if you want to use trusted authentication with embedded views.

How Trusted Authentication Works

The diagram below describes how trusted authentication works between the client's web browser, your web server(s) and Tableau Server.

1 User visits the webpage: When a user visits the webpage with the embedded Tableau Server view, the webpage sends a GET request to your web server for the HTML for that page.

2 Web server POSTS to Tableau Server: The web server sends a POST request to the trusted Tableau Server (for example, `https://<server_name>/trusted`, not `https://<server_name>`). That POST request must have a `username` parameter. The `username` value must be the username for a licensed Tableau Server user. If Tableau Server is hosting multiple sites and the view is on a site other than the Default site, then the POST request must also include a `target_site` parameter.

3 Tableau Server creates a ticket: Tableau Server checks the IP address or host name of the web server (192.168.1.XXX in the above diagram) that sent the POST request. If the web server is listed as a trusted host then Tableau Server creates a ticket in the form of a unique string. Tickets must be redeemed within three minutes after they are issued.

Tableau Server responds to the POST request with that ticket. Or if there is an error and the ticket cannot be created, then Tableau Server responds with a value of `-1`. The server must have an IPv4 address. IPv6 addresses are not supported. For more information, see [Ticket Value of -1 Returned from Tableau Server](#).

4 Web server passes the URL to the browser: The web server constructs the URL for the view and inserts it into the HTML for the page. The ticket is included (for example, `https://<server_name>/trusted/<unique_ticket>/views/<view_name>`). The web server passes the HTML back to the client's web browser.

5 Browser requests view from Tableau Server: The client web browser sends a GET request to Tableau Server that includes the URL with the ticket.

6 Tableau Server redeems the ticket: Tableau Server redeems the ticket, creates a session, logs the user in, removes the ticket from the URL, and then sends the final URL for the embedded view to the client.

The session allows the user to access any of the views that the user would have if they logged onto the server. In the default configuration, users authenticated with trusted tickets have restricted access such that only views are available. They cannot access workbooks, project pages, or other content hosted on the server.

To change this behavior, see the `wgserver.unrestricted_ticket` option at [tsm configuration set Options](#).

How is a trusted ticket stored?

Tableau Server stores trusted tickets in the Tableau Server repository using the following process:

1. Tableau Server generates a two-part ticket: the first part is a Base64-encoded unique ID (UUID) and the second part is a 24-character random secret string.
2. Tableau Server hashes the secret string and stores it with the unique ID in the repository. Hashing takes the secret string as input, and uses an algorithm to compute a

unique string. This unique string protects the security of the secret string from unauthorized users.

3. Tableau Server sends the Base64 UUID and the original 24-character random string to the client.
4. The client returns the Base64 UUID and the original 24-character secret string to Tableau Server as part of the request for a view.
5. Tableau Server locates the string pair with the Base64 UUID, and then hashes the secret string to verify that it matches the hash stored in the repository.

This process ensures that any trusted ticket content stored on Tableau Server cannot be used to impersonate users or access content protected by authentication. However, because the full trusted ticket is sent over HTTP between Tableau Server and the client, the process relies on secure and encrypted transmission of HTTP data. Therefore, we recommend that you only deploy trusted tickets over SSL/TLS or another layer of network encryption.

Add Trusted IP Addresses or Host Names to Tableau Server

The first step in setting up trusted authentication is to configure Tableau Server to recognize and trust requests from one or more web servers:

Use the TSM web interface

1. Open TSM in a browser:

https://<server_name>:8850. For more information, see Sign in to Tableau Services Manager Web UI.
2. Click User **Identity & Access** on the **Configuration** tab and then click **Trusted Authentication**.
3. Under **Trusted Authentication**, for each trusted host, enter the name or IP address and then click **Add**:

Tableau Server on Windows Help

Trusted Authentication

Use trusted authentication to allow single sign-on to view Tableau Server content embedded in webpages. Establish a trusted relationship between Tableau Server and one or more web server by adding trusted hosts and specifying token length for each trusted ticket. Do not set up trusted authentication if your web server uses SSPI. [Learn more](#)

Trusted hosts	<input type="text" value="10.32.139.6"/>	<input type="button" value="Delete"/>
	<input type="text" value="webserv1"/>	<input type="button" value="Delete"/>
	<input type="text" value="webserv2"/>	<input type="button" value="Add"/>
Token Length	<input type="text" value="24"/>	<input type="button" value="x"/>

Notes:

The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts if you want to amend an existing list.

Static IP addresses are required: The web servers you specify must use static IP addresses, even if you use host names.

If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted` option. See [Configuring Proxies for Tableau Server](#) for steps.

4. Enter a value in **Token Length** (Optional).

The token length determines the number of characters in each trusted ticket. The default setting of 24 characters provides 144 bits of randomness. The value can be set to any integer between 9 and 255, inclusive.

5. Click **Save Pending Changes** after you've entered your configuration information.
6. Click **Pending Changes** at the top of the page:

7. Click **Apply Changes and Restart**.

Use the TSM CLI

1. Enter the following command:

```
tsm authentication trusted configure -th <trusted IP
address or host name>
```

In the command above, <trusted IP address> should be a comma-separated list of the IPv4 addresses or host names of your web server(s), with each host name or IP address in quotes.

Note: The values you specify completely overwrite any previous setting. Therefore, you must include the full list of hosts in the `tsm authentication trusted configure -th` command. (You cannot amend the list of hosts by running the `tsm authentication trusted configure -th` command repeatedly.)

For example:

```
tsm authentication trusted configure -th "192.168.1.101",
"192.168.1.102", "192.168.1.103"
```

or

```
tsm authentication trusted configure -th "webserv1", "web-
serv2", "webserv3"
```

Notes:

Each host name or IP address in the list must be in double-quotes, followed by a

comma and one space after each comma.

The web servers you specify must use static IP addresses, even if you use host names.

2. If you have one or more proxy servers between the computer that is requesting the trusted ticket (one of those configured in Step 2 as shown at Trusted Authentication) and Tableau Server, you also need to add them as trusted gateways using the `tsm configuration set gateway.trusted` option. See [Configuring Proxies for Tableau Server](#) for steps.

3. Type the following command to save the changes to all the server configuration files:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

There are other optional trusted authentication configurations (legacy support, logging, and timeout settings) that you can make by passing a json file to Tableau Server. See `trustedAuthenticationSettings` Entity.

Next, you need to [configure your web server to receive tickets from Tableau Server](#).

Get a Ticket from Tableau Server

After you've [added trusted IP addresses](#) to Tableau Server, you're ready to configure your web server to get tickets from Tableau Server via POST requests ([Step 2 in the diagram](#)). The POST request must be sent to `http://<server_name>/trusted`. For example, the POST request must be sent to `http://tabserv/trusted` not `http://tabserv`.

Note: If SSL is enabled you must use https instead of http. For example: `https://tabserv/trusted`.

Here's the data you can use in a POST request to Tableau Server:

- **username=<username>** (required): The username for a licensed Tableau Server user. If you are using Local Authentication the username can be a simple string (for example, `username=jsmith`). If you are using Active Directory with multiple domains you must include the domain name with the user name (for example, `username=MyCo\jsmith`).
- **target_site=<site id>** (required if view not on Default site): Specifies the site containing the view if Tableau Server is running **multiple sites** and the view is on a site other than the Default site (for example, `target_site=Sales`). The value you use for `<site id>` should be the **Site ID** that was provided when the site was created. This value is case sensitive. If the **Site ID** is `SAles`, then the `target_site=Sales`.
- **client_ip=<IP address>** (optional): Used to specify the IP address of the computer whose web browser is accessing the view (for example, `client_ip=123.45.67.891`). It is not the IP address of the web server making the POST request of Tableau Server. If you decide to use this parameter, see [Optional: Configure Client IP Matching](#) for more information.

Tableau Server's response to the POST request will be a unique string (the ticket). If Tableau Server isn't able to process the request, the return will be `-1`. See [Ticket Value of -1 Returned from Tableau Server](#) for tips on how to correct this. Also, in order for users to successfully authenticate when they click an embedded view, their browsers must be configured to [allow third-party cookies](#).

The ticket format changed in Tableau Server 10.2. The ticket format is now a string composed of two parts. Each part is a 128 bit string that is encoded before it is returned to the client. The first part is a universally unique ID (UUID v4) that is Base64-encoded. The second

Tableau Server on Windows Help

part is a 24-character secure random string. The concatenation of these parts can be expressed as Base64(UUIDv4):SecureRandomString. An example of a ticket might look like this: 9D10byqDQmSIOyQpKdy4Sw==: dg62gCsSE0QRArXNTOp6m1J5.

Next, you need to add code that allows the web server to **construct an URL** for the view that includes the view's location and the ticket.

Display the View with the Ticket

After you **create the POST request**, you need to write code that provides the web server with the view's location and the ticket from Tableau Server. It will use this information to display the view. How you specify it depends on whether the view is embedded, and if Tableau Server is running multiple sites.

Tableau Server View Examples

Here's an example of how to specify a view that users only access via Tableau Server (the view is not embedded):

```
http://<server_name>/trusted/<unique_ticket>/views/<workbook_name>/<view_name>
```

If Tableau Server is running **multiple sites** and the view is on a site other than the Default site, you need to add `t/<site_id>` to the path. For example:

```
http://<server_name>/trusted/<unique_ticket>/t/Sales/views/<workbook_name>/<view_name>
```

Use the same capitalization that you see in the Tableau Server URL.

Embedded View Examples

Here are some examples of how to specify embedded views. Because there are two approaches you can take with embed code, both ways are provided below. Regardless of which you use, there is some information unique to trusted authentication that you must provide. For more information, search for "Writing Embed Code" in the Tableau Server Help.

Note: The examples below use embed code parameters. For more information, see [Embed Code Parameters](#) in the Tableau Help.

Script Tag Examples

This example uses the `ticket` object parameter:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="800" height="600" style-
e="display:none;">
  <param name="name" value="MyCoSales/SalesScoreCard" />
  <param name="ticket" value-
e="9D10byqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRARXNTOp6mlJ5" />
</object>
```

Here's what the above example looks like for a multi-site Tableau Server, where the view is published on the `Sales` site:

```
<script type="text/javascript" src-
c="http://myserver/javascripts/api/viz_v1.js"></script>
<object class="tableauViz" width="800" height="600" style-
e="display:none;">
  <param name="site_root" value="/t/Sales" />
  <param name="name" value="MyCoSales/SalesScoreCard" />
  <param name="ticket" value-
e="9D10byqDQmSIOyQpKdy4Sw==:dg62gCsSE0QRARXNTOp6mlJ5" />
</object>
```

Instead of using `ticket`, you can use the `path` parameter to state the full path of the view explicitly. When `path` is used, you do not also need the `name` parameter, which is usually a required parameter in Tableau JavaScript embed code:

Tableau Server on Windows Help

```
<script type="text/javascript" src-  
c="http://myserver/javascripts/api/viz_v1.js"></script>  
<object class="tableauViz" width="900" height="700" style-  
e="display:none;">  
    <param name="path" value-  
="tru-  
sted/9D1ObyqDQmSIOyQpKdy4Sw-  
w==:dg62gCsSE0QRARXNTOp6mlJ5/views/MyCoSales/SalesScoreCard" />  
</object>
```

Here's the same example, but for a multi-site server. Note that `/t/<site_id>` is used here:

```
<script type="text/javascript" src-  
c="http://myserver/javascripts/api/viz_v1.js"></script>  
<object class="tableauViz" width="900" height="700" style-  
e="display:none;">  
    <param name="path" value-  
="tru-  
sted/9D1ObyqDQmSIOyQpKdy4Sw-  
==:dg62gCsSE0QRARXNTOp-  
p6mlJ5/t/Sales/views/MyCoSales/SalesScoreCard" />  
</object>
```

Iframe Tag Example

```
<iframe src-  
="h-  
ttp://t-  
abserver-  
/trus-  
ted/9D1ObyqDQmSIOyQpKdy4Sw-  
==:dg62gCsSE0QRARXNTOp-  
p6mlJ5/views/workbookQ4/SalesQ4?:embed=yes" width="800"  
height="600"></iframe>
```

Optional: Configure Client IP Matching

By default, Tableau Server does not consider the client web browser IP address when it creates or redeems tickets. To change this, you need to do two things: specify an IP address using the `client_ip` parameter in the POST request that obtains the ticket, and follow the steps below to configure Tableau Server to enforce client IP address matching.

1. Open TSM CLI and type the following command:

```
tsm configuration set -k wgserver.extended_trusted_ip_
checking -v true
```

2. Then type the following command:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Test Trusted Authentication

The steps below provide a method you can use to test retrieving a trusted ticket from your web server. This simple test can help evaluate connectivity between the web server and Tableau Server, and whether or not trusted authentication has been configured correctly.

Important: The test code provided in this topic runs client-side in the browser to provide a quick, visual validation that trusted authentication is configured correctly on Tableau Server. If the client browser loading the html page is not on the trusted web server, you may have to temporarily trust the client IP. In practice, you should never trust client IP addresses as part of your trusted authentication configuration. All trusted IP addresses are able to request tickets as any user including your administrator. In a

production environment, all trusted authentication flows should run server-side, between Tableau Server and the trusted web server(s) only.

Because the test is run on a client browser, the test isn't an exact replica of the communication path in a production environment. After successfully running the test, we recommend that you then test requesting tickets for your users with a server-side post request for final verification.

An alternative testing method is to run a trusted ticket generator to test your configuration. The following URL references a trusted ticket generator that is not supported by Tableau. However the generator has been used by many customers to test their trusted ticket configuration: <https://github.com/mkannan-tsi/Trusted-Ticket-Generator>.

Step 1: Add a test user

Create a user on the Tableau Server that you can use to test trusted ticket functionality. See [Add Users to Tableau Server](#). Add that user to a site on the server, and set the user's site role to **Explorer**.

Step 2: Create a test HTML page

Paste the following code into a new .html file that you save on the Tableau Server machine where you're performing the test from. You can change the labels and style attributes as you prefer.

```
<html>
<head>
<title>Trusted Ticket Requester</title>
<script type="text/javascript">
  function submitForm(){
    document.getElementById('form1').action =
    document.getElementById('server').value + "/trusted";
  }

```

```

</script>
<style type="text/css">
  .style1 {width: 100%;}
  .style2 {width: 429px;}
  #server {width: 254px;}
</style>
</head>
<body>
<h3>Trusted Ticketer</h3>
<form method="POST" id="form1" onSubmit="submitForm()" >
  <table class="style1">
    <tr>
      <td class="style2">Username</td>
      <td><input type="text" name="username" value="" /></td>
    </tr>
    <tr>
      <td class="style2">Server</td>
      <td><input type="text" id="server" name="server" value-
e="https://" /></td>
    </tr>
    <tr>
      <td class="style2">Client IP (optional)</td>
      <td><input type="text" id="client_ip" name="client_ip"
value="" /></td>
    </tr>
    <tr>
      <td class="style2">Site (leave blank for Default site;
otherwise enter the site name)</td>
      <td><input type="text" id="target_site" name="target_
site" value="" /></td>
    </tr>
  </table>
</form>

```

Tableau Server on Windows Help

```
<tr>
  <td class="style2"><input type="submit" name="submittable"
value="Get Ticket" /></td>
  <td>&#160;</td>
</tr>
</table>
</form>
<h4>Be sure to add your IP as a Trusted IP address to the server-
</h4>
</body>
</html>
```

Step 3: Retrieve a trusted ticket from Tableau Server

The following procedure will return a trusted ticket from Tableau Server.

1. Open the web page that you created in the previous step.

Trusted Ticketer

Username	<input type="text"/>
Server	<input type="text"/>
Client IP (optional)	<input type="text"/>
Site (leave blank for Default site; otherwise enter the site name)	<input type="text"/>

Be sure to add your IP as a Trusted IP address to the server

This operation requires JavaScript, so the web browser might prompt you to allow scripts to run.

2. In the text boxes, enter the following:
 - **Username:** The test user that was created in Step 1.
 - **Server:** the address of your Tableau Server, e.g., `https://<server_name>`.

- **Client IP (optional):** The IP address of the user's computer, if it's configured for client trusted IP matching.
- **Site:** The name of the Tableau Server site that the test user is a member of.

3. Click **Get Ticket**. One of the following will be returned:

- **A unique ticket:** A trusted ticket is a string composed of a base64-encoded UUID and a 24-character random string, for example,
9D101xmDQmSIOyQpKdy4Sw== : dg62gCsSE0QRArXNTOp6mlJ5.
- **-1:** If the value, -1 is returned, the configuration contains an error. See Ticket Value of -1 Returned from Tableau Server.

Step 4: Test access with trusted ticket

Now that you have a ticket, you can use it to access content on Tableau Server.

Construct a URL with the unique ticket that you generated in the previous step to verify access with the trusted ticket. The URL syntax is different if you are accessing a Tableau Server with a single site vs a server that hosts multiple sites.

Default site server url

```
https://<server_name>/trusted/<unique_ticket>/views/<workbook_name>/<view_name>
```

Non-default site server url

```
https://<server_name>/trusted/<unique_ticket>/t/<site_name>/views/<workbook_name>/<view_name>
```

Variables in the URLs are indicated by angle brackets (< and >). All other syntax is literal.

Troubleshoot Trusted Authentication

This section includes some common issues and errors you might encounter when you're configuring trusted authentication.

A common source for trusted authentication errors are misconfiguration with a proxy server or load balancer. If your Tableau Server operates behind a reverse proxy server or a load

Tableau Server on Windows Help

balancer, see [Configure Tableau Server to work with a reverse proxy server and Add a Load Balancer](#).

Trusted authentication information is written to `ProgramData\Tableau\Tableau Server\data\tabsvc\logs\vizqlserver\vizql-*.log`.

To increase the logging level from `info` to `debug`, run the following commands:

```
tsm configuration set -k vizqlserver.trustedticket.log_level -v
debug
tsm pending-changes apply
```

To test your trusted authentication deployment, see [Test Trusted Authentication](#).

See also

For more troubleshooting information for specific errors, see the following topics accessible from the **Other articles in this section** below:

Request for ticket by web server

- Ticket Value of -1 Returned from Tableau Server
- HTTP 401 - Not Authorized
- HTTP 404 - File Not Found
- Invalid User (SharePoint or C#)

Viewer redeeming ticket

- Attempting to Redeem the Ticket from the Wrong IP Address
- Cookie Restriction Error

Navigating between several embedded views

- An error occurred communicating with the server (403)

Ticket Value of -1 Returned from Tableau Server

Tableau Server returns -1 for the ticket value if it cannot issue the ticket as part of the trusted authentication process. Before troubleshooting this scenario, be sure to set the log level for

trusted authentication to `debug` as specified in Troubleshoot Trusted Authentication.

The exact reason for this message is written to the `vizqlserver_node*-*.log.*` files in the following folder:

```
ProgramData\Tableau\Tableau Server\data\tabsvc\logs\vizqlserver
```

Here are some things to confirm:

- **All web server host names or IP addresses are added to trusted hosts**

The log error, "Invalid request host: <ip_address>" may indicate that the IP address or host name for the computer sending the POST request is not in the list of trusted hosts on Tableau Server. See Add Trusted IP Addresses or Host Names to Tableau Server to learn how to add IP addresses or host names to this list.

- **IP addresses are IPv4**

If you are using IP addresses to specify trusted hosts, they must be in Internet Protocol version 4 (IPv4) format. An IPv4 address looks like this: 123.456.7.890. IPv6 addresses (for example, fe12::3c4a:5eab:6789:01c%34) are not supported as a way of inputting trusted hosts.

- **Username in POST request is a valid Tableau Server user**

The username you send in the POST request must be a licensed Tableau Server user. You can see a list of users by signing in to Tableau Server as an administrator.

The following log errors indicate a user POST issue:

- "Missing username and/or client_ip"
- "Invalid user: <username>"
- "Unlicensed user is not allowed: <username>"

Username in POST request includes domain

Tableau Server on Windows Help

If Tableau Server is configured to use Local Authentication, the username that you send in the POST can be a simple string. However, if the server is configured for Active Directory you must include the domain name with the user name (domain\username). For example, the username parameter might be: `username=dev\jsmith`. A common error log for this scenario is `"Invalid user: <username>".`

- **Content-Type is specified**

If you are designing an ASP.NET or C# application, you need to declare the content type in your HTTP request. For example:

```
http.setRequestHeader("Content-Type", "application/x-www-form-urlencoded; charset=UTF-8")
```

If you do not specify content type and Tableau Server returns a -1, the log files contain the error: `"missing username and/or client_ip"`.

HTTP 401 - Not Authorized

If you receive a **401- Not Authorized error**, it could be for one of the following reasons:

- You may have configured Tableau Server to use Active Directory with SSPI. If your web server uses SSPI, you do not need to set up trusted authentication. You can embed views and your users will have access to them as long as they are licensed Tableau server users and members of your Active Directory. For more information, see `tsm authentication sspi <commands>`.

Note: SSPI can only be configured on Tableau Server for Windows.

- Or a **302- Redirect error** after you have deployed Tableau Server 2021.4, then it's likely the trusted ticket code you have written to construct the URL for the client has not been updated to account for the two-part ticket URL format. For more information, see [Get a Ticket from Tableau Server](#).

HTTP 404 - File Not Found

You may receive this error if your program code references a Tableau Server URL that does not exist. For example, your web server may construct an invalid URL that cannot be found when the webpage tries to retrieve it.

Another cause for this error is if you did not enter the trusted web servers as specified in Add Trusted IP Addresses or Host Names to Tableau Server. If you have already entered the trusted web servers, verify that the IP addresses or host names are correct.

Invalid User (SharePoint or C#)

You may encounter this error if you've configured Tableau Server for trusted authentication.

The example code for the SharePoint .dll references the following GET request:

```
SPContext.Current.Web.CurrentUser.Name
```

The above request will return the display name of the current Windows Active Directory user. If you want to use the login ID, then you will need to change the code to:

```
SPContext.Current.Web.CurrentUser.LoginName
```

After you make the change, recompile the SharePoint .dll.

Attempting to Redeem the Ticket from the Wrong IP Address

When you've configured Tableau Server for trusted authentication, you may encounter issues with redeeming the ticket.

This issue can occur when Tableau Server is configured to enforce client IP address matching. Because the client web browser IP address is not considered by default when redeeming the ticket, make sure that the client's web browser IP address that is sent in the POST request to Tableau Server is the same as when the browser tries to retrieve the embedded view.

Tableau Server on Windows Help

For example, in the Trusted Authentication diagram, if the **POST request in step 3** sends the parameter `client_ip=74.125.19.147`, then the **GET request in step 5** must come from that same IP address.

For more information, see [Optional: Configure Client IP Matching](#) to learn how to configure Tableau Server to enforce client IP address matching.

Cookie Restriction Error

When a user signs in to Tableau Server, a session cookie is stored in their local browser. The stored cookie is how Tableau Server maintains that the signed in user has been authenticated and can access the server. Because the cookie is set with the same domain or sub-domain as the browser's address bar, it is considered a first-party cookie. If a user's browser is configured to block first-party cookies, they will be unable to sign in to Tableau Server.

When a user signs in to Tableau Server via an embedded view, or in an environment where trusted authentication has been configured, the same thing happens: a cookie is stored. In this case, however, the browser treats the cookie as a third-party cookie. This is because the cookie is set with a domain that's different from the one shown in the browser's address bar. If a user's web browser is set to block third-party cookies, authentication to Tableau Server will fail. To prevent this from occurring, web browsers must be configured to allow third-party cookies.

An error occurred communicating with the server (403)

If Tableau Server is configured for trusted authentication, you may receive this error after opening a new view in a browser and attempting to navigate back to views you'd opened earlier.

Tableau Server provides protection against unauthorized reuse of VizQL sessions through the tsm configuration set `Options vizqlserver.protect_sessions`, which is set to `true` by default. Because Tableau Server is configured for trusted authentication, you might not need this level of protection. To disable this option, you can use tsm configuration set `Options` to change `vizqlserver.protect_sessions` to `false`.

Personal Access Tokens

Personal access tokens (PATs) provide Tableau Server users the ability to create long-lived authentication tokens. The tokens allow users to run automation with Tableau REST APIs without requiring hard-coded credentials or interactive signin. More information about using personal access tokens with Tableau REST APIs is at [Signing In and Out \(Authentication\)](#).

Personal access tokens are not used for generic client access to the Tableau Server web interface, TSM, or tabcmd interfaces.

We recommend creating personal access tokens for automated scripts and tasks that are created with Tableau REST API:

- **Improve security:** Personal access tokens reduce risk in the event credentials are compromised. In the case where Tableau Server uses Active Directory or LDAP as an identity store, you can reduce the scope of credential compromise by using a personal access token for automated tasks. In this case, using an application-specific token doesn't expose the broader system in the event that automation or script files are compromised. If a token gets compromised or is used in automation that is failing or posing a risk, you can just revoke the token. You do not need to rotate or revoke the user's credentials.
- **Audit and track:** As an administrator, you can review Tableau Server logs to track when a token is used, what sessions are created from that token, and the actions that are performed in those sessions. You can also determine if a session and the related tasks were performed from a session that was generated from a token or from an interactive signin.
- **Manage automation:** A token can be created for each script or task that is run. This allows you to silo and review automation tasks across your organization. Additionally, by using tokens then password resets or metadata changes (username, email, etc.) on user accounts will not disrupt automation as it would when credentials are hard-coded into the scripts.

Understand personal access tokens

When a token is created, it is hashed then stored in the repository. After the token is hashed and stored, the original token is deleted. Users are instructed to copy the token to a safe

Tableau Server on Windows Help

place and to handle it as they would a password. When the token is used at run-time, Tableau Server hashes the token presented by the user and compares it to the hashed value stored in the repository. If a match is made, then an authenticated session is started.

Note: One personal access token is required per concurrent request. Signing in again with the same access token, whether at the same site or a different site, will terminate the previous session and result in an authentication error.

In the context of authorization, Tableau Server handles the authenticated session with same permissions and rights that the user has as an interactive user.

Server administrator impersonation

Beginning with version 2021.1, you can enable Tableau Server personal access token impersonation. In this scenario, access tokens that are created by server administrators can be used for [user impersonation](#) when using the Tableau Server REST API. Impersonation is useful in scenarios where you are embedding end-user-specific Tableau content within your application. Specifically, impersonation access tokens allow you to build applications that query as a given user and retrieve content that the user is authorized for within Tableau Server, without hard-coding any credentials.

For more information, see the Tableau REST API Help section, [Impersonating a User](#).

Enable Tableau Server to accept personal access tokens during impersonation sign-in requests

By default, Tableau Server does not allow impersonation for server administrator personal access tokens. You must enable the server-wide setting by running the following commands.

```
tsm authentication pat-impersonation enable [global options]
```

```
tsm pending-changes apply
```

Important: After you have run the commands, all personal access tokens created by server administrators (including preexisting tokens) can be used for impersonation. To bulk-revoke all existing server administrator personal access tokens, you can post the `DELETE /api/{api-version}/auth/serverAdminAccessTokens` URI. See the Tableau REST API Help section, [Impersonating a User](#).

Create tokens

Users with accounts on Tableau Server can create, manage, and revoke personal access tokens on the **My Account Settings** page. See [Manage Your Account Settings](#) in the *Tableau Desktop and Web Authoring Help* for more information.

Users must create their own personal access tokens. Administrators cannot create tokens for users.

Token expiry

Personal access tokens will expire if they are not used after 15 consecutive days. If they are used more frequently than every 15 days, an access token will expire after 1 year. After a year, you must create a new token. Expired personal access tokens will not display on the **My Account Settings** page.

You can change refresh token expiry time span using the `refresh_token.absolute_expiry_in_seconds` option with the `tsm configuration set` command.

Revoke users' tokens

Users are able to revoke their own tokens on the **My Account Settings** page. As an administrator, you can also revoke personal access tokens.

1. Sign in to the Tableau Server Admin Area as a site administrator or server administrator.

Tableau Server on Windows Help

2. Locate the user whose token you want to revoke. For more information about navigating Server Admin pages and locating users, see [View, Manage, or Remove Users](#).
3. Click the user's name to open their profile page.
4. On the user's profile page, click the **Settings** tab.
5. In the **Personal Access Tokens** section, identify the token that you want to revoke and then click **Revoke**.
6. On the verification pop-up, click **Delete**.

Track and monitor usage

All token-related actions are logged in the Tableau Server Application Server (vizportal) service.

To locate token-related activities, filter log entries containing the string, `RefreshTokenService`.

Tokens are stored in this format `:Token Guid: <TokenID(Guid)>`, where the `TokenID` is a base64 encoded string. The token secret is not included in the logs. For example:

```
Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1caf1c700).
```

The following is an example snippet of two log entries. The first shows how a user is mapped to a token. The second shows a refresh event for the same token:

```
RefreshTokenService - Issued refresh token to the following user: jsmith. Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1caf1c700)
```

```
RefreshTokenService - Redeemed refresh token. Token Guid: 49P+CxmARY6A2GHxyvHHAA== (e3d3fe0b-1980-458e-80d8-61f1caf1c700)
```

To locate key operations, filter log entries containing the string, `OAuthController`.

Register EAS to Enable SSO for Embedded Content

As a Tableau Server admin, you can register an external authorization server (EAS) to establish a trust relationship between Tableau Server and the EAS. By establishing a trust

relationship, you're able to provide your users a single sign-on (SSO) experience to Tableau content embedded in your custom applications through the identity provider (IdP) you've already configured for Tableau Server. When embedded Tableau content is loaded in your custom application, a standard OAuth flow is used. After users successfully sign in to the IdP, they are then automatically signed in to Tableau Server.

Follow the steps described below to register your EAS with Tableau Server.

Important: Some of the procedures in this topic require configuration with third party software and services. We've made a best effort to verify the procedures to enable the EAS feature on Tableau Server. However, third-party software and services might change or your organization might differ. If you encounter issues, refer to your third-party documentation for authoritative configuration details and support.

Step 1: Before you begin

To register an EAS with Tableau Server, you must have an EAS already configured. In addition, the EAS must send a valid JSON web token (JWT) that contains the registered claims and header listed in the table below.

Claim	Description or required value
"iss" (Issuer)	Unique issuer URI that identifies the trusted EAS and its signing key.
"alg" (Algorithm)	JWT signing algorithm. Supported algorithm names are listed in the Class JWSSAlgorithm page in the javadoc.io documentation. The signing algorithm can be configured using the <code>vizportal.oauth.external_authorization_server.blocklisted_jws_algorithms</code> command.
"sub" (Subject)	Tableau Server username of the authenticated user.
"aud" (Audience)	Value must be: "tableau"
"exp" (ExpirationTime)	A valid JWT must not be expired. The expiration time of the JWT must be within the configured maximum validity period.

Tableau Server on Windows Help

	Maximum validity period can be configured using <code>viz-portal.oauth.external_authorization_server.max_expiration_period_in_minutes</code> command.
"jti" (JWT ID)	The JWT ID claim provides a unique identifier for the JWT and is case sensitive.
"scp" (Scope)	Supported values include: <code>"tableau:views:embed"</code> <code>"tableau:metrics:embed"</code> Notes: <ul style="list-style-type: none">• Values must be passed as a list type.• For <code>tableau:views:embed</code>, the scope respects users' permissions already configured in Tableau Server and allows users to interact with the tools in the embedded view if available in the original view.• We recommend the embed code exclude the toolbar parameter. For more information see Known issues below.

Note: The JWT claims above are documented in the [Registered Claim Names](#) section in the documentation distributed by the Internet Engineering Task Force (IETF) organization.

Step 2: Register your EAS with Tableau Server

By registering your EAS with Tableau Server, you establish a trust relationship between the EAS and Tableau Server. This means when users access Tableau content embedded in your custom application, they are redirected to authenticate with the IdP. The EAS generates the authentication token, which is passed to Tableau Server for verification. After the trust relationship is verified, access to the embedded content is granted to the users.

After registering the EAS, the trust established trust relationship applies to all sites on Tableau Server.

Note: Some EAS support the option to display a consent dialog that asks for users' approval for the application to access Tableau content. To ensure the best experience for your users, we recommend you configure your EAS to automatically consent to the custom application's request on users' behalf.

Use the TSM web interface

1. As a Tableau Server admin, sign in to the Tableau Services Manager (TSM) web UI. For more information, see [Sign in to Tableau Services Manager Web UI](#).
2. Navigate to **User Identity & Access > Authorization Server**, and do the following:
 - a. Select the **Enable OAuth access for embedded content** check box.
 - b. In the **Issuer URL** text box, paste the issuer URL of the EAS.
 - c. Click the **Save Pending Changes** button.

User Identity & Access
Configure user access to Tableau Server and manage user identities. [Learn more](#)

Identity Store Authentication Method Trusted Authentication **Authorization Server**

Register External Authorization Server
Establish trusted relationship with an external authorization server. [Learn more](#)

Enable OAuth access for embedded content

Server-wide trust

Enter information about the external authorization server that will generate the access token.

Issuer URL

JWKS URI

3. When finished, do the following:
 - a. In the upper-right corner of the page, click the **Pending Changes** button.
 - b. In the bottom-right corner of the page, click the **Apply Changes and Restart**

button to stop and restart Tableau Server.

Use the TSM CLI

1. Open a command prompt as an admin on the initial node (where TSM is installed) in the cluster.
2. Run the following commands:

```
tsm configuration set -k vizportal.oauth.external_authorization.enabled -v true
tsm configuration set -k vizportal.oauth.external_authorization_server.issuer -v "<issuer_url_of_EAS>"
tsm restart
```

Step 3: Embedding next steps

After configuring Tableau Server to use your EAS, you must add embed code to your custom application. Ensure that you include the valid JWT generated by your EAS, as described in Step 1, in the web component that your custom application calls.

For more information about embedding Tableau content, see one or both of the following:

- Embed metrics, see [Embed Metrics into Webpages](#) topic in the Tableau Help.
- Embed Tableau views and metrics using the [Tableau Embedding API v3](#).

Note: For users to successfully authenticate when they access embedded content, browsers must be configured to allow third-party cookies or use partitioned storage. Partitioned storage is on by default for Mozilla Firefox and can be enabled on Google Chrome browsers.

Known issues

There are a couple of known issues when using connected apps that will be addressed in a future release.

- **Toolbar features:** When embedded content has the toolbar parameter defined, not all toolbar features will work. To work around this issue, we recommend you hide the toolbar parameter like in the example below.

```
<tableau-viz id='tab-viz' src='https://<your_server>/t/<y-
our_site>/...'
      toolbar='hidden'>
</tableau-viz>
```

- **Published data sources:** Published data sources set to **Prompt User** for database credentials will not display. To work around this issue, if possible, we recommend data source owners embed their database credentials instead.

Troubleshoot

When embedded content fails to display in your custom application, you can use a browser's developer tools to inspect and identify error codes that might be associated with the EAS feature enabled on Tableau Server.

Refer to the table below to review the description of the error code and potential resolution.

Error code	Summary	Description	Potential resolution or explanation
5	SYSTEM_USER_	Tableau user	To resolve this issue, verify the

Tableau Server on Windows Help

	NOT_FOUND	could not be found	'sub' (Subject) claim value in the JWT is "username" for Tableau Server. This value is case sensitive.
16	LOGIN_FAILED	Login failed	<p>This error is typically caused by one of the following claim issues in the JWT:</p> <ul style="list-style-type: none"> • The 'exp' (ExpirationTime) exceeds the default maximum validity period. To resolve this issue, review registered claims required for a valid JWT and ensure the correct value is used. To change the maximum validity period, you can use the viz-portal.oauth.external_authorization_server.max_expiration_period_in_minutes command. • The 'sub' (Subject) is calling an unknown user. To resolve this issue, verify the 'sub' claim is "username". This value is case sensitive.
10081	COULD_NOT_RETRIEVE_IDP_METADATA	Missing EAS metadata endpoint	To resolve this issue, verify the EAS is configured correctly and the correct issuer is being called.
10082	AUTHORIZATION_SERVER_ISSUER_NOT_SPECIFIED	Missing issuer	To resolve this issue, verify the correct issuer is being called. To

			change the issuer URL, you can use the <code>vizportal.oauth.external_authorization_server.issuer</code> command.
10083	BAD_JWT	JWT header contains issues	<p>This error is typically caused by one of the following issues with the JWT header:</p> <ul style="list-style-type: none"> • The 'secret key' (Kid) or 'clientId' (Issuer) claims are missing from the JWT header. To resolve this issue, ensure this information is included. • The JWT is unsigned or encrypted. Tableau does not support unsigned or encrypted JWTs.
10084	JWT_PARSE_ERROR	JWT contains issues	<p>To resolve this issue, verify following:</p> <ul style="list-style-type: none"> • The 'aud' (Audience) value referenced in the JWT uses the "tableau" value. This value is case sensitive. • The 'aud' (Audience), 'sub' (Subject), 'jti' (JWT ID) are included in the JWT.
10085	COULD_NOT_FETCH_JWT_KEYS	JWT could not find keys	<p>Could not find the secret.</p> <p>To resolve this issue, verify the correct issuer is being called. To change the issuer URL, you can use the <code>vizportal.oauth.external_</code></p>

			authorization_server.issuer command.
10087	BLOCKLISTED_JWS_ALGORITHM_USED_TO_SIGN	Issue with the JWT signing algorithm	To resolve the issue, you can remove the signing algorithm. For more information, see vizportal.oauth.external_authorization_server.blocklisted_jws_algorithms.
10088	RSA_KEY_SIZE_INVALID	Issue with JWT signing requirements	To resolve this issue, verify with the EAS or IdP the JWT is being signed with an RSA key size of 2048.
10091	JTI_ALREADY_USED	Unique JWT required	The JWT has already been used in the authentication process. To resolve this issue, the EAS or IdP must generate a new JWT.

Data Connection Authentication

You can configure data connection authentication using Kerberos, OAuth, and single sign-on.

More information

- [Setting an Oracle Connection to Use TNSNames.ora or LDAP.ora](#) (Tableau Support)

Enable Kerberos Delegation

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

Supported data sources

Tableau supports Kerberos delegation with the following data sources:

- Cloudera: Hive/Impala
- Denodo
- Hortonworks
- MSAS
- Oracle
- PostgreSQL
- Spark
- SQL Server
- Teradata
- Vertica
- TIBCO

Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server information store must be configured to use LDAP - Active Directory.
- The computer where Tableau Server is installed must be joined to Active Directory domain.
- MIT KDC is not supported.
- A domain account must be configured as the Run As service account on Tableau Server. See [Change the Run As Service Account](#). If your users are in a different Active Directory domain than Tableau Server and the data source, then domain trust must be configured. See [Domain Trust Requirements for Active Directory Deployments](#).
- Delegation configured. Grant delegation rights for the Run As service account to the target database Service Principal Names (SPNs). The Run As service account is delegated authority to access resources on behalf of the initiating source user.

Tableau Server on Windows Help

- If you are configuring delegation on Tableau Server 2020.2 or later with an Oracle data source using a JDBC-based connector, see [Enable Kerberos Delegation for JDBC Connectors](#). Starting in Tableau 2020.2, the Oracle connector uses JDBC.

Web authoring

There are two web authoring scenarios that do not support Kerberos delegation: "Connect to data on the web" and "Create datasource on the web." feature does not support delegation yet. Specifically, if you create a datasource that uses Kerberos on the with web authoring, the data source will use Run As service account authentication. If you want to use Kerberos delegation to create a datasource, then you must publish with Tableau Desktop. For more information on Run As service account, see [Data Access with the Run As Service Account](#).

Configuration process

This section provides an example of the process to enable Kerberos delegation. The scenario also includes example names to help describe the relationships between the configuration elements.

1. On all nodes in Tableau Server, configure the Run As User to act as part of the operating system. For more information, see [Enable Run As Service Account to Act as the Operating System](#).
2. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the delegation/Run As account is `tabsrv@example.com`.

The account must be configured with Active Directory User and Computers on a Windows Server that is connected to the user domain:

- Open the **Properties** page for the Run As service account, click the **Delegation** tab and select **Trust this user for delegation to specified services only** and **Use any authentication protocol**.

3. Run the following TSM command to enable Kerberos delegation:

```
tsm configuration set -k wgservers.delegation.enabled -v true
```

4. Run the following TSM command apply the changes to Tableau Server:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

5. (Optional) Configure Tableau Server to use MIT Kerberos principal format.

By default, Tableau Server generates Kerberos principals using the Active Directory short name. For example, if Tableau Server performs Kerberos delegation for a user in `EXAMPLE.COM`, with a short name `EXAMPLE`, then the principal name will be: `user@example`.

If your database is running on Linux, you may need to adjust the `auth_to_local` mapping in `krb5.conf`. For information about editing the `krb5.conf` file, see [Kerberos delegation multi-domain configuration](#). Alternatively, you can configure Tableau Server to use the full domain name for Kerberos principals by running the following commands:

```
tsm configuration set -k native_api.protocol_transition_added_short_domain -v false --force-keys
tsm configuration set -k native_api.protocol_transition_uppercase_realm -v true --force-keys
tsm pending-changes apply
```

6. Enable delegation for data connections:

Tableau Server on Windows Help

- **SQL Server**—See [Enabling Kerberos Delegation for SQL Server](#) in the Tableau Community.
- **MSAS**—See [Enabling Kerberos Delegation for MSAS](#) in the Tableau Community.
- **PostgreSQL**—See [Enabling Kerberos Delegation for PostgreSQL](#) in the Tableau Community.
- **Teradata**—See [Enabling Kerberos Delegation for Teradata](#) in the Tableau Community.
- **Oracle**—See [Enable Kerberos Delegation for Oracle](#) in the Tableau Community.
- **Cloudera**—See [Enable Kerberos Delegation for Hive/Impala](#) in the Tableau Community.
- **Vertica**—See [Enabling Kerberos Delegation for Vertica](#) in the Tableau Community.
- **TIBCO**—See [Section 4, Kerberos SSO Configuration for TDV on Windows](#) in the TIBCO Professional Services guide, *TDV Integration with Kerberos*.

Troubleshoot Kerberos

Enable Kerberos Delegation for JDBC Connectors

As of version 2020.2, Tableau Server supports Kerberos delegation for JDBC connectors.

Kerberos delegation enables Tableau Server to use the Kerberos credentials of the viewer of a workbook or view to execute a query on behalf of the viewer. This is useful in the following situations:

- You need to know who is accessing the data (the viewer's name will appear in the access logs for the data source).
- Your data source has row-level security, where different users have access to different rows.

Supported data sources

Tableau supports JDBC Kerberos RunAs authentication with the following data sources:

- Oracle
- PostgreSQL

If you are configuring delegation with an Oracle data source using a JDBC-based connector, then follow the procedure in this topic. Alternatively, if the connector you are running on Tableau Server uses a native driver, then follow the procedure in the help topic, [Enable Kerberos Delegation](#).

Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server information store must be configured to use LDAP - Active Directory.
- MIT KDC is not supported.

Note: You do not need to enable the Run As account to act as the operating system.

Configuration process

This section provides an example of the process to enable Kerberos delegation.

Tableau Server on Windows Help

1. Tableau Server will need a Kerberos service ticket to delegate on behalf of the user that is initiating the call to the database. You must create a domain account that will be used to delegate to the given database. This account is referred to as the Run As service account. In this topic, the example user configured as the Run As account is `tab-srv@EXAMPLE.COM`.

The account must be configured for delegation in Active Directory:

- a. On a Windows Server that is connected to the user domain, open Active Directory Users and Computers.
 - b. On the **Properties** page for the Run As service account, click the **Delegation** tab and select **Trust this user for delegation to specified services only** and **Use any authentication protocol**.
2. Create a keytab file for the Run As service account.

This following example uses the ktab tool that is provided with the JDK . You can download the tool at [AdoptOpenJDK](#). When using ktab to create the keytab, use a logon principal in UPN format (for example, `service@EXAMPLE.COM`), and not a service principal name (for example, `HTTP/service.example.com@EXAMPLE.COM`). You may also generate keytabs with the ktpass utility, in which case you can use either style of principal name.

```
<JDK_HOME>/bin/ktab -k E:/tmp/tabsrv.keytab -a tab-srv@EXAMPLE.COM
```

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

3. Copy the keytab into the Tableau Server data directory and verify that the Run As service account can access and read the keytab file. By default the Tableau Server data directory is at `C:\ProgramData\Tableau`. If you are running Tableau Server in a distributed deployment, perform this step on each node in the cluster.
4. Create a `krb5.conf` file, and install in `C:\Windows` on all Tableau Server nodes.

If you already have a krb5.ini file deployed on computers in your organization, copy that file and use it for Tableau Server. For more information, see the MIT Kerberos Documentation topic, [krb5.conf](#).

To change the location of Kerberos configuration file run the following TSM command:

```
tsm configuration set -k native_api.kerberos_config_path -
-force-keys -v "C:\temp\krb5.ini"
```

The following is an example of a krb5.conf file. Tableau Support cannot assist with creating krb5.conf.

```
[libdefaults]
forwardable = true
default_realm = EXAMPLE.COM
default_tkt_enctypes = rc4-hmac
default_tgs_enctypes = rc4-hmac

[realms]
EXAMPLE.COM = {
kdc = kdc.example.com
admin_server = kdc.example.com
}

[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

5. Run the following TSM commands to enable Kerberos delegation, set the delegation service account, and associate the keytab file with the service account:

```
tsm configuration set -k wgserver.delegation.enabled -v
true
tsm configuration set -k native_api.datasource_
```

Tableau Server on Windows Help

```
impersonation_runas_principal -v tabsrv@EXAMPLE.COM
tsm configuration set -k native_api.datasource_impersonation_runas_keytab_path -v <path-to-file>kerberos.keytab
tsm configuration set -k native_api.protocol_transition_ad_short_domain -v false
tsm configuration set -k native_api.protocol_transition_uppercase_realm -v true
```

In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys` parameter appended to the argument.

6. Run the following TSM command apply the changes to Tableau Server:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

Enable Run As Service Account to Act as the Operating System

To use Kerberos delegation with Tableau Server, you must configure the Run As service account account to act as the operating system on each Tableau Server node.

1. On the computer that is running Tableau Server, select **Start > Control Panel > Administrative Tools > Local Security Policy**.
2. In the Local Security Settings window, expand **Local Policies**, click **User Rights Assignments**, and then right-click **Act as part of the operating system** and select **Properties**.

3. In the Act as part of the operating system Properties window, click **Add User or Group**.
4. Type the <domain>\<username> for the Tableau Server Run As service account (for example: MYCOMPANY\tableau_server), and then click **Check Names**.
5. When the account resolves correctly, it is underlined. Click **OK**.
6. Click **OK** to close the Local Security Policy windows.

Enable Kerberos Run As Authentication for JDBC Connectors

As of version 2020.2, Tableau Server supports Kerberos authentication for JDBC connectors.

Tableau Server on Windows Help

You can configure Tableau Server to use a Kerberos service account to access a database. In this scenario, Tableau Server connects to databases with a service account, also referred to as a "Run As service account". This scenario is referred to as "Run As authentication"

See [Run As Service Account](#).

To use Run As authentication on Tableau Server you must first create a workbook or data-source in Tableau Desktop that uses integrated authentication. When you publish to Tableau Server you will get the option to use Run As authentication. When creating a datasource with Web Authoring, Run As authentication is the default operation if you select integrated authentication.

Supported data sources

Tableau supports JDBC Kerberos delegation with the following data source:

- Oracle

If you are configuring Run As authentication for an Oracle data source using a JDBC-based connector, then follow the procedure in this topic. Alternatively, if the connector you are running on Tableau Server uses a native driver, you do not have to follow the steps in this topic. Instead, follow the steps to create a Run As service account as documented in the topic, [Change the Run As Service Account](#).

Requirements

Kerberos delegation requires Active Directory.

- The Tableau Server information store must be configured to use LDAP - Active Directory.
- MIT KDC is not supported.

Configuration process

This section provides an example of the process to enable Kerberos RunAs authentication.

1. Create a keytab file for the Run As service account.

This following example uses the `ktab` tool that is provided with the JDK . You can download the tool at [AdoptOpenJDK](#). When using `ktab` to create the keytab, use a logon principal in UPN format (for example, `service@EXAMPLE.COM`), and not a service principal name (for example, `HTTP/ser-vice.example.com@EXAMPLE.COM`). You may also generate keytabs with the `ktpass` utility, in which case you can use either style of principal name.

```
<JDK_HOME>/bin/ktab -k E:/tmp/tabsrv.keytab -a tabsrv@EXAMPLE.COM
```

Tableau Server will use the Run As service account and the associated keytab to authenticate and make a direct connection to the database.

2. Copy the keytab into the Tableau Server data directory and verify that the Run As service account can access and read the keytab file. By default the Tableau Server data directory is at `C:\ProgramData\Tableau`. If you are running Tableau Server in a distributed deployment, perform this step on each node in the cluster.
3. Run the following TSM commands to set the Run As service account and the path to the keytab file:

```
tsm configuration set -k native_api.datasource_runas_principal -v tabsrv@EXAMPLE.COM
tsm configuration set -k native_api.datasource_runas_keytab_path -v <path-to-keytab>
```

In some cases, TSM may return an error mentioning `--force-keys`. If you get this error, run the command again with the `--force-keys` parameter appended to the argument.

4. Create a `krb5.conf` file, and install in `C:\Windows` on all Tableau Server nodes.

Tableau Server on Windows Help

If you already have a krb5.ini file deployed on computers in your organization, copy that file and use it for Tableau Server. For more information, see the MIT Kerberos Documentation topic, [krb5.conf](#).

To change the location of Kerberos configuration file run the following TSM command:

```
tsm configuration set -k native_api.kerberos_config_path --force-keys -v "C:\temp\krb5.ini"
```

The following is an example of a krb5.conf file. Tableau Support cannot assist with creating krb5.conf.

```
[libdefaults]
forwardable = true
default_realm = EXAMPLE.COM
default_tkt_enctypes = rc4-hmac
default_tgs_enctypes = rc4-hmac
```

```
[realms]
EXAMPLE.COM = {
kdc = kdc.example.com
admin_server = kdc.example.com
}
```

```
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

5. Run the following TSM command apply the changes to Tableau Server:

```
tsm pending-changes apply
```

If the pending changes require a server restart, the `pending-changes apply` command will display a prompt to let you know a restart will occur. This prompt displays even if the server is stopped, but in that case there is no restart. You can

suppress the prompt using the `--ignore-prompt` option, but this does not change the restart behavior. If the changes do not require a restart, the changes are applied without a prompt. For more information, see `tsm pending-changes apply`.

OAuth Connections

Tableau Server supports OAuth for a number of different connectors. In many cases, OAuth functionality does not require additional configuration on Tableau Server.

From Tableau, when users sign in to data with a connector that uses OAuth, users are redirected to the authentication provider's sign-in page. After user provide their credentials and authorize Tableau to access their data, the authentication provider sends Tableau an **access token** that uniquely identifies Tableau and the users. This access token is used to access data on users' behalf. For more information, see [Overview of the OAuth process](#) below.

Using OAuth-based connections provides the following benefits:

- **Security:** Your database credentials are never known to or stored in Tableau Server, and the access token can be used only by Tableau on behalf of users.
