# Table of Contents

<b>What is AWS Glue?</b> .....	<b>1</b>
AWS Glue features .....	2
Learning about innovations in AWS Glue .....	3
Getting started with AWS Glue .....	3
Accessing AWS Glue .....	4
Related services .....	4
<b>How it works</b> .....	<b>5</b>
Serverless ETL jobs run in isolation .....	6
Concepts .....	7
AWS Glue terminology .....	8
Components .....	11
AWS Glue console .....	12
AWS Glue Data Catalog .....	12
AWS Glue crawlers and classifiers .....	13
AWS Glue ETL operations .....	13
Streaming ETL in AWS Glue .....	13
The AWS Glue jobs system .....	14
Visual ETL components .....	14
AWS Glue for Spark and AWS Glue for Ray .....	20
What is AWS Glue for Ray? .....	21
Converting semi-structured schemas to relational schemas .....	22
AWS Glue types .....	24
AWS Glue Data Catalog Types .....	24
Types in AWS Glue with Spark scripts .....	24
AWS Glue Crawler Types .....	25
<b>Getting started</b> .....	<b>26</b>
Overview of using AWS Glue .....	26
Setting up IAM permissions .....	28
Next steps .....	33
IAM permissions for using the visual ETL .....	33
Getting started with notebooks in AWS Glue Studio .....	44
Getting started with the AWS Glue Data Catalog .....	47
Overview .....	47
Step 1: Create a database .....	47

Step 2. Create a table .....	49
Next steps .....	50
Setting up network access to data stores .....	53
Setting up a VPC to connect to PyPI for AWS Glue .....	54
Setting up DNS in your VPC .....	56
Setting up encryption .....	57
Setting up networking for development .....	61
Setting up your network for a development endpoint .....	61
Setting up Amazon EC2 for a notebook server .....	63
<b>Data discovery and cataloging .....</b>	<b>65</b>
Populating the Data Catalog .....	67
Using an AWS Glue crawler .....	68
Defining metadata manually .....	166
Integrating with other AWS services .....	184
Data Catalog settings .....	186
Populating and managing transactional tables .....	189
Creating Iceberg tables .....	189
Optimizing Iceberg tables .....	193
Managing the Data Catalog .....	205
Updating the schema and adding new partitions .....	206
Optimizing query performance using column statistics .....	213
Encrypting your Data Catalog .....	225
Securing your Data Catalog using Lake Formation .....	226
Accessing the Data Catalog .....	226
Data Catalog best practices .....	227
AWS Glue Schema Registry .....	228
Schemas .....	229
Registries .....	231
Schema versioning and compatibility .....	232
Open source Serde libraries .....	237
Quotas of the Schema Registry .....	237
How it works .....	238
Getting started .....	240
Integrating with AWS Glue Schema Registry .....	262
Migrating to AWS Glue Schema Registry .....	288
<b>Connecting to data .....</b>	<b>290</b>

AWS Glue connection properties .....	291
Required connection properties .....	292
JDBC connection properties .....	293
MongoDB and MongoDB Atlas connection properties .....	298
Salesforce connection properties .....	298
Snowflake connection .....	299
Vertica connection .....	300
SAP HANA connection .....	301
Azure SQL connection .....	302
Teradata Vantage connection .....	302
OpenSearch Service connection .....	303
Azure Cosmos connection .....	304
SSL connection properties .....	305
Kafka connection properties for authentication .....	307
Google BigQuery connection .....	308
Vertica connection .....	300
Storing connection credentials in AWS Secrets Manager .....	309
Adding an AWS Glue connection .....	310
Connecting to Redshift .....	310
Connecting to Azure Cosmos DB .....	315
Connecting to Azure SQL .....	318
Connecting to BigQuery .....	321
Connecting to MongoDB .....	325
Connecting to OpenSearch Service .....	329
Connecting to Salesforce .....	332
Connecting to SAP HANA .....	344
Connecting to Snowflake .....	348
Connecting to Teradata .....	352
Connecting to Vertica .....	355
Using connectors and connections .....	359
Connecting to data sources .....	387
Adding a JDBC connection using your own JDBC drivers .....	395
Testing an AWS Glue connection .....	399
Configuring AWS calls to go through your VPC .....	400
Connecting to a JDBC data store in a VPC .....	401
Accessing VPC Data Using elastic network interfaces .....	402

Elastic network interface properties .....	403
Using a MongoDB or MongoDB Atlas connection .....	403
Crawling an Amazon S3 data store using a VPC endpoint .....	404
Prerequisites .....	404
Creating the connection to Amazon S3 .....	405
Testing the connection to Amazon S3 .....	408
Creating a crawler for an Amazon S3 data store .....	409
Creating a crawler for Amazon S3 backed Data Catalog tables .....	412
Running a crawler .....	413
Troubleshooting .....	413
Troubleshooting connection issues .....	413
Tutorial: Using the AWS Glue Connector for Elasticsearch .....	414
Prerequisites .....	415
Step 1: (Optional) Create an AWS secret for your OpenSearch cluster information .....	415
Step 2: Subscribe to the connector .....	416
Step 3: Activate the connector in AWS Glue Studio and create a connection .....	417
Step 4: Configure an IAM role for your ETL job .....	418
Step 5: Create a job that uses the OpenSearch connection .....	418
Step 6: Run the job .....	420
<b>Building AWS Glue jobs with interactive sessions .....</b>	<b>421</b>
Overview of AWS Glue interactive sessions .....	421
Limitations .....	422
Getting started with AWS Glue interactive sessions .....	422
Prerequisites for setting up interactive sessions locally .....	422
Installing Jupyter and AWS Glue interactive sessions Jupyter kernels .....	422
Running Jupyter .....	423
Configuring session credentials and region .....	423
Upgrading from the interactive sessions preview .....	425
Using interactive sessions with SageMaker Studio .....	425
Using interactive sessions with Microsoft Visual Studio Code .....	425
Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks .....	429
Introduction to Jupyter Magics .....	429
Magics supported by AWS Glue interactive sessions for Jupyter .....	429
Naming sessions .....	446
Specifying an IAM role for interactive sessions .....	446
Configuring sessions with named profiles .....	447

---

AWS Glue for Ray interactive sessions (preview) .....	448
Ray interactive sessions in the AWS Glue Studio Console .....	449
Ray interactive sessions using the Jupyter Kernel .....	449
Ray interactive session timeout defaults .....	450
Magics supported by AWS Glue Ray interactive sessions .....	450
Interactive sessions with IAM .....	451
IAM principals used with interactive sessions .....	452
Setting up a client principal .....	452
Setting up a runtime role .....	453
Make your session private with TagOnCreate .....	454
IAM policy considerations .....	459
Converting a script or notebook into an AWS Glue job .....	459
AWS Glue interactive sessions for streaming .....	460
Switching streaming session type .....	460
Sampling input stream for interactive development .....	460
Running streaming applications in interactive sessions .....	461
Developing and testing locally .....	462
Developing using AWS Glue Studio .....	463
Developing using interactive sessions .....	464
Developing using a Docker image .....	464
Developing using the AWS Glue ETL library .....	475
Dev endpoints .....	483
Migrating from dev endpoints to interactive sessions .....	484
Developing scripts using development endpoints .....	486
Managing notebooks .....	514
<b>Building visual ETL jobs with AWS Glue Studio .....</b>	<b>516</b>
Signing in to the console .....	516
Next steps for creating a job in AWS Glue Studio .....	516
Visual ETL with AWS Glue Studio .....	517
Starting jobs in AWS Glue Studio .....	517
Job editor features .....	519
Editing AWS Glue managed data transform nodes .....	526
Custom visual transforms .....	588
Using Data Lake frameworks with AWS Glue Studio .....	605
Configuring data target nodes .....	616
Editing or uploading a job script .....	621

Changing the parent nodes for a node in the job diagram .....	625
Deleting nodes from the job diagram .....	626
Adding source and target parameters to the AWS Glue Data Catalog node .....	630
Using Git version control systems in AWS Glue .....	632
Authoring code with AWS Glue Studio notebooks .....	640
Overview of using notebooks .....	641
Creating an ETL job using notebooks in AWS Glue Studio .....	642
Notebook editor components .....	643
Saving your notebook and job script .....	644
Managing notebook sessions .....	645
Using CodeWhisperer with AWS Glue Studio notebooks .....	646
View job runs .....	647
Accessing the job monitoring dashboard .....	647
Overview of the job monitoring dashboard .....	647
Job runs view .....	647
Viewing the job run logs .....	651
Viewing the details of a job run .....	652
Viewing Amazon CloudWatch metrics for a Spark job run .....	655
Viewing Amazon CloudWatch metrics for a Ray job run .....	655
Detect and process sensitive data .....	657
Choosing how you want the data to be scanned .....	658
Choosing the PII entities to detect .....	659
Specifying the level of detection sensitivity .....	663
Choosing what to do with identified PII data .....	663
Adding fine-grained action overrides .....	664
Managing jobs .....	665
Start a job run .....	666
Schedule job runs .....	666
Manage job schedules .....	668
Stop job runs .....	668
View your jobs .....	669
View information for recent job runs .....	669
View the job script .....	670
Modify the job properties .....	671
Save the job .....	673
Clone a job .....	676

Delete jobs .....	676
<b>Working with jobs .....</b>	<b>678</b>
AWS Glue versions .....	678
AWS Glue versions .....	678
Running Spark ETL jobs with reduced startup times .....	692
Migrating AWS Glue for Spark jobs to AWS Glue version 3.0 .....	697
Migrating AWS Glue for Spark jobs to AWS Glue version 4.0 .....	705
Migrating from AWS Glue for Ray (preview) to AWS Glue for Ray .....	720
AWS Glue version support policy .....	720
Working with Spark jobs .....	722
Job parameters .....	723
Spark and PySpark jobs .....	732
Streaming ETL jobs .....	863
Record matching with FindMatches .....	877
Migrate Spark programs .....	911
Working with Ray jobs .....	918
Getting started with AWS Glue for Ray .....	918
Supported Ray runtime environments .....	920
Accounting for workers in Ray jobs .....	920
Ray job parameters .....	921
Ray job metrics .....	924
Configuring Python shell job properties .....	925
Limitations .....	926
Defining job properties for Python shell jobs .....	926
Supported libraries for Python shell jobs .....	928
Providing your own Python library .....	930
Use AWS CloudFormation with Python shell jobs in AWS Glue .....	933
Monitoring .....	934
AWS tags .....	935
Automating with CloudWatch Events .....	940
AWS Glue resource monitoring .....	942
Logging using CloudTrail .....	945
Job run statuses .....	948
<b>AWS Glue Streaming .....</b>	<b>952</b>
Use cases for streaming .....	952
What are the benefits of using AWS Glue Streaming? .....	953

When to use AWS Glue Streaming? .....	954
Supported data sources .....	955
Supported data targets .....	955
Tutorial: Build your first streaming workload using AWS Glue Studio .....	955
Prerequisites .....	956
Consume streaming data from Amazon Kinesis .....	956
Tutorial: Build your first streaming workload using AWS Glue Studio notebooks .....	967
Prerequisites .....	968
Consume streaming data from Amazon Kinesis .....	968
Streaming concepts .....	975
Anatomy of a AWS Glue streaming job .....	975
Kafka connections .....	979
Kinesis connections .....	985
Streaming options .....	992
AWS Glue streaming autoscaling .....	993
Enabling Auto Scaling in AWS Glue Studio .....	993
Enabling Auto Scaling with the AWS CLI or SDK .....	994
How it works .....	995
Maintenance windows .....	997
Setting up a maintenance window .....	997
Maintenance window behavior .....	998
Job monitoring .....	999
Data loss handling .....	1001
Advanced AWS Glue streaming concepts .....	1002
Time considerations when processing streams .....	1002
Windowing .....	1003
Handling late data and watermarks .....	1008
Monitoring AWS Glue streaming jobs .....	1010
Visualizing metrics .....	1011
Metrics deep dive .....	1012
How to get the best performance .....	1017
<b>AWS Glue Data Quality .....</b>	<b>1019</b>
Benefits and key features .....	1019
How it works .....	1020
Data quality for the AWS Glue Data Catalog .....	1020
Data quality for AWS Glue ETL jobs .....	1020

Comparing AWS Glue Data Quality entry points .....	1021
Considerations .....	1023
Terminology .....	1023
Release notes for AWS Glue Data Quality .....	1024
General availability: new features .....	1024
Nov 27, 2023 (Preview) .....	1024
Mar 12, 2024 .....	1025
Mar 30, 2024 .....	1025
Anomaly detection in AWS Glue Data Quality .....	1025
How it works .....	1026
Using analyzers to inspect your data .....	1026
Using the DetectAnomaly Rule .....	1027
Benefits and use cases of Anomaly Detection .....	1027
IAM permissions for AWS Glue Data Quality .....	1028
IAM permissions .....	1029
IAM setup required for scheduling evaluation runs .....	1031
Example IAM policies .....	1032
Getting started with AWS Glue Data Quality for the Data Catalog .....	1035
Prerequisites .....	1036
Step-by-step example .....	1036
Generating rule recommendations .....	1036
Monitoring rule recommendations .....	1038
Editing recommended rulesets .....	1038
Creating a new ruleset .....	1040
Running a ruleset to evaluate data quality .....	1041
Viewing the data quality score and results .....	1042
Related topics .....	1043
Evaluating data quality with AWS Glue Studio .....	1043
Benefits .....	1044
Evaluating data quality for ETL jobs in AWS Glue Studio .....	1044
Data Quality rule builder .....	1049
Configuring Anomaly detection and generating insights .....	1054
Data Quality for ETL jobs in AWS Glue Studio notebooks .....	1058
Prerequisites .....	1059
Creating an ETL job in AWS Glue Studio .....	1059
Data Quality Definition Language (DQDL) reference .....	1064

Syntax .....	1065
Rule type reference .....	1076
Using APIs to measure and manage data quality .....	1117
Prerequisites .....	1117
Working with AWS Glue Data Quality recommendations .....	1118
Working with AWS Glue Data Quality rulesets .....	1121
Working with AWS Glue Data Quality runs .....	1123
Working with AWS Glue Data Quality results .....	1128
Setting up alerts, deployments, and scheduling .....	1129
Setting up alerts and notifications in Amazon EventBridge integration .....	1129
Set up alerts and notifications in CloudWatch integration .....	1137
Querying data quality results .....	1138
Deploying data quality rules .....	1142
Scheduling data quality rules .....	1142
Troubleshooting AWS Glue Data Quality errors .....	1143
Error: missing module .....	1144
Error: insufficient permissions .....	1144
Error: rulesets not unique .....	1144
Error: tables with special characters .....	1144
Error: overflow with a large ruleset .....	1144
Error: rule status is failed .....	1145
AnalysisException: Unable to verify existence of default database .....	1145
Provided key map not suitable for given data frames .....	1145
java.lang.RuntimeException : Failed to fetch data. ....	1146
LAUNCH ERROR: Error downloading from S3 for bucket .....	1146
InvalidInputException (status: 400): DataQuality rules cannot be parsed .....	1146
Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup .....	1147
CustomSQL errors .....	1147
Dynamic Rules .....	1148
Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException .....	1150
<b>Amazon Q data integration in AWS Glue .....</b>	<b>1151</b>
What is Amazon Q? .....	1151
Amazon Q data integration in AWS Glue .....	1151
Working with Amazon Q data integration .....	1152
Best practices .....	1154

Service improvement .....	1154
Considerations .....	1155
Setting up Amazon Q data integration .....	1155
Configuring IAM permissions .....	1155
Supported code generation .....	1157
Example interactions .....	1158
Amazon Q chat interactions .....	1158
AWS Glue Studio notebook interactions .....	1160
<b>Orchestration .....</b>	<b>1164</b>
Starting jobs and crawlers using triggers .....	1164
AWS Glue triggers .....	1164
Adding triggers .....	1167
Activating and deactivating triggers .....	1171
Performing complex ETL activities using blueprints and workflows .....	1172
Overview of workflows .....	1173
Creating and building out a workflow manually .....	1176
Starting a workflow with an EventBridge event .....	1181
Viewing the EventBridge events that started a workflow .....	1188
Running and monitoring a workflow .....	1189
Stopping a workflow run .....	1191
Repairing and resuming a workflow run .....	1192
Getting and setting workflow run properties .....	1198
Querying workflows using the AWS Glue API .....	1199
Blueprint and workflow restrictions .....	1204
Troubleshooting blueprint errors .....	1205
Permissions for blueprint personas and roles .....	1210
Developing blueprints .....	1214
Overview of blueprints .....	1215
Developing blueprints .....	1218
Registering a blueprint .....	1243
Viewing blueprints .....	1245
Updating a blueprint .....	1247
Creating a workflow from a blueprint .....	1249
Viewing blueprint runs .....	1250
<b>AWS CloudFormation for AWS Glue .....</b>	<b>1252</b>
Sample database .....	1254

Sample database, table, partitions .....	1255
Sample grok classifier .....	1259
Sample JSON classifier .....	1260
Sample XML classifier .....	1261
Sample Amazon S3 crawler .....	1262

# What is AWS Glue?

AWS Glue is a serverless data integration service that makes it easy for analytics users to discover, prepare, move, and integrate data from multiple sources. You can use it for analytics, machine learning, and application development. It also includes additional productivity and data ops tooling for authoring, running jobs, and implementing business workflows.

With AWS Glue, you can discover and connect to more than 70 diverse data sources and manage your data in a centralized data catalog. You can visually create, run, and monitor extract, transform, and load (ETL) pipelines to load data into your data lakes. Also, you can immediately search and query cataloged data using Amazon Athena, Amazon EMR, and Amazon Redshift Spectrum.

AWS Glue consolidates major data integration capabilities into a single service. These include data discovery, modern ETL, cleansing, transforming, and centralized cataloging. It's also serverless, which means there's no infrastructure to manage. With flexible support for all workloads like ETL, ELT, and streaming in one service, AWS Glue supports users across various workloads and types of users.

Also, AWS Glue makes it easy to integrate data across your architecture. It integrates with AWS analytics services and Amazon S3 data lakes. AWS Glue has integration interfaces and job-authoring tools that are easy to use for all users, from developers to business users, with tailored solutions for varied technical skill sets.

With the ability to scale on demand, AWS Glue helps you focus on high-value activities that maximize the value of your data. It scales for any data size, and supports all data types and schema variances. To increase agility and optimize costs, AWS Glue provides built-in high availability and pay-as-you-go billing.

For pricing information, see [AWS Glue pricing](#).

## AWS Glue Studio

AWS Glue Studio is a graphical interface that makes it easy to create, run, and monitor data integration jobs in AWS Glue. You can visually compose data transformation workflows and seamlessly run them on the Apache Spark-based serverless ETL engine in AWS Glue.

With AWS Glue Studio, you can create and manage jobs that gather, transform, and clean data. You can also use AWS Glue Studio to troubleshoot and edit job scripts.

## Topics

- [AWS Glue features](#)
- [Learning about innovations in AWS Glue](#)
- [Getting started with AWS Glue](#)
- [Accessing AWS Glue](#)
- [Related services](#)

## AWS Glue features

AWS Glue features fall into three major categories:

- Discover and organize data
- Transform, prepare, and clean data for analysis
- Build and monitor data pipelines

### Discover and organize data

- **Unify and search across multiple data stores** – Store, index, and search across multiple data sources and sinks by cataloging all your data in AWS.
- **Automatically discover data** – Use AWS Glue crawlers to automatically infer schema information and integrate it into your AWS Glue Data Catalog.
- **Manage schemas and permissions** – Validate and control access to your databases and tables.
- **Connect to a wide variety of data sources** – Tap into multiple data sources, both on premises and on AWS, using AWS Glue connections to build your data lake.

### Transform, prepare, and clean data for analysis

- **Visually transform data with a job canvas interface** – Define your ETL process in the visual job editor and automatically generate the code to extract, transform, and load your data.
- **Build complex ETL pipelines with simple job scheduling** – Invoke AWS Glue jobs on a schedule, on demand, or based on an event.
- **Clean and transform streaming data in transit** – Enable continuous data consumption, and clean and transform it in transit. This makes it available for analysis in seconds in your target data store.

- **Deduplicate and cleanse data with built-in machine learning** – Clean and prepare your data for analysis without becoming a machine learning expert by using the FindMatches feature. This feature deduplicates and finds records that are imperfect matches for each other.
- **Built-in job notebooks** – AWS Glue job notebooks provide serverless notebooks with minimal setup in AWS Glue so you can get started quickly.
- **Edit, debug, and test ETL code** – With AWS Glue interactive sessions, you can interactively explore and prepare data. You can explore, experiment on, and process data interactively using the IDE or notebook of your choice.
- **Define, detect, and remediate sensitive data** – AWS Glue sensitive data detection lets you define, identify, and process sensitive data in your data pipeline and in your data lake.

## Build and monitor data pipelines

- **Automatically scale based on workload** – Dynamically scale resources up and down based on workload. This assigns workers to jobs only when needed.
- **Automate jobs with event-based triggers** – Start crawlers or AWS Glue jobs with event-based triggers, and design a chain of dependent jobs and crawlers.
- **Run and monitor jobs** – Run AWS Glue jobs with your choice of engine, Spark or Ray. Monitor them with automated monitoring tools, AWS Glue job run insights, and AWS CloudTrail. Improve your monitoring of Spark-backed jobs with the Apache Spark UI.
- **Define workflows for ETL and integration activities** – Define workflows for ETL and integration activities for multiple crawlers, jobs, and triggers.

## Learning about innovations in AWS Glue

Learn about the latest innovations in AWS Glue and hear how customers use AWS Glue to enable self-service data preparation across their organization.

Learn about how customers scale AWS Glue beyond the traditional setup and how they configure AWS Glue for job monitoring and performance.

## Getting started with AWS Glue

We recommend that you start with the following sections:

- [Overview of using AWS Glue](#)

- [AWS Glue concepts](#)
- [Setting up IAM permissions for AWS Glue](#)
- [Getting started with the AWS Glue Data Catalog](#)
- [Authoring jobs in AWS Glue](#)
- [Getting started with AWS Glue interactive sessions](#)
- [Orchestration in AWS Glue](#)

## Accessing AWS Glue

You can create, view, and manage your AWS Glue jobs using the following interfaces:

- **AWS Glue console** – Provides a web interface for you to create, view, and manage your AWS Glue jobs. To access the console, see [AWS Glue](#).
- **AWS Glue Studio** – Provides a graphical interface for you to create and edit your AWS Glue jobs visually. For more information, see [What is AWS Glue Studio](#).
- **AWS Glue section of the AWS CLI Reference** – Provides AWS CLI commands that you can use with AWS Glue. For more information, see [AWS CLI Reference for AWS Glue](#).
- **AWS Glue API** – Provides a complete API reference for developers. For more information, see [AWS Glue API](#).

## Related services

Users of AWS Glue also use:

- [AWS Lake Formation](#) – A service that is an authorization layer that provides fine-grained access control to resources in the AWS Glue Data Catalog.
- [AWS Glue DataBrew](#) – A visual data preparation tool that you can use to clean and normalize data without writing any code.

# AWS Glue: How it works

AWS Glue uses other AWS services to orchestrate your ETL (extract, transform, and load) jobs to build data warehouses and data lakes and generate output streams. AWS Glue calls API operations to transform your data, create runtime logs, store your job logic, and create notifications to help you monitor your job runs. The AWS Glue console connects these services into a managed application, so you can focus on creating and monitoring your ETL work. The console performs administrative and job development operations on your behalf. You supply credentials and other properties to AWS Glue to access your data sources and write to your data targets.

AWS Glue takes care of provisioning and managing the resources that are required to run your workload. You don't need to create the infrastructure for an ETL tool because AWS Glue does it for you. When resources are required, to reduce startup time, AWS Glue uses an instance from its warm pool of instances to run your workload.

With AWS Glue, you create jobs using table definitions in your Data Catalog. Jobs consist of scripts that contain the programming logic that performs the transformation. You use triggers to initiate jobs either on a schedule or as a result of a specified event. You determine where your target data resides and which source data populates your target. With your input, AWS Glue generates the code that's required to transform your data from source to target. You can also provide scripts in the AWS Glue console or API to process your data.

## Data sources and destinations

AWS Glue for Spark allows you to read and write data from multiple systems and databases including:

- Amazon S3
- Amazon DynamoDB
- Amazon Redshift
- Amazon Relational Database Service (Amazon RDS)
- Third-party JDBC-accessible databases
- MongoDB and Amazon DocumentDB (with MongoDB compatibility)
- Other marketplace connectors and Apache Spark plugins

## Data streams

AWS Glue for Spark can stream data from the following systems:

- Amazon Kinesis Data Streams
- Apache Kafka

AWS Glue is available in several AWS Regions. For more information, see [AWS Regions and Endpoints](#) in the Amazon Web Services General Reference.

## Topics

- [Serverless ETL jobs run in isolation](#)
- [AWS Glue concepts](#)
- [AWS Glue components](#)
- [AWS Glue for Spark and AWS Glue for Ray](#)
- [Converting semi-structured schemas to relational schemas with AWS Glue](#)
- [AWS Glue type systems](#)

## Serverless ETL jobs run in isolation

AWS Glue runs your ETL jobs in a serverless environment with your choice of engine, Spark or Ray. AWS Glue runs these jobs on virtual resources that it provisions and manages in its own service account.

AWS Glue is designed to do the following:

- Segregate customer data.
- Protect customer data in transit and at rest.
- Access customer data only as needed in response to customer requests, using temporary, scoped-down credentials, or with a customer's consent to IAM roles in their account.

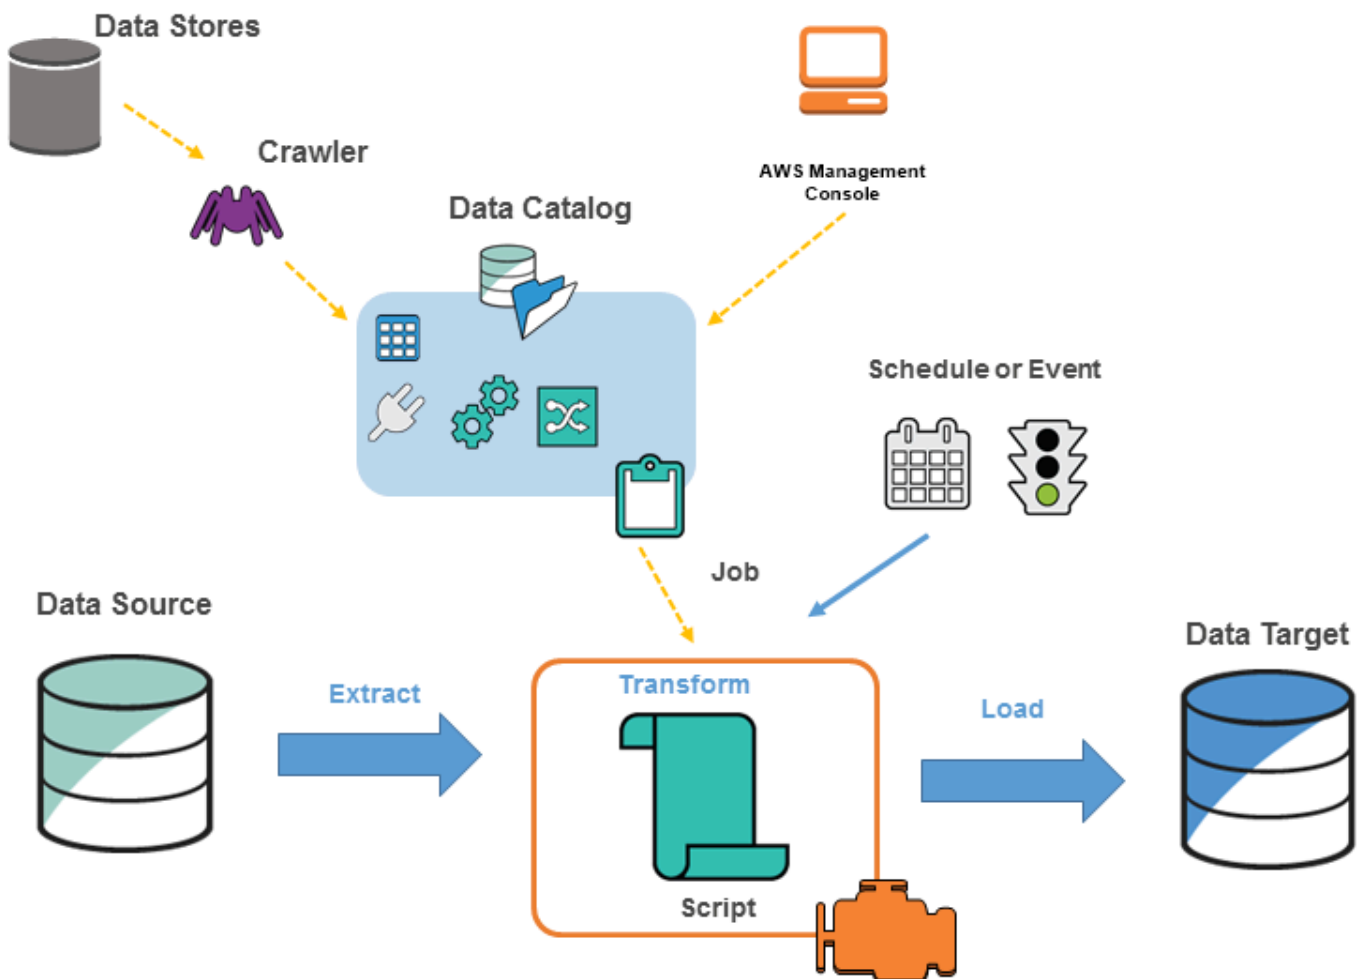

During provisioning of an ETL job, you provide input data sources and output data targets in your virtual private cloud (VPC). In addition, you provide the IAM role, VPC ID, subnet ID, and security group that are needed to access data sources and targets. For each tuple (customer account ID, IAM role, subnet ID, and security group), AWS Glue creates a new environment that is isolated at the network and management level from all other environments inside the AWS Glue service account.

AWS Glue creates elastic network interfaces in your subnet using private IP addresses. Jobs use these elastic network interfaces to access your data sources and data targets. Traffic in, out, and within the job run environment is governed by your VPC and networking policies with one exception: Calls made to AWS Glue libraries can proxy traffic to AWS Glue API operations through the AWS Glue VPC. All AWS Glue API calls are logged; thus, data owners can audit API access by enabling [AWS CloudTrail](#), which delivers audit logs to your account.

AWS Glue managed environments that run your ETL jobs are protected with the same security practices followed by other AWS services. For an overview of the practices and shared security responsibilities, see the [Introduction to AWS Security Processes](#) whitepaper.

## AWS Glue concepts

The following diagram shows the architecture of an AWS Glue environment.

You define *jobs* in AWS Glue to accomplish the work that's required to extract, transform, and load (ETL) data from a data source to a data target. You typically perform the following actions:

- For data store sources, you define a *crawler* to populate your AWS Glue Data Catalog with metadata table definitions. You point your crawler at a data store, and the crawler creates table definitions in the Data Catalog. For streaming sources, you manually define Data Catalog tables and specify data stream properties.

In addition to table definitions, the AWS Glue Data Catalog contains other metadata that is required to define ETL jobs. You use this metadata when you define a job to transform your data.

- AWS Glue can generate a script to transform your data. Or, you can provide the script in the AWS Glue console or API.
- You can run your job on demand, or you can set it up to start when a specified *trigger* occurs. The trigger can be a time-based schedule or an event.

When your job runs, a script extracts data from your data source, transforms the data, and loads it to your data target. The script runs in an Apache Spark environment in AWS Glue.

### Important

Tables and databases in AWS Glue are objects in the AWS Glue Data Catalog. They contain metadata; they don't contain data from a data store.

**Text-based data, such as CSVs, must be encoded in UTF-8 for AWS Glue to process it successfully. For more information, see [UTF-8](#) in Wikipedia.**

## AWS Glue terminology

AWS Glue relies on the interaction of several components to create and manage your extract, transform, and load (ETL) workflow.

## AWS Glue Data Catalog

The persistent metadata store in AWS Glue. It contains table definitions, job definitions, and other control information to manage your AWS Glue environment. Each AWS account has one AWS Glue Data Catalog per region.

### Classifier

Determines the schema of your data. AWS Glue provides classifiers for common file types, such as CSV, JSON, AVRO, XML, and others. It also provides classifiers for common relational database management systems using a JDBC connection. You can write your own classifier by using a grok pattern or by specifying a row tag in an XML document.

### Connection

A Data Catalog object that contains the properties that are required to connect to a particular data store.

### Crawler

A program that connects to a data store (source or target), progresses through a prioritized list of classifiers to determine the schema for your data, and then creates metadata tables in the AWS Glue Data Catalog.

### Database

A set of associated Data Catalog table definitions organized into a logical group.

### Data store, data source, data target

A *data store* is a repository for persistently storing your data. Examples include Amazon S3 buckets and relational databases. A *data source* is a data store that is used as input to a process or transform. A *data target* is a data store that a process or transform writes to.

### Development endpoint

An environment that you can use to develop and test your AWS Glue ETL scripts.

### Dynamic Frame

A distributed table that supports nested data such as structures and arrays. Each record is self-describing, designed for schema flexibility with semi-structured data. Each record contains both

data and the schema that describes that data. You can use both dynamic frames and Apache Spark DataFrames in your ETL scripts, and convert between them. Dynamic frames provide a set of advanced transformations for data cleaning and ETL.

## Job

The business logic that is required to perform ETL work. It is composed of a transformation script, data sources, and data targets. Job runs are initiated by triggers that can be scheduled or triggered by events.

## Job performance dashboard

AWS Glue provides a comprehensive run dashboard for your ETL jobs. The dashboard displays information about job runs from a specific time frame.

## Notebook interface

An enhanced notebook experience with one-click setup for easy job authoring and data exploration. The notebook and connections are configured automatically for you. You can use the notebook interface based on Jupyter Notebook to interactively develop, debug, and deploy scripts and workflows using AWS Glue serverless Apache Spark ETL infrastructure. You can also perform ad-hoc queries, data analysis, and visualization (for example, tables and graphs) in the notebook environment.

## Script

Code that extracts data from sources, transforms it, and loads it into targets. AWS Glue generates PySpark or Scala scripts.

## Table

The metadata definition that represents your data. Whether your data is in an Amazon Simple Storage Service (Amazon S3) file, an Amazon Relational Database Service (Amazon RDS) table, or another set of data, a table defines the schema of your data. A table in the AWS Glue Data Catalog consists of the names of columns, data type definitions, partition information, and other metadata about a base dataset. The schema of your data is represented in your AWS Glue table definition. The actual data remains in its original data store, whether it be in a file or a relational database table. AWS Glue catalogs your files and relational database tables in the AWS Glue Data Catalog. They are used as sources and targets when you create an ETL job.

## Transform

The code logic that is used to manipulate your data into a different format.

## Trigger

Initiates an ETL job. Triggers can be defined based on a scheduled time or an event.

## Visual job editor

The visual job editor is a graphical interface that makes it easy to create, run, and monitor extract, transform, and load (ETL) jobs in AWS Glue. You can visually compose data transformation workflows, seamlessly run them on AWS Glue's Apache Spark-based serverless ETL engine, and inspect the schema and data results in each step of the job.

## Worker

With AWS Glue, you only pay for the time your ETL job takes to run. There are no resources to manage, no upfront costs, and you are not charged for startup or shutdown time. You are charged an hourly rate based on the number of **Data Processing Units** (or DPUs) used to run your ETL job. A single Data Processing Unit (DPU) is also referred to as a *worker*. AWS Glue comes with three worker types to help you select the configuration that meets your job latency and cost requirements. Workers come in Standard, G.1X, G.2X, and G.025X configurations.

## AWS Glue components

AWS Glue provides a console and API operations to set up and manage your extract, transform, and load (ETL) workload. You can use API operations through several language-specific SDKs and the AWS Command Line Interface (AWS CLI). For information about using the AWS CLI, see [AWS CLI Command Reference](#).

AWS Glue uses the AWS Glue Data Catalog to store metadata about data sources, transforms, and targets. The Data Catalog is a drop-in replacement for the Apache Hive Metastore. The AWS Glue Jobs system provides a managed infrastructure for defining, scheduling, and running ETL operations on your data. For more information about the AWS Glue API, see [AWS Glue API](#).

## AWS Glue console

You use the AWS Glue console to define and orchestrate your ETL workflow. The console calls several API operations in the AWS Glue Data Catalog and AWS Glue Jobs system to perform the following tasks:

- Define AWS Glue objects such as jobs, tables, crawlers, and connections.
- Schedule when crawlers run.
- Define events or schedules for job triggers.
- Search and filter lists of AWS Glue objects.
- Edit transformation scripts.

## AWS Glue Data Catalog

The AWS Glue Data Catalog is your persistent technical metadata store in the AWS Cloud.

Each AWS account has one AWS Glue Data Catalog per AWS Region. Each Data Catalog is a highly scalable collection of tables organized into databases. A table is metadata representation of a collection of structured or semi-structured data stored in sources such as Amazon RDS, Apache Hadoop Distributed File System, Amazon OpenSearch Service, and others. The AWS Glue Data Catalog provides a uniform repository where disparate systems can store and find metadata to keep track of data in data silos. You can then use the metadata to query and transform that data in a consistent manner across a wide variety of applications.

You use the Data Catalog together with AWS Identity and Access Management policies and Lake Formation to control access to the tables and databases. By doing this, you can allow different groups in your enterprise to safely publish data to the wider organization while protecting sensitive information in a highly granular fashion.

The Data Catalog, along with CloudTrail and Lake Formation, also provides you with comprehensive audit and governance capabilities, with schema change tracking and data access controls. This helps ensure that data is not inappropriately modified or inadvertently shared.

For information about securing and auditing the AWS Glue Data Catalog, see:

- **AWS Lake Formation** – For more information, see [What Is AWS Lake Formation?](#) in the *AWS Lake Formation Developer Guide*.
- **CloudTrail** – For more information, see [What Is CloudTrail?](#) in the *AWS CloudTrail User Guide*.

The following are other AWS services and open-source projects that use the AWS Glue Data Catalog:

- **Amazon Athena** – For more information, see [Understanding Tables, Databases, and the Data Catalog](#) in the *Amazon Athena User Guide*.
- **Amazon Redshift Spectrum** – For more information, see [Using Amazon Redshift Spectrum to Query External Data](#) in the *Amazon Redshift Database Developer Guide*.
- **Amazon EMR** – For more information, see [Use Resource-Based Policies for Amazon EMR Access to AWS Glue Data Catalog](#) in the *Amazon EMR Management Guide*.
- **AWS Glue Data Catalog client for Apache Hive metastore** – For more information about this GitHub project, see [AWS Glue Data Catalog Client for Apache Hive Metastore](#).

## AWS Glue crawlers and classifiers

AWS Glue also lets you set up crawlers that can scan data in all kinds of repositories, classify it, extract schema information from it, and store the metadata automatically in the AWS Glue Data Catalog. The AWS Glue Data Catalog can then be used to guide ETL operations.

For information about how to set up crawlers and classifiers, see [Using crawlers to populate the Data Catalog](#). For information about how to program crawlers and classifiers using the AWS Glue API, see [Crawlers and classifiers API](#).

## AWS Glue ETL operations

Using the metadata in the Data Catalog, AWS Glue can automatically generate Scala or PySpark (the Python API for Apache Spark) scripts with AWS Glue extensions that you can use and modify to perform various ETL operations. For example, you can extract, clean, and transform raw data, and then store the result in a different repository, where it can be queried and analyzed. Such a script might convert a CSV file into a relational form and save it in Amazon Redshift.

For more information about how to use AWS Glue ETL capabilities, see [Programming Spark scripts](#).

## Streaming ETL in AWS Glue

AWS Glue enables you to perform ETL operations on streaming data using continuously-running jobs. AWS Glue streaming ETL is built on the Apache Spark Structured Streaming engine, and can

ingest streams from Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK). Streaming ETL can clean and transform streaming data and load it into Amazon S3 or JDBC data stores. Use Streaming ETL in AWS Glue to process event data like IoT streams, clickstreams, and network logs.

If you know the schema of the streaming data source, you can specify it in a Data Catalog table. If not, you can enable schema detection in the streaming ETL job. The job then automatically determines the schema from the incoming data.

The streaming ETL job can use both AWS Glue built-in transforms and transforms that are native to Apache Spark Structured Streaming. For more information, see [Operations on streaming DataFrames/Datasets](#) on the Apache Spark website.

For more information, see [the section called "Streaming ETL jobs"](#).

## The AWS Glue jobs system

The AWS Glue Jobs system provides managed infrastructure to orchestrate your ETL workflow. You can create jobs in AWS Glue that automate the scripts you use to extract, transform, and transfer data to different locations. Jobs can be scheduled and chained, or they can be triggered by events such as the arrival of new data.

For more information about using the AWS Glue Jobs system, see [Monitoring AWS Glue](#). For information about programming using the AWS Glue Jobs system API, see [Jobs API](#).

## Visual ETL components

AWS Glue allows you to create ETL jobs through a visual canvas that you can manipulate.

## ETL job menu

Menu options at the top of the canvas allow you to access the various views and configuration details about your job.

- **Visual** – The Visual job editor canvas. This is where you can add nodes to create a job.
- **Script** – The script representation of your ETL job. AWS Glue generates the script based on the visual representation of your job. You can also edit your script or download it.

### Note

If you choose to edit the script, the job authoring experience is permanently converted to a script-only mode. Afterwards, you cannot use the visual editor to edit the job anymore.

You should add all the job sources, transforms, and targets, and make all the changes you require with the visual editor before choosing to edit the script.

- **Job details** – The Job details tab allows you to configure your job by setting job properties. There are basic properties, such as name and description of your job, IAM role, job type, AWS Glue version, language, worker type, number of workers, job bookmark, flex execution, number of retries, and job timeout, and there are advanced properties, such as connections, libraries, job parameters, and tags.
- **Runs** – After your job runs, this tab can be accessed to view your past job runs.
- **Data quality** – Data quality evaluates and monitors the quality of your data assets. You can learn more about how to use data quality on this tab and add a data quality transform to your job.
- **Schedules** – Jobs that you've scheduled appear in this tab. If there are no schedules attached to this job, then this tab is not accessible.
- **Version control** – You can use Git with your job by configuring your job to a Git repository.

## Visual ETL panels

When you work in the canvas, several panels are available to help you configure your nodes, or help you to preview your data and view the output schema.

- **Properties** – The Properties panel appears when you choose a node on your canvas.
- **Data preview** – The Data preview panel provides a preview of the data output so that you can make decisions before you run your job and examine your output.
- **Output schema** – The Output schema tab allows you to view and edit the schema of your transform nodes.

## Resizing panels

You can resize the Properties panel on the right-hand side of the screen and the bottom panel which contains the Data preview and Output schema tabs by clicking on the edge of the panel and dragging it left and right or up and down.

- **Properties panel** – Resize the properties panel by clicking and dragging the edge of the canvas on the right side of the screen and drag it left to expand its width. By default, the panel is collapsed and when a node is selected, the properties panel opens up to its default size.

- **Data preview and Output schema panel** – Resize the bottom panel by clicking and dragging the bottom edge of the canvas at the bottom of the screen and drag it up to expand its height. By default, the panel is collapsed and when a node is selected, the bottom panel opens up to its default size.

## Job canvas

You can add, remove, and move/reorder nodes directly on the Visual ETL canvas. Think of it as your workspace to create a fully functional ETL job that starts with a data source and can end with a data target.

When you work with nodes on the canvas, you have a toolbar that can help you zoom in and out, remove nodes, make or edit connections between nodes, change the job flow orientation, and undo or redo an action.

The floating toolbar is anchored to the upper right-hand side of the canvas and contains several images that perform actions:

- **Layout icon** – The first icon in the toolbar is the layout icon. By default, the direction of visual jobs is top to bottom. It rearranges the direction of your visual job by arranging the nodes horizontally from left to right. Clicking the layout icon again changes the direction back to top to bottom.

- **Recenter icon** – The recenter icon changes the canvas view by centering it. You can use this with large jobs to get back to the center position.
- **Zoom in icon** – The zoom in icon enlarges the size of the nodes on the canvas.
- **Zoom out icon** – The zoom out icon decreases the size of the nodes on the canvas.
- **Trash icon** – The trash icon removes a node from the visual job. You must select a node first.
- **Undo icon** – The undo icon reverses the last action taken on the visual job.
- **Redo icon** – The redo icon repeats the last action taken on the visual job.

## Using the mini-map

## Resource panel

The resource panel contains all of the data sources, transform actions, and connections available to you. Open the resource panel on the canvas by clicking the "+" icon. This will open the resource panel.

To close the resource panel, click the **X** in the upper-right hand corner of the resource panel. This will hide the panel until you're ready to open it again.

**▼ Sources**

- 

**AWS Glue Data Catalog**

AWS Glue Data Catalog table as the data source.
- 

**Amazon S3**

JSON, CSV, or Parquet files stored in S3.
- 

**Amazon Kinesis**

Read from an Amazon Kinesis Data Stream.
- 

**Apache Kafka**

Read from an Apache Kafka or Amazon MSK topic.
- 

**Relational DB**

AWS Glue Data Catalog table with a relational database as the data source.
- 

**Amazon Redshift**

Read your data from Amazon Redshift.
- 

**MySQL**

AWS Glue Data Catalog table with MySQL as the data source.
- 

**PostgreSQL**

AWS Glue Data Catalog table with PostgreSQL as the data source.
- 

**Oracle SQL**

AWS Glue Data Catalog table with Oracle SQL as the data source.
- 

**Microsoft SQL Server**

AWS Glue Data Catalog table with SQL Server as the data source.
- 

**Amazon DynamoDB**

AWS Glue Data Catalog table with DynamoDB as the data source.
- 

**Snowflake**

Read your data from Snowflake.

## Popular transforms & data

At the top of the panel is a collection of **Popular transforms & data**. These nodes are commonly used in AWS Glue. Choose one to add it to the canvas. You can also hide the **Popular transforms & data** by clicking the triangle next to the **Popular transforms & data** heading.

Beneath the **Popular transforms & data** section, you can search for transforms and data source nodes. Results appear as you type. The more letters you add to your search query, the list of results will get smaller. Search results are populated from the node name and/or description. Choose the node to add it to your canvas.

## Transforms and Data

There are two tabs that organize the nodes into **Transforms** and **Data**.

**Transforms** – When you choose the **Transforms** tab, all of the available transforms can be selected. Choose a transform to add it to the canvas. You can also choose **Add Transform** at the bottom of the Transforms list which will open a new page to the documentation for creating [Custom visual transforms](#). Following the steps will allow you to create transforms of your own. Your transforms will then appear in the list of available transforms.

**Data** – The data tab contains all of the nodes for **Sources** and **Targets**. You can hide the Sources and Targets by clicking the triangle next to the Sources or Targets heading. You can unhide the Sources and Targets by clicking the triangle again. Choose a source or target node to add it to the canvas. You can also choose **Manage Connections** to add a new connection. This will open the Connectors page in the console.

## AWS Glue for Spark and AWS Glue for Ray

In AWS Glue on Apache Spark (AWS Glue ETL), you can use PySpark to write Python code to handle data at scale. Spark is a familiar solution for this problem, but data engineers with Python-focused backgrounds can find the transition unintuitive. The Spark DataFrame model is not seamlessly "Pythonic", which reflects the Scala language and Java runtime it is built upon.

In AWS Glue, you can use Python shell jobs to run native Python data integrations. These jobs run on a single Amazon EC2 instance and are limited by the capacity of that instance. This restricts the throughput of the data you can process, and becomes expensive to maintain when dealing with big data.

AWS Glue for Ray allows you to scale up Python workloads without substantial investment into learning Spark. You can take advantage of certain scenarios where Ray performs better. By offering you a choice, you can use the strengths of both Spark and Ray.

AWS Glue ETL and AWS Glue for Ray are different underneath, so they support different features. Please check the documentation to determine supported features.

## What is AWS Glue for Ray?

Ray is an open-source distributed computation framework that you can use to scale up workloads, with a focus on Python. For more information about Ray, see the [Ray website](#). AWS Glue Ray jobs and interactive sessions allow you to use Ray within AWS Glue.

You can use AWS Glue for Ray to write Python scripts for computations that will run in parallel across multiple machines. In Ray jobs and interactive sessions, you can use familiar Python libraries, like pandas, to make your workflows easy to write and run. For more information about Ray datasets, see [Ray Datasets](#) in the Ray documentation. For more information about pandas, see the [Pandas website](#).

When you use AWS Glue for Ray, you can run your pandas workflows against big data at enterprise scale—with only a few lines of code. You can create a Ray job from the AWS Glue console or the AWS SDK. You can also open an AWS Glue interactive session to run your code on a serverless Ray environment. Visual jobs in AWS Glue Studio are not yet supported.

AWS Glue for Ray jobs allow you to run a script on a schedule or in response to an event from Amazon EventBridge. Jobs store log information and monitoring statistics in CloudWatch that enable you to understand the health and reliability of your script. For more information about the AWS Glue job system, see [the section called “Working with Ray jobs”](#).

AWS Glue for Ray interactive sessions (preview) allow you to run snippets of code one after another against the same provisioned resources. You can use this to efficiently prototype and develop scripts, or build your own interactive applications. You can use AWS Glue interactive sessions from AWS Glue Studio Notebooks in the AWS Management Console. For more information, see [Using Notebooks with AWS Glue Studio and AWS Glue](#). You can also use them through a Jupyter kernel, which allows you to run interactive sessions from existing code editing tools that support Jupyter Notebooks, such as VSCode. For more information, see [the section called “AWS Glue for Ray interactive sessions \(preview\)”](#).

Ray automates the work of scaling Python code by distributing the processing across a cluster of machines that it reconfigures in real time, based on the load. This can lead to improved

performance per dollar for certain workloads. With Ray jobs, we have built auto scaling natively into the AWS Glue job model, so you can fully take advantage of this feature. Ray jobs run on AWS Graviton, leading to higher overall price performance.

In addition to cost savings, you can use native auto scaling to run Ray workloads without investing time into cluster maintenance, tuning, and administration. You can use familiar open-source libraries out of the box, such as pandas, and the AWS SDK for Pandas. These improve iteration speed while you're developing on AWS Glue for Ray. When you use AWS Glue for Ray, you will be able to rapidly develop and run cost-effective data integration workloads.

## Converting semi-structured schemas to relational schemas with AWS Glue

It's common to want to convert semi-structured data into relational tables. Conceptually, you are flattening a hierarchical schema to a relational schema. AWS Glue can perform this conversion for you on-the-fly.

Semi-structured data typically contains mark-up to identify entities within the data. It can have nested data structures with no fixed schema. For more information about semi-structured data, see [Semi-structured data](#) in Wikipedia.

Relational data is represented by tables that consist of rows and columns. Relationships between tables can be represented by a primary key (PK) to foreign key (FK) relationship. For more information, see [Relational database](#) in Wikipedia.

AWS Glue uses crawlers to infer schemas for semi-structured data. It then transforms the data to a relational schema using an ETL (extract, transform, and load) job. For example, you might want to parse JSON data from Amazon Simple Storage Service (Amazon S3) source files to Amazon Relational Database Service (Amazon RDS) tables. Understanding how AWS Glue handles the differences between schemas can help you understand the transformation process.

This diagram shows how AWS Glue transforms a semi-structured schema to a relational schema.

## Semi-structured schema

## Relational schema

The diagram illustrates the following:

- Single value A converts directly to a relational column.
- The pair of values, B1 and B2, convert to two relational columns.
- Structure C, with children X and Y, converts to two relational columns.
- Array D[] converts to a relational column with a foreign key (FK) that points to another relational table. Along with a primary key (PK), the second relational table has columns that contain the offset and value of the items in the array.

# AWS Glue type systems

AWS Glue uses multiple type systems to provide a versatile interface over data systems that store data in very different ways. This document disambiguates AWS Glue type systems and data standards.

## AWS Glue Data Catalog Types

The Data Catalog is a registry of tables and fields stored in various data systems, a metastore. When AWS Glue components, such as AWS Glue crawlers and AWS Glue with Spark jobs, write to the Data Catalog, they do so with an internal type system for tracking the types of fields. These values are shown in the **Data type** column of the table schema in the AWS Glue Console. This type system is based on Apache Hive's type system. For more information about the Apache Hive type system, see [Types](#) in the Apache Hive wiki. For more information about specific types and support, examples are provided in the AWS Glue Console, as part of the Schema Builder.

## Validation, compatibility and other uses

The Data Catalog does not validate types written to type fields. When AWS Glue components read and write to the Data Catalog, they will be compatible with each other. AWS Glue components also aim to preserve a high degree of compatibility with the Hive types. However, AWS Glue components do not guarantee compatibility with all Hive types. This allows for interoperability with tools like Athena DDL when working with tables in the Data Catalog.

Since the Data Catalog does not validate types, other services may use the Data Catalog to track types using systems that strictly conform to the Hive type system, or any other system.

## Types in AWS Glue with Spark scripts

When a AWS Glue with Spark script interprets or transforms a dataset, we provide `DynamicFrame`, an in-memory representation of your dataset as it is used in your script. The goal of a `DynamicFrame` is similar to that of the Spark `DataFrame`– it models your dataset so that Spark can schedule and execute transforms on your data. We guarantee that the type representation of `DynamicFrame` is intercompatible with `DataFrame` by providing the `toDF` and `fromDF` methods.

If type information can be inferred or provided to a `DataFrame`, it can be inferred or provided to a `DynamicFrame`, unless otherwise documented. When we provide optimized readers or writers for specific data formats, if Spark can read or write your data, our provided readers and writers will

be able to, subject to documented limitations. For more information about readers and writers, see [the section called "Data format options"](#).

## The Choice Type

`DynamicFrames` provide a mechanism for modeling fields in a dataset whose value may have inconsistent types on disk across rows. For instance, a field may hold a number stored as a string in certain rows, and an integer in others. This mechanism is an in-memory type called Choice. We provide transforms such as the `ResolveChoice` method, to resolve Choice columns to a concrete type. AWS Glue ETL will not write the Choice type to the Data Catalog in the normal course of operation; Choice types only exist in the context of `DynamicFrame` memory models of datasets. For an example of Choice type usage, see [the section called "Data preparation sample"](#).

## AWS Glue Crawler Types

Crawlers aim to produce a consistent, usable schema for your dataset, then store it in Data Catalog for use in other AWS Glue components and Athena. Crawlers deal with types as described in the previous section on the Data Catalog, [the section called "AWS Glue Data Catalog Types"](#). To produce a usable type in "Choice" type scenarios, where a column contains values of two or more types, Crawlers will create a `struct` type that models the potential types.

# Getting started with AWS Glue

The following sections provide information on setting up AWS Glue. Not all of the setting up sections are required to start using AWS Glue. You can use the instructions as needed to set up IAM permissions, encryption, and DNS ( if you're using a VPC environment to access data stores or if you're using interactive sessions).

## Topics

- [Overview of using AWS Glue](#)
- [Setting up IAM permissions for AWS Glue](#)
- [Getting started with the AWS Glue Data Catalog](#)
- [Setting up network access to data stores](#)
- [Setting up encryption in AWS Glue](#)
- [Setting up networking for development for AWS Glue](#)

## Overview of using AWS Glue

With AWS Glue, you store metadata in the AWS Glue Data Catalog. You use this metadata to orchestrate ETL jobs that transform data sources and load your data warehouse or data lake. The following steps describe the general workflow and some of the choices that you make when working with AWS Glue.

### Note

You can use the following steps, or you can create a workflow that automatically performs steps 1 through 3. For more information, see [the section called “Performing complex ETL activities using blueprints and workflows”](#).

#### 1. Populate the AWS Glue Data Catalog with table definitions.

In the console, for persistent data stores, you can add a crawler to populate the AWS Glue Data Catalog. You can start the **Add crawler** wizard from the list of tables or the list of crawlers. You choose one or more data stores for your crawler to access. You can also create a schedule to determine the frequency of running your crawler. For data streams, you can manually create the table definition, and define stream properties.

Optionally, you can provide a custom classifier that infers the schema of your data. You can create custom classifiers using a grok pattern. However, AWS Glue provides built-in classifiers that are automatically used by crawlers if a custom classifier does not recognize your data. When you define a crawler, you don't have to select a classifier. For more information about classifiers in AWS Glue, see [Adding classifiers to a crawler in AWS Glue](#).

Crawling some types of data stores requires a connection that provides authentication and location information. If needed, you can create a connection that provides this required information in the AWS Glue console.

The crawler reads your data store and creates data definitions and named tables in the AWS Glue Data Catalog. These tables are organized into a database of your choosing. You can also populate the Data Catalog with manually created tables. With this method, you provide the schema and other metadata to create table definitions in the Data Catalog. Because this method can be a bit tedious and error prone, it's often better to have a crawler create the table definitions.

For more information about populating the AWS Glue Data Catalog with table definitions, see [Creating tables](#).

## 2. Define a job that describes the transformation of data from source to target.

Generally, to create a job, you have to make the following choices:

- Choose a table from the AWS Glue Data Catalog to be the source of the job. Your job uses this table definition to access your data source and interpret the format of your data.
- Choose a table or location from the AWS Glue Data Catalog to be the target of the job. Your job uses this information to access your data store.
- Tell AWS Glue to generate a script to transform your source to target. AWS Glue generates the code to call built-in transforms to convert data from its source schema to target schema format. These transforms perform operations such as copy data, rename columns, and filter data to transform data as necessary. You can modify this script in the AWS Glue console.

For more information about defining jobs in AWS Glue, see [Building visual ETL jobs with AWS Glue Studio](#).

## 3. Run your job to transform your data.

You can run your job on demand, or start it based on a one of these trigger types:

- A trigger that is based on a cron schedule.

- A trigger that is event-based; for example, the successful completion of another job can start an AWS Glue job.
- A trigger that starts a job on demand.

For more information about triggers in AWS Glue, see [Starting jobs and crawlers using triggers](#).

#### 4. Monitor your scheduled crawlers and triggered jobs.

Use the AWS Glue console to view the following:

- Job run details and errors.
- Crawler run details and errors.
- Any notifications about AWS Glue activities

For more information about monitoring your crawlers and jobs in AWS Glue, see [Monitoring AWS Glue](#).

## Setting up IAM permissions for AWS Glue

The instructions in this topic help you quickly set up AWS Identity and Access Management (IAM) permissions for AWS Glue. You will complete the following tasks:

- Grant your IAM identities access to AWS Glue resources.
- Create a service role for running jobs, accessing data, and running AWS Glue Data Quality tasks.

For detailed instructions that you can use to customize IAM permissions for AWS Glue, see [Configuring IAM permissions for AWS Glue](#).

### To set up IAM permissions for AWS Glue in the AWS Management Console

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose **Getting started**.
3. Under **Prepare your account for AWS Glue**, choose **Set up IAM permissions**.
4. Choose the IAM identities (roles or users) that you want to give AWS Glue permissions to. AWS Glue attaches the [AWSGlueConsoleFullAccess](#) managed policy to these identities. You can skip this step if you want to set these permissions manually or only want to set a default service role.

5. Choose **Next**.
6. Choose the level of Amazon S3 access that your roles and users need. The options that you choose in this step are applied to all of the identities that you selected.
  - a. Under **Choose S3 locations**, choose the Amazon S3 locations that you want to grant access to.
  - b. Next, select whether your identities should have **Read only (recommended)** or **Read and write** access to the locations that you previously selected. AWS Glue adds permissions policies to your identities based on the combination of locations and read or write permissions you select.

The following table displays the permissions that AWS Glue attaches for Amazon S3 access.

If you choose ...	AWS Glue attaches ...
<b>No change</b>	No permissions. AWS Glue won't make any changes to your identity's permissions.
<b>Grant access to specific Amazon S3 locations (read only)</b>	<p>An inline policy embedded in your selected IAM identities. For more information, see <a href="#">Inline policies</a> in the IAM User Guide.</p> <p>AWS Glue names the policy using the following convention: <code>AWSGlueConsole &lt;Role/User&gt; InlinePolicy-read-specific-access- &lt;UUID&gt;</code>. For example: <code>AWSGlueConsoleRoleInlinePolicy-read-specific-access-123456780123</code> .</p> <p>The following is an example of an inline policy that AWS Glue attaches to grant read-only access to a specified Amazon S3 location.</p>

If you choose ...	AWS Glue attaches ...
	<pre data-bbox="917 220 1507 877">{   "Version": "2012-10-17",   "Statement": [     {       "Effect": "Allow",       "Action": [         "s3:Get*",         "s3:List*"       ],       "Resource": [         "arn:aws: s3:::DOC-EXAMPLE-BUCKET/*"       ]     }   ] }</pre>

If you choose ...	AWS Glue attaches ...
<p><b>Grant access to specific Amazon S3 locations (read and write)</b></p>	<p>An inline policy embedded in your selected IAM identities. For more information, see <a href="#">Inline policies</a> in the IAM User Guide.</p> <p>AWS Glue names the policy using the following convention: <code>AWSGlueConsole &lt;Role/User&gt; InlinePolicy-read-and-write-specific-access- &lt;UUID&gt;</code>. For example: <code>AWSGlueConsoleRoleInlinePolicy-read-and-write-specific-access-123456780123</code>.</p> <p>The following is an example of an inline policy that AWS Glue attaches to grant read and write access to specified Amazon S3 locations.</p> <pre data-bbox="915 1079 1507 1810"> {   "Version": "2012-10-17",   "Statement": [     {       "Effect": "Allow",       "Action": [         "s3:Get*",         "s3:List*",         "s3:*Object*"       ],       "Resource": [         "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*",         "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"       ]     }   ] } </pre>

If you choose ...	AWS Glue attaches ...
	}
Grant full access to Amazon S3 (read only)	The <a href="#">AmazonS3ReadOnlyAccess</a> managed IAM policy. To learn more, see <a href="#">AWS managed policy: AmazonS3ReadOnlyAccess</a> .
Grant full access to Amazon S3 (read and write)	The <a href="#">AmazonS3FullAccess</a> managed IAM policy. To learn more, see <a href="#">AWS managed policy: AmazonS3FullAccess</a> .

7. Choose **Next**.
8. Choose a default AWS Glue service role for your account. A service role is an IAM role that AWS Glue uses to access resources in other AWS services on your behalf. For more information, see [Service roles for AWS Glue](#).
  - When you choose the standard AWS Glue service role, AWS Glue creates a new IAM role in your AWS account named `AWSGlueServiceRole` with the following managed policies attached. If your account already has an IAM role named `AWSGlueServiceRole`, AWS Glue attaches these policies to the existing role.
    - [AWSGlueServiceRole](#)
    - [AmazonS3FullAccess](#)
  - When you choose an existing IAM role, AWS Glue sets the role as the default, but doesn't add any permissions to it. Ensure that you've configured the role to use as a service role for AWS Glue. For more information, see [Step 1: Create an IAM policy for the AWS Glue service](#) and [Step 2: Create an IAM role for AWS Glue](#).
9. Choose **Next**.
10. Finally, review the permissions you've selected and then choose **Apply changes**. When you apply the changes, AWS Glue adds IAM permissions to the identities that you selected. You can view or modify the new permissions in the IAM console at <https://console.aws.amazon.com/iam/>.

You've now completed the minimum IAM permissions setup for AWS Glue. In a production environment, we recommend that you familiarize yourself with [Security in AWS Glue](#) and [Identity and access management for AWS Glue](#) to help you secure AWS resources for your use case.

## Next steps

Now that you have IAM permissions set up, you can explore the following topics to get started using AWS Glue:

- [Getting Started with AWS Glue in AWS Skill Builder](#)
- [Getting started with the AWS Glue Data Catalog](#)

## Setting up for AWS Glue Studio

Complete the tasks in this section when you're using AWS Glue for the visual ETL for the first time:

### Topics

- [Review IAM permissions needed for the AWS Glue Studio user](#)
- [Review IAM permissions needed for ETL jobs](#)
- [Set up IAM permissions for AWS Glue Studio](#)
- [Configure a VPC for your ETL job](#)

## Review IAM permissions needed for the AWS Glue Studio user

To use AWS Glue Studio, the user must have access to various AWS resources. The user must be able to view and select Amazon S3 buckets, IAM policies and roles, and AWS Glue Data Catalog objects.

### AWS Glue service permissions

AWS Glue Studio uses the actions and resources of the AWS Glue service. Your user needs permissions on these actions and resources to effectively use AWS Glue Studio. You can grant the AWS Glue Studio user the `AWSGlueConsoleFullAccess` managed policy, or create a custom policy with a smaller set of permissions.

**⚠ Important**

Per security best practices, it is recommended to restrict access by tightening policies to further restrict access to Amazon S3 bucket and Amazon CloudWatch log groups. For an example Amazon S3 policy, see [Writing IAM Policies: How to Grant Access to an Amazon S3 Bucket](#).

**Creating Custom IAM Policies for AWS Glue Studio**

You can create a custom policy with a smaller set of permissions for AWS Glue Studio. The policy can grant permissions for a subset of objects or actions. Use the following information when creating a custom policy.

To use the AWS Glue Studio APIs, include `glue:UseGlueStudio` in the action policy in your IAM permissions. Using `glue:UseGlueStudio` will allow you to access all AWS Glue Studio actions even as more actions are added to the API over time.

**Directed acyclic graph (DAG) Actions**

- CreateDag
- UpdateDag
- GetDag
- DeleteDag

**Job Actions**

- SaveJob
- GetJob
- CreateJob
- DeleteJob
- GetJobs
- UpdateJob

**Job run Actions**

- StartJobRun
- GetJobRuns
- BatchStopJobRun
- GetJobRun
- QueryJobRuns
- QueryJobs
- QueryJobRunsAggregated

### **Schema Actions**

- GetSchema
- GetInferredSchema

### **Database Actions**

- GetDatabases

### **Plan Actions**

- GetPlan

### **Table Actions**

- SearchTables
- GetTables
- GetTable

### **Connection Actions**

- CreateConnection
- DeleteConnection
- UpdateConnection
- GetConnections
- GetConnection

## Mapping Actions

- GetMapping

## S3 Proxy Actions

- ListBuckets
- ListObjectsV2
- GetBucketLocation

## Security Configuration Actions

- GetSecurityConfigurations

## Script Actions

- CreateScript (different from API of same name in AWS Glue)

## Accessing AWS Glue Studio APIs

To access AWS Glue Studio, add `glue:UseGlueStudio` in the actions policy list in the IAM permissions.

In the example below, `glue:UseGlueStudio` is included in the action policy, but the AWS Glue Studio APIs are not individually identified. That is because when you include `glue:UseGlueStudio`, you are automatically granted access to the internal APIs without having to specify the individual AWS Glue Studio APIs in the IAM permissions.

In the example, the additional listed action policies (for example, `glue:SearchTables`) are not AWS Glue Studio APIs, so they will need to be included in the IAM permissions as required. You may also want to include Amazon S3 Proxy actions to specify the level of Amazon S3 access to grant. The example policy below provides access to open AWS Glue Studio, create a visual job, and save/run it if the IAM role selected has sufficient access.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
"Sid": "VisualEditor0",
"Effect": "Allow",
"Action": [
    "glue:UseGlueStudio",
    "iam:ListRoles",
    "iam:ListUsers",
    "iam:ListGroups",
    "iam:ListRolePolicies",
    "iam:GetRole",
    "iam:GetRolePolicy",
    "glue:SearchTables",
    "glue:GetConnections",
    "glue:GetJobs",
    "glue:GetTables",
    "glue:BatchStopJobRun",
    "glue:GetSecurityConfigurations",
    "glue>DeleteJob",
    "glue:GetDatabases",
    "glue:CreateConnection",
    "glue:GetSchema",
    "glue:GetTable",
    "glue:GetMapping",
    "glue:CreateJob",
    "glue>DeleteConnection",
    "glue:CreateScript",
    "glue:UpdateConnection",
    "glue:GetConnection",
    "glue:StartJobRun",
    "glue:GetJobRun",
    "glue:UpdateJob",
    "glue:GetPlan",
    "glue:GetJobRuns",
    "glue:GetTags",
    "glue:GetJob",
    "glue:QueryJobRuns",
    "glue:QueryJobs",
    "glue:QueryJobRunsAggregated"
],
"Resource": "*"
},
{
    "Action": [
        "iam:PassRole"
    ],
```

```
    "Effect": "Allow",
    "Resource": "arn:aws:iam::*:role/AWSGlueServiceRole*",
    "Condition": {
      "StringLike": {
        "iam:PassedToService": [
          "glue.amazonaws.com"
        ]
      }
    }
  ]
}
```

## Notebook and data preview permissions

Data previews and notebooks allow you to see a sample of your data at any stage of your job (reading, transforming, writing), without having to run the job. You specify an AWS Identity and Access Management (IAM) role for AWS Glue Studio to use when accessing the data. IAM roles are intended to be assumable and do not have standard long-term credentials such as a password or access keys associated with it. Instead, when AWS Glue Studio assumes the role, IAM provides it with temporary security credentials.

To ensure data previews and notebook commands work correctly, use a role that has a name that starts with the string `AWSGlueServiceRole`. If you choose to use a different name for your role, then you must add the `iam:passrole` permission and configure a policy for the role in IAM. For more information, see [Create an IAM policy for roles not named "AWSGlueServiceRole"](#).

### Warning

If a role grants the `iam:passrole` permission for a notebook, and you implement role chaining, a user could unintentionally gain access to the notebook. There is currently no auditing implemented which would allow you to monitor which users have been granted access to the notebook.

If you would like to deny an IAM identity the ability to create data preview sessions, consult the following example [the section called "Deny an identity the ability to create data preview sessions"](#).

## Amazon CloudWatch permissions

You can monitor your AWS Glue Studio jobs using Amazon CloudWatch, which collects and processes raw data from AWS Glue into readable, near-real-time metrics. By default, AWS Glue metrics data is sent to CloudWatch automatically. For more information, see [What Is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*, and [AWS Glue Metrics](#) in the *AWS Glue Developer Guide*.

To access CloudWatch dashboards, the user accessing AWS Glue Studio needs one of the following:

- The `AdministratorAccess` policy
- The `CloudWatchFullAccess` policy
- A custom policy that includes one or more of these specific permissions:
  - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to view dashboards
  - `cloudwatch:PutDashboard` to create or modify dashboards
  - `cloudwatch:DeleteDashboards` to delete dashboards

For more information for changing permissions for an IAM user using policies, see [Changing Permissions for an IAM User](#) in the *IAM User Guide*.

## Review IAM permissions needed for ETL jobs

When you create a job using AWS Glue Studio, the job assumes the permissions of the IAM role that you specify when you create it. This IAM role must have permission to extract data from your data source, write data to your target, and access AWS Glue resources.

The name of the role that you create for the job must start with the string `AWSGlueServiceRole` for it to be used correctly by AWS Glue Studio. For example, you might name your role `AWSGlueServiceRole-FlightDataJob`.

## Data source and data target permissions

An AWS Glue Studio job must have access to Amazon S3 for any sources, targets, scripts, and temporary directories that you use in your job. You can create a policy to provide fine-grained access to specific Amazon S3 resources.

- Data sources require `s3:ListBucket` and `s3:GetObject` permissions.
- Data targets require `s3:ListBucket`, `s3:PutObject`, and `s3:DeleteObject` permissions.

If you choose Amazon Redshift as your data source, you can provide a role for cluster permissions. Jobs that run against a Amazon Redshift cluster issue commands that access Amazon S3 for temporary storage using temporary credentials. If your job runs for more than an hour, these credentials will expire causing the job to fail. To avoid this problem, you can assign a role to the Amazon Redshift cluster itself that grants the necessary permissions to jobs using temporary credentials. For more information, see [Moving Data to and from Amazon Redshift](#) in the *AWS Glue Developer Guide*.

If the job uses data sources or targets other than Amazon S3, then you must attach the necessary permissions to the IAM role used by the job to access these data sources and targets. For more information, see [Setting Up Your Environment to Access Data Stores](#) in the *AWS Glue Developer Guide*.

If you're using connectors and connections for your data store, you need additional permissions, as described in [the section called "Permissions required for using connectors"](#).

### Permissions required for deleting jobs

In AWS Glue Studio you can select multiple jobs in the console to delete. To perform this action, you must have the `glue:BatchDeleteJob` permission. This is different from the AWS Glue console, which requires the `glue>DeleteJob` permission for deleting jobs.

### AWS Key Management Service permissions

If you plan to access Amazon S3 sources and targets that use server-side encryption with AWS Key Management Service (AWS KMS), then attach a policy to the AWS Glue Studio role used by the job that enables the job to decrypt the data. The job role needs the `kms:ReEncrypt`, `kms:GenerateDataKey`, and `kms:DescribeKey` permissions. Additionally, the job role needs the `kms:Decrypt` permission to upload or download an Amazon S3 object that is encrypted with an AWS KMS customer master key (CMK).

There are additional charges for using AWS KMS CMKs. For more information, see [AWS Key Management Service Concepts - Customer Master Keys \(CMKs\)](#) and [AWS Key Management Service Pricing](#) in the *AWS Key Management Service Developer Guide*.

### Permissions required for using connectors

If you're using an AWS Glue Custom Connector and connection to access a data store, the role used to run the AWS Glue ETL job needs additional permissions attached:

- The AWS managed policy `AmazonEC2ContainerRegistryReadOnly` for accessing connectors purchased from AWS Marketplace.
- The `glue:GetJob` and `glue:GetJobs` permissions.
- AWS Secrets Manager permissions for accessing secrets that are used with connections. Refer to [Example: Permission to retrieve secret values](#) for example IAM policies.

If your AWS Glue ETL job runs within a VPC running Amazon VPC, then the VPC must be configured as described in [the section called "Configure a VPC for your ETL job"](#).

## Set up IAM permissions for AWS Glue Studio

You can create the roles and assign policies to users and job roles by using the AWS administrator user.

You can use the **AWSGlueConsoleFullAccess** AWS managed policy to provide the necessary permissions for using the AWS Glue Studio console.

To create your own policy, follow the steps documented in [Create an IAM Policy for the AWS Glue Service](#) in the *AWS Glue Developer Guide*. Include the IAM permissions described previously in [Review IAM permissions needed for the AWS Glue Studio user](#).

### Topics

- [Attach policies to the AWS Glue Studio user](#)
- [Create an IAM policy for roles not named "AWSGlueServiceRole"](#)

### Attach policies to the AWS Glue Studio user

Any AWS user that signs in to the AWS Glue Studio console must have permissions to access specific resources. You provide those permissions by using assigning IAM policies to the user.

### To attach the **AWSGlueConsoleFullAccess** managed policy to a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to the **AWSGlueConsoleFullAccess**. You can use the **Filter** menu and the search box to filter the list of policies.

4. Choose **Policy actions**, and then choose **Attach**.
5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.
6. Repeat the previous steps to attach additional policies to the user, as needed.

## Create an IAM policy for roles not named "AWSGlueServiceRole"

### To configure an IAM policy for roles used by AWS Glue Studio

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Add a new IAM policy. You can add to an existing policy or create a new IAM inline policy. To create an IAM policy:
  1. Choose **Policies**, and then choose **Create Policy**. If a **Get Started** button appears, choose it, and then choose **Create Policy**.
  2. Next to **Create Your Own Policy**, choose **Select**.
  3. For **Policy Name**, type any value that is easy for you to refer to later. Optionally, type descriptive text in **Description**.
  4. For **Policy Document**, type a policy statement with the following format, and then choose **Create Policy**:
3. Copy and paste the following blocks into the policy under the "Statement" array, replacing *my-interactive-session-role-prefix* with the prefix for all common roles to associate with permissions for AWS Glue.

```
{
  "Action": [
    "iam:PassRole"
  ],
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/my-interactive-session-role-prefix",
  "Condition": {
    "StringLike": {
      "iam:PassedToService": [
        "glue.amazonaws.com "
      ]
    }
  }
}
```

```
    }
  }
}
```

Here is the full example with the Version and Statement arrays included in the policy

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "iam:PassRole"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:iam::*:role/my-interactive-session-role-prefix*",
      "Condition": {
        "StringLike": {
          "iam:PassedToService": [
            "glue.amazonaws.com "
          ]
        }
      }
    }
  ]
}
```

4. To enable the policy for a user, choose **Users**.
5. Choose the user to whom you want to attach the policy.

## Configure a VPC for your ETL job

You can use Amazon Virtual Private Cloud (Amazon VPC) to define a virtual network in your own logically isolated area within the AWS Cloud, known as a *virtual private cloud (VPC)*. You can launch your AWS resources, such as instances, into your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using the scalable infrastructure of AWS. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet. You can connect your VPC to your own corporate data center, making the AWS Cloud an extension of your data center. To protect the resources in each subnet, you can use multiple layers of security, including security groups and network access control lists. For more information, see the [Amazon VPC User Guide](#).

You can configure your AWS Glue ETL jobs to run within a VPC when using connectors. You must configure your VPC for the following, as needed:

- Public network access for data stores not in AWS. All data stores that are accessed by the job must be available from the VPC subnet.
- If your job needs to access both VPC resources and the public internet, the VPC needs to have a network address translation (NAT) gateway inside the VPC.

For more information, see [Setting Up Your Environment to Access Data Stores](#) in the *AWS Glue Developer Guide*.

## Getting started with notebooks in AWS Glue Studio

When you start a notebook through AWS Glue Studio, all the configuration steps are done for you so that you can explore your data and start developing your job script after only a few seconds.

The following sections describe how to create a role and grant the appropriate permissions to use notebooks in AWS Glue Studio for ETL jobs.

### Topics

- [Granting permissions for the IAM role](#)

## Granting permissions for the IAM role

Setting up AWS Glue Studio is a pre-requisite to using notebooks.

To use notebooks in AWS Glue, your role requires the following:

- A trust relationship with AWS Glue for the `sts:AssumeRole` action and, if you want tagging then `sts:TagSession`.
- An IAM policy containing all the API operations for notebooks, AWS Glue, and interactive sessions.
- An IAM policy for a pass role since the role needs to be able to pass itself from the notebook to interactive sessions.

For example, when you create a new role, you can add a standard AWS managed policy like `AWSGlueConsoleFullAccessRole` to the role, and then add a new policy for the notebook operations and another for the IAM PassRole policy.

### Actions needed for a trust relationship with AWS Glue

When starting a notebook session, you must add the `sts:AssumeRole` to the trust relationship of the role that is passed to the notebook. If your session includes tags, you must also pass the `sts:TagSession` action. Without these actions, the notebook session cannot start.

For example:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

### Policies containing the API operations for notebooks

The following sample policy describes the required AWS IAM permissions for notebooks. If you are creating a new role, create a policy that contains the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartNotebook",
        "glue:TerminateNotebook",
        "glue:GlueNotebookRefreshCredentials",
        "glue:DeregisterDataPreview",

```

```

        "glue:GetNotebookInstanceStatus",
        "glue:GlueNotebookAuthorize"
    ],
    "Resource": "*"
}
]
}

```

You can use the following IAM policies to allow access to specific resources:

- *AwsGlueSessionUserRestrictedNotebookServiceRole*: Provides full access to all AWS Glue resources except for sessions. Allows users to create and use only the notebook sessions that are associated with the user. This policy also includes other permissions needed by AWS Glue to manage AWS Glue resources in other AWS services.
- *AwsGlueSessionUserRestrictedNotebookPolicy*: Provides permissions that allows users to create and use only the notebook sessions that are associated with the user. This policy also includes permissions to explicitly allow users to pass a restricted AWS Glue session role.

### IAM policy to pass a role

When you create a notebook with a role, that role is then passed to interactive sessions so that the same role can be used in both places. As such, the `iam:PassRole` permission needs to be part of the role's policy.

Create a new policy for your role using the following example. Replace the account number with your own and the role name.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::090000000210:role/<role_name>"
    }
  ]
}

```

# Getting started with the AWS Glue Data Catalog

The AWS Glue Data Catalog is your persistent technical metadata store. It is a managed service that you can use to store, annotate, and share metadata in the AWS Cloud. For more information, see [AWS Glue Data Catalog](#).

The AWS Glue console and some user interfaces were recently updated.

## Overview

You can use this tutorial to create your first AWS Glue Data Catalog, which uses an Amazon S3 bucket as your data source.

In this tutorial, you'll do the following using the AWS Glue console:

1. Create a database
2. Create a table
3. Use an Amazon S3 bucket as a data source

After completing these steps, you will have successfully used an Amazon S3 bucket as the data source to populate the AWS Glue Data Catalog.

## Step 1: Create a database

To get started, sign in to the AWS Management Console and open the [AWS Glue console](#).

**To create a database using the AWS Glue console:**

1. In the AWS Glue console, choose **Databases** under **Data catalog** from the left-hand menu.
2. Choose **Add database**.
3. In the Create a database page, enter a name for the database. In the **Location - optional** section, set the URI location for use by clients of the Data Catalog. If you don't know this, you can continue with creating the database.
4. (Optional). Enter a description for the database.
5. Choose **Create database**.

Congratulations, you've just set up your first database using the AWS Glue console. Your new database will appear in the list of available databases. You can edit the database by choosing the database's name from the **Databases** dashboard.

## Next steps

### Other ways to create a database:

You just created a database using the AWS Glue console, but there are other ways to create a database:

- You can use crawlers to create a database and tables for you automatically. To set up a database using crawlers, see [Working with Crawlers in the AWS Glue Console](#).
- You can use AWS CloudFormation templates. See [Creating AWS Glue Resources Using AWS Glue Data Catalog Templates](#).
- You can also create a database using the AWS Glue Database API operations.

To create a database using the `create` operation, structure the request by including the `DatabaseInput` (required) parameters.

For example:

The following are examples of how you can use the CLI, Boto3, or DDL to define a table based on the same `flights_data.csv` file from the S3 bucket that you used in the tutorial.

#### CLI

```
aws glue create-database --database-input "{\"Name\":\"clidb\"}"
```

#### Boto3

```
glueClient = boto3.client('glue')

response = glueClient.create_database(
    DatabaseInput={
        'Name': 'boto3db'
    }
)
```

For more information about the Database API data types, structure, and operations, see [Database API](#).

## Next Steps

In the next section, you'll create a table and add that table to your database.

You can also explore the settings and permissions for your Data Catalog. See [Working with Data Catalog Settings in the AWS Glue Console](#).

## Step 2. Create a table

In this step, you create a table using the AWS Glue console.

1. In the AWS Glue console, choose **Tables** in the left-hand menu.
2. Choose **Add table**.
3. Set your table's properties by entering a name for your table in **Table details**.
4. In the **Databases** section, choose the database that you created in Step 1 from the drop-down menu.
5. In **Add a data store** section, **S3** will be selected by default as the type of source.
6. For **Data is located in**, choose **Specified path in another account**.
7. Copy and paste the path for the **Include path** input field:  

```
s3://crawler-public-us-west-2/flight/2016/csv/
```
8. In the section **Data format**, for **Classification**, choose **CSV**. and for **Delimiter**, choose **comma (,)**. Choose **Next**.
9. You are asked to define a schema. A schema defines the structure and format of a data record. Choose **Add column**. (For more information, see [See Schema registries](#)).
10. Specify the column properties:
  - a. Enter a column name.
  - b. For **Column type**, 'string' is already selected by default.
  - c. For **Column number**, '1' is already selected by default.
  - d. Choose **Add**.
11. You are asked to add partition indexes. This is optional. To skip this step, choose **Next**.
12. A summary of the table properties is displayed. If everything looks as expected, choose **Create**. Otherwise, choose **Back** and make edits as needed.

Congratulations, you've successfully created a table manually and associated it to a database. Your newly created table will appear in the Tables dashboard. From the dashboard, you can modify and manage all your tables.

For more information, see [Working with Tables in the AWS Glue Console](#).

## Next steps

### Next steps

Now that the Data Catalog is populated, you can begin authoring jobs in AWS Glue. See [Building visual ETL jobs with AWS Glue Studio](#).

In addition to using the console, there are other ways to define tables in the Data Catalog including:

- [Creating and running a crawler](#)
- [Adding classifiers to a crawler in AWS Glue](#)
- [Using the AWS Glue Table API](#)
- [Using the AWS Glue Data Catalog template](#)
- [Migrating an Apache Hive metastore](#)
- [Using the AWS CLI](#), Boto3, or data definition language (DDL)

The following are examples of how you can use the CLI, Boto3, or DDL to define a table based on the same `flights_data.csv` file from the S3 bucket that you used in the tutorial.

See the documentation on how to structure an AWS CLI command. The CLI example contains the JSON syntax for the `'aws glue create-table --table-input'` value.

CLI

```
{
  "Name": "flights_data_cli",
  "StorageDescriptor": {
    "Columns": [
      {
        "Name": "year",
        "Type": "bigint"
      },
      {
        "Name": "quarter",
```

```

        "Type": "bigint"
    }
],
"Location": "s3://crawler-public-us-west-2/flight/2016/csv",
"InputFormat": "org.apache.hadoop.mapred.TextInputFormat",
"OutputFormat":
"org.apache.hadoop.hive.q1.io.HiveIgnoreKeyTextOutputFormat",
"Compressed": false,
"NumberOfBuckets": -1,
"SerdeInfo": {
    "SerializationLibrary":
"org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe",
    "Parameters": {
        "field.delim": ",",
        "serialization.format": ","
    }
}
},
"PartitionKeys": [
    {
        "Name": "mon",
        "Type": "string"
    }
],
"TableType": "EXTERNAL_TABLE",
"Parameters": {
    "EXTERNAL": "TRUE",
    "classification": "csv",
    "columnsOrdered": "true",
    "compressionType": "none",
    "delimiter": ",",
    "skip.header.line.count": "1",
    "typeOfData": "file"
}
}

```

## Boto3

```

import boto3

glue_client = boto3.client("glue")

```

```
response = glue_client.create_table(  
    DatabaseName='sampledb',  
    TableInput={  
        'Name': 'flights_data_manual',  
        'StorageDescriptor': {  
            'Columns': [{  
                'Name': 'year',  
                'Type': 'bigint'  
            }], {  
                'Name': 'quarter',  
                'Type': 'bigint'  
            }  
        ]},  
        'Location': 's3://crawler-public-us-west-2/flight/2016/csv',  
        'InputFormat': 'org.apache.hadoop.mapred.TextInputFormat',  
        'OutputFormat':  
        'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat',  
        'Compressed': False,  
        'NumberOfBuckets': -1,  
        'SerdeInfo': {  
            'SerializationLibrary':  
            'org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe',  
            'Parameters': {  
                'field.delim': ',',  
                'serialization.format': ','  
            }  
        },  
        'PartitionKeys': [{  
            'Name': 'mon',  
            'Type': 'string'  
        }],  
        'TableType': 'EXTERNAL_TABLE',  
        'Parameters': {  
            'EXTERNAL': 'TRUE',  
            'classification': 'csv',  
            'columnsOrdered': 'true',  
            'compressionType': 'none',  
            'delimiter': ',',  
            'skip.header.line.count': '1',  
            'typeOfData': 'file'  
        }  
    }  
)
```

## DDL

```
CREATE EXTERNAL TABLE `sampledb`.`flights_data` (  
  `year` bigint,  
  `quarter` bigint)

  'skip.header.line.count'='1',  
  'typeOfData'='file')
```

## Setting up network access to data stores

To run your extract, transform, and load (ETL) jobs, AWS Glue must be able to access your data stores. If a job doesn't need to run in your virtual private cloud (VPC) subnet—for example, transforming data from Amazon S3 to Amazon S3—no additional configuration is needed.

If a job needs to run in your VPC subnet—for example, transforming data from a JDBC data store in a private subnet—AWS Glue sets up [elastic network interfaces](#) that enable your jobs to connect securely to other resources within your VPC. Each elastic network interface is assigned a private IP address from the IP address range within the subnet you specified. No public IP addresses are assigned. Security groups specified in the AWS Glue connection are applied on each of the elastic network interfaces. For more information, see [Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from AWS Glue](#).

All JDBC data stores that are accessed by the job must be available from the VPC subnet. To access Amazon S3 from within your VPC, a [VPC endpoint](#) is required. If your job needs to access both VPC resources and the public internet, the VPC needs to have a Network Address Translation (NAT) gateway inside the VPC.

A job or development endpoint can only access one VPC (and subnet) at a time. If you need to access data stores in different VPCs, you have the following options:

- Use VPC peering to access the data stores. For more about VPC peering, see [VPC Peering Basics](#)
- Use an Amazon S3 bucket as an intermediary storage location. Split the work into two jobs, with the Amazon S3 output of job 1 as the input to job 2.

For details on how to connect to a Amazon Redshift data store using Amazon VPC, see [the section called "Configure Redshift"](#).

For details on how to connect to Amazon RDS data stores using Amazon VPC, see [the section called "Setting up Amazon VPC to connect to Amazon RDS data stores"](#).

Once necessary rules are set in Amazon VPC, you create a connection in AWS Glue with the necessary properties to connect to your data stores. For more information about the connection, see [Connecting to data](#).

#### Note

Make sure you set up your DNS environment for AWS Glue. For more information, see [Setting up DNS in your VPC](#).

## Topics

- [Setting up a VPC to connect to PyPI for AWS Glue](#)
- [Setting up DNS in your VPC](#)

## Setting up a VPC to connect to PyPI for AWS Glue

The Python Package Index (PyPI) is a repository of software for the Python programming language. This topic addresses the details needed to support the use of pip installed packages (as specified by the session creator using the `--additional-python-modules` flag).

Using AWS Glue interactive sessions with a connector results in the use of VPC network via the subnet specified for the connector. Consequently AWS services and other network destinations are not available unless you set up a special configuration.

The resolutions to this issue include:

- Use of an internet gateway which is reachable by your session.
- Set up and use of an S3 bucket with a PyPI/simple repo containing the transitive closure of a package set's dependencies.
- Use of a CodeArtifact repository which is mirroring PyPI and attached to your VPC.

## Setting up an internet gateway

The technical aspects are detailed in [NAT gateway use cases](#) but note these requirements for using `--additional-python-modules`. Specifically, `--additional-python-modules` requires access to pypi.org which is determined by the configuration of your VPC. Note the following requirements:

1. The requirement of installing additional python modules via `pip install` for a user's session. If the session uses a connector, your configuration may be affected.
2. When a connector is being used with `--additional-python-modules`, when the session is started the subnet associated with the connector's `PhysicalConnectionRequirements` has to provide a network path for reaching pypi.org.
3. You must determine whether or not your configuration is correct.

## Setting up an Amazon S3 bucket to host a targeted PyPI/simple repo

This example sets up a PyPI mirror in Amazon S3 for a set of packages and their dependencies.

To set up the PyPI mirror for a set of packages:

```
# pip download all the dependencies
pip download -d s3pypi --only-binary :all: plotly ggplot
pip download -d s3pypi --platform manylinux_2_17_x86_64 --only-binary :all: psycopg2-
binary
# create and upload the pypi/simple index and wheel files to the s3 bucket
s3pypi -b test-domain-name --put-root-index -v s3pypi/*
```

If you already have an existing artifact repository, it will have an index URL for pip's use that you can provide in place of the example URL for the Amazon S3 bucket as above.

To use the custom index-url, with some example packages:

```
%%configure
{
  "--additional-python-modules": "psycopy2_binary==2.9.5",
  "python-modules-installer-option": "--no-cache-dir --verbose --index-url https://
test-domain-name.s3.amazonaws.com/ --trusted-host test-domain-name.s3.amazonaws.com"
}
```

## Setting up a CodeArtifact mirror of pypi attached to your VPC

To set up a mirror:

1. Create a repository in the same region as the subnet used by the connector.

Select `Public upstream repositories` and choose `pypi-store`.

2. Provide access to the repository from the VPC for the subnet.
3. Specify the correct `--index-url` using the `python-modules-installer-option`.

```
%%configure
{
  "--additional-python-modules": "psycopy2_binary==2.9.5",
  "python-modules-installer-option": "--no-cache-dir --verbose --index-url https://
test-domain-name.s3.amazonaws.com/ --trusted-host test-domain-name.s3.amazonaws.com"
}
```

For more information, see [Use CodeArtifact from a VPC](#).

## Setting up DNS in your VPC

Domain Name System (DNS) is a standard by which names used on the internet are resolved to their corresponding IP addresses. A DNS hostname uniquely names a computer and consists of a host name and a domain name. DNS servers resolve DNS hostnames to their corresponding IP addresses.

To set up DNS in your VPC, ensure that DNS hostnames and DNS resolution are both enabled in your VPC. The VPC network attributes `enableDnsHostnames` and `enableDnsSupport`

must be set to `true`. To view and modify these attributes, go to the VPC console at <https://console.aws.amazon.com/vpc/>.

For more information, see [Using DNS with your VPC](#). Also, you can use the AWS CLI and call the [modify-vpc-attribute](#) command to configure the VPC network attributes.

### Note

If you are using Route 53, confirm that your configuration does not override DNS network attributes.

## Setting up encryption in AWS Glue

The following example workflow highlights the options to configure when you use encryption with AWS Glue. The example demonstrates the use of specific AWS Key Management Service (AWS KMS) keys, but you might choose other settings based on your particular needs. This workflow highlights only the options that pertain to encryption when setting up AWS Glue.

1. If the user of the AWS Glue console doesn't use a permissions policy that allows all AWS Glue API operations (for example, `"glue: *"`), confirm that the following actions are allowed:
  - `"glue:GetDataCatalogEncryptionSettings"`
  - `"glue:PutDataCatalogEncryptionSettings"`
  - `"glue:CreateSecurityConfiguration"`
  - `"glue:GetSecurityConfiguration"`
  - `"glue:GetSecurityConfigurations"`
  - `"glue>DeleteSecurityConfiguration"`
2. Any client that accesses or writes to an encrypted catalog—that is, any console user, crawler, job, or development endpoint—needs the following permissions.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:GenerateDataKey",
      "kms:Decrypt",
      "kms:Encrypt"
    ]
  }
}
```

```

    ],
    "Resource": "<key-arns-used-for-data-catalog>"
  }
}

```

3. Any user or role that accesses an encrypted connection password needs the following permissions.

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Decrypt"
    ],
    "Resource": "<key-arns-used-for-password-encryption>"
  }
}

```

4. The role of any extract, transform, and load (ETL) job that writes encrypted data to Amazon S3 needs the following permissions.

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Decrypt",
      "kms:Encrypt",
      "kms:GenerateDataKey"
    ],
    "Resource": "<key-arns-used-for-s3>"
  }
}

```

5. Any ETL job or crawler that writes encrypted Amazon CloudWatch Logs requires the following permissions in the key and IAM policies.

In the key policy (not the IAM policy):

```

{
  "Effect": "Allow",
  "Principal": {

```

```

    "Service": "logs.region.amazonaws.com"
  },
  "Action": [
    "kms:Encrypt*",
    "kms:Decrypt*",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:Describe*"
  ],
  "Resource": "<arn of key used for ETL/crawler cloudwatch encryption>"
}

```

For more information about key policies, see [Using Key Policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

In the IAM policy attach the `logs:AssociateKmsKey` permission:

```

{
  "Effect": "Allow",
  "Principal": {
    "Service": "logs.region.amazonaws.com"
  },
  "Action": [
    "logs:AssociateKmsKey"
  ],
  "Resource": "<arn of key used for ETL/crawler cloudwatch encryption>"
}

```

6. Any ETL job that uses an encrypted job bookmark needs the following permissions.

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Decrypt",
      "kms:Encrypt"
    ],
    "Resource": "<key-arns-used-for-job-bookmark-encryption>"
  }
}

```

7. On the AWS Glue console, choose **Settings** in the navigation pane.

- a. On the **Data catalog settings** page, encrypt your Data Catalog by selecting **Metadata encryption**. This option encrypts all the objects in the Data Catalog with the AWS KMS key that you choose.
- b. For **AWS KMS key**, choose **aws/glue**. You can also choose a AWS KMS key that you created.

 **Important**

AWS Glue supports only symmetric customer master keys (CMKs). The **AWS KMS key** list displays only symmetric keys. However, if you select **Choose a AWS KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

When encryption is enabled, the client that is accessing the Data Catalog must have AWS KMS permissions.

8. In the navigation pane, choose **Security configurations**. A security configuration is a set of security properties that can be used to configure AWS Glue processes. Then choose **Add security configuration**. In the configuration, choose any of the following options:
  - a. Select **S3 encryption**. For **Encryption mode**, choose **SSE-KMS**. For the **AWS KMS key**, choose **aws/s3** (ensure that the user has permission to use this key). This enables data written by the job to Amazon S3 to use the AWS managed AWS Glue AWS KMS key.
  - b. Select **CloudWatch logs encryption**, and choose a CMK. (Ensure that the user has permission to use this key). For more information, see [Encrypt Log Data in CloudWatch Logs Using AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

 **Important**

AWS Glue supports only symmetric customer master keys (CMKs). The **AWS KMS key** list displays only symmetric keys. However, if you select **Choose a AWS KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

- c. Choose **Advanced properties**, and select **Job bookmark encryption**. For the **AWS KMS key**, choose **aws/glue** (ensure that the user has permission to use this key). This enables encryption of job bookmarks written to Amazon S3 with the AWS Glue AWS KMS key.
9. In the navigation pane, choose **Connections**.

- a. Choose **Add connection** to create a connection to the Java Database Connectivity (JDBC) data store that is the target of your ETL job.
- b. To enforce that Secure Sockets Layer (SSL) encryption is used, select **Require SSL connection**, and test your connection.

10 In the navigation pane, choose **Jobs**.

- a. Choose **Add job** to create a job that transforms data.
- b. In the job definition, choose the security configuration that you created.

11 On the AWS Glue console, run your job on demand. Verify that any Amazon S3 data written by the job, the CloudWatch Logs written by the job, and the job bookmarks are all encrypted.

## Setting up networking for development for AWS Glue

To run your extract, transform, and load (ETL) scripts with AWS Glue, you can develop and test your scripts using a *development endpoint*. Development endpoints are not supported for use with AWS Glue version 2.0 jobs. For versions 2.0 and later, the preferred development method is using Jupyter Notebook with one of the AWS Glue kernels. For more information, see [the section called "Getting started with AWS Glue interactive sessions"](#).

### Setting up your network for a development endpoint

When you set up a development endpoint, you specify a virtual private cloud (VPC), subnet, and security groups.

#### Note

Make sure you set up your DNS environment for AWS Glue. For more information, see [Setting up DNS in your VPC](#).

To enable AWS Glue to access required resources, add a row in your subnet route table to associate a prefix list for Amazon S3 to the VPC endpoint. A prefix list ID is required for creating an outbound security group rule that allows traffic from a VPC to access an AWS service through a VPC endpoint. To ease connecting to a notebook server that is associated with this development endpoint, from your local machine, add a row to the route table to add an internet gateway ID. For more information, see [VPC Endpoints](#). Update the subnet routes table to be similar to the following table:

Destination	Target		
10.0.0.0/16	local		
pl-id for Amazon S3	vpce-id		
0.0.0.0/0	igw-xxxx		

To enable AWS Glue to communicate between its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC, and it's not open to all networks. The default security group for your VPC might already have a self-referencing inbound rule for ALL Traffic.

### To set up a security group

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Security Groups**.
3. Either choose an existing security group from the list, or **Create Security Group** to use with the development endpoint.
4. In the security group pane, navigate to the **Inbound** tab.
5. Add a self-referencing rule to allow AWS Glue components to communicate. Specifically, add or confirm that there is a rule of **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

The inbound rule looks similar to this:

Type	Protocol	Port range	Source
All TCP	TCP	0–65535	<i>security-group</i>

The following shows an example of a self-referencing inbound rule:

6. Add a rule to for outbound traffic also. Either open outbound traffic to all ports, or create a self-referencing rule of **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

The outbound rule looks similar to one of these rules:

Type	Protocol	Port range	Destination
All TCP	TCP	0–65535	<i>security-group</i>
All Traffic	ALL	ALL	0.0.0.0/0

## Setting up Amazon EC2 for a notebook server

With a development endpoint, you can create a notebook server to test your ETL scripts with Jupyter notebooks. To enable communication to your notebook, specify a security group with inbound rules for both HTTPS (port 443) and SSH (port 22). Ensure that the rule's source is either 0.0.0.0/0 or the IP address of the machine that is connecting to the notebook.

### To set up a security group

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Security Groups**.
3. Either choose an existing security group from the list, or **Create Security Group** to use with your notebook server. The security group that is associated with your development endpoint is also used to create your notebook server.
4. In the security group pane, navigate to the **Inbound** tab.
5. Add inbound rules similar to this:

Type	Protocol	Port range	Source
SSH	TCP	22	0.0.0.0/0
HTTPS	TCP	443	0.0.0.0/0

The following shows an example of the inbound rules for the security group:

Security Group: **sg-19e1b768**

Description

**Inbound**

Outbound

SSH	TCP	22	0.0.0.0/0
HTTPS	TCP	443	0.0.0.0/0

# Data discovery and cataloging in AWS Glue

The AWS Glue Data Catalog is a centralized repository that stores metadata about your organization's data sets. It acts as an index to the location, schema, and runtime metrics of your data sources. The metadata is stored in metadata tables, where each table represents a single data store.

You can populate the Data Catalog using a crawler, which automatically scans your data sources and extracts metadata. A crawler can connect to data sources that are internal (AWS-based) and external to AWS.

For more information about the supported data sources, see [Which data stores can I crawl?](#)

You can also create tables in the Data Catalog manually by defining the table structure, schema, and partitioning structure according to your specific requirements.

For more information about creating metadata tables manually, see [Defining metadata manually](#).

You can use the information in the Data Catalog to create and monitor your ETL jobs. The Data Catalog integrates with other AWS analytics services, providing a unified view of data sources making it easier to manage and analyze data.

- Amazon Athena – Store and query table metadata in the Data Catalog for the Amazon S3 data using SQL.
- AWS Lake Formation – Centrally define and manage fine-grained data access policies and audit data access.
- Amazon EMR – Access data sources defined in the Data Catalog for big data processing.
- Amazon SageMaker – Quickly and confidently build, train, and deploy machine learning models.

## Key features of the Data Catalog

The following are the key aspects of the Data Catalog.

### Metadata repository

The Data Catalog acts as a central metadata repository, storing information about the location, schema, and properties of your data sources. This metadata is organized into databases and tables, similar to a traditional relational database catalog.

## Automatic data discoverability

AWS Glue crawlers can automatically discover and catalog new or updated data sources, reducing the overhead of manual metadata management and ensuring that your Data Catalog remains up-to-date. By cataloging your data sources, the Data Catalog makes it easier for users and applications to discover and understand the available data assets within your organization, promoting data reuse and collaboration.

The Data Catalog supports a wide range of data sources, including Amazon S3, Amazon RDS, Amazon Redshift, Apache Hive, and more. It can automatically infer and store metadata from these sources using AWS Glue crawlers.

For more information see, [Using crawlers to populate the Data Catalog](#) .

## Schema management

The Data Catalog automatically captures and manages the schema of your data sources, including schema inference, evolution, and versioning. You can update your schema and partitions in the Data Catalog using AWS Glue ETL jobs.

## Table optimization

For better read performance by AWS analytics services such as Amazon Athena and Amazon EMR, and AWS Glue ETL jobs, the Data Catalog provides managed compaction (a process that compacts small Amazon S3 objects into larger objects) for Iceberg tables in the Data Catalog. You can use AWS Glue console, AWS Lake Formation console, AWS CLI, or AWS API to enable or disable compaction for individual Iceberg tables that are in the Data Catalog.

For more information, see [Optimizing Iceberg tables](#).

## Column statistics

You can compute column-level statistics for Data Catalog tables in data formats such as Parquet, ORC, JSON, ION, CSV, and XML without setting up additional data pipelines. Column statistics help you to understand data profiles by getting insights about values within a column. The Data Catalog supports generating statistics for column values such as minimum value, maximum value, total null values, total distinct values, average length of values, and total occurrences of true values.

For more information, see [Optimizing query performance using column statistics](#).

## Data lineage

The Data Catalog maintains a record of the transformations and operations performed on your data, providing data lineage information. This lineage information is valuable for auditing, compliance, and understanding the data's provenance.

## Integration with other AWS services

The Data Catalog seamlessly integrates with other AWS services, such as AWS Lake Formation, Amazon Athena, Amazon Redshift Spectrum, and Amazon EMR. This integration allows you to query and analyze data across various data stores using a single, consistent metadata layer.

## Security and access control

AWS Glue integrates with AWS Lake Formation to support fine-grained access control for Data Catalog resources, allowing you to manage permissions and secure access to your data assets based on your organization's policies and requirements. AWS Glue integrates with AWS Key Management Service (AWS KMS) to encrypt metadata that's stored in the Data Catalog.

## Topics

- [Populating the AWS Glue Data Catalog](#)
- [Populating and managing transactional tables](#)
- [Managing the Data Catalog](#)
- [Accessing the Data Catalog](#)
- [AWS Glue Data Catalog best practices](#)
- [AWS Glue Schema Registry](#)

# Populating the AWS Glue Data Catalog

You can populate the AWS Glue Data Catalog using the following methods:

- **AWS Glue crawler** – An AWS Glue crawler can automatically discover and catalog data sources like databases, data lakes, and streaming data. The crawlers are the most common and recommended method to populate the Data Catalog as they can automatically discover and infer metadata for a wide variety of data sources.
- **Manually adding metadata** – You can manually define databases, tables, and connection details and add them to the Data Catalog using the AWS Glue console, Lake Formation console, AWS

CLI, or AWS Glue APIs. Manual entry is useful when you want to catalog data sources that cannot be crawled.

- Integrating with other AWS services – You can populate the Data Catalog with metadata from services like AWS Lake Formation and Amazon Athena. These services can discover and register data sources in the Data Catalog.
- Populating from an existing metadata repository – If you have an existing metadata store like Apache Hive Metastore, you can use AWS Glue to import that metadata into the Data Catalog. For more information, see [Migration between the Hive Metastore and the AWS Glue Data Catalog](#) on GitHub.

## Topics

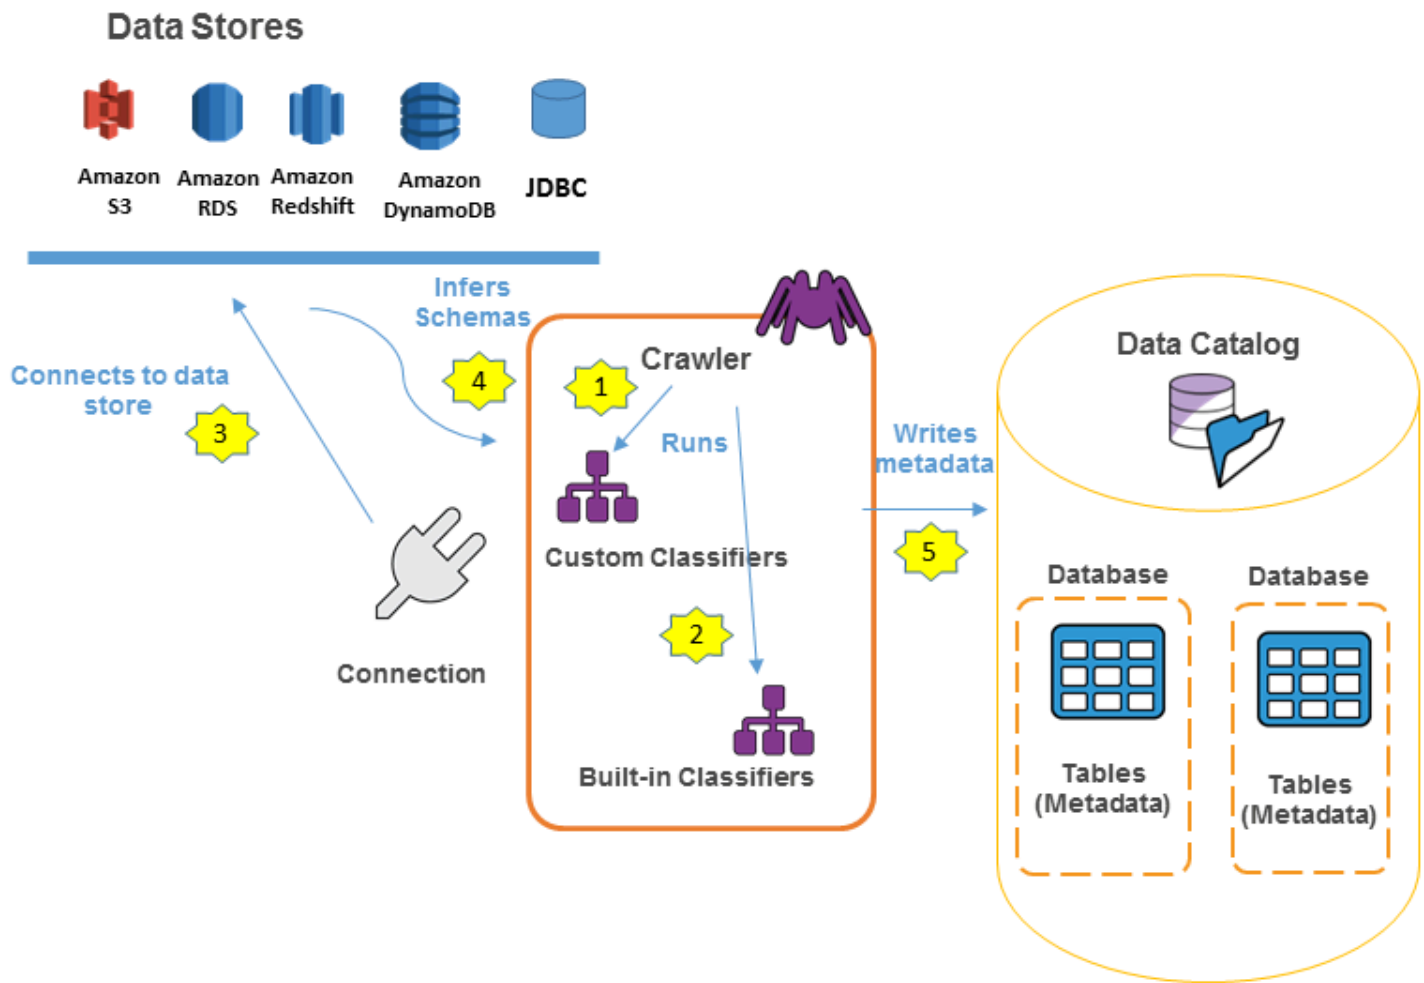

- [Using crawlers to populate the Data Catalog](#)
- [Defining metadata manually](#)
- [Integrating with other AWS services](#)
- [Data Catalog settings](#)

## Using crawlers to populate the Data Catalog

You can use an AWS Glue crawler to populate the AWS Glue Data Catalog with databases and tables. This is the primary method used by most AWS Glue users. A crawler can crawl multiple data stores in a single run. Upon completion, the crawler creates or updates one or more tables in your Data Catalog. Extract, transform, and load (ETL) jobs that you define in AWS Glue use these Data Catalog tables as sources and targets. The ETL job reads from and writes to the data stores that are specified in the source and target Data Catalog tables.

## Workflow

The following workflow diagram shows how AWS Glue crawlers interact with data stores and other elements to populate the Data Catalog.

The following is the general workflow for how a crawler populates the AWS Glue Data Catalog:

1. A crawler runs any custom *classifiers* that you choose to infer the format and schema of your data. You provide the code for custom classifiers, and they run in the order that you specify.

The first custom classifier to successfully recognize the structure of your data is used to create a schema. Custom classifiers lower in the list are skipped.

2. If no custom classifier matches your data's schema, built-in classifiers try to recognize your data's schema. An example of a built-in classifier is one that recognizes JSON.
3. The crawler connects to the data store. Some data stores require connection properties for crawler access.
4. The inferred schema is created for your data.

5. The crawler writes metadata to the Data Catalog. A table definition contains metadata about the data in your data store. The table is written to a database, which is a container of tables in the Data Catalog. Attributes of a table include classification, which is a label created by the classifier that inferred the table schema.

## Topics

- [Which data stores can I crawl?](#)
- [How does a crawler determine when to create partitions?](#)
- [Crawler prerequisites](#)
- [Configuring a crawler](#)
- [Adding classifiers to a crawler in AWS Glue](#)
- [Scheduling an AWS Glue crawler](#)
- [Viewing crawler results and details](#)
- [Customizing crawler behavior](#)
- [Tutorial: Adding an AWS Glue crawler](#)

## How crawlers work

When a crawler runs, it takes the following actions to interrogate a data store:

- **Classifies data to determine the format, schema, and associated properties of the raw data** – You can configure the results of classification by creating a custom classifier.
- **Groups data into tables or partitions** – Data is grouped based on crawler heuristics.
- **Writes metadata to the Data Catalog** – You can configure how the crawler adds, updates, and deletes tables and partitions.

When you define a crawler, you choose one or more classifiers that evaluate the format of your data to infer a schema. When the crawler runs, the first classifier in your list to successfully recognize your data store is used to create a schema for your table. You can use built-in classifiers or define your own. You define your custom classifiers in a separate operation, before you define the crawlers. AWS Glue provides built-in classifiers to infer schemas from common files with formats that include JSON, CSV, and Apache Avro. For the current list of built-in classifiers in AWS Glue, see [Built-in classifiers in AWS Glue](#).

The metadata tables that a crawler creates are contained in a database when you define a crawler. If your crawler does not specify a database, your tables are placed in the default database. In addition, each table has a classification column that is filled in by the classifier that first successfully recognized the data store.

If the file that is crawled is compressed, the crawler must download it to process it. When a crawler runs, it interrogates files to determine their format and compression type and writes these properties into the Data Catalog. Some file formats (for example, Apache Parquet) enable you to compress parts of the file as it is written. For these files, the compressed data is an internal component of the file, and AWS Glue does not populate the `compressionType` property when it writes tables into the Data Catalog. In contrast, if an *entire file* is compressed by a compression algorithm (for example, gzip), then the `compressionType` property is populated when tables are written into the Data Catalog.

The crawler generates the names for the tables that it creates. The names of the tables that are stored in the AWS Glue Data Catalog follow these rules:

- Only alphanumeric characters and underscore (`_`) are allowed.
- Any custom prefix cannot be longer than 64 characters.
- The maximum length of the name cannot be longer than 128 characters. The crawler truncates generated names to fit within the limit.
- If duplicate table names are encountered, the crawler adds a hash string suffix to the name.

If your crawler runs more than once, perhaps on a schedule, it looks for new or changed files or tables in your data store. The output of the crawler includes new tables and partitions found since a previous run.

## Which data stores can I crawl?

Crawlers can crawl the following file-based and table-based data stores.

Access type that crawler uses	Data stores
Native client	<ul style="list-style-type: none"><li>• Amazon Simple Storage Service (Amazon S3)</li><li>• Amazon DynamoDB</li><li>• Delta Lake 2.0.x</li></ul>

Access type that crawler uses	Data stores
	<ul style="list-style-type: none"> <li>• Apache Iceberg 1.5</li> <li>• Apache Hudi 0.14</li> </ul>
JDBC	Amazon Redshift  Snowflake  Within Amazon Relational Database Service (Amazon RDS) or external to Amazon RDS: <ul style="list-style-type: none"> <li>• Amazon Aurora</li> <li>• MariaDB</li> <li>• Microsoft SQL Server</li> <li>• MySQL</li> <li>• Oracle</li> <li>• PostgreSQL</li> </ul>
MongoDB client	<ul style="list-style-type: none"> <li>• MongoDB</li> <li>• MongoDB Atlas</li> <li>• Amazon DocumentDB (with MongoDB compatibility)</li> </ul>

 **Note**

Currently AWS Glue does not support crawlers for data streams.

For JDBC, MongoDB, MongoDB Atlas, and Amazon DocumentDB (with MongoDB compatibility) data stores, you must specify an AWS Glue *connection* that the crawler can use to connect to the data store. For Amazon S3, you can optionally specify a connection of type Network. A connection is a Data Catalog object that stores connection information, such as credentials, URL, Amazon Virtual Private Cloud information, and more. For more information, see [Connecting to data](#).

The following are the versions of drivers supported by the crawler:

Product	Crawler supported driver
PostgreSQL	42.2.1
Amazon Aurora	Same as native crawler drivers
MariaDB	8.0.13
Microsoft SQL Server	6.1.0
MySQL	8.0.13
Oracle	11.2.2
Amazon Redshift	4.1
Snowflake	3.13.20
MongoDB	4.7.2
MongoDB Atlas	4.7.2

The following are notes about the various data stores.

### Amazon S3

You can choose to crawl a path in your account or in another account. If all the Amazon S3 files in a folder have the same schema, the crawler creates one table. Also, if the Amazon S3 object is partitioned, only one metadata table is created and partition information is added to the Data Catalog for that table.

### Amazon S3 and Amazon DynamoDB

Crawlers use an AWS Identity and Access Management (IAM) role for permission to access your data stores. *The role you pass to the crawler must have permission to access Amazon S3 paths and Amazon DynamoDB tables that are crawled.*

### Amazon DynamoDB

When defining a crawler using the AWS Glue console, you specify one DynamoDB table. If you're using the AWS Glue API, you can specify a list of tables. You can choose to crawl only a small sample of the data to reduce crawler run times.

## Delta Lake

For each Delta Lake data store, you specify how to create the Delta tables:

- **Create Native tables:** Allow integration with query engines that support querying of the Delta transaction log directly. For more information, see [Querying Delta Lake tables](#).
- **Create Symlink tables:** Create a `_symlink_manifest` folder with manifest files partitioned by the partition keys, based on the specified configuration parameters.

## Iceberg

For each Iceberg data store, you specify an Amazon S3 path that contains the metadata for your Iceberg tables. If crawler discovers Iceberg table metadata, it registers it in the Data Catalog. You can set a schedule for the crawler to keep the tables updated.

You can define these parameters for the data store:

- **Exclusions:** Allows you to skip certain folders.
- **Maximum Traversal Depth:** Sets the depth limit the crawler can crawl in your Amazon S3 bucket. The default maximum traversal depth is 10 and the maximum depth you can set is 20.

## Hudi

For each Hudi data store, you specify an Amazon S3 path that contains the metadata for your Hudi tables. If crawler discovers Hudi table metadata, it registers it in the Data Catalog. You can set a schedule for the crawler to keep the tables updated.

You can define these parameters for the data store:

- **Exclusions:** Allows you to skip certain folders.
- **Maximum Traversal Depth:** Sets the depth limit the crawler can crawl in your Amazon S3 bucket. The default maximum traversal depth is 10 and the maximum depth you can set is 20.

### Note

Timestamp columns with `millis` as logical types will be interpreted as `bigint`, due to an incompatibility with Hudi 0.13.1 and timestamp types. A resolution may be provided in the upcoming Hudi release.

Hudi tables are categorized as follows, with specific implications for each:

- **Copy on Write (CoW):** Data is stored in a columnar format (Parquet), and each update creates a new version of files during a write.
- **Merge on Read (MoR):** Data is stored using a combination of columnar (Parquet) and row-based (Avro) formats. Updates are logged to row-based delta files and are compacted as needed to create new versions of the columnar files.

With CoW datasets, each time there is an update to a record, the file that contains the record is rewritten with the updated values. With a MoR dataset, each time there is an update, Hudi writes only the row for the changed record. MoR is better suited for write- or change-heavy workloads with fewer reads. CoW is better suited for read-heavy workloads on data that change less frequently.

Hudi provides three query types for accessing the data:

- **Snapshot queries:** Queries that see the latest snapshot of the table as of a given commit or compaction action. For MoR tables, snapshot queries expose the most recent state of the table by merging the base and delta files of the latest file slice at the time of the query.
- **Incremental queries:** Queries only see new data written to the table, since a given commit/compaction. This effectively provides change streams to enable incremental data pipelines.
- **Read optimized queries:** For MoR tables, queries see the latest data compacted. For CoW tables, queries see the latest data committed.

For Copy-On-Write tables, the crawler creates a single table in the Data Catalog with the ReadOptimized serde `org.apache.hudi.hadoop.HoodieParquetInputFormat`.

For Merge-On-Read tables, the crawler creates two tables in the Data Catalog for the same table location:

- A table with suffix `_ro` which uses the ReadOptimized serde `org.apache.hudi.hadoop.HoodieParquetInputFormat`.
- A table with suffix `_rt` which uses the RealTime Serde allowing for Snapshot queries: `org.apache.hudi.hadoop.realtime.HoodieParquetRealtimeInputFormat`.

## **MongoDB and Amazon DocumentDB (with MongoDB compatibility)**

MongoDB versions 3.2 and later are supported. You can choose to crawl only a small sample of the data to reduce crawler run times.

## **Relational database**

Authentication is with a database user name and password. Depending on the type of database engine, you can choose which objects are crawled, such as databases, schemas, and tables.

## Snowflake

The Snowflake JDBC crawler supports crawling the Table, External Table, View, and Materialized View. The Materialized View Definition will not be populated.

For Snowflake external tables, the crawler only will crawl if it points to an Amazon S3 location. In addition to the the table schema, the crawler will also crawl the Amazon S3 location, file format and output as table parameters in the Data Catalog table. Note that the partition information of the partitioned external table is not populated.

ETL is currently not supported for Data Catalog tables created using the Snowflake crawler.

### How does a crawler determine when to create partitions?

When an AWS Glue crawler scans Amazon S3 and detects multiple folders in a bucket, it determines the root of a table in the folder structure and which folders are partitions of a table. The name of the table is based on the Amazon S3 prefix or folder name. You provide an **Include path** that points to the folder level to crawl. When the majority of schemas at a folder level are similar, the crawler creates partitions of a table instead of separate tables. To influence the crawler to create separate tables, add each table's root folder as a separate data store when you define the crawler.

For example, consider the following Amazon S3 folder structure.

The paths to the four lowest level folders are the following:

```
S3://sales/year=2019/month=Jan/day=1
```

```
S3://sales/year=2019/month=Jan/day=2
S3://sales/year=2019/month=Feb/day=1
S3://sales/year=2019/month=Feb/day=2
```

Assume that the crawler target is set at Sales, and that all files in the `day=n` folders have the same format (for example, JSON, not encrypted), and have the same or very similar schemas. The crawler will create a single table with four partitions, with partition keys `year`, `month`, and `day`.

In the next example, consider the following Amazon S3 structure:

```
s3://bucket01/folder1/table1/partition1/file.txt
s3://bucket01/folder1/table1/partition2/file.txt
s3://bucket01/folder1/table1/partition3/file.txt
s3://bucket01/folder1/table2/partition4/file.txt
s3://bucket01/folder1/table2/partition5/file.txt
```

If the schemas for files under `table1` and `table2` are similar, and a single data store is defined in the crawler with **Include path** `s3://bucket01/folder1/`, the crawler creates a single table with two partition key columns. The first partition key column contains `table1` and `table2`, and the second partition key column contains `partition1` through `partition3` for the `table1` partition and `partition4` and `partition5` for the `table2` partition. To create two separate tables, define the crawler with two data stores. In this example, define the first **Include path** as `s3://bucket01/folder1/table1/` and the second as `s3://bucket01/folder1/table2/`.

### Note

In Amazon Athena, each table corresponds to an Amazon S3 prefix with all the objects in it. If objects have different schemas, Athena does not recognize different objects within the same prefix as separate tables. This can happen if a crawler creates multiple tables from the same Amazon S3 prefix. This might lead to queries in Athena that return zero results. For Athena to properly recognize and query tables, create the crawler with a separate **Include path** for each different table schema in the Amazon S3 folder structure. For more information, see [Best Practices When Using Athena with AWS Glue](#) and this [AWS Knowledge Center article](#).

## Crawler prerequisites

The crawler assumes the permissions of the AWS Identity and Access Management (IAM) role that you specify when you define it. This IAM role must have permissions to extract data from your data store and write to the Data Catalog. The AWS Glue console lists only IAM roles that have attached a trust policy for the AWS Glue principal service. From the console, you can also create an IAM role with an IAM policy to access Amazon S3 data stores accessed by the crawler. For more information about providing roles for AWS Glue, see [Identity-based policies for AWS Glue](#).

### Note

When crawling a Delta Lake data store, you must have Read/Write permissions to the Amazon S3 location.

For your crawler, you can create a role and attach the following policies:

- The `AWSGlueServiceRole` AWS managed policy, which grants the required permissions on the Data Catalog
- An inline policy that grants permissions on the data source.
- An inline policy that grants `iam:PassRole` permission on the role.

A quicker approach is to let the AWS Glue console crawler wizard create a role for you. The role that it creates is specifically for the crawler, and includes the `AWSGlueServiceRole` AWS managed policy plus the required inline policy for the specified data source.

If you specify an existing role for a crawler, ensure that it includes the `AWSGlueServiceRole` policy or equivalent (or a scoped down version of this policy), plus the required inline policies. For example, for an Amazon S3 data store, the inline policy would at a minimum be the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ]
    }
  ]
}
```

```

    ],
    "Resource": [
        "arn:aws:s3:::bucket/object*"
    ]
}
]
}

```

For an Amazon DynamoDB data store, the policy would at a minimum be the following:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeTable",
        "dynamodb:Scan"
      ],
      "Resource": [
        "arn:aws:dynamodb:region:account-id:table/table-name*"
      ]
    }
  ]
}

```

In addition, if the crawler reads AWS Key Management Service (AWS KMS) encrypted Amazon S3 data, then the IAM role must have decrypt permission on the AWS KMS key. For more information, see [Step 2: Create an IAM role for AWS Glue](#).

## Configuring a crawler

A crawler accesses your data store, extracts metadata, and creates table definitions in the AWS Glue Data Catalog. The **Crawlers** pane in the AWS Glue console lists all the crawlers that you create. The list displays status and metrics from the last run of your crawler.

### Note

If you choose to bring in your own JDBC driver versions, AWS Glue crawlers will consume resources in AWS Glue jobs and Amazon S3 buckets to ensure your provided driver are run in your environment. The additional usage of resources will be reflected in your account.

Additionally, providing your own JDBC driver does not mean that the crawler is able to leverage all of the driver's features. Drivers are limited to the properties described in [Adding an AWS Glue connection](#).

## To configure a crawler

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>. Choose **Crawlers** in the navigation pane.
2. Choose **Create crawler**, and follow the instructions in the **Add crawler** wizard. The wizard will guide you the steps required to create a crawler. If you want to add custom classifiers to define the schema, see [Adding classifiers to a crawler in AWS Glue](#).

### Step 1: Set crawler properties

Enter a name for your crawler and description (optional). Optionally, you can tag your crawler with a **Tag key** and optional **Tag value**. Once created, tag keys are read-only. Use tags on some resources to help you organize and identify them. For more information, see AWS tags in AWS Glue.

#### Name

Name may contain letters (A-Z), numbers (0-9), hyphens (-), or underscores (\_), and can be up to 255 characters long.

#### Description

Descriptions can be up to 2048 characters long.

#### Tags

Use tags to organize and identify your resources. For more information, see the following:

- [AWS tags in AWS Glue](#)

### Step 2: Choose data sources and classifiers

#### Data source configuration

Select the appropriate option for **Is your data already mapped to AWS Glue tables?** choose 'Not yet' or 'Yes'. By default, 'Not yet' is selected.

The crawler can access data stores directly as the source of the crawl, or it can use existing tables in the Data Catalog as the source. If the crawler uses existing catalog tables, it crawls the data stores that are specified by those catalog tables.

- Not yet: Select one or more data sources to be crawled. A crawler can crawl multiple data stores of different types (Amazon S3, JDBC, and so on).

You can configure only one data store at a time. After you have provided the connection information and include paths and exclude patterns, you then have the option of adding another data store.

- Yes: Select existing tables from your AWS Glue Data Catalog. The catalog tables specify the data stores to crawl. The crawler can crawl only catalog tables in a single run; it can't mix in other source types.

A common reason to specify a catalog table as the source is when you create the table manually (because you already know the structure of the data store) and you want a crawler to keep the table updated, including adding new partitions. For a discussion of other reasons, see [Updating manually created Data Catalog tables using crawlers](#).

When you specify existing tables as the crawler source type, the following conditions apply:

- Database name is optional.
- Only catalog tables that specify Amazon S3 or Amazon DynamoDB data stores are permitted.
- No new catalog tables are created when the crawler runs. Existing tables are updated as needed, including adding new partitions.
- Deleted objects found in the data stores are ignored; no catalog tables are deleted. Instead, the crawler writes a log message. (`SchemaChangePolicy.DeleteBehavior=LOG`)
- The crawler configuration option to create a single schema for each Amazon S3 path is enabled by default and cannot be disabled. (`TableGroupingPolicy=CombineCompatibleSchemas`) For more information, see [How to create a single schema for each Amazon S3 include path](#).
- You can't mix catalog tables as a source with any other source types (for example Amazon S3 or Amazon DynamoDB).

## Data sources

Select or add the list of data sources to be scanned by the crawler.

(Optional) If you choose JDBC as the data source, you can use your own JDBC drivers when specifying the Connection access where the driver info is stored.

## Include path

When evaluating what to include or exclude in a crawl, a crawler starts by evaluating the required include path. For Amazon S3, MongoDB, MongoDB Atlas, Amazon DocumentDB (with MongoDB compatibility), and relational data stores, you must specify an include path.

### For an Amazon S3 data store

Choose whether to specify a path in this account or in a different account, and then browse to choose an Amazon S3 path.

For Amazon S3 data stores, include path syntax is `bucket-name/folder-name/file-name.ext`. To crawl all objects in a bucket, you specify just the bucket name in the include path. The exclude pattern is relative to the include path

### For a Delta Lake data store

Specify one or more Amazon S3 paths to Delta tables as `s3://bucket/prefix/object`.

### For an Iceberg or Hudi data store

Specify one or more Amazon S3 paths that contain folders with Iceberg or Hudi table metadata as `s3://bucket/prefix`.

For a Hudi data store, the Hudi folder may be located in a child folder of the root folder. The crawler will scan all folders underneath a path for a Hudi folder.

### For a JDBC data store

Enter `<database>/<schema>/<table>` or `<database>/<table>`, depending on the database product. Oracle Database and MySQL don't support schema in the path. You can substitute the percent (%) character for `<schema>` or `<table>`. For example, for an Oracle database with a system identifier (SID) of `orcl`, enter `orcl/%` to import all tables to which the user named in the connection has access.

#### Important

This field is case-sensitive.

## For a MongoDB, MongoDB Atlas, or Amazon DocumentDB data store

Enter *database/collection*.

For MongoDB, MongoDB Atlas, and Amazon DocumentDB (with MongoDB compatibility), the syntax is `database/collection`.

For JDBC data stores, the syntax is either `database-name/schema-name/table-name` or `database-name/table-name`. The syntax depends on whether the database engine supports schemas within a database. For example, for database engines such as MySQL or Oracle, don't specify a `schema-name` in your include path. You can substitute the percent sign (%) for a schema or table in the include path to represent all schemas or all tables in a database. You cannot substitute the percent sign (%) for database in the include path.

## Maximum transversal depth (for Iceberg or Hudi data stores only)

Defines the maximum depth of the Amazon S3 path that the crawler can traverse to discover the Iceberg or Hudi metadata folder in your Amazon S3 path. The purpose of this parameter is to limit the crawler run time. The default value is 10 and the maximum is 20.

## Exclude patterns

These enable you to exclude certain files or tables from the crawl. The exclude path is relative to the include path. For example, to exclude a table in your JDBC data store, type the table name in the exclude path.

A crawler connects to a JDBC data store using an AWS Glue connection that contains a JDBC URI connection string. The crawler only has access to objects in the database engine using the JDBC user name and password in the AWS Glue connection. *The crawler can only create tables that it can access through the JDBC connection.* After the crawler accesses the database engine with the JDBC URI, the include path is used to determine which tables in the database engine are created in the Data Catalog. For example, with MySQL, if you specify an include path of `MyDatabase/%`, then all tables within `MyDatabase` are created in the Data Catalog. When accessing Amazon Redshift, if you specify an include path of `MyDatabase/%`, then all tables within all schemas for database `MyDatabase` are created in the Data Catalog. If you specify an include path of `MyDatabase/MySchema/%`, then all tables in database `MyDatabase` and schema `MySchema` are created.

After you specify an include path, you can then exclude objects from the crawl that your include path would otherwise include by specifying one or more Unix-style `glob` exclude patterns.

These patterns are applied to your include path to determine which objects are excluded. These patterns are also stored as a property of tables created by the crawler. AWS Glue PySpark extensions, such as `create_dynamic_frame.from_catalog`, read the table properties and exclude objects defined by the exclude pattern.

AWS Glue supports the following kinds of `glob` patterns in the exclude pattern.

Exclude pattern	Description
<code>*.csv</code>	Matches an Amazon S3 path that represents an object name in the current folder ending in <code>.csv</code>
<code>*.*</code>	Matches all object names that contain a dot
<code>*.{csv,avro}</code>	Matches object names ending with <code>.csv</code> or <code>.avro</code>
<code>foo.?</code>	Matches object names starting with <code>foo.</code> that are followed by a single character extension
<code>myfolder/*</code>	Matches objects in one level of subfolder from <code>myfolder</code> , such as <code>/myfolder/mysource</code>
<code>myfolder/**</code>	Matches objects in two levels of subfolders from <code>myfolder</code> , such as <code>/myfolder/mysource/data</code>
<code>myfolder/***</code>	Matches objects in all subfolders of <code>myfolder</code> , such as <code>/myfolder/mysource/mydata</code> and <code>/myfolder/mysource/data</code>
<code>myfolder**</code>	Matches subfolder <code>myfolder</code> as well as files below <code>myfolder</code> , such as <code>/myfolder</code> and <code>/myfolder/mydata.txt</code>

Exclude pattern	Description
Market*	Matches tables in a JDBC database with names that begin with Market, such as Market_us and Market_fr

AWS Glue interprets glob exclude patterns as follows:

- The slash (/) character is the delimiter to separate Amazon S3 keys into a folder hierarchy.
- The asterisk (\*) character matches zero or more characters of a name component without crossing folder boundaries.
- A double asterisk (\*\*) matches zero or more characters crossing folder or schema boundaries.
- The question mark (?) character matches exactly one character of a name component.
- The backslash (\) character is used to escape characters that otherwise can be interpreted as special characters. The expression \\ matches a single backslash, and \{ matches a left brace.
- Brackets [ ] create a bracket expression that matches a single character of a name component out of a set of characters. For example, [abc] matches a, b, or c. The hyphen (-) can be used to specify a range, so [a-z] specifies a range that matches from a through z (inclusive). These forms can be mixed, so [abce-g] matches a, b, c, e, f, or g. If the character after the bracket (]) is an exclamation point (!), the bracket expression is negated. For example, [!a-c] matches any character except a, b, or c.

Within a bracket expression, the \*, ?, and \ characters match themselves. The hyphen (-) character matches itself if it is the first character within the brackets, or if it's the first character after the ! when you are negating.

- Braces ({ }) enclose a group of subpatterns, where the group matches if any subpattern in the group matches. A comma (,) character is used to separate the subpatterns. Groups cannot be nested.
- Leading period or dot characters in file names are treated as normal characters in match operations. For example, the \* exclude pattern matches the file name .hidden.

### Example Amazon S3 exclude patterns

Each exclude pattern is evaluated against the include path. For example, suppose that you have the following Amazon S3 directory structure:

```

/mybucket/myfolder/
  departments/
    finance.json
    market-us.json
    market-emea.json
    market-ap.json
  employees/
    hr.json
    john.csv
    jane.csv
    juan.txt

```

Given the include path `s3://mybucket/myfolder/`, the following are some sample results for exclude patterns:

Exclude pattern	Results
<code>departments/**</code>	Excludes all files and folders below <code>departments</code> and includes the <code>employees</code> folder and its files
<code>departments/market*</code>	Excludes <code>market-us.json</code> , <code>market-emea.json</code> , and <code>market-ap.json</code>
<code>** .csv</code>	Excludes all objects below <code>myfolder</code> that have a name ending with <code>.csv</code>
<code>employees/*.csv</code>	Excludes all <code>.csv</code> files in the <code>employees</code> folder

### Example Excluding a subset of Amazon S3 partitions

Suppose that your data is partitioned by day, so that each day in a year is in a separate Amazon S3 partition. For January 2015, there are 31 partitions. Now, to crawl data for only the first week of January, you must exclude all partitions except days 1 through 7:

```
2015/01/{[!0],0[8-9]}**, 2015/0[2-9]/**, 2015/1[0-2]**
```

Take a look at the parts of this glob pattern. The first part, `2015/01/{[!0],0[8-9]}**,` excludes all days that don't begin with a "0" in addition to day 08 and day 09 from month 01 in year 2015. Notice that "\*\*" is used as the suffix to the day number pattern and crosses folder boundaries to lower-level folders. If "\*" is used, lower folder levels are not excluded.

The second part, `2015/0[2-9]**,` excludes days in months 02 to 09, in year 2015.

The third part, `2015/1[0-2]**,` excludes days in months 10, 11, and 12, in year 2015.

### Example JDBC exclude patterns

Suppose that you are crawling a JDBC database with the following schema structure:

```
MyDatabase/MySchema/
  HR_us
  HR_fr
  Employees_Table
  Finance
  Market_US_Table
  Market_EMEA_Table
  Market_AP_Table
```

Given the include path `MyDatabase/MySchema/%`, the following are some sample results for exclude patterns:

Exclude pattern	Results
<code>HR*</code>	Excludes the tables with names that begin with HR
<code>Market_*</code>	Excludes the tables with names that begin with Market_
<code>**_Table</code>	Excludes all tables with names that end with _Table

### Additional crawler source parameters

Each source type requires a different set of additional parameters. The following is an incomplete list:

## Connection

Select or add an AWS Glue connection. For information about connections, see [Connecting to data](#).

### Additional metadata - optional (for JDBC data stores)

Select additional metadata properties for the crawler to crawl.

- Comments: Crawl associated table level and column level comments.
- Raw types: Persist the raw datatypes of the table columns in additional metadata. As a default behavior, the crawler translates the raw datatypes to Hive-compatible types.

### JDBC Driver Class name - optional (for JDBC data stores)

Type a custom JDBC driver class name for the crawler to connect to the data source:

- Postgres: org.postgresql.Driver
- MySQL: com.mysql.jdbc.Driver, com.mysql.cj.jdbc.Driver
- Redshift: com.amazon.redshift.jdbc.Driver, com.amazon.redshift.jdbc42.Driver
- Oracle: oracle.jdbc.driver.OracleDriver
- SQL Server: com.microsoft.sqlserver.jdbc.SQLServerDriver

### JDBC Driver S3 Path - optional (for JDBC data stores)

Choose an existing Amazon S3 path to a `.jar` file. This is where the `.jar` file will be stored when using a custom JDBC driver for the crawler to connect to the data source.

### Enable data sampling (for Amazon DynamoDB, MongoDB, MongoDB Atlas, and Amazon DocumentDB data stores only)

Select whether to crawl a data sample only. If not selected the entire table is crawled. Scanning all the records can take a long time when the table is not a high throughput table.

### Create tables for querying (for Delta Lake data stores only)

Select how you want to create the Delta Lake tables:

- Create Native tables: Allow integration with query engines that support querying of the Delta transaction log directly.
- Create Symlink tables: Create a symlink manifest folder with manifest files partitioned by the partition keys, based on the specified configuration parameters.

## Scanning rate - optional (for DynamoDB data stores only)

Specify the percentage of the DynamoDB table Read Capacity Units to use by the crawler. Read capacity units is a term defined by DynamoDB, and is a numeric value that acts as rate limiter for the number of reads that can be performed on that table per second. Enter a value between 0.1 and 1.5. If not specified, defaults to 0.5% for provisioned tables and 1/4 of maximum configured capacity for on-demand tables. Note that only provisioned capacity mode should be used with AWS Glue crawlers.

### Note

For DynamoDB data stores, set the provisioned capacity mode for processing reads and writes on your tables. The AWS Glue crawler should not be used with the on-demand capacity mode.

## Network connection - optional (for Amazon S3 data stores only)

Optionally include a Network connection to use with this Amazon S3 target. Note that each crawler is limited to one Network connection so any other Amazon S3 targets will also use the same connection (or none, if left blank).

For information about connections, see [Connecting to data](#).

## Sample only a subset of files and Sample size (for Amazon S3 data stores only)

Specify the number of files in each leaf folder to be crawled when crawling sample files in a dataset. When this feature is turned on, instead of crawling all the files in this dataset, the crawler randomly selects some files in each leaf folder to crawl.

The sampling crawler is best suited for customers who have previous knowledge about their data formats and know that schemas in their folders do not change. Turning on this feature will significantly reduce crawler runtime.

A valid value is an integer between 1 and 249. If not specified, all the files are crawled.

## Subsequent crawler runs

This field is a global field that affects all Amazon S3 data sources.

- Crawl all sub-folders: Crawl all folders again with every subsequent crawl.

- **Crawl new sub-folders only:** Only Amazon S3 folders that were added since the last crawl will be crawled. If the schemas are compatible, new partitions will be added to existing tables. For more information, see [the section called “Incremental crawls for adding new partitions”](#).
- **Crawl based on events:** Rely on Amazon S3 events to control what folders to crawl. For more information, see [the section called “Accelerating crawls using Amazon S3 event notifications”](#).

### Custom classifiers - optional

Define custom classifiers before defining crawlers. A classifier checks whether a given file is in a format the crawler can handle. If it is, the classifier creates a schema in the form of a `StructType` object that matches that data format.

For more information, see [Adding classifiers to a crawler in AWS Glue](#).

## Step 3: Configure security settings

### IAM role

The crawler assumes this role. It must have permissions similar to the AWS managed policy `AWSGlueServiceRole`. For Amazon S3 and DynamoDB sources, it must also have permissions to access the data store. If the crawler reads Amazon S3 data encrypted with AWS Key Management Service (AWS KMS), then the role must have decrypt permissions on the AWS KMS key.

For an Amazon S3 data store, additional permissions attached to the role would be similar to the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::bucket/object*"
      ]
    }
  ]
}
```

```
}

```

For an Amazon DynamoDB data store, additional permissions attached to the role would be similar to the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DescribeTable",
        "dynamodb:Scan"
      ],
      "Resource": [
        "arn:aws:dynamodb:region:account-id:table/table-name*"
      ]
    }
  ]
}
```

In order to add your own JDBC driver, additional permissions need to be added.

- Grant permissions for the following job actions: CreateJob, DeleteJob, GetJob, GetJobRun, StartJobRun.
- Grant permissions for Amazon S3 actions: s3:DeleteObjects, s3:GetObject, s3:ListBucket, s3:PutObject.

 **Note**

The s3:ListBucket is not needed if the Amazon S3 bucket policy is disabled.

- Grant service principal access to bucket/folder in the Amazon S3 policy.

Example Amazon S3 policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
```

```

    "Action": [
      "s3:PutObject",
      "s3:GetObject",
      "s3:ListBucket",
      "s3:DeleteObject"
    ],
    "Resource": [
      "arn:aws:s3:::bucket-name/driver-parent-folder/driver.jar",
      "arn:aws:s3:::bucket-name"
    ]
  }
]
}

```

AWS Glue creates the following folders (`_crawler` and `_glue_job_crawler` at the same level as the JDBC driver in your Amazon S3 bucket. For example, if the driver path is `<s3-path/driver_folder/driver.jar>`, then the following folders will be created if they do not already exist:

- `<s3-path/driver_folder/_crawler>`
- `<s3-path/driver_folder/_glue_job_crawler>`

Optionally, you can add a security configuration to a crawler to specify at-rest encryption options.

For more information, see [Step 2: Create an IAM role for AWS Glue](#) and [Identity and access management for AWS Glue](#).

### Lake Formation configuration - optional

Allow the crawler to use Lake Formation credentials for crawling the data source.

Checking **Use Lake Formation credentials for crawling S3 data source** will allow the crawler to use Lake Formation credentials for crawling the data source. If the data source belongs to another account, you must provide the registered account ID. Otherwise, the crawler will crawl only those data sources associated to the account. Only applicable to Amazon S3 and Data Catalog data sources.

### Security configuration - optional

Settings include security configurations. For more information, see the following:

- [Encrypting data written by AWS Glue](#)

**Note**

Once a security configuration has been set on a crawler, you can change, but you cannot remove it. To lower the level of security on a crawler, explicitly set the security feature to DISABLED within your configuration, or create a new crawler.

## Step 4: Set output and scheduling

### Output configuration

Options include how the crawler should handle detected schema changes, deleted objects in the data store, and more. For more information, see [Customizing crawler behavior](#)

### Crawler schedule

You can run a crawler on demand or define a time-based schedule for your crawlers and jobs in AWS Glue. The definition of these schedules uses the Unix-like cron syntax. For more information, see [Scheduling an AWS Glue crawler](#).

## Step 5: Review and create

Review the crawler settings you configured, and create the crawler.

## Adding classifiers to a crawler in AWS Glue

A classifier reads the data in a data store. If it recognizes the format of the data, it generates a schema. The classifier also returns a certainty number to indicate how certain the format recognition was.

AWS Glue provides a set of built-in classifiers, but you can also create custom classifiers. AWS Glue invokes custom classifiers first, in the order that you specify in your crawler definition. Depending on the results that are returned from custom classifiers, AWS Glue might also invoke built-in classifiers. If a classifier returns `certainty=1.0` during processing, it indicates that it's 100 percent certain that it can create the correct schema. AWS Glue then uses the output of that classifier.

If no classifier returns `certainty=1.0`, AWS Glue uses the output of the classifier that has the highest certainty. If no classifier returns a certainty greater than `0.0`, AWS Glue returns the default classification string of UNKNOWN.

## When do I use a classifier?

You use classifiers when you crawl a data store to define metadata tables in the AWS Glue Data Catalog. You can set up your crawler with an ordered set of classifiers. When the crawler invokes a classifier, the classifier determines whether the data is recognized. If the classifier can't recognize the data or is not 100 percent certain, the crawler invokes the next classifier in the list to determine whether it can recognize the data.

For more information about creating a classifier using the AWS Glue console, see [Working with classifiers on the AWS Glue console](#).

## Custom classifiers

The output of a classifier includes a string that indicates the file's classification or format (for example, json) and the schema of the file. For custom classifiers, you define the logic for creating the schema based on the type of classifier. Classifier types include defining schemas based on grok patterns, XML tags, and JSON paths.

If you change a classifier definition, any data that was previously crawled using the classifier is not reclassified. A crawler keeps track of previously crawled data. New data is classified with the updated classifier, which might result in an updated schema. If the schema of your data has evolved, update the classifier to account for any schema changes when your crawler runs. To reclassify data to correct an incorrect classifier, create a new crawler with the updated classifier.

For more information about creating custom classifiers in AWS Glue, see [Writing custom classifiers](#).

### Note

If your data format is recognized by one of the built-in classifiers, you don't need to create a custom classifier.

## Built-in classifiers in AWS Glue

AWS Glue provides built-in classifiers for various formats, including JSON, CSV, web logs, and many database systems.

If AWS Glue doesn't find a custom classifier that fits the input data format with 100 percent certainty, it invokes the built-in classifiers in the order shown in the following table. The built-in classifiers return a result to indicate whether the format matches (`certainty=1.0`) or does not match (`certainty=0.0`). The first classifier that has `certainty=1.0` provides the classification string and schema for a metadata table in your Data Catalog.

Classifier type	Classification string	Notes
Apache Avro	avro	Reads the schema at the beginning of the file to determine format.
Apache ORC	orc	Reads the file metadata to determine format.
Apache Parquet	parquet	Reads the schema at the end of the file to determine format.
JSON	json	Reads the beginning of the file to determine format.
Binary JSON	bson	Reads the beginning of the file to determine format.
XML	xml	Reads the beginning of the file to determine format. AWS Glue determines the table schema based on XML tags in the document.  For information about creating a custom XML classifier to specify rows in the document, see <a href="#">Writing XML custom classifiers</a> .
Amazon Ion	ion	Reads the beginning of the file to determine format.
Combined Apache log	combined_apache	Determines log formats through a grok pattern.
Apache log	apache	Determines log formats through a grok pattern.

Classifier type	Classification string	Notes
Linux kernel log	linux_kernel	Determines log formats through a grok pattern.
Microsoft log	microsoft_log	Determines log formats through a grok pattern.
Ruby log	ruby_logger	Reads the beginning of the file to determine format.
Squid 3.x log	squid	Reads the beginning of the file to determine format.
Redis monitor log	redismonlog	Reads the beginning of the file to determine format.
Redis log	redislog	Reads the beginning of the file to determine format.
CSV	csv	Checks for the following delimiters: comma (,), pipe ( ), tab (\t), semicolon (;), and Ctrl-A (\u0001). Ctrl-A is the Unicode control character for Start Of Heading.
Amazon Redshift	redshift	Uses JDBC connection to import metadata.
MySQL	mysql	Uses JDBC connection to import metadata.
PostgreSQL	postgresql	Uses JDBC connection to import metadata.
Oracle database	oracle	Uses JDBC connection to import metadata.
Microsoft SQL Server	sqlserver	Uses JDBC connection to import metadata.
Amazon DynamoDB	dynamodb	Reads data from the DynamoDB table.

Files in the following compressed formats can be classified:

- ZIP (supported for archives containing only a single file). Note that Zip is not well-supported in other services (because of the archive).
- BZIP
- GZIP
- LZ4
- Snappy (supported for both standard and Hadoop native Snappy formats)

### Built-in CSV classifier

The built-in CSV classifier parses CSV file contents to determine the schema for an AWS Glue table. This classifier checks for the following delimiters:

- Comma (,)
- Pipe (|)
- Tab (\t)
- Semicolon (;)
- Ctrl-A (\u0001)

Ctrl-A is the Unicode control character for Start Of Heading.

To be classified as CSV, the table schema must have at least two columns and two rows of data. The CSV classifier uses a number of heuristics to determine whether a header is present in a given file. If the classifier can't determine a header from the first row of data, column headers are displayed as `col1`, `col2`, `col3`, and so on. The built-in CSV classifier determines whether to infer a header by evaluating the following characteristics of the file:

- Every column in a potential header parses as a `STRING` data type.
- Except for the last column, every column in a potential header has content that is fewer than 150 characters. To allow for a trailing delimiter, the last column can be empty throughout the file.
- Every column in a potential header must meet the AWS Glue regex requirements for a column name.
- The header row must be sufficiently different from the data rows. To determine this, one or more of the rows must parse as other than `STRING` type. If all columns are of type `STRING`, then the first row of data is not sufficiently different from subsequent rows to be used as the header.

**Note**

If the built-in CSV classifier does not create your AWS Glue table as you want, you might be able to use one of the following alternatives:

- Change the column names in the Data Catalog, set the `SchemaChangePolicy` to `LOG`, and set the partition output configuration to `InheritFromTable` for future crawler runs.
- Create a custom grok classifier to parse the data and assign the columns that you want.
- The built-in CSV classifier creates tables referencing the `LazySimpleSerDe` as the serialization library, which is a good choice for type inference. However, if the CSV data contains quoted strings, edit the table definition and change the SerDe library to `OpenCSVSerDe`. Adjust any inferred types to `STRING`, set the `SchemaChangePolicy` to `LOG`, and set the partitions output configuration to `InheritFromTable` for future crawler runs. For more information about SerDe libraries, see [SerDe Reference](#) in the Amazon Athena User Guide.

## Writing custom classifiers

You can provide a custom classifier to classify your data in AWS Glue. You can create a custom classifier using a grok pattern, an XML tag, JavaScript Object Notation (JSON), or comma-separated values (CSV). An AWS Glue crawler calls a custom classifier. If the classifier recognizes the data, it returns the classification and schema of the data to the crawler. You might need to define a custom classifier if your data doesn't match any built-in classifiers, or if you want to customize the tables that are created by the crawler.

For more information about creating a classifier using the AWS Glue console, see [Working with classifiers on the AWS Glue console](#).

AWS Glue runs custom classifiers before built-in classifiers, in the order you specify. When a crawler finds a classifier that matches the data, the classification string and schema are used in the definition of tables that are written to your AWS Glue Data Catalog.

## Topics

- [Writing grok custom classifiers](#)
- [Writing XML custom classifiers](#)

- [Writing JSON custom classifiers](#)
- [Writing CSV custom classifiers](#)

## Writing grok custom classifiers

Grok is a tool that is used to parse textual data given a matching pattern. A grok pattern is a named set of regular expressions (regex) that are used to match data one line at a time. AWS Glue uses grok patterns to infer the schema of your data. When a grok pattern matches your data, AWS Glue uses the pattern to determine the structure of your data and map it into fields.

AWS Glue provides many built-in patterns, or you can define your own. You can create a grok pattern using built-in patterns and custom patterns in your custom classifier definition. You can tailor a grok pattern to classify custom text file formats.

### Note

AWS Glue grok custom classifiers use the GrokSerDe serialization library for tables created in the AWS Glue Data Catalog. If you are using the AWS Glue Data Catalog with Amazon Athena, Amazon EMR, or Redshift Spectrum, check the documentation about those services for information about support of the GrokSerDe. Currently, you might encounter problems querying tables created with the GrokSerDe from Amazon EMR and Redshift Spectrum.

The following is the basic syntax for the components of a grok pattern:

```
%{PATTERN:field-name}
```

Data that matches the named PATTERN is mapped to the field-name column in the schema, with a default data type of string. Optionally, the data type for the field can be cast to byte, boolean, double, short, int, long, or float in the resulting schema.

```
%{PATTERN:field-name:data-type}
```

For example, to cast a num field to an int data type, you can use this pattern:

```
%{NUMBER:num:int}
```

Patterns can be composed of other patterns. For example, you can have a pattern for a SYSLOG timestamp that is defined by patterns for month, day of the month, and time (for example, Feb 1 06:25:43). For this data, you might define the following pattern:

```
SYSLOGTIMESTAMP %{MONTH} +%{MONTHDAY} %{TIME}
```

### Note

Grok patterns can process only one line at a time. Multiple-line patterns are not supported. Also, line breaks within a pattern are not supported.

## Custom classifier values in AWS Glue

When you define a grok classifier, you supply the following values to AWS Glue to create the custom classifier.

### Name

Name of the classifier.

### Classification

The text string that is written to describe the format of the data that is classified; for example, `special-logs`.

### Grok pattern

The set of patterns that are applied to the data store to determine whether there is a match. These patterns are from AWS Glue [built-in patterns](#) and any custom patterns that you define.

The following is an example of a grok pattern:

```
%{TIMESTAMP_ISO8601:timestamp} \[%{MESSAGEPREFIX:message_prefix}\]  
%{CRAWLERLOGLEVEL:loglevel} : %{GREEDYDATA:message}
```

When the data matches `TIMESTAMP_ISO8601`, a schema column `timestamp` is created. The behavior is similar for the other named patterns in the example.

## Custom patterns

Optional custom patterns that you define. These patterns are referenced by the `grok` pattern that classifies your data. You can reference these custom patterns in the `grok` pattern that is applied to your data. Each custom component pattern must be on a separate line. [Regular expression \(regex\)](#) syntax is used to define the pattern.

The following is an example of using custom patterns:

```
CRAWLERLOGLEVEL (BENCHMARK|ERROR|WARN|INFO|TRACE)
MESSAGEPREFIX .*-.*-.*-.*-.*
```

The first custom named pattern, `CRAWLERLOGLEVEL`, is a match when the data matches one of the enumerated strings. The second custom pattern, `MESSAGEPREFIX`, tries to match a message prefix string.

AWS Glue keeps track of the creation time, last update time, and version of your classifier.

## AWS Glue built-in patterns

AWS Glue provides many common patterns that you can use to build a custom classifier. You add a named pattern to the `grok` pattern in a classifier definition.

The following list consists of a line for each pattern. In each line, the pattern name is followed its definition. [Regular expression \(regex\)](#) syntax is used in defining the pattern.

```
#<noLoc>&GLU;</noLoc> Built-in patterns
USERNAME [a-zA-Z0-9._-]+
USER %{USERNAME:UNWANTED}

## Writing XML custom classifiers

XML defines the structure of a document with the use of tags in the file. With an XML custom classifier, you can specify the tag name used to define a row.

## Custom classifier values in AWS Glue

When you define an XML classifier, you supply the following values to AWS Glue to create the classifier. The classification field of this classifier is set to `xml`.

## Name

Name of the classifier.

## Row tag

The XML tag name that defines a table row in the XML document, without angle brackets `< >`. The name must comply with XML rules for a tag.

### Note

The element containing the row data **cannot** be a self-closing empty element. For example, this empty element is **not** parsed by AWS Glue:

```
<row att1="xx" att2="yy" />
```

Empty elements can be written as follows:

```
<row att1="xx" att2="yy"> </row>
```

AWS Glue keeps track of the creation time, last update time, and version of your classifier.

For example, suppose that you have the following XML file. To create an AWS Glue table that only contains columns for author and title, create a classifier in the AWS Glue console with **Row tag** as `AnyCompany`. Then add and run a crawler that uses this custom classifier.

```
<?xml version="1.0"?>
<catalog>
  <book id="bk101">
    <AnyCompany>
      <author>Rivera, Martha</author>
      <title>AnyCompany Developer Guide</title>
    </AnyCompany>
  </book>
  <book id="bk102">
    <AnyCompany>
```

```
<author>Stiles, John</author>
<title>Style Guide for AnyCompany</title>
</AnyCompany>
</book>
</catalog>
```

## Writing JSON custom classifiers

JSON is a data-interchange format. It defines data structures with name-value pairs or an ordered list of values. With a JSON custom classifier, you can specify the JSON path to a data structure that is used to define the schema for your table.

### Custom classifier values in AWS Glue

When you define a JSON classifier, you supply the following values to AWS Glue to create the classifier. The classification field of this classifier is set to `json`.

#### Name

Name of the classifier.

#### JSON path

A JSON path that points to an object that is used to define a table schema. The JSON path can be written in dot notation or bracket notation. The following operators are supported:

#### Description

Root element of a JSON object. This starts all path expressions

Wildcard character. Available anywhere a name or numeric are required in the JSON path.

Dot-notated child. Specifies a child field in a JSON object.

Bracket-notated child. Specifies child field in a JSON object. Only a single child field can be specified.

Array index. Specifies the value of an array by index.

AWS Glue keeps track of the creation time, last update time, and version of your classifier.

## Example Using a JSON classifier to pull records from an array

Suppose that your JSON data is an array of records. For example, the first few lines of your file might look like the following:

```
[
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:ak",
    "name": "Alaska"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:1",
    "name": "Alabama's 1st congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:2",
    "name": "Alabama's 2nd congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:3",
    "name": "Alabama's 3rd congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:4",
    "name": "Alabama's 4th congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:5",
    "name": "Alabama's 5th congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:al\cd:6",
    "name": "Alabama's 6th congressional district"
  },
  {
    "type": "constituency",
```

```

    "id": "ocd-division\country:us\state:al\cd:7",
    "name": "Alabama's 7th congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:ar\cd:1",
    "name": "Arkansas's 1st congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:ar\cd:2",
    "name": "Arkansas's 2nd congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:ar\cd:3",
    "name": "Arkansas's 3rd congressional district"
  },
  {
    "type": "constituency",
    "id": "ocd-division\country:us\state:ar\cd:4",
    "name": "Arkansas's 4th congressional district"
  }
]

```

When you run a crawler using the built-in JSON classifier, the entire file is used to define the schema. Because you don't specify a JSON path, the crawler treats the data as one object, that is, just an array. For example, the schema might look like the following:

```

root
|-- record: array

```

However, to create a schema that is based on each record in the JSON array, create a custom JSON classifier and specify the JSON path as `$[*]`. When you specify this JSON path, the classifier interrogates all 12 records in the array to determine the schema. The resulting schema contains separate fields for each object, similar to the following example:

```

root
|-- type: string
|-- id: string

```

```
|-- name: string
```

## Example Using a JSON classifier to examine only parts of a file

Suppose that your JSON data follows the pattern of the example JSON file `s3://awsglue-datasets/examples/us-legislators/all/areas.json` drawn from <http://everypolitician.org/>. Example objects in the JSON file look like the following:

```
{
  "type": "constituency",
  "id": "ocd-division/country:us/state:ak",
  "name": "Alaska"
}
{
  "type": "constituency",
  "identifiers": [
    {
      "scheme": "dmoz",
      "identifier": "Regional/North_America/United_States/Alaska/"
    },
    {
      "scheme": "freebase",
      "identifier": "\m\0hjy"
    },
    {
      "scheme": "fips",
      "identifier": "US02"
    },
    {
      "scheme": "quora",
      "identifier": "Alaska-state"
    },
    {
      "scheme": "britannica",
      "identifier": "place/Alaska"
    },
    {
      "scheme": "wikidata",
      "identifier": "Q797"
    }
  ],
  "other_names": [
```

```

{
  "lang": "en",
  "note": "multilingual",
  "name": "Alaska"
},
{
  "lang": "fr",
  "note": "multilingual",
  "name": "Alaska"
},
{
  "lang": "nov",
  "note": "multilingual",
  "name": "Alaska"
}
],
"id": "ocd-division\country:us\state:ak",
"name": "Alaska"
}

```

When you run a crawler using the built-in JSON classifier, the entire file is used to create the schema. You might end up with a schema like this:

```

root
|-- type: string
|-- id: string
|-- name: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string

```

However, to create a schema using just the "id" object, create a custom JSON classifier and specify the JSON path as \$.id. Then the schema is based on only the "id" field:

```
root
|-- record: string
```

The first few lines of data extracted with this schema look like this:

```
{"record": "ocd-division/country:us/state:ak"}
{"record": "ocd-division/country:us/state:al/cd:1"}
{"record": "ocd-division/country:us/state:al/cd:2"}
{"record": "ocd-division/country:us/state:al/cd:3"}
{"record": "ocd-division/country:us/state:al/cd:4"}
{"record": "ocd-division/country:us/state:al/cd:5"}
{"record": "ocd-division/country:us/state:al/cd:6"}
{"record": "ocd-division/country:us/state:al/cd:7"}
{"record": "ocd-division/country:us/state:ar/cd:1"}
{"record": "ocd-division/country:us/state:ar/cd:2"}
{"record": "ocd-division/country:us/state:ar/cd:3"}
{"record": "ocd-division/country:us/state:ar/cd:4"}
{"record": "ocd-division/country:us/state:as"}
{"record": "ocd-division/country:us/state:az/cd:1"}
{"record": "ocd-division/country:us/state:az/cd:2"}
{"record": "ocd-division/country:us/state:az/cd:3"}
{"record": "ocd-division/country:us/state:az/cd:4"}
{"record": "ocd-division/country:us/state:az/cd:5"}
{"record": "ocd-division/country:us/state:az/cd:6"}
{"record": "ocd-division/country:us/state:az/cd:7"}
```

To create a schema based on a deeply nested object, such as "identifier," in the JSON file, you can create a custom JSON classifier and specify the JSON path as `$.identifiers[*].identifier`. Although the schema is similar to the previous example, it is based on a different object in the JSON file.

The schema looks like the following:

```
root
|-- record: string
```

Listing the first few lines of data from the table shows that the schema is based on the data in the "identifier" object:

```

{"record": "Regional/North_America/United_States/Alaska/"}
{"record": "/m/0hjy"}
{"record": "US02"}
{"record": "5879092"}
{"record": "4001016-8"}
{"record": "destination/alaska"}
{"record": "1116270"}
{"record": "139487266"}
{"record": "n79018447"}
{"record": "01490999-8dec-4129-8254-eef6e80fadc3"}
{"record": "Alaska-state"}
{"record": "place/Alaska"}
{"record": "Q797"}
{"record": "Regional/North_America/United_States/Alabama/"}
{"record": "/m/0gyh"}
{"record": "US01"}
{"record": "4829764"}
{"record": "4084839-5"}
{"record": "161950"}
{"record": "131885589"}

```

To create a table based on another deeply nested object, such as the "name" field in the "other\_names" array in the JSON file, you can create a custom JSON classifier and specify the JSON path as `$.other_names[*].name`. Although the schema is similar to the previous example, it is based on a different object in the JSON file. The schema looks like the following:

```

root
|-- record: string

```

Listing the first few lines of data in the table shows that it is based on the data in the "name" object in the "other\_names" array:

```

{"record": "Alaska"}
{"record": "Alaska"}
{"record": "Аляска"}
{"record": "Alaska"}
{"record": "Alaska"}
{"record": "Alaska"}

```

```
{"record": "Alaska"}
{"record": "Alaska"}
{"record": "Alaska"}
{"record": "#####"}
{"record": "#####"}
{"record": "#####"}
{"record": "Alaska"}
{"record": "Alyaska"}
{"record": "Alaska"}
{"record": "Alaska"}
{"record": "Штат Аляска"}
{"record": "Аляска"}
{"record": "Alaska"}
{"record": "#####"}

```

## Writing CSV custom classifiers

Custom CSV classifiers allows you to specify datatypes for each column in the custom csv classifier field. You can specify each column's datatype separated by a comma. By specifying datatypes, you can override the crawlers inferred datatypes and ensure data will be classified appropriately.

You can set the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog.

When you create a custom classifier, you can also re-use the classifier for different crawlers.

- For csv files with only headers (no data), these files will be classified as UNKNOWN since not enough information is provided. If you specify that the CSV 'Has headings' in the *Column headings* option, and provide the datatypes, we can classify these files correctly.

You can use a custom CSV classifier to infer the schema of various types of CSV data. The custom attributes that you can provide for your classifier include delimiters, a CSV SerDe option, options about the header, and whether to perform certain validations on the data.

## Custom classifier values in AWS Glue

When you define a CSV classifier, you provide the following values to AWS Glue to create the classifier. The classification field of this classifier is set to csv.

### Classifier name

Name of the classifier.

## CSV Serde

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Options are Open CSV SerDe, Lazy Simple SerDe, and None. You can specify the None value when you want the crawler to do the detection.

## Column delimiter

A custom symbol to denote what separates each column entry in the row. Provide a unicode character. If you cannot type your delimiter, you can copy and paste it. This works for printable characters, including those your system does not support (typically shown as □).

## Quote symbol

A custom symbol to denote what combines content into a single column value. Must be different from the column delimiter. Provide a unicode character. If you cannot type your delimiter, you can copy and paste it. This works for printable characters, including those your system does not support (typically shown as □).

## Column headings

Indicates the behavior for how column headings should be detected in the CSV file. If your custom CSV file has column headings, enter a comma-delimited list of the column headings.

## Processing options: Allow files with single column

Enables the processing of files that contain only one column.

## Processing options: Trim white space before identifying column values

Specifies whether to trim values before identifying the type of column values.

## Custom datatypes - *optional*

Enter the custom datatype separated by a comma. Specifies the custom datatypes in the CSV file. The custom datatype must be a supported datatype. Supported datatypes are: "BINARY", "BOOLEAN", "DATE", "DECIMAL", "DOUBLE", "FLOAT", "INT", "LONG", "SHORT", "STRING", "TIMESTAMP". Unsupported datatypes will display an error.

## Working with classifiers on the AWS Glue console

A classifier determines the schema of your data. You can write a custom classifier and point to it from AWS Glue.

## Viewing classifiers

To see a list of all the classifiers that you have created, open the AWS Glue console at <https://console.aws.amazon.com/glue/>, and choose the **Classifiers** tab.

The list displays the following properties about each classifier:

- **Classifier** – The classifier name. When you create a classifier, you must provide a name for it.
- **Classification** – The classification type of tables inferred by this classifier.
- **Last updated** – The last time this classifier was updated.

## Managing classifiers

From the **Classifiers** list in the AWS Glue console, you can add, edit, and delete classifiers. To see more details for a classifier, choose the classifier name in the list. Details include the information you defined when you created the classifier.

## Creating classifiers

To add a classifier in the AWS Glue console, choose **Add classifier**. When you define a classifier, you supply values for the following:

- **Classifier name** – Provide a unique name for your classifier.
- **Classifier type** – The classification type of tables inferred by this classifier.
- **Last updated** – The last time this classifier was updated.

### Classifier name

Provide a unique name for your classifier.

### Classifier type

Choose the type of classifier to create.

Depending on the type of classifier you choose, configure the following properties for your classifier:

### Grok

- **Classification**

Describe the format or type of data that is classified or provide a custom label.

- **Grok pattern**

This is used to parse your data into a structured schema. The grok pattern is composed of named patterns that describe the format of your data store. You write this grok pattern using the named built-in patterns provided by AWS Glue and custom patterns you write and include in the **Custom patterns** field. Although grok debugger results might not match the results from AWS Glue exactly, we suggest that you try your pattern using some sample data with a grok debugger. You can find grok debuggers on the web. The named built-in patterns provided by AWS Glue are generally compatible with grok patterns that are available on the web.

Build your grok pattern by iteratively adding named patterns and check your results in a debugger. This activity gives you confidence that when the AWS Glue crawler runs your grok pattern, your data can be parsed.

- **Custom patterns**

For grok classifiers, these are optional building blocks for the **Grok pattern** that you write. When built-in patterns cannot parse your data, you might need to write a custom pattern. These custom patterns are defined in this field and referenced in the **Grok pattern** field. Each custom pattern is defined on a separate line. Just like the built-in patterns, it consists of a named pattern definition that uses [regular expression \(regex\)](#) syntax.

For example, the following has the name MESSAGEPREFIX followed by a regular expression definition to apply to your data to determine whether it follows the pattern.

```
MESSAGEPREFIX .*-.*-.*-.*-.*
```

## XML

- **Row tag**

For XML classifiers, this is the name of the XML tag that defines a table row in the XML document. Type the name without angle brackets < >. The name must comply with XML rules for a tag.

For more information, see [Writing XML custom classifiers](#).

## JSON

- **JSON path**

For JSON classifiers, this is the JSON path to the object, array, or value that defines a row of the table being created. Type the name in either dot or bracket JSON syntax using AWS Glue supported operators.

For more information, see the list of operators in [Writing JSON custom classifiers](#).

## CSV

- **Column delimiter**

A single character or symbol to denote what separates each column entry in the row. Choose the delimiter from the list, or choose `Other` to enter a custom delimiter.

- **Quote symbol**

A single character or symbol to denote what combines content into a single column value. Must be different from the column delimiter. Choose the quote symbol from the list, or choose `Other` to enter a custom quote character.

- **Column headings**

Indicates the behavior for how column headings should be detected in the CSV file. You can choose `Has headings`, `No headings`, or `Detect headings`. If your custom CSV file has column headings, enter a comma-delimited list of the column headings.

- **Allow files with single column**

To be classified as CSV, the data must have at least two columns and two rows of data. Use this option to allow the processing of files that contain only one column.

- **Trim whitespace before identifying column values**

This option specifies whether to trim values before identifying the type of column values.

- **Custom datatype**

(Optional) - Enter custom datatypes in a comma-delimited list. The supported datatypes are: "BINARY", "BOOLEAN", "DATE", "DECIMAL", "DOUBLE", "FLOAT", "INT", "LONG", "SHORT", "STRING", "TIMESTAMP".

- **CSV Serde**

(Optional) - A SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Choose from Open CSV SerDe, Lazy Simple SerDe, or None. You can specify the None value when you want the crawler to do the detection.

For more information, see [Writing custom classifiers](#).

## Scheduling an AWS Glue crawler

You can run an AWS Glue crawler on demand or on a regular schedule. Crawler schedules can be expressed in *cron* format. For more information, see [cron](#) in Wikipedia.

When you create a crawler based on a schedule, you can specify certain constraints, such as the frequency the crawler runs, which days of the week it runs, and at what time. These constraints are based on cron. When setting up a crawler schedule, you should consider the features and limitations of cron. For example, if you choose to run your crawler on day 31 each month, keep in mind that some months don't have 31 days.

Crawls for each crawler is valid only for up to 12 months

For more information about using cron to schedule jobs and crawlers, see [Time-based schedules for jobs and crawlers](#).

## Viewing crawler results and details

After the crawler runs successfully, it creates table definitions in the Data Catalog. Choose **Tables** in the navigation pane to see the tables that were created by your crawler in the database that you specified.

You can view information related to the crawler itself as follows:

- The **Crawlers** page on the AWS Glue console displays the following properties for a crawler:

Property	Description
<b>Name</b>	When you create a crawler, you must give it a unique name.
<b>Status</b>	A crawler can be ready, starting, stopping, scheduled, or schedule paused. A running crawler progresses from starting to stopping. You can resume or pause a schedule attached to a crawler.
<b>Schedule</b>	You can choose to run your crawler on demand or choose a frequency with a schedule. For more information about scheduling a crawler, see <a href="#">Scheduling a crawler</a> .
<b>Last run</b>	The date and time of the last time the crawler was run.
<b>Log</b>	Links to any available logs from the last run of the crawler.
<b>Tables changes from last run</b>	The number of tables in the AWS Glue Data Catalog that were updated by the latest run of the crawler.

- To view the history of a crawler, choose **Crawlers** in the navigation pane to see the crawlers you created. Choose a crawler from the list of available crawlers. You can view the crawler properties and view the crawler history in the **Crawler runs** tab.

The Crawler runs tab displays information about each time the crawler ran, including **Start time (UTC)**, **End time (UTC)**, **Duration**, **Status**, **DPU hours**, and **Table changes**.

The Crawler runs tab displays only the crawls that have occurred since the launch date of the crawler history feature, and only retains up to 12 months of crawls. Older crawls will not be returned.

- To see additional information, choose a tab in the crawler details page. Each tab will display information related to the crawler.
  - **Schedule:** Any schedules created for the crawler will be visible here.
  - **Data sources:** All data sources scanned by the crawler will be visible here.
  - **Classifiers:** All classifiers assigned to the crawler will be visible here.
  - **Tags:** Any tags created and assigned to an AWS resource will be visible here.

### Parameters set on Data Catalog tables by crawler

These table properties are set by AWS Glue crawlers. We expect users to consume the `classification` and `compressionType` properties. Other properties, including table size estimates, are used for internal calculations, and we do not guarantee their accuracy or applicability to customer use cases. Changing these parameters may alter the behavior of the crawler, we do not support this workflow.

Property key	Property value
UPDATED_BY_CRAWLER	Name of crawler performing update.
connectionName	The name of the connection in the Data Catalog for the crawler used to connect the to the data store.
recordCount	Estimate count of records in table, based on file sizes and headers.
skip.header.line.count	Rows skipped to skip header. Set on tables classified as CSV.
CrawlerSchemaSerializerVersion	For internal use
classification	Format of data, inferred by crawler. For more information about data formats supported by AWS Glue crawlers see <a href="#">the section called "Built-in classifiers in AWS Glue"</a> .

Property key	Property value
CrawlerSchemaDeserializerVersion	For internal use
sizeKey	Combined size of files in table crawled.
averageRecordSize	Average size of row in table, in bytes.
compressionType	Type of compression used on data in the table. For more information about compression types supported by AWS Glue crawlers see <a href="#">the section called "Built-in classifiers in AWS Glue"</a> .
typeOfData	file, table or view.
objectCount	Number of objects under Amazon S3 path for table.

These additional table properties are set by AWS Glue crawlers for Snowflake data stores.

Property key	Property value
aws:RawTableLastAltered	Records the last altered timestamp of the Snowflake table.
ViewOriginalText	View SQL statement.
ViewExpandedText	View SQL statement encoded in Base64 format.
ExternalTable:S3Location	Amazon S3 location of the Snowflake external table.

Property key	Property value
ExternalTable:FileFormat	Amazon S3 file format of the Snowflake external table.

These additional table properties are set by AWS Glue crawlers for JDBC-type data stores such as Amazon Redshift, Microsoft SQL Server, MySQL, PostgreSQL, and Oracle.

Property key	Property value
aws:RawType	When a crawler store the data in the Data Catalog it translates the datatypes to Hive-compatible types, which many times causes the information on the native datatype to be lost. The crawler outputs the <code>aws:RawType</code> parameter to provide the native-level datatype.
aws:RawColumnComment	<p>If a comment is associated with a column in the database, the crawler outputs the corresponding comment in the catalog table. The comment string is truncated to 255 bytes.</p> <p>Comments are not supported for Microsoft SQL Server.</p>
aws:RawTableComment	<p>If a comment is associated with a table in the database, the crawler outputs corresponding comment in the catalog table. The comment string is truncated to 255 bytes.</p> <p>Comments are not supported for Microsoft SQL Server.</p>

## Customizing crawler behavior

When a crawler runs, it might encounter changes to your data store that result in a schema or partition that is different from a previous crawl. You can use the AWS Management Console or the AWS Glue API to configure how your crawler processes certain types of changes.

### Topics

- [Incremental crawls for adding new partitions](#)
- [Setting the partition index crawler configuration option](#)

- [Accelerating crawls using Amazon S3 event notifications](#)
- [How to prevent the crawler from changing an existing schema](#)
- [How to create a single schema for each Amazon S3 include path](#)
- [How to specify the table location and partitioning level](#)
- [How to specify the maximum number of tables the crawler is allowed to create](#)
- [How to specify configuration options for a Delta Lake data store](#)
- [How to configure a crawler to use Lake Formation credentials](#)

## Console

When you define a crawler using the AWS Glue console, you have several options for configuring the behavior of your crawler. For more information about using the AWS Glue console to add a crawler, see [Configuring a crawler](#).

When a crawler runs against a previously crawled data store, it might discover that a schema has changed or that some objects in the data store have been deleted. The crawler logs changes to a schema. Depending on the source type for the crawler, new tables and partitions might be created regardless of the schema change policy.

To specify what the crawler does when it finds changes in the schema, you can choose one of the following actions on the console:

- **Update the table definition in the Data Catalog** – Add new columns, remove missing columns, and modify the definitions of existing columns in the AWS Glue Data Catalog. Remove any metadata that is not set by the crawler. This is the default setting.
- **Add new columns only** – For tables that map to an Amazon S3 data store, add new columns as they are discovered, but don't remove or change the type of existing columns in the Data Catalog. Choose this option when the current columns in the Data Catalog are correct and you don't want the crawler to remove or change the type of the existing columns. If a fundamental Amazon S3 table attribute changes, such as classification, compression type, or CSV delimiter, mark the table as deprecated. Maintain input format and output format as they exist in the Data Catalog. Update SerDe parameters only if the parameter is one that is set by the crawler. *For all other data stores, modify existing column definitions.*
- **Ignore the change and don't update the table in the Data Catalog** – Only new tables and partitions are created.

This is the default setting for incremental crawls.

A crawler might also discover new or changed partitions. By default, new partitions are added and existing partitions are updated if they have changed. In addition, you can set a crawler configuration option to **Update all new and existing partitions with metadata from the table** on the AWS Glue console. When this option is set, partitions inherit metadata properties—such as their classification, input format, output format, SerDe information, and schema—from their parent table. Any changes to these properties in a table are propagated to its partitions. When this configuration option is set on an existing crawler, existing partitions are updated to match the properties of their parent table the next time the crawler runs.

To specify what the crawler does when it finds a deleted object in the data store, choose one of the following actions:

- **Delete tables and partitions from the Data Catalog**
- **Ignore the change and don't update the table in the Data Catalog**

This is the default setting for incremental crawls.

- **Mark the table as deprecated in the Data Catalog** – This is the default setting.

## AWS CLI

```
aws glue create-crawler \  
--name "your-crawler-name" \  
--role "your-iam-role-arn" \  
--database-name "your-database-name" \  
--targets 'S3Targets=[{Path="s3://your-bucket-name/path-to-data"}]' \  
--configuration '{"Version": 1.0, "CrawlerOutput": {"Partitions":  
{"AddOrUpdateBehavior": "InheritFromTable"}, "Tables": {"AddOrUpdateBehavior":  
"MergeNewColumns"}}}'
```

## API

When you define a crawler using the AWS Glue API, you can choose from several fields to configure your crawler. The `SchemaChangePolicy` in the crawler API determines what the crawler does when it discovers a changed schema or a deleted object. The crawler logs schema changes as it runs.

## Sample python code showing the crawler configuration options

```
import boto3
import json

# Initialize a boto3 client for AWS Glue
glue_client = boto3.client('glue', region_name='us-east-1') # Replace 'us-east-1'
with your desired AWS region

# Define the crawler configuration
crawler_configuration = {
    "Version": 1.0,
    "CrawlerOutput": {
        "Partitions": {
            "AddOrUpdateBehavior": "InheritFromTable"
        },
    },
    "Tables": {
        "AddOrUpdateBehavior": "MergeNewColumns"
    }
}

configuration_json = json.dumps(crawler_configuration)
# Create the crawler with the specified configuration
response = glue_client.create_crawler(
    Name='your-crawler-name', # Replace with your desired crawler name
    Role='crawler-test-role', # Replace with the ARN of your IAM role for Glue
    DatabaseName='default', # Replace with your target Glue database name
    Targets={
        'S3Targets': [
            {
                'Path': "s3://your-bucket-name/path/", # Replace with your S3 path
to the data
            },
        ],
        # Include other target types like 'JdbcTargets' if needed
    },
    Configuration=configuration_json,
    # Include other parameters like Schedule, Classifiers, TablePrefix,
    SchemaChangePolicy, etc., as needed
)

print(response)
```

When a crawler runs, new tables and partitions are always created regardless of the schema change policy. You can choose one of the following actions in the `UpdateBehavior` field in the `SchemaChangePolicy` structure to determine what the crawler does when it finds a changed table schema:

- `UPDATE_IN_DATABASE` – Update the table in the AWS Glue Data Catalog. Add new columns, remove missing columns, and modify the definitions of existing columns. Remove any metadata that is not set by the crawler.
- `LOG` – Ignore the changes, and don't update the table in the Data Catalog.

This is the default setting for incremental crawls.

You can also override the `SchemaChangePolicy` structure using a JSON object supplied in the crawler API `Configuration` field. This JSON object can contain a key-value pair to set the policy to not update existing columns and only add new columns. For example, provide the following JSON object as a string:

```
{
  "Version": 1.0,
  "CrawlerOutput": {
    "Tables": { "AddOrUpdateBehavior": "MergeNewColumns" }
  }
}
```

This option corresponds to the **Add new columns only** option on the AWS Glue console. It overrides the `SchemaChangePolicy` structure for tables that result from crawling Amazon S3 data stores only. Choose this option if you want to maintain the metadata as it exists in the Data Catalog (the source of truth). New columns are added as they are encountered, including nested data types. But existing columns are not removed, and their type is not changed. If an Amazon S3 table attribute changes significantly, mark the table as deprecated, and log a warning that an incompatible attribute needs to be resolved. This option is not applicable for incremental crawler.

When a crawler runs against a previously crawled data store, it might discover new or changed partitions. By default, new partitions are added and existing partitions are updated if they have changed. In addition, you can set a crawler configuration option to `InheritFromTable`

(corresponding to the **Update all new and existing partitions with metadata from the table** option on the AWS Glue console). When this option is set, partitions inherit metadata properties from their parent table, such as their classification, input format, output format, SerDe information, and schema. Any property changes to the parent table are propagated to its partitions.

When this configuration option is set on an existing crawler, existing partitions are updated to match the properties of their parent table the next time the crawler runs. This behavior is set crawler API Configuration field. For example, provide the following JSON object as a string:

```
{
  "Version": 1.0,
  "CrawlerOutput": {
    "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" }
  }
}
```

The crawler API Configuration field can set multiple configuration options. For example, to configure the crawler output for both partitions and tables, you can provide a string representation of the following JSON object:

```
{
  "Version": 1.0,
  "CrawlerOutput": {
    "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" },
    "Tables": { "AddOrUpdateBehavior": "MergeNewColumns" }
  }
}
```

You can choose one of the following actions to determine what the crawler does when it finds a deleted object in the data store. The `DeleteBehavior` field in the `SchemaChangePolicy` structure in the crawler API sets the behavior of the crawler when it discovers a deleted object.

- `DELETE_FROM_DATABASE` – Delete tables and partitions from the Data Catalog.
- `LOG` – Ignore the change. Don't update the Data Catalog. Write a log message instead.
- `DEPRECATE_IN_DATABASE` – Mark the table as deprecated in the Data Catalog. This is the default setting.

## Incremental crawls for adding new partitions

The crawler provides an option for adding new partitions resulting in faster crawls for incremental datasets with a stable table schema. The typical use case is for scheduled crawlers, where during each crawl, new partitions are added. When this option is turned on, it will first run a complete crawl on the target dataset to allow the crawler to record the initial schema and partition structure. During a recrawl, new partitions will be added to existing tables only when the schemas are compatible. No schema changes are made and no new tables will be added to the Data Catalog after the first crawl run.

You can use this option when setting up an Amazon S3 data source. You can set the `RecrawlPolicy` with `RecrawlBehavior` as "Crawl\_New\_Folders" in the `CreateCrawler` API or **Subsequent crawler runs as Crawl new sub-folders only** in the console.

Continuing with the example in [the section called "How does a crawler determine when to create partitions?"](#), the following diagram shows that files for the month of March have been added.

If you set the `RecrawlBehavior` as the "Crawl\_New\_Folders" option, only the new folder, `month=Mar` is crawled.

### Notes and restrictions

When this option is turned on, you can't change the Amazon S3 target data stores when editing the crawler. This option affects certain crawler configuration settings. When turned on, it forces the update behavior and delete behavior of the crawler to LOG. This means that:

- If it discovers objects where schemas are not compatible, the crawler will not add the objects in the Data Catalog, and adds this detail as a log in CloudWatch Logs.

- It will not update deleted objects in the Data Catalog.

For more information, see [the section called “Customizing crawler behavior”](#).

### Setting the partition index crawler configuration option

The Data Catalog supports partition indexes to provide efficient lookup for specific partitions. For more information, see [Working with partition indexes in AWS Glue](#). The AWS Glue crawler creates partition indexes for Amazon S3 and Delta Lake targets by default.

When you define a crawler, the option to **Create partition indexes automatically** is enabled by default under **Advanced options** on the **Set output and scheduling** page.

To disable this option, you can unselect the checkbox **Create partition indexes automatically** in the console. You can also disable this option by using the crawler API, set the `CreatePartitionIndex` in the Configuration. The default value is true.

### Usage notes for partition indexes

- Tables created by the crawler do not have the variable `partition_filtering.enabled` by default. For more information, see [AWS Glue partition indexing and filtering](#).
- Creating partition indexes for encrypted partitions is not supported.

### Accelerating crawls using Amazon S3 event notifications

Instead of listing the objects from an Amazon S3 or Data Catalog target, you can configure the crawler to use Amazon S3 events to find any changes. This feature improves the recrawl time by using Amazon S3 events to identify the changes between two crawls by listing all the files from the subfolder which triggered the event instead of listing the full Amazon S3 or Data Catalog target.

The first crawl lists all Amazon S3 objects from the target. After the first successful crawl, you can choose to recrawl manually or on a set schedule. The crawler will list only the objects from those events instead of listing all objects.

The advantages of moving to an Amazon S3 event based crawler are:

- A faster recrawl as the listing of all the objects from the target is not required, instead the listing of specific folders is done where objects are added or deleted.
- A reduction in the overall crawl cost as the listing of specific folders is done where objects are added or deleted.

The Amazon S3 event crawl runs by consuming Amazon S3 events from the SQS queue based on the crawler schedule. There will be no cost if there are no events in the queue. Amazon S3 events can be configured to go directly to the SQS queue or in cases where multiple consumers need the same event, a combination of SNS and SQS. For more information, see [the section called "Setting up your account for Amazon S3 event notifications"](#).

After creating and configuring the crawler in event mode, the first crawl runs in listing mode by performing full a listing of the Amazon S3 or Data Catalog target. The following log confirms the operation of the crawl by consuming Amazon S3 events after the first successful crawl: "The crawl is running by consuming Amazon S3 events."

After creating the Amazon S3 event crawl and updating the crawler properties which may impact the crawl, the crawl operates in list mode and the following log is added: "Crawl is not running in S3 event mode".

#### Note

The maximum number of messages to consume is 10,000 messages per crawl.

## Catalog target

When the target is the Data Catalog the crawler updates the existing tables in the Data Catalog with changes (for example, extra partitions in a table).

## Topics

- [Setting up your account for Amazon S3 event notifications](#)
- [Using encryption with the Amazon S3 event crawler](#)

## Setting up your account for Amazon S3 event notifications

This section describes how to set up your account for Amazon S3 event notifications, and provides instructions for doing so using a script, or the AWS Glue console.

### Prerequisites

Complete the following setup tasks. Note the values in parenthesis reference the configurable settings from the script.

1. Create an Amazon S3 bucket (s3\_bucket\_name).

2. Identify a crawler target (`folder_name`, such as "test1") which is a path in the identified bucket.
3. Prepare a crawler name (`crawler_name`)
4. Prepare an SNS Topic name (`sns_topic_name`) which could be the same as the crawler name.
5. Prepare the AWS Region where the crawler is to run and the S3 bucket exists (`region`).
6. Optionally prepare an email address if email is used to get the Amazon S3 events (`subscribing_email`).

You can also use the CloudFormation stack to create your resources. Complete the following steps:

1. [Launch](#) your CloudFormation stack in US East (N. Virginia):
2. Under Parameters, enter a name for your Amazon S3 bucket (include your account number).
3. Select I acknowledge that AWS CloudFormation might create IAM resources with custom names.
4. Choose Create stack.

#### Limitations:

- Only a single target is supported by the crawler, whether for Amazon S3 or Data Catalog targets.
- SQS on private VPC is not supported.
- Amazon S3 sampling is not supported.
- The crawler target should be a folder for an Amazon S3 target, or one or more AWS Glue Data Catalog tables for a Data Catalog target.
- The 'everything' path wildcard is not supported: `s3://%`
- For a Data Catalog target, all catalog tables should point to same Amazon S3 bucket for Amazon S3 event mode.
- For a Data Catalog target, a catalog table should not point to an Amazon S3 location in the Delta Lake format (containing `_symlink` folders, or checking the catalog table's `InputFormat`).

To use the Amazon S3 event based crawler, you should enable event notification on the S3 bucket with events filtered from the prefix which is the same as the S3 target and store in SQS. You can set up SQS and event notification through the console by following the steps in [Walkthrough: Configuring a bucket for notifications](#) or using the [the section called "Script to generate SQS and configure Amazon S3 events from the target"](#).

## SQS policy

Add the following SQS policy which is required to be attached to the role used by the crawler.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "sqs:DeleteMessage",
        "sqs:GetQueueUrl",
        "sqs:ListDeadLetterSourceQueues",
        "sqs:ReceiveMessage",
        "sqs:GetQueueAttributes",
        "sqs:ListQueueTags",
        "sqs:SetQueueAttributes",
        "sqs:PurgeQueue"
      ],
      "Resource": "arn:aws:sqs:{region}:{accountID}:cfn-sqs-queue"
    }
  ]
}
```

## Script to generate SQS and configure Amazon S3 events from the target

After ensuring the prerequisites are met, you can run the following Python script to create the SQS. Replace the Configurable settings with the names prepared from the prerequisites.

### Note

After running the script, login to the SQS console to find the ARN of the SQS created.

Amazon SQS sets a *visibility timeout*, a period of time during which Amazon SQS prevents other consumers from receiving and processing the message. Set the visibility timeout approximately equal to the crawl run time.

```
#!/venv/bin/python
import boto3
import botocore
```

```

#-----Start : READ ME FIRST -----#
# 1. Purpose of this script is to create the SQS, SNS and enable S3 bucket
notification.
#     The following are the operations performed by the scripts:
#     a. Enable S3 bucket notification to trigger 's3:ObjectCreated:' and
's3:ObjectRemoved:' events.
#     b. Create SNS topic for fan out.
#     c. Create SQS queue for saving events which will be consumed by the crawler.
#         SQS Event Queue ARN will be used to create the crawler after running the
script.
# 2. This script does not create the crawler.
# 3. SNS topic is created to support FAN out of S3 events. If S3 event is also used by
another
#     purpose, SNS topic created by the script can be used.
# 1. Creation of bucket is an optional step.
#     To create a bucket set create_bucket variable to true.
# 2. The purpose of crawler_name is to easily locate the SQS/SNS.
#     crawler_name is used to create SQS and SNS with the same name as crawler.
# 3. 'folder_name' is the target of crawl inside the specified bucket 's3_bucket_name'
#

## Setting up a crawler for Amazon S3 event notifications using the console (Amazon S3 target)

To set up a crawler for Amazon S3 event notifications using the AWS Glue console for an Amazon S3 target:

1. Set your crawler properties. For more information, see [Setting Crawler Configuration Options on the AWS Glue console](#).
2. In the section **Data source configuration**, you are asked *Is your data already mapped to AWS Glue tables?*

By default **Not yet** is already selected. Leave this as the default as you are using an Amazon S3 data source and the data is not already mapped to AWS Glue tables.

3. In the section **Data sources**, choose **Add a data source**.

The screenshot shows the 'Choose data sources and classifiers' step in the AWS Glue console. On the left, a sidebar lists five steps: Step 1 (Set crawler properties), Step 2 (Choose data sources and classifiers), Step 3 (Configure security settings), Step 4 (Set output and scheduling), and Step 5 (Review and create). The main content area is titled 'Choose data sources and classifiers' and contains the following sections:

- Data source configuration:** A section with the question 'Is your data already mapped to Glue tables?'. There are two radio button options: 'Not yet' (selected) with the subtext 'Select one or more data sources to be crawled.', and 'Yes' with the subtext 'Select existing tables from your Glue Data Catalog.'
- Data sources (0):** A section with the subtext 'The list of data sources to be scanned by the crawler.' It includes buttons for 'Edit', 'Remove', and 'Add a data source'. Below this is a table with columns 'Type', 'Data source', and 'Parameters'. The table is empty, and the text 'You don't have any data sources.' is displayed with an 'Add a data source' button below it.
- Custom classifiers - optional:** A section with a right-pointing triangle icon and the subtext 'A classifier checks whether a given file is in a format the crawler can handle. If it is, the classifier creates a schema in the form of a StructType object that matches that data format.'

At the bottom right of the main area, there are three buttons: 'Cancel', 'Previous', and 'Next'.

4. In the **Add data source** modal, configure the Amazon S3 data source:
  - **Data source:** By default, Amazon S3 is selected.
  - **Network connection (Optional):** Choose **Add new connection**.
  - **Location of Amazon S3 data:** By default, **In this account** is selected.
  - **Amazon S3 path:** Specify the Amazon S3 path where folders and files are crawled.
  - **Subsequent crawler runs:** Choose **Crawl based on events** to use Amazon S3 event notifications for your crawler.

- **Include SQS ARN:** Specify the data store parameters including the a valid SQS ARN. (For example, `arn:aws:sqs:region:account:sqs`).
- **Include dead-letter SQS ARN (Optional):** Specify a valid Amazon dead-letter SQS ARN. (For example, `arn:aws:sqs:region:account:deadLetterQueue`).
- **Choose Add an Amazon S3 data source.**

The screenshot shows the 'Add data source' dialog in the AWS Glue console. The dialog is titled 'Add data source' and has a close button (X) in the top right corner. It is divided into several sections:

- Data source:** A dropdown menu is set to 'S3'.
- Network connection - optional:** A text input field is empty, with a refresh icon (G) to its right. Below it are 'Clear selection' and 'Add new connection' buttons.
- Location of S3 data:** Two radio buttons are present: 'In this account' (selected) and 'In a different account'.
- S3 path:** A text input field contains 's3://test', with 'View' and 'Browse' buttons to its right. Below it is a note: 'All folders and files contained in the S3 path are crawled. For example, type s3://MyBucket/MyFolder/ to crawl all objects in MyFolder within MyBucket.'
- Subsequent crawler runs:** Three radio buttons are present: 'Crawl all sub-folders' (unselected), 'Crawl new sub-folders only' (unselected), and 'Crawl based on events' (selected). Below this is the 'Include SQS ARN' section, which has a text input field containing 'arn:aws:sqs:region:account:sqs' and a note: 'SQS ARN must follow the following syntax: arn:aws:sqs:region:account:sqs'. Below that is the 'Include dead-letter SQS ARN - optional' section, which has a text input field containing 'arn:aws:sqs:region:account:deadLetterQueue' and a note: 'Dead-letter SQS ARN must follow the following syntax: arn:aws:sqs:region:account:deadLetterQueue'.
- At the bottom, there are two checkboxes: 'Sample only a subset of files' (unchecked) and 'Exclude files matching pattern' (unchecked).
- At the very bottom, there are 'Cancel' and 'Add an S3 data source' buttons.

## Setting up a crawler for Amazon S3 event notifications using the AWS CLI

The following is an example Amazon S3 AWS CLI call to create SQS queues and setup event notifications on Amazon S3 target bucket.

## S3 Event AWS CLI

```
aws sqs create-queue --queue-name MyQueue --attributes file://create-queue.json
create-queue.json
...
```

```
{
  "Policy": {
    "Version": "2012-10-17",
    "Id": "example-ID",
    "Statement": [
      {

Create Crawler:

### Setting up a crawler for Amazon S3 event notifications using the console (Data Catalog target)

When you have a catalog target, set up a crawler for Amazon S3 event notifications using the AWS Glue console:

1. Set your crawler properties. For more information, see [Setting Crawler Configuration Options on the AWS Glue console](#).
2. In the section **Data source configuration**, you are asked *Is your data already mapped to AWS Glue tables?*

Select **Yes** to select existing tables from your Data Catalog as your data source.

3. In the section **Glue tables**, choose **Add tables**.

The screenshot shows the 'Choose data sources and classifiers' step in the AWS Glue console. On the left, a navigation pane lists five steps: Step 1 (Set crawler properties), Step 2 (Choose data sources and classifiers), Step 3 (Configure security settings), Step 4 (Set output and scheduling), and Step 5 (Review and create). The main content area is titled 'Choose data sources and classifiers' and contains a 'Data source configuration' section. This section asks 'Is your data already mapped to Glue tables?' with two radio button options: 'Not yet' (with subtext 'Select one or more data sources to be crawled.') and 'Yes' (with subtext 'Select existing tables from your Glue Data Catalog.'). Below this is a 'Glue tables (0) Info' section with 'Edit', 'Remove', and 'Add tables' buttons. A table below shows columns for 'Database' and 'Tables', with a message 'You don't have any catalog table sources.' and an 'Add tables' button.

4. In the **Add table** modal, configure the database and tables:

- **Network connection** (Optional): Choose **Add new connection**.
- **Database**: Select a database in the Data Catalog.
- **Tables**: Select one or more tables from that database in the Data Catalog.
- **Subsequent crawler runs**: Choose **Crawl based on events** to use Amazon S3 event notifications for your crawler.
- **Include SQS ARN**: Specify the data store parameters including the a valid SQS ARN. (For example, `arn:aws:sqs:region:account:sqs`).
- **Include dead-letter SQS ARN** (Optional): Specify a valid Amazon dead-letter SQS ARN. (For example, `arn:aws:sqs:region:account:deadLetterQueue`).
- Choose **Confirm**.

## Using encryption with the Amazon S3 event crawler

This section describes using encryption on SQS only or on both SQS and Amazon S3.

### Topics

- [Enabling encryption on SQS only](#)
- [Enabling encryption on both SQS and Amazon S3](#)
- [FAQ](#)

## Enabling encryption on SQS only

Amazon SQS provides encryption in-transit by default. To add optional Server-Side Encryption (SSE) to your queue you can attach a [customer master key \(CMK\)](#) in the edit panel. This means that SQS encrypts all customer data at-rest on SQS servers.

### Create a Customer Master Key (CMK)

1. Choose **Key Management Service (KMS) > Customer Managed Keys > Create key**.
2. Follow the steps to add your own alias and description.
3. Add the respective IAM roles you would like to be able to use this key.
4. In the key policy, add another statement to the "Statement" list so that your [custom key policy](#) gives the Amazon SNS sufficient key usage permissions.

```
"Statement": [  
  {  
    "Effect": "Allow",  
    "Principal": {  
      "Service": "sns.amazonaws.com"  
    },  
    "Action": [  
      "kms:GenerateDataKey",  
      "kms:Decrypt"  
    ],  
    "Resource": "*"   
  }  
]
```

### Enable Server-Side Encryption (SSE) on your queue

1. Choose **Amazon SQS > Queues > sqs\_queue\_name > Encryption** tab.
2. Choose **Edit**, and scroll down to the **Encryption** drop down.
3. Select **Enabled** to add SSE.
4. Select the CMK you created earlier, and not the default key with the name `alias/aws/sqs`.

▼ **Encryption - Optional**  
 Amazon SQS provides in-transit encryption by default. To add at-rest encryption to your queue, enable server-side encryption. [Info](#)

Server-side encryption

Disabled

Enabled

Customer master key [Info](#)

alias/sqs-key ▼

After adding this, your Encryption tab is updated with the key you added.

SNS subscriptions | Lambda triggers | Dead-letter queue | Monitoring | Tagging | Access policy | **Encryption**

**Encryption** Edit  
 Amazon SQS provides encryption in-transit by default. You can also add Server-Side Encryption (SSE) to your queue, which means that SQS encrypts all customer data at-rest on SQS servers. [Info](#)

CMK alias alias/sqs-key	Data key reuse period 5 Minutes
----------------------------	------------------------------------

### Note

Amazon SQS automatically deletes messages that have been in a queue for more than the maximum message retention period. The default message retention period is 4 days. To avoid missing events change the SQS **MessageRetentionPeriod** to the maximum of 14 days.

## Enabling encryption on both SQS and Amazon S3

### Enable Server-Side Encryption (SSE) on SQS

1. Follow the steps in [the section called "Enabling encryption on SQS only"](#).
2. In the last step of the CMK setup, give Amazon S3 sufficient key usage permissions.

Paste the following in to the "Statement" list:

```
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
```

```

        "Service": "s3.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
    ],
    "Resource": "*"
}
]

```

## Enable Server-Side Encryption (SSE) on your Amazon S3 bucket

1. Follow the steps in [the section called “Enabling encryption on S3 only”](#).
2. Do one of the following:
  - To enable SSE for your entire S3 bucket, navigate to the **Properties** tab in your target bucket.

Here you can enable SSE and choose the encryption type you would like to use. Amazon S3 provides an encryption key that Amazon S3 creates, manages, and uses for you, or you can choose a key from KMS as well.

### Edit default encryption

**Default encryption**  
Automatically encrypt new objects stored in this bucket. [Learn more](#)

Cancel

Save changes

- To enable SSE on a specific folder, click the checkbox beside your target folder and choose **Edit server-side encryption** under the **Actions** drop down.

## FAQ

### Why aren't messages that I publish to my Amazon SNS topic getting delivered to my subscribed Amazon SQS queue that has server-side encryption (SSE) enabled?

Double check that your Amazon SQS queue is using:

1. A [customer master key \(CMK\)](#) that is customer managed. Not the default one provided by SQS.
2. Your CMK from (1) includes a [custom key policy](#) that gives the Amazon SNS sufficient key usage permissions.

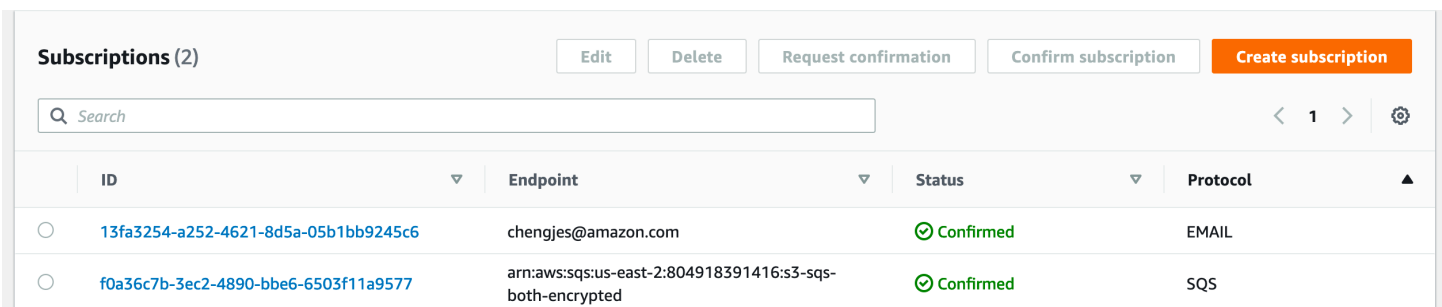

For more information, [see this article](#) in the knowledge center.

### I've subscribed to email notifications, but I don't receive any email updates when I edit my Amazon S3 bucket.

Make sure that you have confirmed your email address by clicking the "Confirm Subscription" link in your email. You can verify the status of your confirmation by checking the **Subscriptions** table under your SNS topic.

Choose **Amazon SNS > Topics > sns\_topic\_name > Subscriptions table**.

If you followed our prerequisite script, you will find that the sns\_topic\_name is equal to your sqs\_queue\_name. It should look similar to the following:

Subscriptions (2)				
ID	Endpoint	Status	Protocol	
13fa3254-a252-4621-8d5a-05b1bb9245c6	chengjes@amazon.com	Confirmed	EMAIL	
f0a36c7b-3ec2-4890-bbe6-6503f11a9577	arn:aws:sqs:us-east-2:804918391416:s3-sqs-both-encrypted	Confirmed	SQS	

### Only some of the folders I added are showing up in my table after enabling server-side encryption on my SQS queue. Why am I missing some parquets?

If the Amazon S3 bucket changes were made before enabling SSE on your SQS queue, they may not be picked up by the crawler. To ensure that you have crawled all the updates to your S3 bucket, run the crawler again in listing mode ("Crawl All Folders"). Another option is to start fresh by creating a new crawler with S3 events enabled.

## How to prevent the crawler from changing an existing schema

If you don't want a crawler to overwrite updates you made to existing fields in an Amazon S3 table definition, choose the option on the console to **Add new columns only** or set the configuration option `MergeNewColumns`. This applies to tables and partitions, unless `Partitions.AddOrUpdateBehavior` is overridden to `InheritFromTable`.

If you don't want a table schema to change at all when a crawler runs, set the schema change policy to `LOG`. You can also set a configuration option that sets partition schemas to inherit from the table.

If you are configuring the crawler on the console, you can choose the following actions:

- **Ignore the change and don't update the table in the Data Catalog**
- **Update all new and existing partitions with metadata from the table**

When you configure the crawler using the API, set the following parameters:

- Set the `UpdateBehavior` field in `SchemaChangePolicy` structure to `LOG`.
- Set the `Configuration` field with a string representation of the following JSON object in the crawler API; for example:

```
{
  "Version": 1.0,
  "CrawlerOutput": {
    "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" }
  }
}
```

## How to create a single schema for each Amazon S3 include path

By default, when a crawler defines tables for data stored in Amazon S3, it considers both data compatibility and schema similarity. Data compatibility factors that it considers include whether the data is of the same format (for example, JSON), the same compression type (for example, GZIP), the structure of the Amazon S3 path, and other data attributes. Schema similarity is a measure of how closely the schemas of separate Amazon S3 objects are similar.

You can configure a crawler to CombineCompatibleSchemas into a common table definition when possible. With this option, the crawler still considers data compatibility, but ignores the similarity of the specific schemas when evaluating Amazon S3 objects in the specified include path.

If you are configuring the crawler on the console, to combine schemas, select the crawler option **Create a single schema for each S3 path**.

When you configure the crawler using the API, set the following configuration option:

- Set the Configuration field with a string representation of the following JSON object in the crawler API; for example:

```
{
  "Version": 1.0,
  "Grouping": {
    "TableGroupingPolicy": "CombineCompatibleSchemas" }
}
```

To help illustrate this option, suppose that you define a crawler with an include path `s3://bucket/table1/`. When the crawler runs, it finds two JSON files with the following characteristics:

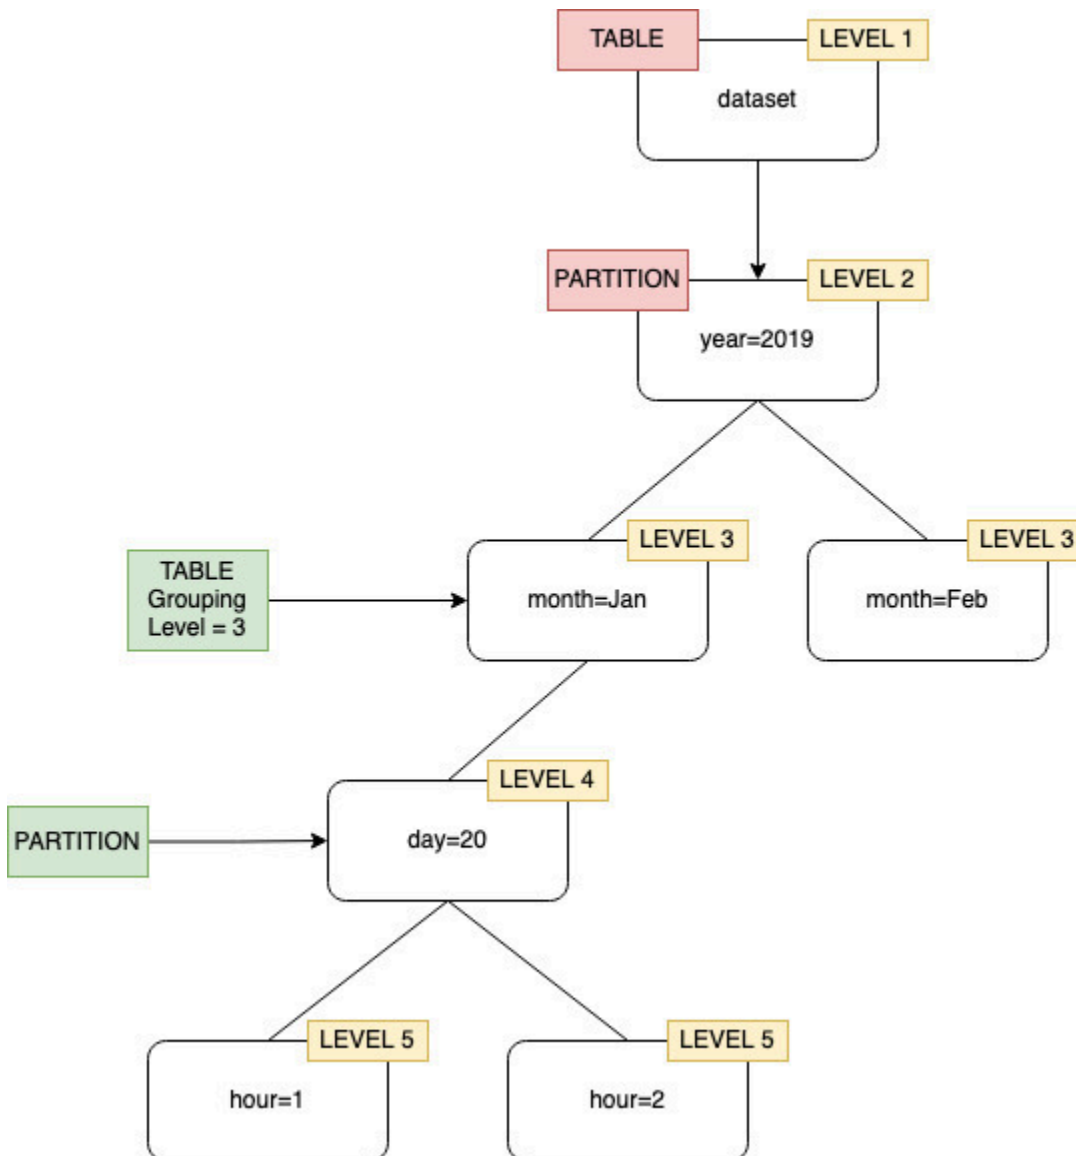

- **File 1** – `S3://bucket/table1/year=2017/data1.json`
- *File content* – `{"A": 1, "B": 2}`
- *Schema* – `A:int, B:int`
  
- **File 2** – `S3://bucket/table1/year=2018/data2.json`
- *File content* – `{"C": 3, "D": 4}`
- *Schema* – `C: int, D: int`

By default, the crawler creates two tables, named `year_2017` and `year_2018` because the schemas are not sufficiently similar. However, if the option **Create a single schema for each S3 path** is selected, and if the data is compatible, the crawler creates one table. The table has the schema `A:int,B:int,C:int,D:int` and `partitionKey year:string`.

## How to specify the table location and partitioning level

By default, when a crawler defines tables for data stored in Amazon S3 the crawler attempts to merge schemas together and create top-level tables (year=2019). In some cases, you may expect the crawler to create a table for the folder month=Jan but instead the crawler creates a partition since a sibling folder (month=Mar) was merged into the same table.

The table level crawler option provides you the flexibility to tell the crawler where the tables are located, and how you want partitions created. When you specify a **Table level**, the table is created at that absolute level from the Amazon S3 bucket.

When configuring the crawler on the console, you can specify a value for the **Table level** crawler option. The value must be a positive integer that indicates the table location (the absolute level in

the dataset). The level for the top level folder is 1. For example, for the path `mydataset/year/month/day/hour`, if the level is set to 3, the table is created at location `mydataset/year/month`.

## Console

Step 1  
[Set crawler properties](#)

---

Step 2  
[Choose data sources and classifiers](#)

---

Step 3  
[Configure security settings](#)

---

Step 4  
**Set output and scheduling**

---

Step 5  
[Review and create](#)

### Set output and scheduling

**Output configuration**

Target database  
 ↕ ↻

Table name prefix - *optional*

Maximum table threshold - *optional*  
This field sets the maximum number of tables the crawler is allowed to generate. In the event that this number is surpassed, the crawl will fail with an error. If not set, the crawler will automatically generate the number of tables depending on the data schema.

▼ **Advanced options**

S3 schema grouping

Create a single schema for each S3 path  
By default, when a crawler defines tables for data stored in S3, it considers both data compatibility and schema similarity. Select this check box to group compatible schemas into a single table definition across all S3 objects under the provided include path. Other criteria will still be considered to determine proper grouping.

Table level - *optional*  
The value must be a positive integer that indicates table location (the absolute level in the dataset). The level for the top level folder is 1. For example, for the path `mydataset/a/b`, if the level is set to 3, the table is created at location `mydataset/a/b`.

## API

When you configure the crawler using the API, set the `Configuration` field with a string representation of the following JSON object; for example:

```
configuration = jsonencode(
{
  "Version": 1.0,
  "Grouping": {
    TableLevelConfiguration = 2
  }
})
```

## CloudFormation

In this example, you set the **Table level** option available in the console within your CloudFormation template:

```
"Configuration": "{
  \"Version\":1.0,
  \"Grouping\":{\"TableLevelConfiguration\":2}
}"
```

### How to specify the maximum number of tables the crawler is allowed to create

You can optionally specify the maximum number of tables the crawler is allowed to create by specifying a `TableThreshold` via the AWS Glue console or CLI. If the tables detected by the crawler during its crawl is greater than this input value, the crawl fails and no data is written to the Data Catalog.

This parameter is useful when the tables that would be detected and created by the crawler are much greater more than what you expect. There can be multiple reasons for this, such as:

- When using an AWS Glue job to populate your Amazon S3 locations you can end up with empty files at the same level as a folder. In such cases when you run a crawler on this Amazon S3 location, the crawler creates multiple tables due to files and folders present at the same level.
- If you do not configure `"TableGroupingPolicy": "CombineCompatibleSchemas"` you may end up with more tables than expected.

You specify the `TableThreshold` as an integer value greater than 0. This value is configured on a per crawler basis. That is, for every crawl this value is considered. For example: a crawler has the `TableThreshold` value set as 5. In each crawl AWS Glue compares the number of tables detected with this table threshold value (5) and if the number of tables detected is less than 5, AWS Glue writes the tables to the Data Catalog and if not, the crawl fails without writing to the Data Catalog.

### Console

To set `TableThreshold` using the AWS console:

## Set output and scheduling

**Output configuration** [Info](#)

Target database

Choose a database

▼

Table name prefix - *optional*

Type a prefix added to table names

Maximum table threshold - *optional*

This field sets the maximum number of tables the crawler is allowed to generate. In the event that this number is surpassed, the crawl will fail with an error. If not set, the crawler will automatically generate the number of tables depending on the data schema.

Type a number greater than 0

▶ [Advanced options](#)

**CLI**

To set `TableThreshold` using the AWS CLI:

```

{"Version":1.0,
"CrawlerOutput":
{"Tables":{"AddOrUpdateBehavior":"MergeNewColumns",
"TableThreshold":5}}};

```

Error messages are logged to help you identify table paths and clean-up your data. Example log in your account if the crawler fails because the table count was greater than table threshold value provided:

```
Table Threshold value = 28, Tables detected - 29
```

In CloudWatch, we log all table locations detected as an INFO message. An error is logged as the reason for the failure.

```

ERROR com.amazonaws.services.glue.customerLogs.CustomerLogService - CustomerLogService
received CustomerFacingException with message
The number of tables detected by crawler: 29 is greater than the table threshold value
provided: 28. Failing crawler without writing to Data Catalog.
com.amazonaws.services.glue.exceptions.CustomerFacingInternalException: The number of
tables detected by crawler: 29 is greater than the table threshold value provided:
28.
Failing crawler without writing to Data Catalog.

```

**How to specify configuration options for a Delta Lake data store**

When you configure a crawler for a Delta Lake data store, you specify these configuration parameters:

## Connection

Optionally select or add a Network connection to use with this Amazon S3 target. For information about connections, see [Connecting to data](#).

## Create tables for querying

Select how you want to create the Delta Lake tables:

- **Create Native tables:** Allow integration with query engines that support querying of the Delta transaction log directly.
- **Create Symlink tables:** Create a symlink manifest folder with manifest files partitioned by the partition keys, based on the specified configuration parameters.

Enable write manifest (configurable only you've selected to **Create Symlink tables** for a Delta Lake source

Select whether to detect table metadata or schema changes in the Delta Lake transaction log; it regenerates the manifest file. You should not choose this option if you configured an automatic manifest update with Delta Lake SET TBLPROPERTIES.

## Include delta lake table path(s)

Specify one or more Amazon S3 paths to Delta tables as `s3://bucket/prefix/object`.

## Add data source ✕

**Data source**  
Choose the source of data to be crawled.

Delta Lake ▼

**Connection - optional**  
Select a connection to access the data sources below.

▼ ↻

Clear selection Add new connection [↗](#)

**Include delta lake table paths**  
Browse for or enter an existing S3 path.

`s3://bucket/prefix/object` Remove

Add new delta table path

**Enable write manifest**  
When enabled, if the crawler detects table metadata or schema changes in the Delta Lake transaction log, it regenerates the manifest file. You should not choose this option if you configured automatic manifest updates with Delta Lake SET TBLPROPERTIES.

Cancel Add a Delta Lake data source

### How to configure a crawler to use Lake Formation credentials

You can configure a crawler to use AWS Lake Formation credentials to access an Amazon S3 data store or a Data Catalog table with an underlying Amazon S3 location within the same AWS account or another AWS account. You can configure an existing Data Catalog table as a crawler's target, if

the crawler and the Data Catalog table reside in the same account. Currently, only a single catalog target with a single catalog table is allowed when using a Data Catalog table as a crawler's target.

 **Note**

When you are defining a Data Catalog table as a crawler target, make sure that the underlying location of the Data Catalog table is an Amazon S3 location. Crawlers that use Lake Formation credentials only support Data Catalog targets with underlying Amazon S3 locations.

### Setup required when the crawler and registered Amazon S3 location or Data Catalog table reside in the same account (in-account crawling)

To allow the crawler to access a data store or Data Catalog table by using Lake Formation credentials, you need to register the data location with Lake Formation. Also, the crawler's IAM role must have permissions to read the data from the destination where the Amazon S3 bucket is registered.

You can complete the following configuration steps using the AWS Management Console or AWS Command Line Interface (AWS CLI).

#### AWS Management Console

1. Before configuring a crawler to access the crawler source, register the data location of the data store or the Data Catalog with Lake Formation. In the Lake Formation console (<https://console.aws.amazon.com/lakeformation/>), register an Amazon S3 location as the root location of your data lake in the AWS account where the crawler is defined. For more information, see [Registering an Amazon S3 location](#).
2. Grant **Data location** permissions to the IAM role that's used for the crawler run so that the crawler can read the data from the destination in Lake Formation. For more information, see [Granting data location permissions \(same account\)](#).
3. Grant the crawler role access permissions (Create) to the database, which is specified as the output database. For more information, see [Granting database permissions using the Lake Formation console and the named resource method](#).
4. In the IAM console (<https://console.aws.amazon.com/iam/>), create an IAM role for the crawler. Add the `lakeformation:GetDataAccess` policy to the role.

5. In the AWS Glue console (<https://console.aws.amazon.com/glue/>), while configuring the crawler, select the option **Use Lake Formation credentials for crawling Amazon S3 data source**.

 **Note**

The accountId field is optional for in-account crawling.

## AWS CLI

```
aws glue --profile demo create-crawler --debug --cli-input-json '{
  "Name": "prod-test-crawler",
  "Role": "arn:aws:iam::111122223333:role/service-role/AWSGlueServiceRole-prod-
test-run-role",
  "DatabaseName": "prod-run-db",
  "Description": "",
  "Targets": {
    "S3Targets": [
      {
        "Path": "s3://crawl-testbucket"
      }
    ]
  },
  "SchemaChangePolicy": {
    "UpdateBehavior": "LOG",
    "DeleteBehavior": "LOG"
  },
  "RecrawlPolicy": {
    "RecrawlBehavior": "CRAWL_EVERYTHING"
  },
  "LineageConfiguration": {
    "CrawlerLineageSettings": "DISABLE"
  },
  "LakeFormationConfiguration": {
    "UseLakeFormationCredentials": true,
    "AccountId": "111122223333"
  },
  "Configuration": {
    "Version": 1.0,
    "CrawlerOutput": {
      "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" },
```

```
        "Tables": {"AddOrUpdateBehavior": "MergeNewColumns" }
    },
    "Grouping": { "TableGroupingPolicy": "CombineCompatibleSchemas" }
},
"CrawlerSecurityConfiguration": "",
"Tags": {
  "KeyName": ""
}
}'
```

## Setup required when the crawler and registered Amazon S3 location reside in different accounts (cross-account crawling)

To allow the crawler to access a data store in a different account using Lake Formation credentials, you must first register the Amazon S3 data location with Lake Formation. Then, you grant data location permissions to the crawler's account by taking the following steps.

You can complete the following steps using the AWS Management Console or AWS CLI.

### AWS Management Console

1. In the account where the Amazon S3 location is registered (account B):
  - a. Register an Amazon S3 path with Lake Formation. For more information, see [Registering Amazon S3 location](#).
  - b. Grant **Data location** permissions to the account (account A) where the crawler will be run. For more information, see [Grant data location permissions](#).
  - c. Create an empty database in Lake Formation with the underlying location as the target Amazon S3 location. For more information, see [Creating a database](#).
  - d. Grant account A (the account where the crawler will be run) access to the database that you created in the previous step. For more information, see [Granting database permissions](#).
2. In the account where the crawler is created and will be run (account A):
  - a. Using the AWS RAM console, accept the database that was shared from the external account (account B). For more information, see [Accepting a resource share invitation from AWS Resource Access Manager](#).
  - b. Create an IAM role for the crawler. Add `lakeformation:GetDataAccess` policy to the role.

- c. In the Lake Formation console (<https://console.aws.amazon.com/lakeformation/>), grant **Data location** permissions on the target Amazon S3 location to the IAM role used for the crawler run so that the crawler can read the data from the destination in Lake Formation. For more information, see [Granting data location permissions](#).
- d. Create a resource link on the shared database. For more information, see [Create a resource link](#).
- e. Grant the crawler role access permissions (Create) on the shared database and (Describe) the resource link. The resource link is specified in the output for the crawler.
- f. In the AWS Glue console (<https://console.aws.amazon.com/glue/>), while configuring the crawler, select the option **Use Lake Formation credentials for crawling Amazon S3 data source**.

For cross-account crawling, specify the AWS account ID where the target Amazon S3 location is registered with Lake Formation. For in-account crawling, the accountId field is optional.

## AWS CLI

```
aws glue --profile demo create-crawler --debug --cli-input-json '{
  "Name": "prod-test-crawler",
```

```

    "Role": "arn:aws:iam::111122223333:role/service-role/AWSGlueServiceRole-prod-
test-run-role",
    "DatabaseName": "prod-run-db",
    "Description": "",
    "Targets": {
    "S3Targets":[
        {
            "Path": "s3://crawl-testbucket"
        }
    ]
    },
    "SchemaChangePolicy": {
        "UpdateBehavior": "LOG",
        "DeleteBehavior": "LOG"
    },
    "RecrawlPolicy": {
        "RecrawlBehavior": "CRAWL_EVERYTHING"
    },
    "LineageConfiguration": {
        "CrawlerLineageSettings": "DISABLE"
    },
    "LakeFormationConfiguration": {
        "UseLakeFormationCredentials": true,
        "AccountId": "111111111111"
    },
    "Configuration": {
        "Version": 1.0,
        "CrawlerOutput": {
            "Partitions": { "AddOrUpdateBehavior": "InheritFromTable" },
            "Tables": {"AddOrUpdateBehavior": "MergeNewColumns" }
        },
        "Grouping": { "TableGroupingPolicy": "CombineCompatibleSchemas" }
    },
    "CrawlerSecurityConfiguration": "",
    "Tags": {
        "KeyName": ""
    }
}

```

**Note**

- A crawler using Lake Formation credentials is only supported for Amazon S3 and Data Catalog targets.
- For targets using Lake Formation credential vending, the underlying Amazon S3 locations must belong to the same bucket. For example, customers can use multiple targets (`s3://bucket1/folder1`, `s3://bucket1/folder2`) as long as all target locations are under the same bucket (bucket1). Specifying different buckets (`s3://bucket1/folder1`, `s3://bucket2/folder2`) is not allowed.
- Currently for Data Catalog target crawlers, only a single catalog target with a single catalog table is allowed.

## Tutorial: Adding an AWS Glue crawler

For this AWS Glue scenario, you're asked to analyze arrival data for major air carriers to calculate the popularity of departure airports month over month. You have flights data for the year 2016 in CSV format stored in Amazon S3. Before you transform and analyze your data, you catalog its metadata in the AWS Glue Data Catalog.

In this tutorial, let's add a crawler that infers metadata from these flight logs in Amazon S3 and creates a table in your Data Catalog.

### Topics

- [Prerequisites](#)
- [Step 1: Add a crawler](#)
- [Step 2: Run the crawler](#)
- [Step 3: View AWS Glue Data Catalog objects](#)

### Prerequisites

This tutorial assumes that you have an AWS account and access to AWS Glue.

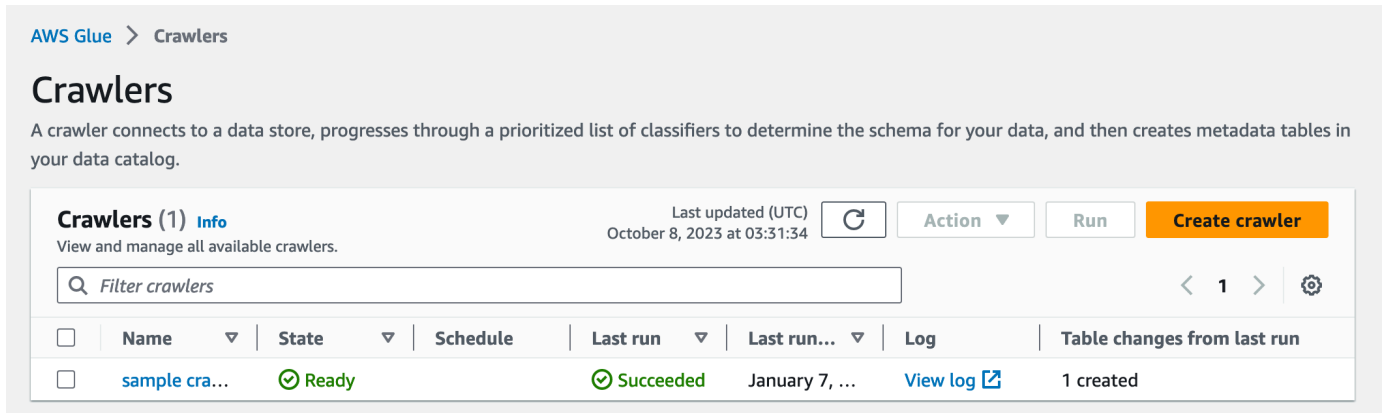

### Step 1: Add a crawler

Use these steps to configure and run a crawler that extracts the metadata from a CSV file stored in Amazon S3.

## To create a crawler that reads files stored on Amazon S3

1. On the AWS Glue service console, on the left-side menu, choose **Crawlers**.
2. On the Crawlers page, choose **Create crawler**. This starts a series of pages that prompt you for the crawler details.

3. In the Crawler name field, enter **Flights Data Crawler**, and choose **Next**.

Crawlers invoke classifiers to infer the schema of your data. This tutorial uses the built-in classifier for CSV by default.

4. For the crawler source type, choose **Data stores** and choose **Next**.
5. Now let's point the crawler to your data. On the **Add a data store** page, choose the Amazon S3 data store. This tutorial doesn't use a connection, so leave the **Connection** field blank if it's visible.

For the option **Crawl data in**, choose **Specified path in another account**. Then, for the **Include path**, enter the path where the crawler can find the flights data, which is **s3://crawler-public-us-east-1/flight/2016/csv**. After you enter the path, the title of this field changes to **Include path**. Choose **Next**.

6. You can crawl multiple data stores with a single crawler. However, in this tutorial, we're using only a single data store, so choose **No**, and then choose **Next**.
7. The crawler needs permissions to access the data store and create objects in the AWS Glue Data Catalog. To configure these permissions, choose **Create an IAM role**. The IAM role name starts with **AWSGlueServiceRole-**, and in the field, you enter the last part of the role name. Enter **CrawlerTutorial**, and then choose **Next**.

**Note**

To create an IAM role, your AWS user must have `CreateRole`, `CreatePolicy`, and `AttachRolePolicy` permissions.

The wizard creates an IAM role named `AWSGlueServiceRole-CrawlerTutorial`, attaches the AWS managed policy `AWSGlueServiceRole` to this role, and adds an inline policy that allows read access to the Amazon S3 location `s3://crawler-public-us-east-1/flight/2016/csv`.

8. Create a schedule for the crawler. For **Frequency**, choose **Run on demand**, and then choose **Next**.
9. Crawlers create tables in your Data Catalog. Tables are contained in a database in the Data Catalog. First, choose **Add database** to create a database. In the pop-up window, enter **test-flights-db** for the database name, and then choose **Create**.

Next, enter **flights** for **Prefix added to tables**. Use the default values for the rest of the options, and choose **Next**.

10. Verify the choices you made in the **Add crawler** wizard. If you see any mistakes, you can choose **Back** to return to previous pages and make changes.

After you have reviewed the information, choose **Finish** to create the crawler.

## Step 2: Run the crawler

After creating a crawler, the wizard sends you to the Crawlers view page. Because you create the crawler with an on-demand schedule, you're given the option to run the crawler.

### To run the crawler

1. The banner near the top of this page lets you know that the crawler was created, and asks if you want to run it now. Choose **Run it now?** to run the crawler.

The banner changes to show "Attempting to run" and "Running" messages for your crawler. After the crawler starts running, the banner disappears, and the crawler display is updated to show a status of Starting for your crawler. After a minute, you can click the Refresh icon to update the status of the crawler that is displayed in the table.

2. When the crawler completes, a new banner appears that describes the changes made by the crawler. You can choose the **test-flights-db** link to view the Data Catalog objects.

### Step 3: View AWS Glue Data Catalog objects

The crawler reads data at the source location and creates tables in the Data Catalog. A table is the metadata definition that represents your data, including its schema. The tables in the Data Catalog do not contain data. Instead, you use these tables as a source or target in a job definition.

#### To view the Data Catalog objects created by the crawler

1. In the left-side navigation, under **Data catalog**, choose **Databases**. Here you can view the `flights-db` database that is created by the crawler.
2. In the left-side navigation, under **Data catalog** and below **Databases**, choose **Tables**. Here you can view the `flightscsv` table created by the crawler. If you choose the table name, then you can view the table settings, parameters, and properties. Scrolling down in this view, you can view the schema, which is information about the columns and data types of the table.
3. If you choose **View partitions** on the table view page, you can see the partitions created for the data. The first column is the partition key.

## Defining metadata manually

The AWS Glue Data Catalog is a central repository that stores metadata about your data sources and data sets. While a crawler can automatically crawl and populate metadata for supported data sources, there are certain scenarios where you may need to define metadata manually in the Data Catalog:

- **Unsupported data formats** – If you have data sources that are not supported by the crawler, you need to manually define the metadata for those data sources in the Data Catalog.
- **Custom metadata requirements** – The AWS Glue crawler infers metadata based on predefined rules and conventions. If you have specific metadata requirements that are not covered by the AWS Glue crawler inferred metadata, you can manually define the metadata to meet your needs.
- **Data governance and standardization** – In some cases, you may want to have more control over the metadata definitions for data governance, compliance, or security reasons. Manually defining metadata allows you to ensure that the metadata adheres to your organization's standards and policies.

- Placeholder for future data ingestion – If you have data sources that are not immediately available or accessible, you can create empty schema tables as placeholders. Once the data sources become available, you can populate the tables with the actual data, while maintaining the predefined structure.

To define metadata manually, you can use the AWS Glue console, Lake Formation console, AWS Glue API, or the AWS Command Line Interface (AWS CLI). You can create databases, tables, and partitions, and specify metadata properties such as column names, data types, descriptions, and other attributes.

## Creating databases

Databases are used to organize metadata tables in the AWS Glue. When you define a table in the AWS Glue Data Catalog, you add it to a database. A table can be in only one database.

Your database can contain tables that define data from many different data stores. This data can include objects in Amazon Simple Storage Service (Amazon S3) and relational tables in Amazon Relational Database Service.

### Note

When you delete a database from the AWS Glue Data Catalog, all the tables in the database are also deleted.

To view the list of databases, sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>. Choose **Databases**, and then choose a database name in the list to view the details.

From the **Databases** tab in the AWS Glue console, you can add, edit, and delete databases:

- To create a new database, choose **Add database** and provide a name and description. For compatibility with other metadata stores, such as Apache Hive, the name is folded to lowercase characters.

**Note**

If you plan to access the database from Amazon Athena, then provide a name with only alphanumeric and underscore characters. For more information, see [Athena names](#).

- To edit the description for a database, select the check box next to the database name and choose **Edit**.
- To delete a database, select the check box next to the database name and choose **Remove**.
- To display the list of tables contained in the database, choose the database name and the database properties will display all tables in the database.

To change the database that a crawler writes to, you must change the crawler definition. For more information, see [Using crawlers to populate the Data Catalog](#).

### Database resource links

The AWS Glue console was recently updated. The current version of the console does not support Database Resource Links.

The Data Catalog can also contain *resource links* to databases. A database resource link is a link to a local or shared database. Currently, you can create resource links only in AWS Lake Formation. After you create a resource link to a database, you can use the resource link name wherever you would use the database name. Along with databases that you own or that are shared with you, database resource links are returned by `glue:GetDatabases()` and appear as entries on the **Databases** page of the AWS Glue console.

The Data Catalog can also contain table resource links.

For more information about resource links, see [Creating Resource Links](#) in the *AWS Lake Formation Developer Guide*.

### Creating tables

Even though running a crawler is the recommended method to take inventory of the data in your data stores, you can add metadata tables to the AWS Glue Data Catalog manually. This approach allows you to have more control over the metadata definitions and customize them according to your specific requirements.

You can also add tables to the Data Catalog manually in the following ways:

- Use the AWS Glue console to manually create a table in the AWS Glue Data Catalog. For more information, see [Working with tables on the AWS Glue console](#).
- Use the CreateTable operation in the [AWS Glue API](#) to create a table in the AWS Glue Data Catalog. For more information, see [CreateTable action \(Python: create\\_table\)](#).
- Use AWS CloudFormation templates. For more information, see [AWS CloudFormation for AWS Glue](#).

When you define a table manually using the console or an API, you specify the table schema and the value of a classification field that indicates the type and format of the data in the data source. If a crawler creates the table, the data format and schema are determined by either a built-in classifier or a custom classifier. For more information about creating a table using the AWS Glue console, see [Working with tables on the AWS Glue console](#).

## Topics

- [Table partitions](#)
- [Table resource links](#)
- [Updating manually created Data Catalog tables using crawlers](#)
- [Data Catalog table properties](#)
- [Working with tables on the AWS Glue console](#)
- [Working with partition indexes in AWS Glue](#)

## Table partitions

An AWS Glue table definition of an Amazon Simple Storage Service (Amazon S3) folder can describe a partitioned table. For example, to improve query performance, a partitioned table might separate monthly data into different files using the name of the month as a key. In AWS Glue, table definitions include the partitioning key of a table. When AWS Glue evaluates the data in Amazon S3 folders to catalog a table, it determines whether an individual table or a partitioned table is added.

You can create partition indexes on a table to fetch a subset of the partitions instead of loading all the partitions in the table. For information about working with partition indexes, see [Working with partition indexes in AWS Glue](#).

All the following conditions must be true for AWS Glue to create a partitioned table for an Amazon S3 folder:

- The schemas of the files are similar, as determined by AWS Glue.
- The data format of the files is the same.
- The compression format of the files is the same.

For example, you might own an Amazon S3 bucket named `my-app-bucket`, where you store both iOS and Android app sales data. The data is partitioned by year, month, and day. The data files for iOS and Android sales have the same schema, data format, and compression format. In the AWS Glue Data Catalog, the AWS Glue crawler creates one table definition with partitioning keys for year, month, and day.

The following Amazon S3 listing of `my-app-bucket` shows some of the partitions. The `=` symbol is used to assign partition key values.

```
my-app-bucket/Sales/year=2010/month=feb/day=1/iOS.csv
my-app-bucket/Sales/year=2010/month=feb/day=1/Android.csv
my-app-bucket/Sales/year=2010/month=feb/day=2/iOS.csv
my-app-bucket/Sales/year=2010/month=feb/day=2/Android.csv
...
my-app-bucket/Sales/year=2017/month=feb/day=4/iOS.csv
my-app-bucket/Sales/year=2017/month=feb/day=4/Android.csv
```

## Table resource links

The AWS Glue console was recently updated. The current version of the console does not support Table Resource Links.

The Data Catalog can also contain *resource links* to tables. A table resource link is a link to a local or shared table. Currently, you can create resource links only in AWS Lake Formation. After you create a resource link to a table, you can use the resource link name wherever you would use the table name. Along with tables that you own or that are shared with you, table resource links are returned by `glue:GetTables()` and appear as entries on the **Tables** page of the AWS Glue console.

The Data Catalog can also contain database resource links.

For more information about resource links, see [Creating Resource Links](#) in the *AWS Lake Formation Developer Guide*.

## Updating manually created Data Catalog tables using crawlers

You might want to create AWS Glue Data Catalog tables manually and then keep them updated with AWS Glue crawlers. Crawlers running on a schedule can add new partitions and update the tables with any schema changes. This also applies to tables migrated from an Apache Hive metastore.

To do this, when you define a crawler, instead of specifying one or more data stores as the source of a crawl, you specify one or more existing Data Catalog tables. The crawler then crawls the data stores specified by the catalog tables. In this case, no new tables are created; instead, your manually created tables are updated.

The following are other reasons why you might want to manually create catalog tables and specify catalog tables as the crawler source:

- You want to choose the catalog table name and not rely on the catalog table naming algorithm.
- You want to prevent new tables from being created in the case where files with a format that could disrupt partition detection are mistakenly saved in the data source path.

For more information, see [Step 2: Choose data sources and classifiers](#).

## Data Catalog table properties

Table properties, or parameters, as they are known in the AWS CLI, are unvalidated key and value strings. You can set your own properties on the table to support uses of the Data Catalog outside of AWS Glue. Other services using the Data Catalog may do so as well. AWS Glue sets some table properties when running jobs or crawlers. Unless otherwise described, these properties are for internal use, we do not support that they will continue to exist in their current form, or support product behavior if these properties are manually changed.

For more information about table properties set by AWS Glue crawlers, see [the section called "Parameters set on Data Catalog tables by crawler"](#).

## Working with tables on the AWS Glue console

A table in the AWS Glue Data Catalog is the metadata definition that represents the data in a data store. You create tables when you run a crawler, or you can create a table manually in the AWS Glue

console. The **Tables** list in the AWS Glue console displays values of your table's metadata. You use table definitions to specify sources and targets when you create ETL (extract, transform, and load) jobs.

### Note

With recent changes to the AWS management console, you may need to modify your existing IAM roles to have the [SearchTables](#) permission. For new role creation, the SearchTables API permission has already been added as default.

To get started, sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>. Choose the **Tables** tab, and use the **Add tables** button to create tables either with a crawler or by manually typing attributes.

## Adding tables on the console

To use a crawler to add tables, choose **Add tables**, **Add tables using a crawler**. Then follow the instructions in the **Add crawler** wizard. When the crawler runs, tables are added to the AWS Glue Data Catalog. For more information, see [Using crawlers to populate the Data Catalog](#).

If you know the attributes that are required to create an Amazon Simple Storage Service (Amazon S3) table definition in your Data Catalog, you can create it with the table wizard. Choose **Add tables**, **Add table manually**, and follow the instructions in the **Add table** wizard.

When adding a table manually through the console, consider the following:

- If you plan to access the table from Amazon Athena, then provide a name with only alphanumeric and underscore characters. For more information, see [Athena names](#).
- The location of your source data must be an Amazon S3 path.
- The data format of the data must match one of the listed formats in the wizard. The corresponding classification, SerDe, and other table properties are automatically populated based on the format chosen. You can define tables with the following formats:

### Avro

Apache Avro JSON binary format.

## CSV

Character separated values. You also specify the delimiter of either comma, pipe, semicolon, tab, or Ctrl-A.

## JSON

JavaScript Object Notation.

## XML

Extensible Markup Language format. Specify the XML tag that defines a row in the data. Columns are defined within row tags.

## Parquet

Apache Parquet columnar storage.

## ORC

Optimized Row Columnar (ORC) file format. A format designed to efficiently store Hive data.

- You can define a partition key for the table.
- Currently, partitioned tables that you create with the console cannot be used in ETL jobs.

## Table attributes

The following are some important attributes of your table:

### Name

The name is determined when the table is created, and you can't change it. You refer to a table name in many AWS Glue operations.

### Database

The container object where your table resides. This object contains an organization of your tables that exists within the AWS Glue Data Catalog and might differ from an organization in your data store. When you delete a database, all tables contained in the database are also deleted from the Data Catalog.

### Description

The description of the table. You can write a description to help you understand the contents of the table.

## Table format

Specify creating a standard AWS Glue table, or a table in Apache Iceberg format.

## Enable compaction

Choose **Enable compaction** to compact small Amazon S3 objects in the table into larger objects.

## IAM role

To run compaction, the service assumes an IAM role on your behalf. You can choose an IAM role using the drop-down. Ensure that the role has the permissions required to enable compaction.

To learn more about the required permissions for the IAM role, see [Table optimization prerequisites](#).

## Location

The pointer to the location of the data in a data store that this table definition represents.

## Classification

A categorization value provided when the table was created. Typically, this is written when a crawler runs and specifies the format of the source data.

## Last updated

The time and date (UTC) that this table was updated in the Data Catalog.

## Date added

The time and date (UTC) that this table was added to the Data Catalog.

## Deprecated

If AWS Glue discovers that a table in the Data Catalog no longer exists in its original data store, it marks the table as deprecated in the data catalog. If you run a job that references a deprecated table, the job might fail. Edit jobs that reference deprecated tables to remove them as sources and targets. We recommend that you delete deprecated tables when they are no longer needed.

## Connection

If AWS Glue requires a connection to your data store, the name of the connection is associated with the table.

## Viewing and editing table details

To see the details of an existing table, choose the table name in the list, and then choose **Action, View details**.

The table details include properties of your table and its schema. This view displays the schema of the table, including column names in the order defined for the table, data types, and key columns for partitions. If a column is a complex type, you can choose **View properties** to display details of the structure of that field, as shown in the following example:

```
{
  "StorageDescriptor":
    {
      "cols": {
        "FieldSchema": [
          {
            "name": "primary-1",
            "type": "CHAR",
            "comment": ""
          },
          {
            "name": "second ",
            "type": "STRING",
            "comment": ""
          }
        ]
      },
      "location": "s3://aws-logs-111122223333-us-east-1",
      "inputFormat": "",
      "outputFormat": "org.apache.hadoop.hive.q1.io.HiveIgnoreKeyTextOutputFormat",
      "compressed": "false",
      "numBuckets": "0",
      "SerDeInfo": {
        "name": "",
        "serializationLib": "org.apache.hadoop.hive.serde2.OpenCSVSerde",
        "parameters": {
          "separatorChar": "|"
        }
      },
      "bucketCols": [],
      "sortCols": [],
      "parameters": {},
      "SkewedInfo": {}
    }
}
```

```
    "storedAsSubDirectories": "false"
  },
  "parameters": {
    "classification": "csv"
  }
}
```

For more information about the properties of a table, such as `StorageDescriptor`, see [StorageDescriptor structure](#).

To change the schema of a table, choose **Edit schema** to add and remove columns, change column names, and change data types.

To compare different versions of a table, including its schema, choose **Compare versions** to see a side-by-side comparison of two versions of the schema for a table. For more information, see [Compare table schema versions](#).

To display the files that make up an Amazon S3 partition, choose **View partition**. For Amazon S3 tables, the **Key** column displays the partition keys that are used to partition the table in the source data store. Partitioning is a way to divide a table into related parts based on the values of a key column, such as date, location, or department. For more information about partitions, search the internet for information about "hive partitioning."

#### Note

To get step-by-step guidance for viewing the details of a table, see the **Explore table** tutorial in the console.

## Compare table schema versions

When you compare two versions of table schemas, you can compare nested row changes by expanding and collapsing nested rows, compare schemas of two versions side-by-side, and view table properties side-by-side.

To compare versions

1. From the AWS Glue console, choose **Tables**, then **Actions** and choose **Compare versions**.

2. Choose a version to compare by choosing the version drop-down menu. When comparing schemas, the Schema tab is highlighted in orange.
3. When you compare tables between two versions, the table schemas are presented to you on the left and right side of the screen. This enables you to determine changes visually by comparing the Column name, data type, key, and comment fields side-by-side. When there is a change, a colored icon displays the type of change that was made.
  - Deleted – displayed by a red icon indicates where the column was removed from a previous version of the table schema.
  - Edited or Moved – displayed by a blue icon indicates where the column was modified or moved in a newer version of the table schema.
  - Added – displayed by a green icon indicates where the column was added to a newer version of the table schema.

- Nested changes – displayed by a yellow icon indicates where the nested column contains changes. Choose the column to expand and view the columns that have either been deleted, edited, moved, or added.

Compare versions: cloudtrail\_data

Legend: Deleted Edited/Moved Added Nested Changes Deleted

4. Use the filter fields search bar to display fields based on the characters you enter here. If you enter a column name in either table version, the filtered fields are displayed in both table versions to show you where the changes have occurred.
5. To compare properties, choose the **Properties** tab.
6. To stop comparing versions, choose **Stop comparing** to return to the list of tables.

## Working with partition indexes in AWS Glue

Over time, hundreds of thousands of partitions get added to a table. The [GetPartitions API](#) is used to fetch the partitions in the table. The API returns partitions which match the expression provided in the request.

Lets take a *sales\_data* table as an example which is partitioned by the keys *Country*, *Category*, *Year*, *Month*, and *creationDate*. If you want to obtain sales data for all the items sold for the *Books* category in the year 2020 after 2020-08-15, you have to make a GetPartitions request with the expression "Category = 'Books' and creationDate > '2020-08-15'" to the Data Catalog.

If no partition indexes are present on the table, AWS Glue loads all the partitions of the table, and then filters the loaded partitions using the query expression provided by the user in the GetPartitions request. The query takes more time to run as the number of partitions increase on a table with no indexes. With an index, the GetPartitions query will try to fetch a subset of the partitions instead of loading all the partitions in the table.

### Topics

- [About partition indexes](#)
- [Creating a table with partition indexes](#)
- [Adding a partition index to an existing table](#)
- [Describing partition indexes on a table](#)
- [Limitations on using partition indexes](#)
- [Using indexes for an optimized GetPartitions call](#)
- [Integration with engines](#)

### About partition indexes

When you create a partition index, you specify a list of partition keys that already exist on a given table. Partition index is sub list of partition keys defined in the table. A partition index can be created on any permutation of partition keys defined on the table. For the above *sales\_data* table, the possible indexes are (country, category, creationDate), (country, category, year), (country, category), (country), (category, country, year, month), and so on.

The Data Catalog will concatenate the partition values in the order provided at the time of index creation. The index is built consistently as partitions are added to the table. Indexes can be created

for String (string, char, and varchar), Numeric (int, bigint, long, tinyint, and smallint), and Date (yyyy-MM-dd) column types.

## Supported data types

- Date – A date in ISO format, such as YYYY-MM-DD. For example, date 2020-08-15. The format uses hyphens (-) to separate the year, month, and day. The permissible range for dates for indexing spans from 0000-01-01 to 9999-12-31.
- String – A string literal enclosed in single or double quotes.
- Char – Fixed length character data, with a specified length between 1 and 255, such as char(10).
- Varchar – Variable length character data, with a specified length between 1 and 65535, such as varchar(10).
- Numeric – int, bigint, long, tinyint, and smallint

Indexes on Numeric, String, and Date data types support =, >, >=, <, <= and between operators. The indexing solution currently only supports the AND logical operator. Sub-expressions with the operators "LIKE", "IN", "OR", and "NOT" are ignored in the expression for filtering using an index. Filtering for the ignored sub-expression is done on the partitions fetched after applying index filtering.

For each partition added to a table, there is a corresponding index item created. For a table with 'n' partitions, 1 partition index will result in 'n' partition index items. 'm' partition index on same table will result into 'm\*n' partition index items. Each partition index item will be charged according to the current AWS Glue pricing policy for data catalog storage. For details on storage object pricing, see [AWS Glue pricing](#).

## Creating a table with partition indexes

You can create a partition index during table creation. The CreateTable request takes a list of [PartitionIndex objects](#) as an input. A maximum of 3 partition indexes can be created on a given table. Each partition index requires a name and a list of partitionKeys defined for the table. Created indexes on a table can be fetched using the [GetPartitionIndexes API](#)

## Adding a partition index to an existing table

To add a partition index to an existing table, use the CreatePartitionIndex operation. You can create one PartitionIndex per CreatePartitionIndex operation. Adding an index does

not affect the availability of a table, as the table continues to be available while indexes are being created.

The index status for an added partition is set to `CREATING` and the creation of the index data is started. If the process for creating the indexes is successful, the `indexStatus` is updated to `ACTIVE` and for an unsuccessful process, the index status is updated to `FAILED`. Index creation can fail for multiple reasons, and you can use the `GetPartitionIndexes` operation to retrieve the failure details. The possible failures are:

- `ENCRYPTED_PARTITION_ERROR` — Index creation on a table with encrypted partitions is not supported.
- `INVALID_PARTITION_TYPE_DATA_ERROR` — Observed when the `partitionKey` value is not a valid value for the corresponding `partitionKey` data type. For example: a `partitionKey` with the 'int' datatype has a value 'foo'.
- `MISSING_PARTITION_VALUE_ERROR` — Observed when the `partitionValue` for an `indexedKey` is not present. This can happen when a table is not partitioned consistently.
- `UNSUPPORTED_PARTITION_CHARACTER_ERROR` — Observed when the value for an indexed partition key contains the characters `\u0000`, `\u0001` or `\u0002`.
- `INTERNAL_ERROR` — An internal error occurred while indexes were being created.

### Describing partition indexes on a table

To fetch the partition indexes created on a table, use the `GetPartitionIndexes` operation. The response returns all the indexes on the table, along with the current status of each index (the `IndexStatus`).

The `IndexStatus` for a partition index will be one of the following:

- `CREATING` — The index is currently being created, and is not yet available for use.
- `ACTIVE` — The index is ready for use. Requests can use the index to perform an optimized query.
- `DELETING` — The index is currently being deleted, and can no longer be used. An index in the active state can be deleted using the `DeletePartitionIndex` request, which moves the status from `ACTIVE` to `DELETING`.
- `FAILED` — The index creation on an existing table failed. Each table stores the last 10 failed indexes.

The possible state transitions for indexes created on an existing table are:

- CREATING → ACTIVE → DELETING
- CREATING → FAILED

### Limitations on using partition indexes

Once you have created a partition index, note these changes to table and partition functionality:

#### New partition creation (after Index Addition)

After a partition index is created on a table, all new partitions added to the table will be validated for the data type checks for indexed keys. The partition value of the indexed keys will be validated for data type format. If the data type check fails, the create partition operation will fail. For the *sales\_data* table, if an index is created for keys (category, year) where the category is of type `string` and year of type `int`, the creation of the new partition with a value of YEAR as "foo" will fail.

After indexes are enabled, the addition of partitions with indexed key values having the characters U+0000, U+00001, and U+0002 will start to fail.

### Table updates

Once a partition index is created on a table, you cannot modify the partition key names for existing partition keys, and you cannot change the type, or order, of keys which are registered with the index.

### Using indexes for an optimized GetPartitions call

When you call `GetPartitions` on a table with an index, you can include an expression, and if applicable the Data Catalog will use an index if possible. The first key of the index should be passed in the expression for the indexes to be used in filtering. Index optimization in filtering is applied as a best effort. The Data Catalog tries to use index optimization as much as possible, but in case of a missing index, or unsupported operator, it falls back to the existing implementation of loading all partitions.

For the *sales\_data* table above, let's add the index [Country, Category, Year]. If "Country" is not passed in the expression, the registered index will not be able to filter partitions using indexes. You can add up to 3 indexes to support various query patterns.

Lets take some example expressions and see how indexes work on them:

Expressions	How index will be used
Country = 'US'	Index will be used to filter partitions.
Country = 'US' and Category = 'Shoes'	Index will be used to filter partitions.
Category = 'Shoes'	Indexes will not be used as "country" is not provided in the expression. All partitions will be loaded to return a response.
Country = 'US' and Category = 'Shoes' and Year > '2018'	Index will be used to filter partitions.
Country = 'US' and Category = 'Shoes' and Year > '2018' and month = 2	Index will be used to fetch all partitions with country = "US" and category = "shoes" and year > 2018. Then, filtering on the month expression will be performed.
Country = 'US' AND Category = 'Shoes' OR Year > '2018'	Indexes will not be used as an OR operator is present in the expression.
Country = 'US' AND Category = 'Shoes' AND (Year = 2017 OR Year = '2018')	Index will be used to fetch all partitions with country = "US" and category = "shoes", and then filtering on the year expression will be performed.
Country in ('US', 'UK') AND Category = 'Shoes'	Indexes will not be used for filtering as the IN operator is not supported currently.
Country = 'US' AND Category in ('Shoes', 'Books')	Index will be used to fetch all partitions with country = "US", and then filtering on the Category expression will be performed.
Country = 'US' AND Category in ('Shoes', 'Books') AND (creationDate > '2023-9-01')	Index will be used to fetch all partitions with country = "US", with creationDate > '2023-9-01', and then filtering on the Category expression will be performed.

## Integration with engines

Redshift Spectrum, Amazon EMR and AWS Glue ETL Spark DataFrames are able to utilize indexes for fetching partitions after indexes are in an ACTIVE state in AWS Glue. [Athena](#) and [AWS Glue ETL Dynamic frames](#) require you to follow extra steps to utilize indexes for query improvement.

### Enable partition filtering

To enable partition filtering in Athena, you need to update the table properties as follows:

1. In the AWS Glue console, under **Data Catalog**, choose **Tables**.
2. Choose a table.
3. Under **Actions**, choose **Edit table**.
4. Under **Table properties**, add the following:
  - Key – `partition_filtering.enabled`
  - Value – `true`
5. Choose **Apply**.

Alternatively, you can set this parameter by running an [ALTER TABLE SET PROPERTIES](#) query in Athena.

```
ALTER TABLE partition_index.table_with_index
SET TBLPROPERTIES ('partition_filtering.enabled' = 'true')
```

## Integrating with other AWS services

While you can use AWS Glue crawlers to populate the AWS Glue Data Catalog, there are several AWS services that can automatically integrate with and populate the catalog for you. The following sections provide more information about the specific use cases supported by AWS services that can populate the Data Catalog.

### Topics

- [AWS Lake Formation](#)
- [Amazon Athena](#)

## AWS Lake Formation

AWS Lake Formation is a service that makes it easier to set up a secure data lake in AWS. Lake Formation is built on AWS Glue, and Lake Formation and AWS Glue share the same AWS Glue Data Catalog. You can register your Amazon S3 data location with Lake Formation, and use Lake Formation console to create databases and tables in the AWS Glue Data Catalog, define data access policies, and audit data access across your data lake from a central place. You can use the Lake Formation fine-grained access control to manage your existing Data Catalog resources and Amazon S3 data locations.

With data registered with Lake Formation, you can securely share Data Catalog resources across IAM principals, AWS accounts, AWS organizations, and organizational units.

For more information about creating Data Catalog resources using Lake Formation, see [Creating Data Catalog tables and databases](#) in the AWS Lake Formation Developer Guide.

## Amazon Athena

Amazon Athena uses the Data Catalog to store and retrieve table metadata for the Amazon S3 data in your AWS account. The table metadata lets the Athena query engine know how to find, read, and process the data that you want to query.

You can populate the AWS Glue Data Catalog by using Athena `CREATE TABLE` statements directly. You can manually define and populate the schema and partition metadata in the Data Catalog without needing to run a crawler.

1. In the Athena console, create a database that will store the table metadata in the Data Catalog.
2. Use the `CREATE EXTERNAL TABLE` statement to define the schema of your data source.
3. Use the `PARTITIONED BY` clause to define any partition keys if your data is partitioned.
4. Use the `LOCATION` clause to specify the Amazon S3 path where your actual data files are stored.
5. Run the `CREATE TABLE` statement.

This query creates the table metadata in the Data Catalog based on your defined schema and partitions, without actually crawling the data.

You can query the table in Athena, and it will use the metadata from the Data Catalog to access and query your data files in Amazon S3.

For more information, see [Creating databases and tables](#) in the Amazon Athena User Guide.

## Data Catalog settings

The Data Catalog settings contains options to set encryption and permissions options for the Data Catalog in your account.

# Data catalog settings

Last updated (UTC)  
January 1, 1970 at 00:00:00

Choose encryption and permission options for your accounts data catalog.

## Encryption options

Metadata encryption

Enable at-rest encryption for metadata stored in the data catalog.

Encrypt connection passwords

When enabled, the password you provide when you create a connection is encrypted with the given KMS key.

## Permissions

Add a policy to define fine-grained access control of the data catalog.

1	
---	--

JSON Ln 1, Col 1 Errors: 0 Warnings: 0

Cancel

Save

## To change the fine-grained access control of the Data Catalog

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose an encryption option.
  - **Metadata encryption** – Select this check box to encrypt the metadata in your Data Catalog. Metadata is encrypted at rest using the AWS Key Management Service (AWS KMS) key that you specify. For more information, see [Encrypting your Data Catalog](#).
  - **Encrypt connection passwords** – Select this check box to encrypt passwords in the AWS Glue connection object when the connection is created or updated. Passwords are encrypted using the AWS KMS key that you specify. When passwords are returned, they are encrypted. This option is a global setting for all AWS Glue connections in the Data Catalog. If you clear this check box, previously encrypted passwords remain encrypted using the key that was used when they were created or updated. For more information about AWS Glue connections, see [Connecting to data](#).

When you enable this option, choose an AWS KMS key, or choose **Enter a key ARN** and provide the Amazon Resource Name (ARN) for the key. Enter the ARN in the form `arn:aws:kms:region:account-id:key/key-id` . You can also provide the ARN as a key alias, such as `arn:aws:kms:region:account-id:alias/alias-name` .

### Important

If this option is selected, any user or role that creates or updates a connection must have `kms:Encrypt` permission on the specified KMS key.

For more information, see [Encrypting connection passwords](#).

3. Choose **Settings**, and then in the **Permissions** editor, add the policy statement to change fine-grained access control of the Data Catalog for your account. Only one policy at a time can be attached to a Data Catalog. You can paste a JSON resource policy into this control. For more information, see [Resource-based policies within AWS Glue](#).
4. Choose **Save** to update your Data Catalog with any changes you made.

You can also use AWS Glue API operations to put, get, and delete resource policies. For more information, see [Security APIs in AWS Glue](#).

# Populating and managing transactional tables

[Apache Iceberg](#), [Apache Hudi](#), and Linux Foundation [Delta Lake](#) are open-source table formats designed for handling large-scale data analytics and data lake workloads in Apache Spark.

You can populate Iceberg, Hudi, and Delta Lake tables in the AWS Glue Data Catalog using the following methods:

- AWS Glue crawler; – AWS Glue crawlers can automatically discover and populate Iceberg, Hudi and Delta Lake table metadata in the Data Catalog. For more information, see [Using crawlers to populate the Data Catalog](#).
- AWS Glue ETL Jobs – You can create ETL jobs to write data to Iceberg, Hudi, and Delta Lake tables and populate their metadata in the Data Catalog. For more information, see [Using data lake frameworks with AWS Glue ETL jobs](#).
- AWS Glue console, AWS Lake Formation console, AWS CLI or API – You can use the AWS Glue console, Lake Formation console, or API to create and manage Iceberg table definitions in the Data Catalog.

## Topics

- [Creating Apache Iceberg tables](#)
- [Optimizing Iceberg tables](#)

## Creating Apache Iceberg tables

You can create Apache Iceberg tables that use the Apache Parquet data format in the AWS Glue Data Catalog with data residing in Amazon S3. A table in the Data Catalog is the metadata definition that represents the data in a data store. By default, AWS Glue creates Iceberg v2 tables. For the difference between v1 and v2 tables, see [Format version changes](#) in the Apache Iceberg documentation.

[Apache Iceberg](#) is an open table format for very large analytic datasets. Iceberg allows for easy changes to your schema, also known as schema evolution, meaning that users can add, rename, or remove columns from a data table without disrupting the underlying data. Iceberg also provides support for data versioning, which allows users to track changes to data overtime. This enables the time travel feature, which allows users to access and query historical versions of data and analyze changes to the data between updates and deletes.

You can use AWS Glue or Lake Formation console or the `CreateTable` operation in the AWS Glue API to create an Iceberg table in the Data Catalog. For more information, see [CreateTable action \(Python: create\\_table\)](#).

When you create an Iceberg table in the Data Catalog, you must specify the table format and metadata file path in Amazon S3 to be able to perform reads and writes.

You can use Lake Formation to secure your Iceberg table using fine-grained access control permissions when you register the Amazon S3 data location with AWS Lake Formation. For source data in Amazon S3 and metadata that is not registered with Lake Formation, access is determined by IAM permissions policies for Amazon S3 and AWS Glue actions. For more information, see [Managing permissions](#).

### Note

Data Catalog doesn't support creating partitions and adding Iceberg table properties.

## Prerequisites

To create Iceberg tables in the Data Catalog, and set up Lake Formation data access permissions, you need to complete the following requirements:

### 1. **Permissions required to create Iceberg tables without the data registered with Lake Formation.**

In addition to the permissions required to create a table in the Data Catalog, the table creator requires the following permissions:

- `s3:PutObject` on resource `arn:aws:s3:::{bucketName}`
- `s3:GetObject` on resource `arn:aws:s3:::{bucketName}`
- `s3:DeleteObject` on resource `arn:aws:s3:::{bucketName}`

### 2. **Permissions required to create Iceberg tables with data registered with Lake Formation:**

To use Lake Formation to manage and secure the data in your data lake, register your Amazon S3 location that has the data for tables with Lake Formation. This is so that Lake Formation can vend credentials to AWS analytical services such as Athena, Redshift Spectrum, and Amazon EMR to access data. For more information on registering an Amazon S3 location, see [Adding an Amazon S3 location to your data lake](#).

A principal who reads and writes the underlying data that is registered with Lake Formation requires the following permissions:

- `lakeformation:GetDataAccess`
- `DATA_LOCATION_ACCESS`

A principal who has data location permissions on a location also has location permissions on all child locations.

For more information on data location permissions, see [Underlying data access control](#) link.

To enable compaction, the service needs to assume an IAM role that has permissions to update tables in the Data Catalog. For details, see [Table optimization prerequisites](#)

## Creating an Iceberg table

You can create Iceberg v1 and v2 tables using AWS Glue or Lake Formation console or AWS Command Line Interface as documented on this page. You can also create Iceberg tables using the AWS Glue crawler. For more information, see [Data Catalog and Crawlers](#) in the AWS Glue Developer Guide.

### To create an Iceberg table

#### Console

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Under Data Catalog, choose **Tables**, and use the **Create table** button to specify the following attributes:
  - **Table name** – Enter a name for the table. If you're using Athena to access tables, use these [naming tips](#) in the Amazon Athena User Guide.
  - **Database** – Choose an existing database or create a new one.
  - **Description** – The description of the table. You can write a description to help you understand the contents of the table.
  - **Table format** – For **Table format**, choose Apache Iceberg.
  - **Enable compaction** – Choose **Enable compaction** to compact small Amazon S3 objects in the table into larger objects.

- **IAM role** – To run compaction, the service assumes an IAM role on your behalf. You can choose an IAM role using the drop-down. Ensure that the role has the permissions required to enable compaction.

To learn more about the required permissions, see [Table optimization prerequisites](#).

- **Location** – Specify the path to the folder in Amazon S3 that stores the metadata table. Iceberg needs a metadata file and location in the Data Catalog to be able to perform reads and writes.
- **Schema** – Choose **Add columns** to add columns and data types of the columns. You have the option to create an empty table and update the schema later. Data Catalog supports Hive data types. For more information, see [Hive data types](#).

Iceberg allows you to evolve schema and partition after you create the table. You can use [Athena queries](#) to update the table schema and [Spark queries](#) for updating partitions.

## AWS CLI

```
aws glue create-table \
  --database-name iceberg-db \
  --region us-west-2 \
  --open-table-format-input '{
    "IcebergInput": {
      "MetadataOperation": "CREATE",
      "Version": "2"
    }
  }' \
  --table-input '{"Name":"test-iceberg-input-demo",
    "TableType": "EXTERNAL_TABLE",
    "StorageDescriptor":{
      "Columns":[
        {"Name":"col1", "Type":"int"},
        {"Name":"col2", "Type":"int"},
        {"Name":"col3", "Type":"string"}
      ],
      "Location":"s3://DOC_EXAMPLE_BUCKET_ICEBERG/"
    }
  }'
```

## Optimizing Iceberg tables

The Amazon S3 data lakes using open table formats such as Apache Iceberg store the data as Amazon S3 objects. Having thousands of small Amazon S3 objects in a data lake table increases metadata overhead on Iceberg tables and affects the read performance. For better read performance by AWS analytics services such as Amazon Athena and Amazon EMR, and AWS Glue ETL jobs, AWS Glue Data Catalog provides managed compaction (a process that compacts small Amazon S3 objects into larger objects) for Iceberg tables in Data Catalog. You can use Lake Formation console, AWS Glue console, AWS CLI, or AWS API to enable or disable compaction for individual Iceberg tables that are in the Data Catalog.

The table optimizer continuously monitors table partitions and kicks off the compaction process when the threshold is exceeded for the number of files and file sizes. An Iceberg table qualifies for compaction if the file size specified in the `write.target-file-size-bytes` property is within the 128MB to 512MB range. In the Data Catalog, the compaction process starts if the table has more than five files, each smaller than 75% of the `write.target-file-size-bytes` property.

For example, you have a table with the file size threshold set to 512MB in the `write.target-file-size-bytes` property (within the prescribed range of 128MB to 512MB), and the table contains 10 files. If 6 out of the 10 files are less than 384MB ( $.75 \times 512$ ) each, then the Data Catalog triggers compaction.

Data Catalog performs compaction without interfering with concurrent queries. Data Catalog supports data compaction only for tables in the Parquet format.

For supported data types, compression formats, and limitations, see [Supported formats and limitations for managed data compaction](#).

### Topics

- [Table optimization prerequisites](#)
- [Enabling compaction](#)
- [Disabling compaction](#)
- [Viewing compaction details](#)
- [Viewing Amazon CloudWatch metrics](#)
- [Deleting an optimizer](#)
- [Supported formats and limitations for managed data compaction](#)

## Table optimization prerequisites

The table optimizer assumes the permissions of the AWS Identity and Access Management (IAM) role that you specify when you enable compaction for a table. The IAM role must have the permissions to read data and update metadata in the Data Catalog. You can create an IAM role and attach the following inline policies:

- Add the following inline policy that grants Amazon S3 read/write permissions on the location for data that is not registered with Lake Formation. This policy also includes permissions to update the table in the Data Catalog, and to permit AWS Glue to add logs in Amazon CloudWatch logs and publish metrics. For source data in Amazon S3 that isn't registered with Lake Formation, access is determined by IAM permissions policies for Amazon S3 and AWS Glue actions.

In the following inline policies, replace `bucket-name` with your Amazon S3 bucket name, `aws-account-id` and `region` with a valid AWS account number and Region of the Data Catalog, `database_name` with the name of your database, and `table_name` with the name of the table.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::<bucket-name>/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::<bucket-name>"
      ]
    },
    {
      "Effect": "Allow",
```

```

        "Action": [
            "glue:UpdateTable",
            "glue:GetTable"
        ],
        "Resource": [
            "arn:aws:glue:<region>:<aws-account-id>:table/<database-name>/<table-
name>",
            "arn:aws:glue:<region>:<aws-account-id>:database/<database-name>",
            "arn:aws:glue:<region>:<aws-account-id>:catalog"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "logs:CreateLogGroup",
            "logs:CreateLogStream",
            "logs:PutLogEvents"
        ],
        "Resource": "arn:aws:logs:<region>:<aws-account-id>:log-group:/aws-glue/
iceberg-compaction/logs:*"
    }
}

```

- Use the following policy to enable compaction for data registered with Lake Formation.

If the compaction role doesn't have `IAM_ALLOWED_PRINCIPALS` group permissions granted on the table, the role requires Lake Formation `ALTER`, `DESCRIBE`, `INSERT` and `DELETE` permissions on the table.

For more information on registering an Amazon S3 bucket with Lake Formation, see [Adding an Amazon S3 location to your data lake](#).

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "lakeformation:GetDataAccess"
      ],
      "Resource": "*"
    }
  ],
}

```

```

{
  "Effect": "Allow",
  "Action": [
    "glue:UpdateTable",
    "glue:GetTable"
  ],
  "Resource": [
    "arn:aws:glue:<region>:<aws-account-id>:table/<databaseName>/<tableName>",
    "arn:aws:glue:<region>:<aws-account-id>:database/<database-name>",
    "arn:aws:glue:<region>:<aws-account-id>:catalog"
  ]
},
{
  "Effect": "Allow",
  "Action": [
    "logs:CreateLogGroup",
    "logs:CreateLogStream",
    "logs:PutLogEvents"
  ],
  "Resource": "arn:aws:logs:<region>:<aws-account-id>:log-group:/aws-glue/iceberg-compaction/logs:*"
}
]
}

```

- (Optional) To compact Iceberg tables with data in Amazon S3 buckets encrypted using [Server-side encryption](#), the compaction role requires permissions to decrypt Amazon S3 objects and generate a new data key to write objects to the encrypted buckets. Add the following policy to the desired AWS KMS key. We support only bucket-level encryption.

```

{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::<aws-account-id>:role/<compaction-role-name>"
  },
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey"
  ],
  "Resource": "*"
}

```

```
}

```

- (Optional) For data location registered with Lake Formation, the role used to register the location requires permissions to decrypt Amazon S3 objects and generate a new data key to write objects to the encrypted buckets. For more information, see [Registering an encrypted Amazon S3 location](#).
- (Optional) If the AWS KMS key is stored in a different AWS account, you need to include the following permissions to the compaction role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": ["arn:aws:kms:<REGION>:<KEY_OWNER_ACCOUNT_ID>:key/<KEY_ID>"] ]
    ]
  ]
}
```

- The role you use to run compaction must have the `iam:PassRole` permission on the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::<account-id>:role/<compaction-role-name>"
      ]
    ]
  ]
}
```

- Add the following trust policy to the role for AWS Glue service to assume the IAM role to run the compaction process.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

## Enabling compaction

You can use Lake Formation console, AWS Glue console, AWS CLI, or AWS API to enable compaction for your Apache Iceberg tables in the Data Catalog. For new tables, you can choose Apache Iceberg as table format and enable compaction when you create the table. Compaction is disabled by default for new tables.

### Console

#### To enable compaction

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/> and sign in as a data lake administrator, the table creator, or a user who has been granted the `glue:UpdateTable` and `lakeformation:GetDataAccess` permissions on the table.
2. In the navigation pane, under **Data Catalog**, choose **Tables**.
3. On the **Tables** page, choose a table in open table format that you want to enable compaction for, then under **Actions** menu, choose **Enable compaction**.
4. You can also enable compaction by selecting the table and opening the **Table details** page. Choose the **Table optimization** tab on the lower section of the page, and choose **Enable compaction**.

5. Next, select an existing IAM role from the drop down with the permissions shown in the [Table optimization prerequisites](#) section.

When you choose **Create a new IAM role** option, the service creates a custom role with the required permissions to run compaction.

Follow the steps below to update an existing IAM role:

- a. To update the permissions policy for the IAM role, in the IAM console, go to the IAM role that is being used for running compaction.
- b. In the Add permissions section, choose Create policy. In the newly opened browser window, create a new policy to use with your role.
- c. On the Create policy page, choose the JSON tab. Copy the JSON code shown in the Prerequisites into the policy editor field.

## AWS CLI

The following example shows how to enable compaction. Replace the account ID with a valid AWS account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the AWS Resource Name (ARN) of the IAM role and name of the IAM role that has the required permissions to run compaction.

```
aws glue create-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration \  
  '{"roleArn":"arn:aws:iam::123456789012:role/compaction_role", "enabled":'true'}' \  
  --type compaction
```

## AWS API

Call `CreateTableOptimizer` operation to enable compaction for a table.

After you enable compaction, **Table optimization** tab shows the following compaction details (after approximately 15-20 minutes):

## Start time

The time at which the compaction process started within Lake Formation. The value is a timestamp in UTC time.

## End time

The time at which the compaction process ended in Data Catalog. The value is a timestamp in UTC time.

## Status

The status of the compaction run. Values are success or fail.

## Files compacted

Total number of files compacted.

## Bytes compacted

Total number of bytes compacted.

## Disabling compaction

You can disable automatic compaction for a particular Apache Iceberg table using AWS Glue console or AWS CLI.

### Console

1. Choose **Data Catalog** and choose **Tables**. From the tables list, choose the table in open table format that you want to disable compaction.
2. You can choose an Iceberg table, and choose **Disable compaction** under **Actions**.

You can also disable compaction for the table by choosing **Disable compaction** on the lower section of the **Tables details** page.

3. Choose **Disable compaction** on the confirmation message. You can re-enable compaction at a later time.

After the you confirm, compaction is disabled and the compaction status for the table turns back to Off.

## AWS CLI

In the following example, replace the account ID with a valid AWS account ID. Replace the database name and table name with actual Iceberg table name and the database name. Replace the `roleArn` with the AWS Resource Name (ARN) of the IAM role and actual name of the IAM role that has the required permissions to run compaction.

```
aws glue update-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --table-optimizer-configuration  
'{"roleArn":"arn:aws:iam::123456789012:role/compaction_role", "enabled":'false'}'\  
  --type compaction
```

## AWS API

Call `UpdateTableOptimizer` operation to disable compaction for a specific table.

## Viewing compaction details

You can view compaction status for Apache Iceberg in the Lake Formation console, AWS CLI, or using AWS API operations.

### Console

#### To view compaction status for Iceberg tables (console)

- You can view compaction status for Iceberg tables on the Lake Formation console by choosing **Tables** under **Data Catalog**. The **Compaction status** field shows the status of the compaction run. You can display table format and compaction status using the table preferences.
- To view the compaction run history for a specific table, choose **Tables** under AWS Glue Data Catalog, and choose a table to view the table details. The **Table optimization** tab shows the compaction history for the table.

## AWS CLI

You can view the compaction details using AWS CLI.

In the following examples, replace the account ID with a valid AWS account ID, the database name, and table name with actual Iceberg table name.

- **To get the last compaction run details for a table**

```
aws get-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --type compaction
```

- Use the following example to retrieve the history of an optimizer for a specific table.

```
aws list-table-optimizer-runs \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --type compaction
```

- The following example shows how to retrieve the compaction run and configuration details for multiple optimizers. You can specify a maximum of 20 optimizers.

```
aws glue batch-get-table-optimizer \  
  --entries '[{"catalogId":"123456789012", "databaseName":"iceberg_db",  
  "tableName":"iceberg_table", "type":"compaction"}]'
```

## AWS API

- Use `GetTableOptimizer` operation to retrieve the last run details of an optimizer.
- Use `ListTableOptimizerRuns` operation to retrieve history of a given optimizer on a specific table. You can specify 20 optimizers in a single API call.
- Use `BatchGetTableOptimizer` operation to retrieve configuration details for multiple optimizers in your account. This operation doesn't support cross account calls.

## Viewing Amazon CloudWatch metrics

After running the compaction successfully, the service creates Amazon CloudWatch metrics on the compaction job performance. You can go to the **CloudWatch Metrics** and choose **Metrics, All**

**metrics.** You can filter metrics by the specific namespace (for example AWS Glue), table name, or database name.

For more information, see [View available metrics](#) in the *Amazon CloudWatch User Guide*.

- Number of bytes compacted
- Number of files compacted
- Number of DPU allocated to job
- Duration of job (Hours)

## Deleting an optimizer

You can delete an optimizer and associated metadata for the table using AWS CLI or AWS API operation.

Run the following AWS CLI command to delete compaction history for a table.

```
aws glue delete-table-optimizer \  
  --catalog-id 123456789012 \  
  --database-name iceberg_db \  
  --table-name iceberg_table \  
  --type compaction
```

Use DeleteTableOptimizer operation to delete an optimizer for a table.

## Supported formats and limitations for managed data compaction

For better read performance by AWS analytics services such as Amazon Athena, Amazon EMR, and AWS Glue ETL jobs, AWS Glue Data Catalog provides managed compaction (a process that compacts small Amazon S3 objects into larger objects) for Iceberg tables in Data Catalog.

Data compaction supports a variety of data types and compression formats for reading and writing data, including reading data from encrypted tables.

### Data compaction supports:

- **File types** – Parquet
- **Data types** – Boolean, Integer, Long, Float, Double, String, Decimal, Date, Time, Timestamp, String, UUID, Binary
- **Compression** – zstd, gzip, snappy, uncompressed

- **Encryption** – Data compaction only supports default Amazon S3 encryption (SSE-S3) and server-side KMS encryption (SSE-KMS).
- **Bin pack compaction**
- **Schema evolution**
- **Tables with target file size (write.target-file-size-bytes property in iceberg configuration) within the inclusive range 128MB to 512 MB.**
- **Regions**
  - Asia Pacific (Tokyo)
  - Asia Pacific (Seoul)
  - Asia Pacific (Mumbai)
  - Asia Pacific (Singapore)
  - Europe (Ireland)
  - Europe (Frankfurt)
  - US East (N. Virginia)
  - US East (Ohio)
  - US West (N. California)
  - South America (São Paulo)
- You can run compaction from the account where Data Catalog resides when the Amazon S3 bucket that stores the underlying data is in another account. To do this, the compaction role requires access to the Amazon S3 bucket.

#### **Data compaction currently doesn't support:**

- **File types** – Avro, ORC
- **Data types** – Fixed
- **Compression** – brotli, lz4
- **Compaction of files while the partition spec evolves.**
- **Regular sorting or z-order sorting**
- **Merge or delete files** – The compaction process skips data files that have delete files associated with them.
- **Compaction on cross-account tables** – You can't run compaction on cross-account tables.
- **Compaction on cross-Region tables** – You can't run compaction on cross-Region tables.

- **Enabling compaction on resource links**
- **VPC endpoints for Amazon S3 buckets**
- **[DynamoDB lock manager](#)** – When using data compaction, no other data loading jobs should use `lock-impl` as `org.apache.iceberg.aws.dynamodb.DynamoDbLockManager`.

## Managing the Data Catalog

The AWS Glue Data Catalog is a central metadata repository that stores structural and operational metadata for your Amazon S3 data sets. Managing the Data Catalog effectively is crucial for maintaining data quality, performance, security, and governance.

By understanding and applying these Data Catalog management practices, you can ensure your metadata remains accurate, performant, secure, and well-governed as your data landscape evolves.

This section covers the following aspects of Data Catalog management:

- *Updating table schema and partitions* As your data evolves, you may need to update the table schema or partition structure defined in the Data Catalog. For more information on how to make these updates programmatically using the AWS Glue ETL, see [Updating the schema, and adding new partitions in the Data Catalog using AWS Glue ETL jobs](#).
- *Managing column statistics*: Accurate column statistics help optimize query plans and improve performance. For more information on how to generate, update, and manage column statistics, see [Optimizing query performance using column statistics](#).
- *Encrypting the Data Catalog* To protect sensitive metadata, you can encrypt your Data Catalog using AWS Key Management Service (AWS KMS). This section explains how to enable and manage encryption for your Data Catalog.
- *Securing the Data Catalog with AWS Lake Formation* Lake Formation provides a comprehensive approach to data lake security and access control. You can use Lake Formation to secure and govern access to your Data Catalog and underlying data.

### Topics

# Updating the schema, and adding new partitions in the Data Catalog using AWS Glue ETL jobs

Your extract, transform, and load (ETL) job might create new table partitions in the target data store. Your dataset schema can evolve and diverge from the AWS Glue Data Catalog schema over time. AWS Glue ETL jobs now provide several features that you can use within your ETL script to update your schema and partitions in the Data Catalog. These features allow you to see the results of your ETL work in the Data Catalog, without having to rerun the crawler.

## New partitions

If you want to view the new partitions in the AWS Glue Data Catalog, you can do one of the following:

- When the job finishes, rerun the crawler, and view the new partitions on the console when the crawler finishes.
- When the job finishes, view the new partitions on the console right away, without having to rerun the crawler. You can enable this feature by adding a few lines of code to your ETL script, as shown in the following examples. The code uses the `enableUpdateCatalog` argument to indicate that the Data Catalog is to be updated during the job run as the new partitions are created.

### Method 1

Pass `enableUpdateCatalog` and `partitionKeys` in an options argument.

Python

```
additionalOptions = {"enableUpdateCatalog": True}
additionalOptions["partitionKeys"] = ["region", "year", "month", "day"]

sink = glueContext.write_dynamic_frame_from_catalog(frame=last_transform,
    database=<target_db_name>,
    table_name=<target_table_name>, transformation_ctx="write_sink",
    additional_options=additionalOptions)
```

## Scala

```
val options = JsonOptions(Map(
  "path" -> <S3_output_path>,
  "partitionKeys" -> Seq("region", "year", "month", "day"),
  "enableUpdateCatalog" -> true))
val sink = glueContext.getCatalogSink(
  database = <target_db_name>,
  tableName = <target_table_name>,
  additionalOptions = options)sink.writeDynamicFrame(df)
```

## Method 2

Pass `enableUpdateCatalog` and `partitionKeys` in `getSink()`, and call `setCatalogInfo()` on the `DataSink` object.

## Python

```
sink = glueContext.getSink(
  connection_type="s3",
  path="<S3_output_path>",
  enableUpdateCatalog=True,
  partitionKeys=["region", "year", "month", "day"])
sink.setFormat("json")
sink.setCatalogInfo(catalogDatabase=<target_db_name>,
  catalogTableName=<target_table_name>)
sink.writeFrame(last_transform)
```

## Scala

```
val options = JsonOptions(
  Map("path" -> <S3_output_path>,
    "partitionKeys" -> Seq("region", "year", "month", "day"),
    "enableUpdateCatalog" -> true))
val sink = glueContext.getSink("s3", options).withFormat("json")
sink.setCatalogInfo(<target_db_name>, <target_table_name>)
sink.writeDynamicFrame(df)
```

Now, you can create new catalog tables, update existing tables with modified schema, and add new table partitions in the Data Catalog using an AWS Glue ETL job itself, without the need to re-run crawlers.

## Updating table schema

If you want to overwrite the Data Catalog table's schema you can do one of the following:

- When the job finishes, rerun the crawler and make sure your crawler is configured to update the table definition as well. View the new partitions on the console along with any schema updates, when the crawler finishes. For more information, see [Configuring a Crawler Using the API](#).
- When the job finishes, view the modified schema on the console right away, without having to rerun the crawler. You can enable this feature by adding a few lines of code to your ETL script, as shown in the following examples. The code uses `enableUpdateCatalog` set to `true`, and also `updateBehavior` set to `UPDATE_IN_DATABASE`, which indicates to overwrite the schema and add new partitions in the Data Catalog during the job run.

### Python

```
additionalOptions = {
    "enableUpdateCatalog": True,
    "updateBehavior": "UPDATE_IN_DATABASE"}
additionalOptions["partitionKeys"] = ["partition_key0", "partition_key1"]

sink = glueContext.write_dynamic_frame_from_catalog(frame=last_transform,
    database=<dst_db_name>,
    table_name=<dst_tbl_name>, transformation_ctx="write_sink",
    additional_options=additionalOptions)
job.commit()
```

### Scala

```
val options = JsonOptions(Map(
    "path" -> outputPath,
    "partitionKeys" -> Seq("partition_0", "partition_1"),
    "enableUpdateCatalog" -> true))
val sink = glueContext.getCatalogSink(database = nameSpace, tableName = tableName,
    additionalOptions = options)
sink.writeDynamicFrame(df)
```

You can also set the `updateBehavior` value to `LOG` if you want to prevent your table schema from being overwritten, but still want to add the new partitions. The default value of `updateBehavior`

is `UPDATE_IN_DATABASE`, so if you don't explicitly define it, then the table schema will be overwritten.

If `enableUpdateCatalog` is not set to `true`, regardless of whichever option selected for `updateBehavior`, the ETL job will not update the table in the Data Catalog.

## Creating new tables

You can also use the same options to create a new table in the Data Catalog. You can specify the database and new table name using `setCatalogInfo`.

### Python

```
sink = glueContext.getSink(connection_type="s3", path="s3://path/to/data",
    enableUpdateCatalog=True, updateBehavior="UPDATE_IN_DATABASE",
    partitionKeys=["partition_key0", "partition_key1"])
sink.setFormat("<format>")
sink.setCatalogInfo(catalogDatabase=<dst_db_name>, catalogTableName=<dst_tbl_name>)
sink.writeFrame(last_transform)
```

### Scala

```
val options = JsonOptions(Map(
    "path" -> outputPath,
    "partitionKeys" -> Seq("<partition_1>", "<partition_2>"),
    "enableUpdateCatalog" -> true,
    "updateBehavior" -> "UPDATE_IN_DATABASE"))
val sink = glueContext.getSink(connectionType = "s3", connectionOptions =
    options).withFormat("<format>")
sink.setCatalogInfo(catalogDatabase = "<dst_db_name>", catalogTableName =
    "<dst_tbl_name>")
sink.writeDynamicFrame(df)
```

## Restrictions

Take note of the following restrictions:

- Only Amazon Simple Storage Service (Amazon S3) targets are supported.
- The `enableUpdateCatalog` feature is not supported for governed tables.
- Only the following formats are supported: json, csv, avro, and parquet.

- To create or update tables with the parquet classification, you must utilize the AWS Glue optimized parquet writer for DynamicFrames. This can be achieved with one of the following:
  - If you're updating an existing table in the catalog with parquet classification, the table must have the "useGlueParquetWriter" table property set to true before you update it. You can set this property via the AWS Glue APIs/SDK, via the console or via an Athena DDL statement.

The screenshot shows the AWS Glue console interface for editing a table. The left sidebar contains navigation options like 'Data Catalog tables', 'Data Catalog', and 'Data Integration and ETL'. The main content area is titled 'Edit table' and has three sections: 'Table details', 'Serde parameters', and 'Table properties'. The 'Table properties' section is expanded to show a table with columns for 'Key', 'Value', and 'Remove'. The table contains several properties such as 'skip.header.line.count', 'has\_encrypted\_data', 'columnsOrdered', 'areColumnsQuoted', 'delimiter', 'classification', and 'typeOfData'. At the bottom of this section, there is an 'Add' button highlighted with a red box, and input fields for 'Enter a unique key' and 'Enter a value'.

Once the catalog table property is set, you can use the following snippet of code to update the catalog table with the new data:

```
glueContext.write_dynamic_frame.from_catalog(
    frame=frameToWrite,
    database="dbName",
    table_name="tableName",
    additional_options={
        "enableUpdateCatalog": True,
        "updateBehavior": "UPDATE_IN_DATABASE"
```

```
    }
  )
}
```

- If the table doesn't already exist within catalog, you can utilize the `getSink()` method in your script with `connection_type="s3"` to add the table and its partitions to the catalog, along with writing the data to Amazon S3. Provide the appropriate `partitionKeys` and compression for your workflow.

```
s3sink = glueContext.getSink(
  path="s3://bucket/folder",
  connection_type="s3",
  updateBehavior="UPDATE_IN_DATABASE",
  partitionKeys=[],
  compression="snappy",
  enableUpdateCatalog=True
)

s3sink.setCatalogInfo(
  catalogDatabase="dbName", catalogTableName="tableName"
)

s3sink.setFormat("parquet", useGlueParquetWriter=true)
s3sink.writeFrame(frameToWrite)
```

- The `glueparquet` format value is a legacy method of enabling the AWS Glue parquet writer.
- When the `updateBehavior` is set to `LOG`, new partitions will be added only if the `DynamicFrame` schema is equivalent to or contains a subset of the columns defined in the Data Catalog table's schema.
- Schema updates are not supported for non-partitioned tables (not using the "partitionKeys" option).
- Your `partitionKeys` must be equivalent, and in the same order, between your parameter passed in your ETL script and the `partitionKeys` in your Data Catalog table schema.
- This feature currently does not yet support updating/creating tables in which the updating schemas are nested (for example, arrays inside of structs).

For more information, see [the section called "AWS Glue for Spark"](#).

## Working with MongoDB connections in ETL jobs

You can create a connection for MongoDB and then use that connection in your AWS Glue job. For more information, see [the section called “MongoDB connections”](#) in the AWS Glue programming guide. The connection `url`, `username` and `password` are stored in the MongoDB connection. Other options can be specified in your ETL job script using the `additionalOptions` parameter of `glueContext.getCatalogSource`. The other options can include:

- `database`: (Required) The MongoDB database to read from.
- `collection`: (Required) The MongoDB collection to read from.

By placing the database and collection information inside the ETL job script, you can use the same connection for in multiple jobs.

1. Create an AWS Glue Data Catalog connection for the MongoDB data source. See [“connectionType”: “mongodb”](#) for a description of the connection parameters. You can create the connection using the console, APIs or CLI.
2. Create a database in the AWS Glue Data Catalog to store the table definitions for your MongoDB data. See [Creating databases](#) for more information.
3. Create a crawler that crawls the data in the MongoDB using the information in the connection to connect to the MongoDB. The crawler creates the tables in the AWS Glue Data Catalog that describe the tables in the MongoDB database that you use in your job. See [Using crawlers to populate the Data Catalog](#) for more information.
4. Create a job with a custom script. You can create the job using the console, APIs or CLI. For more information, see [Adding Jobs in AWS Glue](#).
5. Choose the data targets for your job. The tables that represent the data target can be defined in your Data Catalog, or your job can create the target tables when it runs. You choose a target location when you author the job. If the target requires a connection, the connection is also referenced in your job. If your job requires multiple data targets, you can add them later by editing the script.
6. Customize the job-processing environment by providing arguments for your job and generated script.

Here is an example of creating a `DynamicFrame` from the MongoDB database based on the table structure defined in the Data Catalog. The code uses `additionalOptions` to provide the additional data source information:

## Scala

```
val resultFrame: DynamicFrame = glueContext.getCatalogSource(  
    database = catalogDB,  
    tableName = catalogTable,  
    additionalOptions = JsonOptions(Map("database" -> DATABASE_NAME,  
        "collection" -> COLLECTION_NAME))  
).getDynamicFrame()
```

## Python

```
glue_context.create_dynamic_frame_from_catalog(  
    database = catalogDB,  
    table_name = catalogTable,  
    additional_options = {"database": "database_name",  
        "collection": "collection_name"})
```

7. Run the job, either on-demand or through a trigger.

## Optimizing query performance using column statistics

You can compute column-level statistics for AWS Glue Data Catalog tables in data formats such as Parquet, ORC, JSON, ION, CSV, and XML without setting up additional data pipelines. Column statistics help you to understand data profiles by getting insights about values within a column. Data Catalog supports generating statistics for column values such as minimum value, maximum value, total null values, total distinct values, average length of values, and total occurrences of true values.

AWS analytical services such as Amazon Redshift and Amazon Athena can use these column statistics to generate query execution plans, and choose the optimal plan that improves query performance.

You can configure to run column statistics generation task using AWS Glue console or AWS CLI. When you initiate the process, AWS Glue starts a Spark job in the background and updates the AWS Glue table metadata in the Data Catalog. You can view column statistics using AWS Glue console or AWS CLI or by calling the [GetColumnStatisticsForTable](#) API operation.

**Note**

If you're using Lake Formation permissions to control access to the table, the role assumed by the column statistics task requires full table access to generate statistics.

**Topics**

- [Prerequisites for generating column statistics](#)
- [Generating column statistics](#)
- [Viewing column statistics](#)
- [Updating column statistics](#)
- [Deleting column statistics](#)
- [Viewing column statistics task runs](#)
- [Stopping column statistics task run](#)
- [Considerations and limitations](#)

**Prerequisites for generating column statistics**

To generate or update column statistics, the statistics generation task assumes an AWS Identity and Access Management (IAM) role on your behalf. Based on the permissions granted to the role, the column statistics generation task can read the data from the Amazon S3 data store.

**Note**

To generate statistics for tables managed by Lake Formation, the IAM role used to generate statistics requires full table access.

To use role-based access control, you must create an IAM role with the permissions listed in the policy below, and add that role to the column statistics generation task.

**To create an IAM role for generating column statistics**

1. To create an IAM role, see [Create an IAM role for AWS Glue](#).
2. To update an existing role, in the IAM console, go to the IAM role that is being used by the generate column statistics process.

3. In the **Add permissions** section, choose **Attach policies**. In the newly opened browser window, choose `AWSGlueServiceRole` AWS managed policy.
4. You also need to include permissions to read data from the Amazon S3 data location.

In the **Add permissions** section, choose **Create policy**. In the newly opened browser window, create a new policy to use with your role.

5. In the **Create policy** page, choose the **JSON** tab. Copy the following JSON code into the policy editor field.

**Note**

In the following policies, replace account ID with a valid AWS account, and replace region with the Region of the table, and `bucket-name` with the Amazon S3 bucket name.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3BucketAccess",
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::<bucket-name>/*",
        "arn:aws:s3:::<bucket-name>"
      ]
    }
  ]
}
```

6. (Optional) If you're using Lake Formation permissions to provide access to your data, the IAM role requires `lakeformation:GetDataAccess` permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

    {
      "Sid": "LakeFormationDataAccess",
      "Effect": "Allow",
      "Action": "lakeformation:GetDataAccess",
      "Resource": [
        "*"
      ]
    }
  ]
}

```

If the Amazon S3 data location is registered with Lake Formation, and the IAM role assumed by the column statistics generation task doesn't have IAM\_ALLOWED\_PRINCIPALS group permissions granted on the table, the role requires Lake Formation ALTER and DESCRIBE permissions on the table. The role used for registering the Amazon S3 bucket requires Lake Formation INSERT and DELETE permissions on the table.

If the Amazon S3 data location is not registered with Lake Formation, and the IAM role doesn't have IAM\_ALLOWED\_PRINCIPALS group permissions granted on the table, the role requires Lake Formation ALTER, DESCRIBE, INSERT and DELETE permissions on the table.

7. (Optional) The column statistics generation task that writes encrypted Amazon CloudWatch Logs requires the following permissions in the key policy.

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "CWLogsKmsPermissions",
    "Effect": "Allow",
    "Action": [
      "logs:CreateLogGroup",
      "logs:CreateLogStream",
      "logs:PutLogEvents",
      "logs:AssociateKmsKey"
    ],
    "Resource": [
      "arn:aws:logs:<region>:111122223333:log-group:/aws-glue:*"
    ]
  }],
  {
    "Sid": "KmsPermissions",

```

```

    "Effect": "Allow",
    "Action": [
      "kms:GenerateDataKey",
      "kms:Decrypt",
      "kms:Encrypt"
    ],
    "Resource": [
      "arn:aws:kms:<region>:111122223333:key/"arn of key used for ETL cloudwatch
      encryption"
    ],
    "Condition": {
      "StringEquals": {
        "kms:ViaService": ["glue.<region>.amazonaws.com"]
      }
    }
  }
]
}

```

8. The role you use to run column statistics must have the `iam:PassRole` permission on the role.

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "iam:PassRole"
    ],
    "Resource": [
      "arn:aws:iam::111122223333:role/<columnstats-role-name>"
    ]
  }]
}

```

9. When you create an IAM role for generating column statistics, that role must also have the following trust policy that enables the service to assume the role.

```

{
  "Version": "2012-10-17",
  "Statement": [

```

```
{
  "Sid": "TrustPolicy",
  "Effect": "Allow",
  "Principal": {
    "Service": "glue.amazonaws.com"
  },
  "Action": "sts:AssumeRole",
}
]
```

## Generating column statistics

Follow these steps to manage statistics generation in the Data Catalog using AWS Glue console or AWS CLI.

### Console

#### To generate column statistics using the console

1. Sign in to the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose Data Catalog tables.
3. Choose a table from the list.
4. Choose **Generate statistics** under **Actions** menu.

You can also choose **Generate statistics** button under **Column statistics** tab in the lower section of the **Tables** page.

5. On the **Generate statistics** page, specify the following options:

## Generate statistics

Generate column statistics for the table to improve query performance and potentially save costs. [View pricing](#)

### Choose columns

**Table (All columns)**  
 Generate statistics for all columns.

**Selected columns**  
 Choose the columns to generate statistics.

### Row sampling options

We recommend to use all rows to compute accurate column statistics. You can use sampling when the dataset is potentially large and approximate results are acceptable.

**All rows**  
 Generate column statistics on entire data.

**Sample rows**  
 Generate approximate statistics using sample rows.

### IAM role

To generate statistics, the IAM role assumed by the job should have necessary permissions. [Learn more](#)

Choose an existing IAM role

12495-pentestRole

▶ **Security configuration - optional**  
 Enable at-rest encryption with a security configuration.

- **Table (all columns)** – Choose this option to generate statistics for all columns in the table.
- **Selected columns** – Choose this option to generate statistics for specific columns. You can select the columns from the drop-down list.
- **All rows** – Choose all rows from the table to generate accurate statistics.
- **Sample rows** – Choose only a specific percent of rows from the table to generate statistics. The default is all rows. Use the up and down arrows to increase or decrease the percent value.

### Note

We recommend to include all rows in the table to compute accurate statistics. Use sample rows to generate column statistics only when approximate values are acceptable.

6. (Optional) Next, choose a security configuration to enable at-rest encryption for logs.
7. Choose **Generate statistics** to run the process.

## AWS CLI

In the following example, replace values for `DatabaseName`, `TableName`, and `ColumnNameList` with actual database, table, and column names. Replace account ID with a valid AWS account, and role name with the name of the IAM role that you're using to generate statistics.

```
aws glue start-column-statistics-task-run --input-cli-json file://input.json
{
  "DatabaseName": "<test-db>",
  "TableName": "<test-table>",
  "ColumnNameList": [
    "<column1>",
    "<column2>",
  ],
  "Role": "arn:aws:iam::<123456789012>:role/<Stats-Role>",
  "SampleSize": 10.0
}
```

You can generate column statistics also by calling the [StartColumnStatisticsTaskRun](#) operation.

## Viewing column statistics

After generating the statistics successfully, Data Catalog stores this information for the cost-based optimizers in Amazon Athena and Amazon Redshift to make optimal choices when running queries. The statistics varies based on the type of the column.

### AWS Management Console

#### To view column statistics for a table

- After running column statistics task, the **Column statistics** tab on the **Table details** page shows the statistics for the table.

AWS Glue > Tables > pentest\_orders\_xml

pentest\_orders\_xml Last updated (UTC)  
October 25, 2023 at 19:14:47 Version 15 (Current version) Actions

o_totalprice	October 25, 2023 at 19:14:	-	3062	-	-	422359.65	974.04	-	-

The following statistics are available:

- **Column name:** Column name used to generate statistics
- **Last updated:** Data and time when the statistics were generated
- **Average length:** Average length of values in the column
- **Distinct values:** Total number of distinct values in the column. We estimate the number of distinct values in a column with 5% relative error.
- **Max value:** The largest value in the column.
- **Min value:** The smallest value in the column.
- **Max length:** The length of the highest value in the column.
- **Null values:** The total number of null values in the column.
- **True values:** The total number of true values in the column.
- **False values:** The total number of false values in the column.

## AWS CLI

The following example shows how to retrieve column statistics using AWS CLI.

```
aws glue get-column-statistics-for-table \
```

```
--database-name <test_db> \  
--table-name <test_tble> \  
--column-names <col1>
```

You can also view the column statistics using the [GetColumnStatisticsForTable](#) API operation.

## Updating column statistics

Keeping statistics current improves query performance by enabling the query planner to choose optimal plans. You need to explicitly run the **Generate statistics** task from the AWS Glue console to refresh the column statistics. Data Catalog doesn't automatically refresh the statistics.

If you are not using AWS Glue's statistics generation feature in the console, you can manually update column statistics using the [UpdateColumnStatisticsForTable](#) API operation or AWS CLI. The following example shows how to update column statistics using AWS CLI.

```
aws glue update-column-statistics-for-table --cli-input-json:  
  
{  
  "CatalogId": "111122223333",  
  "DatabaseName": "test_db",  
  "TableName": "test_table",  
  "ColumnStatisticsList": [  
    {  
      "ColumnName": "col1",  
      "ColumnType": "Boolean",  
      "AnalyzedTime": "1970-01-01T00:00:00",  
      "StatisticsData": {  
        "Type": "BOOLEAN",  
        "BooleanColumnStatisticsData": {  
          "NumberOfTrues": 5,  
          "NumberOfFalses": 5,  
          "NumberOfNulls": 0  
        }  
      }  
    }  
  ]  
}
```

## Deleting column statistics

You can delete column statistics using the [DeleteColumnStatisticsForTable](#) API operation or AWS CLI. The following example shows how to delete column statistics using AWS Command Line Interface (AWS CLI).

```
aws glue delete-column-statistics-for-table \
  --database-name test_db \
  --table-name test_table \
  --column-name col1
```

## Viewing column statistics task runs

After you run a column statistics task, you can explore the task run details for a table using AWS Glue console, AWS CLI or using [GetColumnStatisticsTaskRuns](#) operation.

### Console

#### To view column statistics task run details

1. On AWS Glue console, choose **Tables** under Data Catalog.
2. Select a table with column statistics.
3. On the **Table details** page, choose **Column statistics**.
4. Choose **View runs**.

You can see information about all runs associated with the specified table.

The screenshot shows the AWS Glue console interface for viewing column statistics task runs. The breadcrumb navigation is 'AWS Glue > Tables > path1 > All column statistics runs'. The main content area is titled 'All runs (1)' and includes a refresh button and a timestamp 'Last updated (UTC) November 16, 2023 at 00:21:44'. Below this is a search bar labeled 'Filter data'. A table displays the run details:

Run ID	Status	Start time (UTC)	End time (UTC)	Duration	Column selection	Row sampling
f6a7b304-ad59-49d1-9:	Running	November 16, 2023 at 00:21:44	-	-	All columns	100%

### AWS CLI

In the following example, replace values for `DatabaseName` and `TableName` with the actual database and table name.

```
aws glue get-column-statistics-task-runs --input-cli-json file://input.json
{
  "DatabaseName": "<test-db>",
  "TableName": "<test-table>"
}
```

## Stopping column statistics task run

You can stop a column statistics task run for a table using AWS Glue console, AWS CLI or using [StopColumnStatisticsTaskRun](#) operation.

### Console

#### To stop a column statistics task run

1. On AWS Glue console, choose **Tables** under Data Catalog.
2. Select the table with the column statistics task run is in progress.
3. On the **Table details** page, choose **Column statistics**.
4. Choose **Stop**.

If you stop the task before the run is complete, column statistics won't be generated for the table.

### AWS CLI

In the following example, replace values for DatabaseName and TableName with the actual database and table name.

```
aws glue stop-column-statistics-task-run --input-cli-json file://input.json
{
  "DatabaseName": "<test-db>",
  "TableName": "<test-table>"
}
```

## Considerations and limitations

The following considerations and limitations apply to generating column statistics.

### Considerations

- Using sampling to generate statistics reduces run time, but can generate inaccurate statistics.
- Each column statistics run requires processing the entire dataset.
- Data Catalog doesn't store different versions of the statistics.
- You can only run one statistics generation task at a time per table.
- If a table is encrypted using customer AWS KMS key registered with Data Catalog, AWS Glue uses the same key to encrypt statistics.

### Column statistics task supports generating statistics:

- When the IAM role has full table permissions (IAM or Lake Formation).
- When the IAM role has permissions on the table using Lake Formation hybrid access mode.

### Column statistics task doesn't support generating statistics for:

- Tables with Lake Formation cell-based access control.
- Transactional data lakes - Linux foundation Delta Lake, Apache Iceberg, Apache Hudi.
- Tables in federated databases - Hive metastore, Amazon Redshift datashares
- Nested columns, arrays, and struct data types.
- Table that is shared with you from another account.

## Encrypting your Data Catalog

You can protect your metadata stored in the AWS Glue Data Catalog at rest using encryption keys managed by AWS Key Management Service (AWS KMS). You can enable Data Catalog encryption for new Data Catalog, by using the **Data Catalog settings**. You can enable or disable encryption for existing Data Catalog as needed. When enabled, AWS Glue encrypts all new metadata written to the catalog, while existing metadata remains unencrypted.

For detailed information about encrypting your Data Catalog, see [Encrypting your Data Catalog](#).

## Securing your Data Catalog using Lake Formation

AWS Lake Formation is a service that makes it easier to set up a secure data lake in AWS. It provides a central place to create and securely manage your data lakes by defining fine-grained access control permissions. Lake Formation uses the Data Catalog to store and retrieve metadata about your data lake, such as table definitions, schema information, and data access control settings.

You can register your Amazon S3 data location of the metadata table or database with Lake Formation and use it to define metadata-level permissions on the Data Catalog resources. You can also use Lake Formation to manage storage access permissions on the underlying data stored in Amazon S3 on behalf of integrated analytical engines.

For more information see [What is AWS Lake Formation?](#).

## Accessing the Data Catalog

You can use the AWS Glue Data Catalog to discover and understand your data. Data Catalog provides a consistent way to maintain schema definitions, data types, locations, and other metadata. You can access the Data Catalog using the following methods:

- **AWS Glue console** – You can access and manage the Data Catalog through the AWS Glue console, a web-based user interface. The console allows you to browse and search for databases, tables, and their associated metadata, as well as create, update, and delete metadata definitions.
- **AWS Glue crawler** – Crawlers are programs that automatically scan your data sources and populate the Data Catalog with metadata. You can create and run crawlers to discover and catalog data from various sources like Amazon S3, Amazon RDS, Amazon DynamoDB, Amazon CloudWatch, and JDBC-compliant relational databases such as MySQL, and PostgreSQL as well as several non-AWS sources such as Snowflake and Google BigQuery.
- **AWS Glue APIs** – You can access the Data Catalog programmatically using the AWS Glue APIs. These APIs allow you to interact with the Data Catalog programmatically, enabling automation and integration with other applications and services.
- **AWS Command Line Interface (AWS CLI)** – You can use the AWS CLI to access and manage the Data Catalog from the command line. The CLI provides commands for creating, updating, and deleting metadata definitions, as well as querying and retrieving metadata information.
- **Integration with other AWS services** – The Data Catalog integrates with various other AWS services, allowing you to access and utilize the metadata stored in the catalog. For example, you

can use Amazon Athena to query data sources using the metadata in the Data Catalog, and use AWS Lake Formation to manage data access and governance for the Data Catalog resources.

## AWS Glue Data Catalog best practices

This section covers best practices for effectively managing and utilizing the AWS Glue Data Catalog. It emphasizes practices such as efficient crawler usage, metadata organization, security, performance optimization, automation, data governance, and integration with other AWS services.

- **Use crawlers effectively** – Run crawlers regularly to keep the Data Catalog up-to-date with changes in your data sources. Use incremental crawls for frequently changing data sources to improve performance. Configure crawlers to automatically add new partitions or update schemas when changes are detected.
- **Organize and name metadata tables** – Establish a consistent naming convention for databases and tables in the Data Catalog. Group related data sources into logical databases or folders for better organization. Use descriptive names that convey the purpose and content of each table.
- **Manage schemas effectively** – Take advantage of the schema inference capabilities of AWS Glue crawlers. Review and update schema changes before applying them to avoid breaking downstream applications. Use schema evolution features to handle schema changes gracefully.
- **Secure the Data Catalog** – Enable data encryption at rest and in transit for the Data Catalog. Implement fine-grained access control policies to restrict access to sensitive data. Regularly audit and review Data Catalog permissions and activity logs.
- **Integrate with other AWS services** Data Catalog Use the Data Catalog as a centralized metadata layer for services like Amazon Athena, Redshift Spectrum, and AWS Lake Formation. Leverage AWS Glue ETL jobs to transform and load data into various data stores while maintaining metadata in the Data Catalog.
- **Monitor and optimize performance** Data Catalog Monitor the performance of crawlers and ETL jobs using Amazon CloudWatch metrics. Partition large datasets in the Data Catalog to improve query performance. Implement performance optimizations for frequently accessed metadata.
- **Stay updated with AWS Glue documentation and best practices** Data Catalog Regularly check the AWS Glue documentation and AWS Glue resources for the latest updates, best practices, and recommendations. Attend AWS Glue webinars, workshops, and other events to learn from experts and stay informed about new features and capabilities.

# AWS Glue Schema Registry

## Note

AWS Glue Schema Registry is not supported in the following Regions in the AWS Glue console: Asia Pacific (Jakarta) and Middle East (UAE).

The AWS Glue Schema Registry is a new feature that allows you to centrally discover, control, and evolve data stream schemas. A *schema* defines the structure and format of a data record. With AWS Glue Schema Registry, you can manage and enforce schemas on your data streaming applications using convenient integrations with Apache Kafka, [Amazon Managed Streaming for Apache Kafka](#), [Amazon Kinesis Data Streams](#), [Amazon Managed Service for Apache Flink](#), and [AWS Lambda](#).

The AWS Glue Schema Registry supports AVRO (v1.10.2) data format, JSON Data format with [JSON Schema format](#) for the schema (specifications Draft-04, Draft-06, and Draft-07) with JSON schema validation using the [Everit library](#), Protocol Buffers (Protobuf) versions proto2 and proto3 without support for extensions or groups, and Java language support, with other data formats and languages to come. Supported features include compatibility, schema sourcing via metadata, auto-registration of schemas, IAM compatibility, and optional ZLIB compression to reduce storage and data transfer. AWS Glue Schema Registry is serverless and free to use.

Using a schema as a data format contract between producers and consumers leads to improved data governance, higher quality data, and enables data consumers to be resilient to compatible upstream changes.

The Schema Registry allows disparate systems to share a schema for serialization and de-serialization. For example, assume you have a producer and consumer of data. The producer knows the schema when it publishes the data. The Schema Registry supplies a serializer and deserializer for certain systems such as Amazon MSK or Apache Kafka.

For more information, see [How the Schema Registry works](#).

## Topics

- [Schemas](#)
- [Registries](#)
- [Schema versioning and compatibility](#)
- [Open source Serde libraries](#)

- [Quotas of the Schema Registry](#)
- [How the Schema Registry works](#)
- [Getting started with Schema Registry](#)
- [Integrating with AWS Glue Schema Registry](#)
- [Migration from a third-party schema registry to AWS Glue Schema Registry](#)

## Schemas

A *schema* defines the structure and format of a data record. A schema is a versioned specification for reliable data publication, consumption, or storage.

In this example schema for Avro, the format and structure are defined by the layout and field names, and the format of the field names is defined by the data types (e.g., `string`, `int`).

```
{
  "type": "record",
  "namespace": "ABC_Organization",
  "name": "Employee",
  "fields": [
    {
      "name": "Name",
      "type": "string"
    },
    {
      "name": "Age",
      "type": "int"
    },
    {
      "name": "address",
      "type": {
        "type": "record",
        "name": "addressRecord",
        "fields": [
          {
            "name": "street",
            "type": "string"
          },
          {
            "name": "zipcode",
            "type": "int"
          }
        ]
      }
    }
  ]
}
```

```

    ]
  }
}

```

In this example JSON Schema Draft-07 for JSON, the format is defined by the [JSON Schema organization](#).

```

{
  "$id": "https://example.com/person.schema.json",
  "$schema": "http://json-schema.org/draft-07/schema#",
  "title": "Person",
  "type": "object",
  "properties": {
    "firstName": {
      "type": "string",
      "description": "The person's first name."
    },
    "lastName": {
      "type": "string",
      "description": "The person's last name."
    },
    "age": {
      "description": "Age in years which must be equal to or greater than zero.",
      "type": "integer",
      "minimum": 0
    }
  }
}

```

In this example for Protobuf, the format is defined by the [version 2 of the Protocol Buffers language \(proto2\)](#).

```

syntax = "proto2";

package tutorial;

option java_multiple_files = true;
option java_package = "com.example.tutorial.protos";
option java_outer_classname = "AddressBookProtos";

message Person {

```

```
optional string name = 1;
optional int32 id = 2;
optional string email = 3;

enum PhoneType {
  MOBILE = 0;
  HOME = 1;
  WORK = 2;
}

message PhoneNumber {
  optional string number = 1;
  optional PhoneType type = 2 [default = HOME];
}

repeated PhoneNumber phones = 4;
}

message AddressBook {
  repeated Person people = 1;
}
```

## Registries

A *registry* is a logical container of schemas. Registries allow you to organize your schemas, as well as manage access control for your applications. A registry has an Amazon Resource Name (ARN) to allow you to organize and set different access permissions to schema operations within the registry.

You may use the default registry or create as many new registries as necessary.

### AWS Glue Schema Registry Hierarchy

- RegistryName: [string]
  - RegistryArn: [AWS ARN]
  - CreatedTime: [timestamp]
  - UpdatedTime: [timestamp]
- SchemaName: [string]
  - SchemaArn: [AWS ARN]
  - DataFormat: [Avro, Json, or Protobuf]

- **Compatibility:** [eg. BACKWARD, BACKWARD\_ALL, FORWARD, FORWARD\_ALL, FULL, FULL\_ALL, NONE, DISABLED]
  - **Status:** [eg. PENDING, AVAILABLE, DELETING]
  - **SchemaCheckpoint:** [integer]
  - **CreatedTime:** [timestamp]
  - **UpdatedTime:** [timestamp]
- 
- **SchemaVersion:** [string]
    - **SchemaVersionNumber:** [integer]
    - **Status:** [eg. PENDING, AVAILABLE, DELETING, FAILURE]
    - **SchemaDefinition:** [string, Value: JSON]
    - **CreatedTime:** [timestamp]
- 
- **SchemaVersionMetadata:** [list]
    - **MetadataKey:** [string]
    - **MetadataInfo**
    - **MetadataValue:** [string]
    - **CreatedTime:** [timestamp]

## Schema versioning and compatibility

Each schema can have multiple versions. Versioning is governed by a compatibility rule that is applied on a schema. Requests to register new schema versions are checked against this rule by the Schema Registry before they can succeed.

A schema version that is marked as a checkpoint is used to determine the compatibility of registering new versions of a schema. When a schema first gets created the default checkpoint will be the first version. As the schema evolves with more versions, you can use the CLI/SDK to change the checkpoint to a version of a schema using the `UpdateSchema` API that adheres to a set of constraints. In the console, editing the schema definition or compatibility mode will change the checkpoint to the latest version by default.

Compatibility modes allow you to control how schemas can or cannot evolve over time. These modes form the contract between applications producing and consuming data. When a new version of a schema is submitted to the registry, the compatibility rule applied to the schema name

is used to determine if the new version can be accepted. There are 8 compatibility modes: NONE, DISABLED, BACKWARD, BACKWARD\_ALL, FORWARD, FORWARD\_ALL, FULL, FULL\_ALL.

In the Avro data format, fields may be optional or required. An optional field is one in which the Type includes null. Required fields do not have null as the Type.

In the Protobuf data format, fields can be optional (including repeated) or required in proto2 syntax, while all fields are optional (including repeated) in proto3 syntax. All compatibility rules are determined based on the understanding of the Protocol Buffers specifications as well as the guidance from the [Google Protocol Buffers documentation](#).

- *NONE*: No compatibility mode applies. You can use this choice in development scenarios or if you do not know the compatibility modes that you want to apply to schemas. Any new version added will be accepted without undergoing a compatibility check.
- *DISABLED*: This compatibility choice prevents versioning for a particular schema. No new versions can be added.
- *BACKWARD*: This compatibility choice is recommended because it allows consumers to read both the current and the previous schema version. You can use this choice to check compatibility against the previous schema version when you delete fields or add optional fields. A typical use case for BACKWARD is when your application has been created for the most recent schema.

## AVRO

For example, assume you have a schema defined by first name (required), last name (required), email (required), and phone number (optional).

If your next schema version removes the required email field, this would successfully register. BACKWARD compatibility requires consumers to be able to read the current and previous schema version. Your consumers will be able to read the new schema as the extra email field from old messages is ignored.

If you have a proposed new schema version that adds a required field, for example, zip code, this would not successfully register with BACKWARD compatibility. Your consumers on the new version would not be able to read old messages before the schema change, as they are missing the required zip code field. However, if the zip code field was set as optional in the new schema, then the proposed version would successfully register as consumers can read the old schema without the optional zip code field.

## JSON

For example, assume you have a schema version defined by first name (optional), last name (optional), email (optional) and phone number (optional).

If your next schema version adds the optional phone number property, this would successfully register as long as the original schema version does not allow any additional properties by setting the `additionalProperties` field to false. BACKWARD compatibility requires consumers to be able to read the current and previous schema version. Your consumers will be able to read data produced with the original schema where phone number property does not exist.

If you have a proposed new schema version that adds the optional phone number property, this would not successfully register with BACKWARD compatibility when the original schema version sets the `additionalProperties` field to true, namely allowing any additional property. Your consumers on the new version would not be able to read old messages before the schema change, as they cannot read data with phone number property in a different type, for example string instead of number.

## PROTOBUF

For example, assume you have a schema version defined by a Message Person with `first name` (required), `last name` (required), `email` (required), and `phone number` (optional) fields under proto2 syntax.

Similar to AVRO scenarios, if your next schema version removes the required `email` field, this would successfully register. BACKWARD compatibility requires consumers to be able to read the current and previous schema version. Your consumers will be able to read the new schema as the extra `email` field from old messages is ignored.

If you have a proposed new schema version that adds a required field, for example, `zip code`, this would not successfully register with BACKWARD compatibility. Your consumers on the new version would not be able to read old messages before the schema change, as they are missing the required `zip code` field. However, if the `zip code` field was set as optional in the new schema, then the proposed version would successfully register as consumers can read the old schema without the optional `zip code` field.

In case of a gRPC use case, adding new RPC service or RPC method is a backward compatible change. For example, assume you have a schema version defined by an RPC service `MyService` with two RPC methods `Foo` and `Bar`.

If your next schema version adds a new RPC method called Baz, this would successfully register. Your consumers will be able to read data produced with the original schema according to BACKWARD compatibility since the newly added RPC method Baz is optional.

If you have a proposed new schema version that removes the existing RPC method Foo, this would not successfully register with BACKWARD compatibility. Your consumers on the new version would not be able to read old messages before the schema change, as they cannot understand and read data with the non-existent RPC method Foo in a gRPC application.

- *BACKWARD\_ALL*: This compatibility choice allows consumers to read both the current and all previous schema versions. You can use this choice to check compatibility against all previous schema versions when you delete fields or add optional fields.
- *FORWARD*: This compatibility choice allows consumers to read both the current and the subsequent schema versions, but not necessarily later versions. You can use this choice to check compatibility against the last schema version when you add fields or delete optional fields. A typical use case for FORWARD is when your application has been created for a previous schema and should be able to process a more recent schema.

## AVRO

For example, assume you have a schema version defined by first name (required), last name (required), email (optional).

If you have a new schema version that adds a required field, e.g. phone number, this would successfully register. FORWARD compatibility requires consumers to be able to read data produced with the new schema by using the previous version.

If you have a proposed schema version that deletes the required first name field, this would not successfully register with FORWARD compatibility. Your consumers on the prior version would not be able to read the proposed schemas as they are missing the required first name field. However, if the first name field was originally optional, then the proposed new schema would successfully register as the consumers can read data based on the new schema that doesn't have the optional first name field.

## JSON

For example, assume you have a schema version defined by first name (optional), last name (optional), email (optional) and phone number (optional).

If you have a new schema version that removes the optional phone number property, this would successfully register as long as the new schema version does not allow any additional properties by setting the `additionalProperties` field to `false`. FORWARD compatibility requires consumers to be able to read data produced with the new schema by using the previous version.

If you have a proposed schema version that deletes the optional phone number property, this would not successfully register with FORWARD compatibility when the new schema version sets the `additionalProperties` field to `true`, namely allowing any additional property. Your consumers on the prior version would not be able to read the proposed schemas as they could have phone number property in a different type, for example string instead of number.

## PROTOBUF

For example, assume you have a schema version defined by a Message Person with `first name` (required), `last name` (required), `email` (optional) fields under proto2 syntax.

Similar to AVRO scenarios, if you have a new schema version that adds a required field, e.g. `phone number`, this would successfully register. FORWARD compatibility requires consumers to be able to read data produced with the new schema by using the previous version.

If you have a proposed schema version that deletes the required `first name` field, this would not successfully register with FORWARD compatibility. Your consumers on the prior version would not be able to read the proposed schemas as they are missing the required `first name` field. However, if the `first name` field was originally optional, then the proposed new schema would successfully register as the consumers can read data based on the new schema that doesn't have the optional `first name` field.

In case of a gRPC use case, removing an RPC service or RPC method is a forward-compatible change. For example, assume you have a schema version defined by an RPC service `MyService` with two RPC methods `Foo` and `Bar`.

If your next schema version deletes the existing RPC method named `Foo`, this would successfully register according to FORWARD compatibility as the consumers can read data produced with the new schema by using the previous version. If you have a proposed new schema version that adds an RPC method `Baz`, this would not successfully register with FORWARD compatibility. Your consumers on the prior version would not be able to read the proposed schemas as they are missing the RPC method `Baz`.

- **FORWARD\_ALL**: This compatibility choice allows consumers to read data written by producers of any new registered schema. You can use this choice when you need to add fields or delete optional fields, and check compatibility against all previous schema versions.
- **FULL**: This compatibility choice allows consumers to read data written by producers using the previous or next version of the schema, but not earlier or later versions. You can use this choice to check compatibility against the last schema version when you add or remove optional fields.
- **FULL\_ALL**: This compatibility choice allows consumers to read data written by producers using all previous schema versions. You can use this choice to check compatibility against all previous schema versions when you add or remove optional fields.

## Open source Serde libraries

AWS provides open-source Serde libraries as a framework for serializing and deserializing data. The open source design of these libraries allows common open-source applications and frameworks to support these libraries in their projects.

For more details on how the Serde libraries work, see [How the Schema Registry works](#).

## Quotas of the Schema Registry

Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account. The following are soft limits for the Schema Registry in AWS Glue.

### Schema version metadata key-value pairs

You can have up to 10 key-value pairs per SchemaVersion per AWS Region.

You can view or set the key-value metadata pairs using the [QuerySchemaVersionMetadata action \(Python: `query\_schema\_version\_metadata`\)](#) or [PutSchemaVersionMetadata action \(Python: `put\_schema\_version\_metadata`\)](#) APIs.

The following are hard limits for the Schema Registry in AWS Glue.

### Registries

You can have up to 100 registries per AWS Region for this account.

### SchemaVersion

You can have up to 10000 schema versions per AWS Region for this account.

Each new schema creates a new schema version, so you can theoretically have up to 10000 schemas per account per region, if each schema has only one version.

## Schema payloads

There is a size limit of 170KB for schema payloads.

## How the Schema Registry works

This section describes how the serialization and deserialization processes in Schema Registry work.

1. Register a schema: If the schema doesn't already exist in the registry, the schema can be registered with a schema name equal to the name of the destination (e.g., `test_topic`, `test_stream`, `prod_firehose`) or the producer can provide a custom name for the schema. Producers can also add key-value pairs to the schema as metadata, such as `source: msk_kafka_topic_A`, or apply AWS tags to schemas on schema creation. Once a schema is registered the Schema Registry returns the schema version ID to the serializer. If the schema exists but the serializer is using a new version that doesn't exist, the Schema Registry will check the schema reference a compatibility rule to ensure the new version is compatible before registering it as a new version.

There are two methods of registering a schema: manual registration and auto-registration. You can register a schema manually via the AWS Glue console or CLI/SDK.

When auto-registration is turned on in the serializer settings, automatic registration of the schema will be performed. If `REGISTRY_NAME` is not provided in the producer configurations, then auto-registration will register the new schema version under the default registry (default-registry). See [Installing SerDe Libraries](#) for information on specifying the auto-registration property.

2. Serializer validates data records against the schema: When the application producing data has registered its schema, the Schema Registry serializer validates the record being produced by the application is structured with the fields and data types matching a registered schema. If the schema of the record does not match a registered schema, the serializer will return an exception and the application will fail to deliver the record to the destination.

If no schema exists and if the schema name is not provided via the producer configurations, then the schema is created with the same name as the topic name (if Apache Kafka or Amazon MSK) or stream name (if Kinesis Data Streams).

Every record has a schema definition and data. The schema definition is queried against the existing schemas and versions in the Schema Registry.

By default, producers cache schema definitions and schema version IDs of registered schemas. If a record's schema version definition does not match what's available in cache, the producer will attempt to validate the schema with the Schema Registry. If the schema version is valid, then its version ID and definition will be cached locally on the producer.

You can adjust the default cache period (24 hours) within the optional producer properties in step #3 of [Installing SerDe Libraries](#).

3. **Serialize and deliver records:** If the record complies with the schema, the serializer decorates each record with the schema version ID, serializes the record based on the data format selected (AVRO, JSON, Protobuf, or other formats coming soon), compresses the record (optional producer configuration), and delivers it to the destination.
4. **Consumers deserialize the data:** Consumers reading this data use the Schema Registry deserializer library that parses the schema version ID from the record payload.
5. **Deserializer may request the schema from the Schema Registry:** If this is the first time the deserializer has seen records with a particular schema version ID, using the schema version ID the deserializer will request the schema from the Schema Registry and cache the schema locally on the consumer. If the Schema Registry cannot deserialize the record, the consumer can log the data from the record and move on, or halt the application.
6. **The deserializer uses the schema to deserialize the record:** When the deserializer retrieves the schema version ID from the Schema Registry, the deserializer decompresses the record (if record sent by producer is compressed) and uses the schema to deserialize the record. The application now processes the record.

 **Note**

**Encryption:** Your clients communicate with the Schema Registry via API calls which encrypt data in-transit using TLS encryption over HTTPS. Schemas stored in the Schema Registry are always encrypted at rest using a service-managed AWS Key Management Service (AWS KMS) key.

**Note**

User Authorization: The Schema Registry supports identity-based IAM policies.

## Getting started with Schema Registry

The following sections provide an overview and walk you through setting up and using Schema Registry. For information about Schema Registry concepts and components, see [AWS Glue Schema Registry](#).

### Topics

## Installing SerDe Libraries

**Note**

Prerequisites: Before completing the following steps, you will need to have a Amazon Managed Streaming for Apache Kafka (Amazon MSK) or Apache Kafka cluster running. Your producers and consumers need to be running on Java 8 or above.

The SerDe libraries provide a framework for serializing and deserializing data.

You will install the open source serializer for your applications producing data (collectively the "serializers"). The serializer handles serialization, compression, and the interaction with the Schema Registry. The serializer automatically extracts the schema from a record being written to a Schema Registry compatible destination, such as Amazon MSK. Likewise, you will install the open source deserializer on your applications consuming data.

To install the libraries on producers and consumers:

1. Inside both the producers' and consumers' pom.xml files, add this dependency via the code below:

```
<dependency>
  <groupId>software.amazon.glue</groupId>
  <artifactId>schema-registry-serde</artifactId>
  <version>1.1.5</version>
</dependency>
```

Alternatively, you can clone the [AWS Glue Schema Registry Github repository](#).

2. Setup your producers with these required properties:

```
props.put(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
  StringSerializer.class.getName()); // Can replace StringSerializer.class.getName()
with any other key serializer that you may use
props.put(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
  GlueSchemaRegistryKafkaSerializer.class.getName());
props.put(AWSSchemaRegistryConstants.AWS_REGION, "us-east-2");
properties.put(AWSSchemaRegistryConstants.DATA_FORMAT, "JSON"); // OR "AVRO"
```

If there are no existing schemas, then auto-registration needs to be turned on (next step). If you do have a schema that you would like to apply, then replace "my-schema" with your schema name. Also the "registry-name" has to be provided if schema auto-registration is off. If the schema is created under the "default-registry" then registry name can be omitted.

3. (Optional) Set any of these optional producer properties. For detailed property descriptions, see [the ReadMe file](#).

```
props.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, "true"); // If
not passed, uses "false"
```

```

props.put(AWSSchemaRegistryConstants.SCHEMA_NAME, "my-schema"); // If not passed,
  uses transport name (topic name in case of Kafka, or stream name in case of Kinesis
  Data Streams)
props.put(AWSSchemaRegistryConstants.REGISTRY_NAME, "my-registry"); // If not passed,
  uses "default-registry"
props.put(AWSSchemaRegistryConstants.CACHE_TIME_TO_LIVE_MILLIS, "86400000"); // If
  not passed, uses 86400000 (24 Hours)
props.put(AWSSchemaRegistryConstants.CACHE_SIZE, "10"); // default value is 200
props.put(AWSSchemaRegistryConstants.COMPATIBILITY_SETTING, Compatibility.FULL); //
  Pass a compatibility mode. If not passed, uses Compatibility.BACKWARD
props.put(AWSSchemaRegistryConstants.DESCRPTION, "This registry is used for several
  purposes."); // If not passed, constructs a description
props.put(AWSSchemaRegistryConstants.COMPRESSION_TYPE,
  AWSSchemaRegistryConstants.COMPRESSION.ZLIB); // If not passed, records are sent
  uncompressed

```

Auto-registration registers the schema version under the default registry ("default-registry"). If a `SCHEMA_NAME` is not specified in the previous step, then the topic name is inferred as `SCHEMA_NAME`.

See [Schema versioning and compatibility](#) for more information on compatibility modes.

#### 4. Setup your consumers with these required properties:

```

props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
  StringDeserializer.class.getName());
props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
  GlueSchemaRegistryKafkaDeserializer.class.getName());
props.put(AWSSchemaRegistryConstants.AWS_REGION, "us-east-2"); // Pass an AWS Region
props.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
  AvroRecordType.GENERIC_RECORD.getName()); // Only required for AVRO data format

```

#### 5. (Optional) Set these optional consumer properties. For detailed property descriptions, see [the ReadMe file](#).

```

properties.put(AWSSchemaRegistryConstants.CACHE_TIME_TO_LIVE_MILLIS, "86400000"); //
  If not passed, uses 86400000
props.put(AWSSchemaRegistryConstants.CACHE_SIZE, "10"); // default value is 200
props.put(AWSSchemaRegistryConstants.SECONDARY_DESERIALIZER,
  "com.amazonaws.services.schemaregistry.deserializers.external.ThirdPartyDeserializer"); //
  For migration fall back scenario

```

## Using AWS CLI for the AWS Glue Schema Registry APIs

To use the AWS CLI for the AWS Glue Schema Registry APIs, make sure to update your AWS CLI to the latest version.

### Creating a registry

You may use the default registry or create as many new registries as necessary using the AWS Glue APIs or AWS Glue console.

#### AWS Glue APIs

You can use these steps to perform this task using the AWS Glue APIs.

To add a new registry, use the [CreateRegistry action \(Python: create\\_registry\)](#) API. Specify `RegistryName` as the name of the registry to be created, with a max length of 255, containing only letters, numbers, hyphens, underscores, dollar signs, or hash marks.

Specify a `Description` as a string not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Optionally, specify one or more `Tags` for your registry, as a map array of key-value pairs.

```
aws glue create-registry --registry-name registryName1 --description description
```

When your registry is created it is assigned an Amazon Resource Name (ARN), which you can view in the `RegistryArn` of the API response. Now that you've created a registry, create one or more schemas for that registry.

#### AWS Glue console

To add a new registry in the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose **Add registry**.
4. Enter a **Registry name** for the registry, consisting of letters, numbers, hyphens, or underscores. This name cannot be changed.

5. Enter a **Description** (optional) for the registry.
6. Optionally, apply one or more tags to your registry. Choose **Add new tag** and specify a **Tag key** and optionally a **Tag value**.
7. Choose **Add registry**.

Schema registries > Add registry

## Add a new schema registry

Add a schema registry to store one or multiple new related schemas.

**Registry name**  
Name can't be changed post creation.

Only letters (A-Z), numbers (0-9), hyphens (-), underscores (\_), dollar signs (\$), or hash marks (#) allowed. 255 characters maximum.

**Description - optional**

2048 characters maximum.

**Registry tags - optional**  
No tags defined.

You can add up to 50 more tags.

When your registry is created it is assigned an Amazon Resource Name (ARN), which you can view by choosing the registry from the list in **Schema registries**. Now that you've created a registry, create one or more schemas for that registry.

## Dealing with a specific record (JAVA POJO) for JSON

You can use a plain old Java object (POJO) and pass the object as a record. This is similar to the notion of a specific record in AVRO. The [mbknor-jackson-jjsonschema](#) can generate a JSON schema for the POJO passed. This library can also inject additional information in the JSON schema.

The AWS Glue Schema Registry library uses the injected "className" field in schema to provide a fully classified class name. The "className" field is used by the deserializer to deserialize into an object of that class.

Example class :

```
@JsonSchemaDescription("This is a car")
@JsonSchemaTitle("Simple Car Schema")
@Builder
@AllArgsConstructor
@EqualsAndHashCode
// Fully qualified class name to be added to an additionally injected property
// called className for deserializer to determine which class to deserialize
// the bytes into
@JsonSchemaInject(
    strings = {@JsonSchemaString(path = "className",
        value =
            "com.amazonaws.services.schemaregistry.integrationtests.generators.Car")}
)
// List of annotations to help infer JSON Schema are defined by https://github.com/
mbknor/mbknor-jackson-jsonSchema
public class Car {
    @JsonProperty(required = true)
    private String make;

    @JsonProperty(required = true)
    private String model;

    @JsonSchemaDefault("true")
    @JsonProperty
    public boolean used;

    @JsonSchemaInject(ints = {@JsonSchemaInt(path = "multipleOf", value = 1000)})
    @Max(200000)
    @JsonProperty
    private int miles;

    @Min(2000)
    @JsonProperty
    private int year;

    @JsonProperty
    private Date purchaseDate;
```

```
@JsonProperty
@JsonFormat(shape = JsonFormat.Shape.NUMBER)
private Date listedDate;

@JsonProperty
private String[] owners;

@JsonProperty
private Collection<Float> serviceChecks;

// Empty constructor is required by Jackson to deserialize bytes
// into an Object of this class
public Car() {}
}
```

## Creating a schema

You can create a schema using the AWS Glue APIs or the AWS Glue console.

### AWS Glue APIs

You can use these steps to perform this task using the AWS Glue APIs.

To add a new schema, use the [CreateSchema action \(Python: create\\_schema\)](#) API.

Specify a `RegistryId` structure to indicate a registry for the schema. Or, omit the `RegistryId` to use the default registry.

Specify a `SchemaName` consisting of letters, numbers, hyphens, or underscores, and `DataFormat` as **AVRO** or **JSON**. `DataFormat` once set on a schema is not changeable.

Specify a `Compatibility` mode:

- *Backward (recommended)* — Consumer can read both current and previous version.
- *Backward all* — Consumer can read current and all previous versions.
- *Forward* — Consumer can read both current and subsequent version.
- *Forward all* — Consumer can read both current and all subsequent versions.
- *Full* — Combination of Backward and Forward.
- *Full all* — Combination of Backward all and Forward all.

- *None* — No compatibility checks are performed.
- *Disabled* — Prevent any versioning for this schema.

Optionally, specify Tags for your schema.

Specify a SchemaDefinition to define the schema in Avro, JSON, or Protobuf data format. See the examples.

For Avro data format:

```
aws glue create-schema --registry-id RegistryName="registryName1" --schema-name
testschema --compatibility NONE --data-format AVRO --schema-definition "{\"type\":
\\record\\", \\name\\": \\r1\\", \\fields\\": [ {\\name\\": \\f1\\", \\type\\": \\int\\",
{\\name\\": \\f2\\", \\type\\": \\string\\} ]}"
```

```
aws glue create-schema --registry-id RegistryArn="arn:aws:glue:us-
east-2:901234567890:registry/registryName1" --schema-name testschema --compatibility
NONE --data-format AVRO --schema-definition "{\"type\": \\record\\", \\name\\": \\r1\\",
\\fields\\": [ {\\name\\": \\f1\\", \\type\\": \\int\\", {\\name\\": \\f2\\", \\type\\":
\\string\\} ]}"
```

For JSON data format:

```
aws glue create-schema --registry-id RegistryName="registryName" --schema-name
testSchemaJson --compatibility NONE --data-format JSON --schema-definition "{\"$schema
\\": \\http://json-schema.org/draft-07/schema#\\", \\type\\": \\object\\", \\properties\\":
{\\f1\\": {\\type\\": \\string\\}}}"
```

```
aws glue create-schema --registry-id RegistryArn="arn:aws:glue:us-
east-2:901234567890:registry/registryName" --schema-name testSchemaJson --compatibility
NONE --data-format JSON --schema-definition "{\"$schema\\": \\http://json-schema.org/
draft-07/schema#\\", \\type\\": \\object\\", \\properties\\": {\\f1\\": {\\type\\": \\string\\}}}"
```

For Protobuf data format:

```
aws glue create-schema --registry-id RegistryName="registryName" --schema-name
testSchemaProtobuf --compatibility NONE --data-format PROTOBUF --schema-definition
"syntax = \\proto2\\";package org.test;message Basic { optional int32 basic = 1;}"
```

```
aws glue create-schema --registry-id RegistryArn="arn:aws:glue:us-
east-2:901234567890:registry/registryName" --schema-name testSchemaProtobuf
--compatibility NONE --data-format PROTOBUF --schema-definition "syntax =
\"proto2\";package org.test;message Basic { optional int32 basic = 1;}"
```

## AWS Glue console

To add a new schema using the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schemas**.
3. Choose **Add schema**.
4. Enter a **Schema name**, consisting of letters, numbers, hyphens, underscores, dollar signs, or hashmarks. This name cannot be changed.
5. Choose the **Registry** where the schema will be stored from the drop-down menu. The parent registry cannot be changed post-creation.
6. Leave the **Data format** as *Apache Avro* or *JSON*. This format applies to all versions of this schema.
7. Choose a **Compatibility mode**.
  - *Backward (recommended)* — receiver can read both current and previous versions.
  - *Backward All* — receiver can read current and all previous versions.
  - *Forward* — sender can write both current and previous versions.
  - *Forward All* — sender can write current and all previous versions.
  - *Full* — combination of Backward and Forward.
  - *Full All* — combination of Backward All and Forward All.
  - *None* — no compatibility checks performed.
  - *Disabled* — prevent any versioning for this schema.
8. Enter an optional **Description** for the registry of up to 250 characters.

Schemas &gt; Add schema

## Add a new schema

Specify your new schema name, properties, and schema definition.

## Schema name

Name can't be changed post creation.

Only letters (A-Z), numbers (0-9), hyphens (-), underscores (\_), dollar signs (\$), or hash marks (#) allowed. 255 characters maximum.

## Registry

Parent registry can't be changed post creation.

[Add new registry](#)

## Data format

Glue schemas only support Apache Avro for now, which offers the compatibility options below. [Learn more](#) 

## Compatibility mode

Compatibility may be changed post creation and affects data senders and/or receivers.

**Backward compatibility** [Learn more](#) 

This compatibility choice allows consumers to read both the current and the previous schema version. This means that for instance, a new schema version cannot drop data fields or change the type of these fields, so they can't be read by consumers using the previous version.

## Description - optional

2048 characters maximum.

9. Optionally, apply one or more tags to your schema. Choose **Add new tag** and specify a **Tag key** and optionally a **Tag value**.

10 In the **First schema version** box, enter or paste your initial schema. .

For Avro format, see [Working with Avro data format](#)

For JSON format, see [Working with JSON data format](#)

11. Optionally, choose **Add metadata** to add version metadata to annotate or classify your schema version.

12. Choose **Create schema and version**.

**Schema tags - optional**  
No tags defined.

[Add new tag](#)

You can add up to 50 more tags.

---

**First schema version**  
Please specify the initial definition of your schema below, so that it can be used in your applications or within Amazon Glue. You may change your schema definition by registering new versions at any point later.  
Please enter Apache Avro schema below. [Learn more](#) [↗](#)

1	
---	--

**Version metadata - optional**  
No metadata key-value pairs.

[Add metadata](#)

You can add 10 more metadata key-value pairs.

[Cancel](#) [Create schema and version](#)

The schema is created and appears in the list under **Schemas**.

## Working with Avro data format

Avro provides data serialization and data exchange services. Avro stores the data definition in JSON format making it easy to read and interpret. The data itself is stored in binary format.

For information on defining an Apache Avro schema, see the [Apache Avro specification](#).

## Working with JSON data format

Data can be serialized with JSON format. [JSON Schema format](#) defines the standard for JSON Schema format.

## Updating a schema or registry

Once created you can edit your schemas, schema versions, or registry.

### Updating a registry

You can update a registry using the AWS Glue APIs or the AWS Glue console. The name of an existing registry cannot be edited. You can edit the description for a registry.

### AWS Glue APIs

To update an existing registry, use the [UpdateRegistry action \(Python: update\\_registry\)](#) API.

Specify a `RegistryId` structure to indicate the registry that you want to update. Pass a `Description` to change the description for a registry.

```
aws glue update-registry --description updatedDescription --registry-id
RegistryArn="arn:aws:glue:us-east-2:901234567890:registry/registryName1"
```

### AWS Glue console

To update a registry using the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose a registry from the the list of registries, by checking its box.
4. In the **Action** menu, choose **Edit registry**.

## Updating a schema

You can update the description or compatibility setting for a schema.

To update an existing schema, use the [UpdateSchema action \(Python: `update\_schema`\)](#) API.

Specify a `SchemaId` structure to indicate the schema that you want to update. One of `VersionNumber` or `Compatibility` has to be provided.

Code example 11:

```
aws glue update-schema --description testDescription --schema-id
  SchemaName="testSchema1",RegistryName="registryName1" --schema-version-number
  LatestVersion=true --compatibility NONE
```

```
aws glue update-schema --description testDescription --schema-id
  SchemaArn="arn:aws:glue:us-east-2:901234567890:schema/registryName1/testSchema1" --
  schema-version-number LatestVersion=true --compatibility NONE
```

## Adding a schema version

When you add a schema version, you will need to compare the versions to make sure the new schema will be accepted.

To add a new version to an existing schema, use the [RegisterSchemaVersion action \(Python: `register\_schema\_version`\)](#) API.

Specify a `SchemaId` structure to indicate the schema for which you want to add a version, and a `SchemaDefinition` to define the schema.

Code example 12:

```
aws glue register-schema-version --schema-definition '{"type": "record", "name":
  "r1", "fields": [ {"name": "f1", "type": "int"}, {"name": "f2", "type
  ": "string"} ]}' --schema-id SchemaArn="arn:aws:glue:us-east-1:901234567890:schema/
  registryName/testschema"
```

```
aws glue register-schema-version --schema-definition '{"type": "record", "name":
  "r1", "fields": [ {"name": "f1", "type": "int"}, {"name": "f2", "type
  ": "string"} ]}' --schema-id SchemaName="testschema",RegistryName="testregistry"
```

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schemas**.
3. Choose the schema from the the list of schemas, by checking its box.
4. Choose one or more schemas from the list, by checking the boxes.
5. In the **Action** menu, choose **Register new version**.
6. In the **New version** box, enter or paste your new schema.
7. Choose **Compare with previous version** to see differences with the previous schema version.
8. Optionally, choose **Add metadata** to add version metadata to annotate or classify your schema version. Enter **Key** and optional **Value**.
9. Choose **Register version**.

Schemas &gt; test-1 &gt; Register version

## Register a new schema version

Register version 4 to your schema.

Schema name	test-1
Data format	Apache Avro
Compatibility mode	Backward compatibility
Schema tags	No tags defined.

## New Version 4

This is a copy of version 1's schema definition. A schema definition not associated with any existing schema versions must be defined in order to register a new schema version.

```

1  {
2    "type": "record",
3    "name": "r0",
4    "fields": [
5      {
6        "name": "f1",
7        "type": "int"
8      }
9    ]
10 }
```

[Compare with previous version](#)

## Version metadata - optional

No metadata key-value pairs.

[Add metadata](#)

You can add 10 more metadata key-value pairs.

[Cancel](#)
[Register version](#)

The schema(s) version appears in the list of versions. If the version changed the compatibility mode, the version will be marked as a checkpoint.

### Example of a schema version comparison

When you choose to **Compare with previous version**, you will see the previous and new versions displayed together. Changed information will be highlighted as follows:

- **Yellow:** indicates changed information.

- *Green*: indicates content added in the latest version.
- *Red*: indicates content removed in the latest version.

You can also compare against earlier versions.

## Deleting a schema or registry

Deleting a schema, a schema version, or a registry are permanent actions that cannot be undone.

### Deleting a schema

You may want to delete a schema when it will no longer be used within a registry, using the AWS Management Console, or the [DeleteSchema action \(Python: delete\\_schema\)](#) API.

Deleting one or more schemas is a permanent action that cannot be undone. Make sure that the schema or schemas are no longer needed.

To delete a schema from the registry, call the [DeleteSchema action \(Python: delete\\_schema\)](#) API, specifying the SchemaId structure to identify the schema.

For example:

```
aws glue delete-schema --schema-id SchemaArn="arn:aws:glue:us-east-2:901234567890:schema/registryName1/schemaname"
```

```
aws glue delete-schema --schema-id SchemaName="TestSchema6-deleteschemabyname",RegistryName="default-registry"
```

## AWS Glue console

To delete a schema from the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose the registry that contains your schema from the the list of registries.
4. Choose one or more schemas from the list, by checking the boxes.
5. In the **Action** menu, choose **Delete schema**.
6. Enter the text **Dele**te in the field to confirm deletion.
7. Choose **Delete**.

The schema(s) you specified are deleted from the registry.

## Deleting a schema version

As schemas accumulate in the registry, you may want to delete unwanted schema versions using the AWS Management Console, or the [DeleteSchemaVersions action \(Python: delete\\_schema\\_versions\)](#) API. Deleting one or more schema versions is a permanent action that cannot be undone. Make sure that the schema versions are no longer needed.

When deleting schema versions, take note of the following constraints:

- You cannot delete a check-pointed version.
- The range of contiguous versions cannot be more than 25.
- The latest schema version must not be in a pending state.

Specify the `SchemaId` structure to identify the schema, and specify `Versions` as a range of versions to delete. For more information on specifying a version or range of versions, see [DeleteRegistry action \(Python: delete\\_registry\)](#). The schema versions you specified are deleted from the registry.

Calling the [ListSchemaVersions action \(Python: list\\_schema\\_versions\)](#) API after this call will list the status of the deleted versions.

For example:

```
aws glue delete-schema-versions --schema-id
  SchemaName="TestSchema6",RegistryName="default-registry" --versions "1-1"
```

```
aws glue delete-schema-versions --schema-id SchemaArn="arn:aws:glue:us-
east-2:901234567890:schema/default-registry/TestSchema6-NON-Existent" --versions "1-1"
```

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose the registry that contains your schema from the the list of registries.
4. Choose one or more schemas from the list, by checking the boxes.
5. In the **Action** menu, choose **Delete schema**.
6. Enter the text **De1ete** in the field to confirm deletion.
7. Choose **Delete**.

The schema versions you specified are deleted from the registry.

## Deleting a registry

You may want to delete a registry when the schemas it contains should no longer be organized under that registry. You will need to reassign those schemas to another registry.

Deleting one or more registries is a permanent action that cannot be undone. Make sure that the registry or registries no longer needed.

The default registry can be deleted using the AWS CLI.

## AWS Glue API

To delete the entire registry including the schema and all of its versions, call the [DeleteRegistry action \(Python: delete\\_registry\)](#) API. Specify a RegistryId structure to identify the registry.

For example:

```
aws glue delete-registry --registry-id RegistryArn="arn:aws:glue:us-east-2:901234567890:registry/registryName1"
```

```
aws glue delete-registry --registry-id RegistryName="TestRegistry-deletebyname"
```

To get the status of the delete operation, you can call the GetRegistry API after the asynchronous call.

## AWS Glue console

To delete a registry from the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Schema registries**.
3. Choose a registry from the list, by checking a box.
4. In the **Action** menu, choose **Delete registry**.
5. Enter the text **De1ete** in the field to confirm deletion.
6. Choose **Delete**.

The registries you selected are deleted from AWS Glue.

## IAM examples for serializers

### Note

AWS managed policies grant necessary permissions for common use cases. For information on using managed policies to manage the schema registry, see [AWS managed \(predefined\) policies for AWS Glue](#).

For serializers, you should create a minimal policy similar to that below to give you the ability to find the schemaVersionId for a given schema definition. Note, you should have read permissions

on the registry in order to read the schemas in the registry. You can limit the registries that can be read by using the `Resource` clause.

#### Code example 13:

```
{
  "Sid" : "GetSchemaByDefinition",
  "Effect" : "Allow",
  "Action" :
  [
    "glue:GetSchemaByDefinition"
  ],
  "Resource" : ["arn:aws:glue:us-east-2:012345678:registry/registryname-1",
                "arn:aws:glue:us-east-2:012345678:schema/registryname-1/
schemaname-1",
                "arn:aws:glue:us-east-2:012345678:schema/registryname-1/
schemaname-2"
                ]
}
```

Further, you can also allow producers to create new schemas and versions by including the following extra methods. Note, you should be able to inspect the registry in order to add/remove/evolve the schemas inside it. You can limit the registries that can be inspected by using the `Resource` clause.

#### Code example 14:

```
{
  "Sid" : "RegisterSchemaWithMetadata",
  "Effect" : "Allow",
  "Action" :
  [
    "glue:GetSchemaByDefinition",
    "glue:CreateSchema",
    "glue:RegisterSchemaVersion",
    "glue:PutSchemaVersionMetadata",
  ],
  "Resource" : ["arn:aws:glue:aws-region:123456789012:registry/registryname-1",
                "arn:aws:glue:aws-region:123456789012:schema/registryname-1/
schemaname-1",
                "arn:aws:glue:aws-region:123456789012:schema/registryname-1/
schemaname-2"
                ]
}
```

```
}
```

## IAM examples for deserializers

For deserializers (consumer side), you should create a policy similar to that below to allow the deserializer to fetch the schema from the Schema Registry for deserialization. Note, you should be able to inspect the registry in order to fetch the schemas inside it.

Code example 15:

```
{
  "Sid" : "GetSchemaVersion",
  "Effect" : "Allow",
  "Action" :
  [
    "glue:GetSchemaVersion"
  ],
  "Resource" : ["*"]
}
```

## Private connectivity using AWS PrivateLink

You can use AWS PrivateLink to connect your data producer's VPC to AWS Glue by defining an interface VPC endpoint for AWS Glue. When you use a VPC interface endpoint, communication between your VPC and AWS Glue is conducted entirely within the AWS network. For more information, see [Using AWS Glue with VPC Endpoints](#).

## Accessing Amazon CloudWatch metrics

Amazon CloudWatch metrics are available as part of CloudWatch's free tier. You can access these metrics in the CloudWatch Console. API-Level metrics include CreateSchema (Success and Latency), GetSchemaByDefinition, (Success and Latency), GetSchemaVersion (Success and Latency), RegisterSchemaVersion (Success and Latency), PutSchemaVersionMetadata (Success and Latency). Resource-level metrics include Registry.ThrottledByLimit, SchemaVersion.ThrottledByLimit, SchemaVersion.Size.

## Sample AWS CloudFormation template for Schema Registry

The following is a sample template for creating Schema Registry resources in AWS CloudFormation. To create this stack in your account, copy the above template into a file `SampleTemplate.yaml`, and run the following command:

```
aws cloudformation create-stack --stack-name ABCSchemaRegistryStack --template-body
'cat SampleTemplate.yaml'
```

This example uses `AWS::Glue::Registry` to create a registry, `AWS::Glue::Schema` to create a schema, `AWS::Glue::SchemaVersion` to create a schema version, and `AWS::Glue::SchemaVersionMetadata` to populate schema version metadata.

```
Description: "A sample CloudFormation template for creating Schema Registry resources."
```

```
Resources:
```

```
ABCRegistry:
```

```
  Type: "AWS::Glue::Registry"
```

```
  Properties:
```

```
    Name: "ABCSchemaRegistry"
```

```
    Description: "ABC Corp. Schema Registry"
```

```
    Tags:
```

```
      - Key: "Project"
```

```
        Value: "Foo"
```

```

  Properties:
    SchemaVersionId: !Ref SecondSchemaVersion
    Key: "Application"
    Value: "Kinesis"
```

## Integrating with AWS Glue Schema Registry

These sections describe integrations with AWS Glue Schema Registry. The examples in these section show a schema with AVRO data format. For more examples, including schemas with JSON data format, see the integration tests and ReadMe information in the [AWS Glue Schema Registry open source repository](#).

### Topics

- [Use case: Connecting Schema Registry to Amazon MSK or Apache Kafka](#)
- [Use case: Integrating Amazon Kinesis Data Streams with the AWS Glue Schema Registry](#)
- [Use case: Amazon Managed Service for Apache Flink](#)
- [Use Case: Integration with AWS Lambda](#)
- [Use case: AWS Glue Data Catalog](#)
- [Use case: AWS Glue streaming](#)
- [Use case: Apache Kafka Streams](#)
- [Use case: Apache Kafka Connect](#)

### Use case: Connecting Schema Registry to Amazon MSK or Apache Kafka

Let's assume you are writing data to an Apache Kafka topic, and you can follow these steps to get started.

1. Create an Amazon Managed Streaming for Apache Kafka (Amazon MSK) or Apache Kafka cluster with at least one topic. If creating an Amazon MSK cluster, you can use the AWS Management

Console. Follow these instructions: [Getting Started Using Amazon MSK](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

2. Follow the [Installing SerDe Libraries](#) step above.
3. To create schema registries, schemas, or schema versions, follow the instructions under the [Getting started with Schema Registry](#) section of this document.
4. Start your producers and consumers to use the Schema Registry to write and read records to/from the Amazon MSK or Apache Kafka topic. Example producer and consumer code can be found in [the ReadMe file](#) from the Serde libraries. The Schema Registry library on the producer will automatically serialize the record and decorate the record with a schema version ID.
5. If the schema of this record has been inputted, or if auto-registration is turned on, then the schema will have been registered in the Schema Registry.
6. The consumer reading from the Amazon MSK or Apache Kafka topic, using the AWS Glue Schema Registry library, will automatically lookup the schema from the Schema Registry.

## Use case: Integrating Amazon Kinesis Data Streams with the AWS Glue Schema Registry

This integration requires that you have an existing Amazon Kinesis data stream. For more information, see [Getting Started with Amazon Kinesis Data Streams](#) in the *Amazon Kinesis Data Streams Developer Guide*.

There are two ways that you can interact with data in a Kinesis data stream.

- Through the Kinesis Producer Library (KPL) and Kinesis Client Library (KCL) libraries in Java. Multi-language support is not provided.
- Through the `PutRecords`, `PutRecord`, and `GetRecords` Kinesis Data Streams APIs available in the AWS SDK for Java.

If you currently use the KPL/KCL libraries, we recommend continuing to use that method. There are updated KCL and KPL versions with Schema Registry integrated, as shown in the examples. Otherwise, you can use the sample code to leverage the AWS Glue Schema Registry if using the KDS APIs directly.

Schema Registry integration is only available with KPL v0.14.2 or later and with KCL v2.3 or later. Schema Registry integration with JSON data format is available with KPL v0.14.8 or later and with KCL v2.3.6 or later.

## Interacting with Data Using Kinesis SDK V2

This section describes interacting with Kinesis using Kinesis SDK V2

```
// Example JSON Record, you can construct a AVRO record also
private static final JsonDataWithSchema record =
    JsonDataWithSchema.builder(schemaString, payloadString);
private static final DataFormat dataFormat = DataFormat.JSON;

//Configurations for Schema Registry
GlueSchemaRegistryConfiguration gsrConfig = new GlueSchemaRegistryConfiguration("us-
east-1");

GlueSchemaRegistrySerializer glueSchemaRegistrySerializer =
    new GlueSchemaRegistrySerializerImpl(awsCredentialsProvider, gsrConfig);
GlueSchemaRegistryDataFormatSerializer dataFormatSerializer =
    new GlueSchemaRegistrySerializerFactory().getInstance(dataFormat, gsrConfig);

Schema gsrSchema =
    new Schema(dataFormatSerializer.getSchemaDefinition(record), dataFormat.name(),
    "MySchema");

byte[] serializedBytes = dataFormatSerializer.serialize(record);

byte[] gsrEncodedBytes = glueSchemaRegistrySerializer.encode(streamName, gsrSchema,
    serializedBytes);

PutRecordRequest putRecordRequest = PutRecordRequest.builder()
    .streamName(streamName)
    .partitionKey("partitionKey")
    .data(SdkBytes.fromByteArray(gsrEncodedBytes))
    .build();
shardId = kinesisClient.putRecord(putRecordRequest)
    .get()
    .shardId();

GlueSchemaRegistryDeserializer glueSchemaRegistryDeserializer = new
    GlueSchemaRegistryDeserializerImpl(awsCredentialsProvider, gsrConfig);

GlueSchemaRegistryDataFormatDeserializer gsrDataFormatDeserializer =
    glueSchemaRegistryDeserializerFactory.getInstance(dataFormat, gsrConfig);

GetShardIteratorRequest getShardIteratorRequest = GetShardIteratorRequest.builder()
    .streamName(streamName)
```

```

        .shardId(shardId)
        .shardIteratorType(ShardIteratorType.TRIM_HORIZON)
        .build();

String shardIterator = kinesisClient.getShardIterator(getShardIteratorRequest)
    .get()
    .shardIterator();

GetRecordsRequest getRecordRequest = GetRecordsRequest.builder()
    .shardIterator(shardIterator)
    .build();
GetRecordsResponse recordsResponse = kinesisClient.getRecords(getRecordRequest)
    .get();

List<Object> consumerRecords = new ArrayList<>();
List<Record> recordsFromKinesis = recordsResponse.records();

for (int i = 0; i < recordsFromKinesis.size(); i++) {
    byte[] consumedBytes = recordsFromKinesis.get(i)
        .data()
        .asByteArray();

    Schema gsrSchema = glueSchemaRegistryDeserializer.getSchema(consumedBytes);
    Object decodedRecord =
gsrDataFormatDeserializer.deserialize(ByteBuffer.wrap(consumedBytes),

gsrSchema.getSchemaDefinition());
    consumerRecords.add(decodedRecord);
}

```

## Interacting with data using the KPL/KCL libraries

This section describes integrating Kinesis Data Streams with Schema Registry using the KPL/KCL libraries. For more information on using KPL/KCL, see [Developing Producers Using the Amazon Kinesis Producer Library](#) in the *Amazon Kinesis Data Streams Developer Guide*.

### Setting up the Schema Registry in KPL

1. Define the schema definition for the data, data format and schema name authored in the AWS Glue Schema Registry.
2. Optionally configure the `GlueSchemaRegistryConfiguration` object.
3. Pass the schema object to the `addUserRecord` API.

```
private static final String SCHEMA_DEFINITION = "{\"namespace\": \"example.avro\",\\n\"
+ \" \"type\": \"record\",\\n\"
+ \" \"name\": \"User\",\\n\"
+ \" \"fields\": [\\n\"
+ \" {\"name\": \"name\", \"type\": \"string\"},\\n\"
+ \" {\"name\": \"favorite_number\", \"type\": [\"int\", \"null\"]},\\n\"
+ \" {\"name\": \"favorite_color\", \"type\": [\"string\", \"null\"]}\\n\"
+ \" ]\\n\"
+ \"}\";
```

```
KinesisProducerConfiguration config = new KinesisProducerConfiguration();
config.setRegion("us-west-1")
```

```
//[Optional] configuration for Schema Registry.
```

```
GlueSchemaRegistryConfiguration schemaRegistryConfig =
new GlueSchemaRegistryConfiguration("us-west-1");
```

```
schemaRegistryConfig.setCompression(true);
```

```
config.setGlueSchemaRegistryConfiguration(schemaRegistryConfig);
```

```
///Optional configuration ends.
```

```
final KinesisProducer producer =
    new KinesisProducer(config);
```

```
final ByteBuffer data = getDataToSend();
```

```
com.amazonaws.services.schemaregistry.common.Schema gsrSchema =
    new Schema(SCHEMA_DEFINITION, DataFormat.AVRO.toString(), "demoSchema");
```

```
ListenableFuture<UserRecordResult> f = producer.addUserRecord(
config.getStreamName(), TIMESTAMP, Utils.randomExplicitHashKey(), data, gsrSchema);
```

```
private static ByteBuffer getDataToSend() {
    org.apache.avro.Schema avroSchema =
        new org.apache.avro.Schema.Parser().parse(SCHEMA_DEFINITION);
```

```
    GenericRecord user = new GenericData.Record(avroSchema);
    user.put("name", "Emily");
    user.put("favorite_number", 32);
    user.put("favorite_color", "green");
```

```

    ByteArrayOutputStream outBytes = new ByteArrayOutputStream();
    Encoder encoder = EncoderFactory.get().directBinaryEncoder(outBytes, null);
    new GenericDatumWriter<>(avroSchema).write(user, encoder);
    encoder.flush();
    return ByteBuffer.wrap(outBytes.toByteArray());
}

```

## Setting up the Kinesis client library

You will develop your Kinesis Client Library consumer in Java. For more information, see [Developing a Kinesis Client Library Consumer in Java](#) in the *Amazon Kinesis Data Streams Developer Guide*.

1. Create an instance of `GlueSchemaRegistryDeserializer` by passing a `GlueSchemaRegistryConfiguration` object.
2. Pass the `GlueSchemaRegistryDeserializer` to `retrievalConfig.glueSchemaRegistryDeserializer`.
3. Access the schema of incoming messages by calling `kinesisClientRecord.getSchema()`.

```

GlueSchemaRegistryConfiguration schemaRegistryConfig =
    new GlueSchemaRegistryConfiguration(this.region.toString());

GlueSchemaRegistryDeserializer glueSchemaRegistryDeserializer =
    new
    GlueSchemaRegistryDeserializerImpl(DefaultCredentialsProvider.builder().build(),
    schemaRegistryConfig);

RetrievalConfig retrievalConfig =
    configsBuilder.retrievalConfig().retrievalSpecificConfig(new
    PollingConfig(streamName, kinesisClient));
retrievalConfig.glueSchemaRegistryDeserializer(glueSchemaRegistryDeserializer);

Scheduler scheduler = new Scheduler(
    configsBuilder.checkpointConfig(),
    configsBuilder.coordinatorConfig(),
    configsBuilder.leaseManagementConfig(),
    configsBuilder.lifecycleConfig(),
    configsBuilder.metricsConfig(),
    configsBuilder.processorConfig(),
    retrievalConfig

```

```

    );

    public void processRecords(ProcessRecordsInput processRecordsInput) {
        MDC.put(SHARD_ID_MDC_KEY, shardId);
        try {
            log.info("Processing {} record(s)",
                processRecordsInput.records().size());
            processRecordsInput.records()
                .forEach(
                    r ->
                        log.info("Processed record pk: {} -- Seq: {} : data {} with
schema: {}",
                            r.partitionKey(),
                            r.sequenceNumber(), recordToAvroObj(r).toString(), r.getSchema());
                } catch (Throwable t) {
                    log.error("Caught throwable while processing records. Aborting.");
                    Runtime.getRuntime().halt(1);
                } finally {
                    MDC.remove(SHARD_ID_MDC_KEY);
                }
        }
    }

    private GenericRecord recordToAvroObj(KinesisClientRecord r) {
        byte[] data = new byte[r.data().remaining()];
        r.data().get(data, 0, data.length);
        org.apache.avro.Schema schema = new
        org.apache.avro.Schema.Parser().parse(r.schema().getSchemaDefinition());
        DatumReader datumReader = new GenericDatumReader<>(schema);

        BinaryDecoder binaryDecoder = DecoderFactory.get().binaryDecoder(data, 0,
        data.length, null);
        return (GenericRecord) datumReader.read(null, binaryDecoder);
    }
}

```

## Interacting with data using the Kinesis Data Streams APIs

This section describes integrating Kinesis Data Streams with Schema Registry using the Kinesis Data Streams APIs.

### 1. Update these Maven dependencies:

```
<dependencyManagement>
```

```

    <dependencies>
      <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>aws-java-sdk-bom</artifactId>
        <version>1.11.884</version>
        <type>pom</type>
        <scope>import</scope>
      </dependency>
    </dependencies>
  </dependencyManagement>

  <dependencies>
    <dependency>
      <groupId>com.amazonaws</groupId>
      <artifactId>aws-java-sdk-kinesis</artifactId>
    </dependency>

    <dependency>
      <groupId>software.amazon.glue</groupId>
      <artifactId>schema-registry-serde</artifactId>
      <version>1.1.5</version>
    </dependency>

    <dependency>
      <groupId>com.fasterxml.jackson.dataformat</groupId>
      <artifactId>jackson-dataformat-cbor</artifactId>
      <version>2.11.3</version>
    </dependency>
  </dependencies>

```

2. In the producer, add schema header information using the PutRecords or PutRecord API in Kinesis Data Streams.

```

//The following lines add a Schema Header to the record
    com.amazonaws.services.schemaregistry.common.Schema awsSchema =
        new com.amazonaws.services.schemaregistry.common.Schema(schemaDefinition,
            DataFormat.AVRO.name(),
                schemaName);
    GlueSchemaRegistrySerializerImpl glueSchemaRegistrySerializer =
        new
        GlueSchemaRegistrySerializerImpl(DefaultCredentialsProvider.builder().build(), new
        GlueSchemaRegistryConfiguration(getConfigs()));
    byte[] recordWithSchemaHeader =

```

```
glueSchemaRegistrySerializer.encode(streamName, awsSchema,
recordAsBytes);
```

3. In the producer, use the PutRecords or PutRecord API to put the record into the data stream.
4. In the consumer, remove the schema record from the header, and serialize an Avro schema record.

```
//The following lines remove Schema Header from record
    GlueSchemaRegistryDeserializerImpl glueSchemaRegistryDeserializer =
        new
GlueSchemaRegistryDeserializerImpl(DefaultCredentialsProvider.builder().build(),
getConfigs());
    byte[] recordWithSchemaHeaderBytes = new
byte[recordWithSchemaHeader.remaining()];
    recordWithSchemaHeader.get(recordWithSchemaHeaderBytes, 0,
recordWithSchemaHeaderBytes.length);
    com.amazonaws.services.schemaregistry.common.Schema awsSchema =
        glueSchemaRegistryDeserializer.getSchema(recordWithSchemaHeaderBytes);
    byte[] record =
glueSchemaRegistryDeserializer.getData(recordWithSchemaHeaderBytes);

    //The following lines serialize an AVRO schema record
    if (DataFormat.AVRO.name().equals(awsSchema.getDataFormat())) {
        Schema avroSchema = new
org.apache.avro.Schema.Parser().parse(awsSchema.getSchemaDefinition());
        Object genericRecord = convertBytesToRecord(avroSchema, record);
        System.out.println(genericRecord);
    }
```

## Interacting with data using the Kinesis Data Streams APIs

The following is example code for using the PutRecords and GetRecords APIs.

```
//Full sample code
import
com.amazonaws.services.schemaregistry.deserializers.GlueSchemaRegistryDeserializerImpl;
import
com.amazonaws.services.schemaregistry.serializers.GlueSchemaRegistrySerializerImpl;
import com.amazonaws.services.schemaregistry.utils.AVROUtils;
import com.amazonaws.services.schemaregistry.utils.AWSSchemaRegistryConstants;
import org.apache.avro.Schema;
import org.apache.avro.generic.GenericData;
```

```
import org.apache.avro.generic.GenericDatumReader;
import org.apache.avro.generic.GenericDatumWriter;
import org.apache.avro.generic.GenericRecord;
import org.apache.avro.io.Decoder;
import org.apache.avro.io.DecoderFactory;
import org.apache.avro.io.Encoder;
import org.apache.avro.io.EncoderFactory;
import software.amazon.awssdk.auth.credentials.DefaultCredentialsProvider;
import software.amazon.awssdk.services.glue.model.DataFormat;

import java.io.ByteArrayOutputStream;
import java.io.File;
import java.io.IOException;
import java.nio.ByteBuffer;
import java.util.Collections;
import java.util.HashMap;
import java.util.Map;

public class PutAndGetExampleWithEncodedData {
    static final String regionName = "us-east-2";
    static final String streamName = "testStream1";
    static final String schemaName = "User-Topic";
    static final String AVRO_USER_SCHEMA_FILE = "src/main/resources/user.avsc";
    KinesisApi kinesisApi = new KinesisApi();

    void runSampleForPutRecord() throws IOException {
        Object testRecord = getTestRecord();
        byte[] recordAsBytes = convertRecordToBytes(testRecord);
        String schemaDefinition =
AVROUtils.getInstance().getSchemaDefinition(testRecord);

        //The following lines add a Schema Header to a record
        com.amazonaws.services.schemaregistry.common.Schema awsSchema =
            new com.amazonaws.services.schemaregistry.common.Schema(schemaDefinition,
DataFormat.AVRO.name(),
                schemaName);
        GlueSchemaRegistrySerializerImpl glueSchemaRegistrySerializer =
            new
GlueSchemaRegistrySerializerImpl(DefaultCredentialsProvider.builder().build(), new
GlueSchemaRegistryConfiguration(regionName));
        byte[] recordWithSchemaHeader =
            glueSchemaRegistrySerializer.encode(streamName, awsSchema, recordAsBytes);
    }
}
```

```

    //Use PutRecords api to pass a list of records
    kinesisApi.putRecords(Collections.singletonList(recordWithSchemaHeader),
streamName, regionName);

    //OR
    //Use PutRecord api to pass single record
    //kinesisApi.putRecord(recordWithSchemaHeader, streamName, regionName);
}

byte[] runSampleForGetRecord() throws IOException {
    ByteBuffer recordWithSchemaHeader = kinesisApi.getRecords(streamName,
regionName);

    //The following lines remove the schema registry header
    GlueSchemaRegistryDeserializerImpl glueSchemaRegistryDeserializer =
        new
GlueSchemaRegistryDeserializerImpl(DefaultCredentialsProvider.builder().build(), new
GlueSchemaRegistryConfiguration(regionName));
    byte[] recordWithSchemaHeaderBytes = new
byte[recordWithSchemaHeader.remaining()];
    recordWithSchemaHeader.get(recordWithSchemaHeaderBytes, 0,
recordWithSchemaHeaderBytes.length);

    com.amazonaws.services.schemaregistry.common.Schema awsSchema =
        glueSchemaRegistryDeserializer.getSchema(recordWithSchemaHeaderBytes);

    byte[] record =
glueSchemaRegistryDeserializer.getData(recordWithSchemaHeaderBytes);

    //The following lines serialize an AVRO schema record
    if (DataFormat.AVRO.name().equals(awsSchema.getDataFormat())) {
        Schema avroSchema = new
org.apache.avro.Schema.Parser().parse(awsSchema.getSchemaDefinition());
        Object genericRecord = convertBytesToRecord(avroSchema, record);
        System.out.println(genericRecord);
    }

    return record;
}

private byte[] convertRecordToBytes(final Object record) throws IOException {
    ByteArrayOutputStream recordAsBytes = new ByteArrayOutputStream();
    Encoder encoder = EncoderFactory.get().directBinaryEncoder(recordAsBytes,
null);

```

```
        GenericDatumWriter datumWriter = new
GenericDatumWriter<>(AVROUtils.getInstance().getSchema(record));
        datumWriter.write(record, encoder);
        encoder.flush();
        return recordAsBytes.toByteArray();
    }

    private GenericRecord convertBytesToRecord(Schema avroSchema, byte[] record) throws

        final GenericDatumReader<GenericRecord> datumReader = new
GenericDatumReader<>(avroSchema);
        Decoder decoder = DecoderFactory.get().binaryDecoder(record, null);
        GenericRecord genericRecord = datumReader.read(null, decoder);
        return genericRecord;
    }

    private Map<String, String> getMetadata() {
        Map<String, String> metadata = new HashMap<>();
        metadata.put("event-source-1", "topic1");
        metadata.put("event-source-2", "topic2");
        metadata.put("event-source-3", "topic3");
        metadata.put("event-source-4", "topic4");
        metadata.put("event-source-5", "topic5");
        return metadata;
    }

    private GlueSchemaRegistryConfiguration getConfigs() {
        GlueSchemaRegistryConfiguration configs = new
GlueSchemaRegistryConfiguration(regionName);
        configs.setSchemaName(schemaName);
        configs.setAutoRegistration(true);
        configs.setMetadata(getMetadata());
        return configs;
    }

    private Object getTestRecord() throws IOException {
        GenericRecord genericRecord;
        Schema.Parser parser = new Schema.Parser();
        Schema avroSchema = parser.parse(new File(AVRO_USER_SCHEMA_FILE));

        genericRecord = new GenericData.Record(avroSchema);
        genericRecord.put("name", "testName");
        genericRecord.put("favorite_number", 99);
        genericRecord.put("favorite_color", "red");
    }
}
```

```
        return genericRecord;  
    }  
}
```

## Use case: Amazon Managed Service for Apache Flink

Apache Flink is a popular open source framework and distributed processing engine for stateful computations over unbounded and bounded data streams. Amazon Managed Service for Apache Flink is a fully managed AWS service that enables you to build and manage Apache Flink applications to process streaming data.

Open source Apache Flink provides a number of sources and sinks. For example, predefined data sources include reading from files, directories, and sockets, and ingesting data from collections and iterators. Apache Flink DataStream Connectors provide code for Apache Flink to interface with various third-party systems, such as Apache Kafka or Kinesis as sources and/or sinks.

For more information, see [Amazon Kinesis Data Analytics Developer Guide](#).

### Apache Flink Kafka connector

Apache Flink provides an Apache Kafka data stream connector for reading data from and writing data to Kafka topics with exactly-once guarantees. Flink's Kafka consumer, `FlinkKafkaConsumer`, provides access to read from one or more Kafka topics. Apache Flink's Kafka Producer, `FlinkKafkaProducer`, allows writing a stream of records to one or more Kafka topics. For more information, see [Apache Kafka Connector](#).

### Apache Flink Kinesis streams Connector

The Kinesis data stream connector provides access to Amazon Kinesis Data Streams. The `FlinkKinesisConsumer` is an exactly-once parallel streaming data source that subscribes to multiple Kinesis streams within the same AWS service region, and can transparently handle re-sharding of streams while the job is running. Each subtask of the consumer is responsible for fetching data records from multiple Kinesis shards. The number of shards fetched by each subtask will change as shards are closed and created by Kinesis. The `FlinkKinesisProducer` uses Kinesis Producer Library (KPL) to put data from an Apache Flink stream into a Kinesis stream. For more information, see [Amazon Kinesis Streams Connector](#).

For more information, see the [AWS Glue Schema Github repository](#).

## Integrating with Apache Flink

The SerDes library provided with Schema Registry integrates with Apache Flink. To work with Apache Flink, you are required to implement [SerializationSchema](#) and [DeserializationSchema](#) interfaces called `GlueSchemaRegistryAvroSerializationSchema` and `GlueSchemaRegistryAvroDeserializationSchema`, which you can plug into Apache Flink connectors.

### Adding an AWS Glue Schema Registry dependency into the Apache Flink application

To set up the integration dependencies to AWS Glue Schema Registry in the Apache Flink application:

1. Add the dependency to the `pom.xml` file.

```
<dependency>
  <groupId>software.amazon.glue</groupId>
  <artifactId>schema-registry-flink-serde</artifactId>
  <version>1.0.0</version>
</dependency>
```

## Integrating Kafka or Amazon MSK with Apache Flink

You can use Managed Service for Apache Flink for Apache Flink, with Kafka as a source or Kafka as a sink.

### Kafka as a source

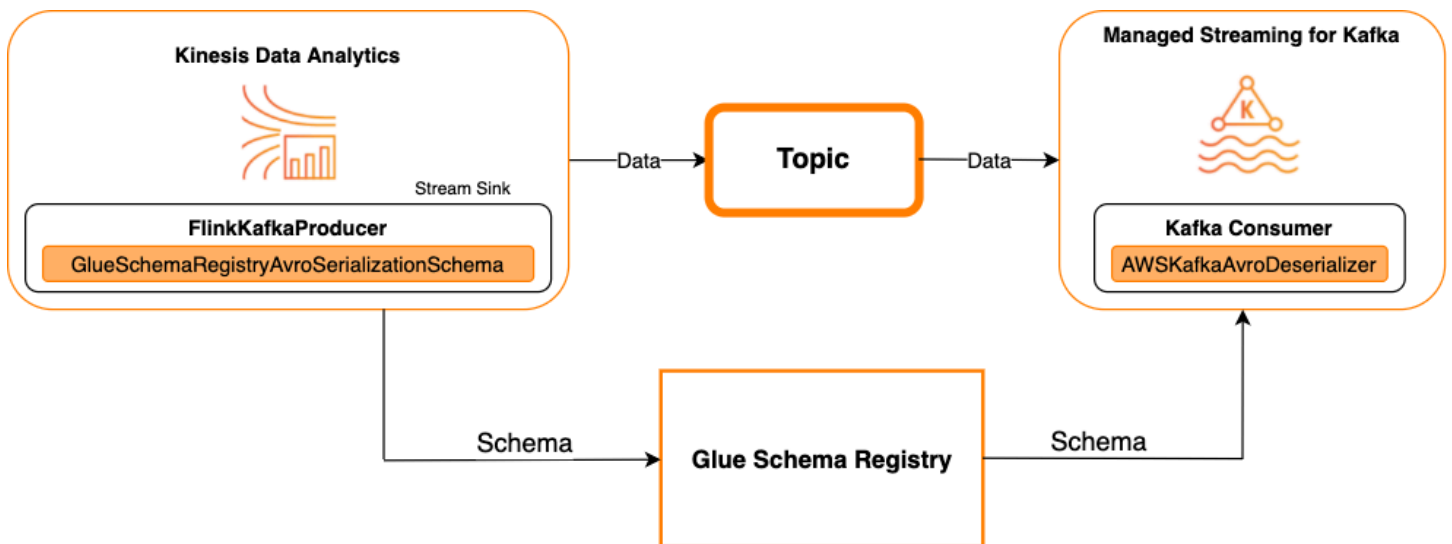

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kafka as a source.

## Kafka as a sink

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kafka as a sink.

To integrate Kafka (or Amazon MSK) with Managed Service for Apache Flink for Apache Flink, with Kafka as a source or Kafka as a sink, make the code changes below. Add the bolded code blocks to your respective code in the analogous sections.

If Kafka is the source, then use the deserializer code (block 2). If Kafka is the sink, use the serializer code (block 3).

```
StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
```

```
String topic = "topic";
Properties properties = new Properties();
properties.setProperty("bootstrap.servers", "localhost:9092");
properties.setProperty("group.id", "test");

// block 1
Map<String, Object> configs = new HashMap<>();
configs.put(AWSSchemaRegistryConstants.AWS_REGION, "aws-region");
configs.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, true);
configs.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
    AvroRecordType.GENERIC_RECORD.getName());

FlinkKafkaConsumer<GenericRecord> consumer = new FlinkKafkaConsumer<>(
    topic,
    // block 2
    GlueSchemaRegistryAvroDeserializationSchema.forGeneric(schema, configs),
    properties);

FlinkKafkaProducer<GenericRecord> producer = new FlinkKafkaProducer<>(
    topic,
    // block 3
    GlueSchemaRegistryAvroSerializationSchema.forGeneric(schema, topic, configs),
    properties);

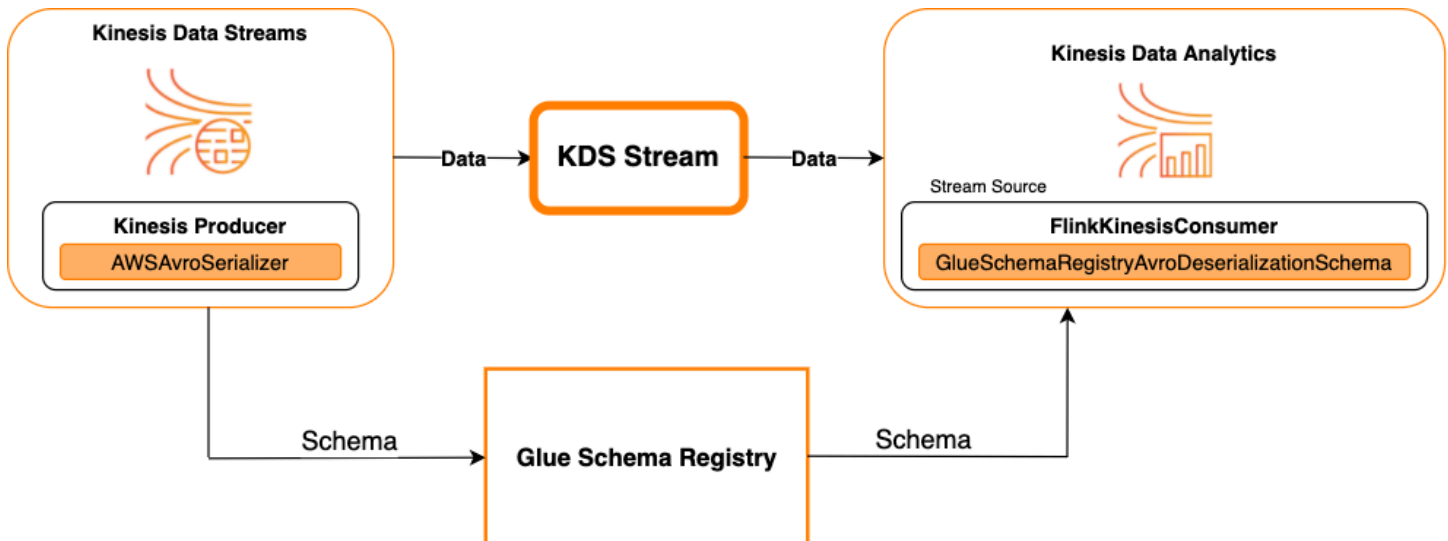

DataStream<GenericRecord> stream = env.addSource(consumer);
stream.addSink(producer);
env.execute();
```

## Integrating Kinesis Data Streams with Apache Flink

You can use Managed Service for Apache Flink for Apache Flink with Kinesis Data Streams as a source or a sink.

### Kinesis Data Streams as a source

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kinesis Data Streams as a source.

## Kinesis Data Streams as a sink

The following diagram shows integrating Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kinesis Data Streams as a sink.

To integrate Kinesis Data Streams with Managed Service for Apache Flink for Apache Flink, with Kinesis Data Streams as a source or Kinesis Data Streams as a sink, make the code changes below. Add the bolded code blocks to your respective code in the analogous sections.

If Kinesis Data Streams is the source, use the deserializer code (block 2). If Kinesis Data Streams is the sink, use the serializer code (block 3).

```
StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
```

```
String streamName = "stream";
Properties consumerConfig = new Properties();
consumerConfig.put(AWSConfigConstants.AWS_REGION, "aws-region");
consumerConfig.put(AWSConfigConstants.AWS_ACCESS_KEY_ID, "aws_access_key_id");
consumerConfig.put(AWSConfigConstants.AWS_SECRET_ACCESS_KEY, "aws_secret_access_key");
consumerConfig.put(ConsumerConfigConstants.STREAM_INITIAL_POSITION, "LATEST");

// block 1
Map<String, Object> configs = new HashMap<>();
configs.put(AWSSchemaRegistryConstants.AWS_REGION, "aws-region");
configs.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, true);
configs.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
    AvroRecordType.GENERIC_RECORD.getName());

FlinkKinesisConsumer<GenericRecord> consumer = new FlinkKinesisConsumer<>(
    streamName,
    // block 2
    GlueSchemaRegistryAvroDeserializationSchema.forGeneric(schema, configs),
    properties);

FlinkKinesisProducer<GenericRecord> producer = new FlinkKinesisProducer<>(
    // block 3
    GlueSchemaRegistryAvroSerializationSchema.forGeneric(schema, topic, configs),
    properties);
producer.setDefaultStream(streamName);
producer.setDefaultPartition("0");

DataStream<GenericRecord> stream = env.addSource(consumer);
stream.addSink(producer);
env.execute();
```

## Use Case: Integration with AWS Lambda

To use an AWS Lambda function as an Apache Kafka/Amazon MSK consumer and deserialize Avro-encoded messages using AWS Glue Schema Registry, visit the [MSK Labs page](#).

## Use case: AWS Glue Data Catalog

AWS Glue tables support schemas that you can specify manually or by reference to the AWS Glue Schema Registry. The Schema Registry integrates with the Data Catalog to allow you to optionally use schemas stored in the Schema Registry when creating or updating AWS Glue tables or partitions in the Data Catalog. To identify a schema definition in the Schema Registry, at a minimum, you need to know the ARN of the schema it is part of. A schema version of a schema,

which contains a schema definition, can be referenced by its UUID or version number. There is always one schema version, the "latest" version, that can be looked up without knowing its version number or UUID.

When calling the `CreateTable` or `UpdateTable` operations, you will pass a `TableInput` structure that contains a `StorageDescriptor`, which may have a `SchemaReference` to an existing schema in the Schema Registry. Similarly, when you call the `GetTable` or `GetPartition` APIs, the response may contain the schema and the `SchemaReference`. When a table or partition was created using a schema references, the Data Catalog will try to fetch the schema for this schema reference. In case it is unable to find the schema in the Schema Registry, it returns an empty schema in the `GetTable` response; otherwise the response will have both the schema and schema reference.

You can also perform the actions from the AWS Glue console.

To perform these operations and create, update, or view the schema information, you must give an IAM role to the calling user that provides permissions for the `GetSchemaVersion` API.

### **Adding a table or updating the schema for a table**

Adding a new table from an existing schema binds the table to a specific schema version. Once new schema versions get registered, you can update this table definition from the View table page in the AWS Glue console or using the [UpdateTable action \(Python: update\\_table\)](#) API.

### **Adding a table from an existing schema**

You can create an AWS Glue table from a schema version in the registry using the AWS Glue console or `CreateTable` API.

### **AWS Glue API**

When calling the `CreateTable` API, you will pass a `TableInput` that contains a `StorageDescriptor` which has a `SchemaReference` to an existing schema in the Schema Registry.

### **AWS Glue console**

To create a table from the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Tables**.

3. In the **Add Tables** menu, choose **Add table from existing schema**.
4. Configure the table properties and data store per the AWS Glue Developer Guide.
5. In the **Choose a Glue schema** page, select the **Registry** where the schema resides.
6. Choose the **Schema name** and select the **Version** of the schema to apply.
7. Review the schema preview, and choose **Next**.
8. Review and create the table.

The schema and version applied to the table appears in the **Glue schema** column in the list of tables. You can view the table to see more details.

### Updating the schema for a table

When a new schema version becomes available, you may want to update a table's schema using the [UpdateTable action \(Python: update\\_table\)](#) API or the AWS Glue console.

#### Important

When updating the schema for an existing table that has an AWS Glue schema specified manually, the new schema referenced in the Schema Registry may be incompatible. This can result in your jobs failing.

### AWS Glue API

When calling the UpdateTable API, you will pass a TableInput that contains a StorageDescriptor which has a SchemaReference to an existing schema in the Schema Registry.

### AWS Glue console

To update the schema for a table from the AWS Glue console:

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Tables**.
3. View the table from the list of tables.
4. Click **Update schema** in the box that informs you about a new version.
5. Review the differences between the current and new schema.

6. Choose **Show all schema differences** to see more details.
7. Choose **Save table** to accept the new version.

## Use case: AWS Glue streaming

AWS Glue streaming consumes data from streaming sources and perform ETL operations before writing to an output sink. Input streaming source can be specified using a Data Table or directly by specifying the source configuration.

AWS Glue streaming supports a Data Catalog table for the streaming source created with the schema present in the AWS Glue Schema Registry. You can create a schema in the AWS Glue Schema Registry and create an AWS Glue table with a streaming source using this schema. This AWS Glue table can be used as an input to an AWS Glue streaming job for deserializing data in the input stream.

One point to note here is when the schema in the AWS Glue Schema Registry changes, you need to restart the AWS Glue streaming job needs to reflect the changes in the schema.

## Use case: Apache Kafka Streams

The Apache Kafka Streams API is a client library for processing and analyzing data stored in Apache Kafka. This section describes the integration of Apache Kafka Streams with AWS Glue Schema Registry, which allows you to manage and enforce schemas on your data streaming applications. For more information on Apache Kafka Streams, see [Apache Kafka Streams](#).

### Integrating with the SerDes Libraries

There is a `GlueSchemaRegistryKafkaStreamsSerde` class that you can configure a Streams application with.

### Kafka Streams application example code

To use the AWS Glue Schema Registry within an Apache Kafka Streams application:

1. Configure the Kafka Streams application.

```
final Properties props = new Properties();
props.put(StreamsConfig.APPLICATION_ID_CONFIG, "avro-streams");
props.put(StreamsConfig.BOOTSTRAP_SERVERS_CONFIG, "localhost:9092");
props.put(StreamsConfig.CACHE_MAX_BYTES_BUFFERING_CONFIG, 0);
```

```
props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
Serdes.String().getClass().getName());
props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
AWSKafkaAvroSerDe.class.getName());
props.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");

props.put(AWSSchemaRegistryConstants.AWS_REGION, "aws-region");
props.put(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING, true);
props.put(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
AvroRecordType.GENERIC_RECORD.getName());
props.put(AWSSchemaRegistryConstants.DATA_FORMAT, DataFormat.AVRO.name());
```

## 2. Create a stream from the topic avro-input.

```
StreamsBuilder builder = new StreamsBuilder();
final KStream<String, GenericRecord> source = builder.stream("avro-input");
```

## 3. Process the data records (the example filters out those records whose value of favorite\_color is pink or where the value of amount is 15).

```
final KStream<String, GenericRecord> result = source
    .filter((key, value) -
> !"pink".equals(String.valueOf(value.get("favorite_color"))));
    .filter((key, value) -> !"15.0".equals(String.valueOf(value.get("amount"))));
```

## 4. Write the results back to the topic avro-output.

```
result.to("avro-output");
```

## 5. Start the Apache Kafka Streams application.

```
KafkaStreams streams = new KafkaStreams(builder.build(), props);
streams.start();
```

## Implementation results

These results show the filtering process of records that were filtered out in step 3 as a favorite\_color of "pink" or value of "15.0".

Records before filtering:

```
{"name": "Sansa", "favorite_number": 99, "favorite_color": "white"}
{"name": "Harry", "favorite_number": 10, "favorite_color": "black"}
{"name": "Hermione", "favorite_number": 1, "favorite_color": "red"}
{"name": "Ron", "favorite_number": 0, "favorite_color": "pink"}
{"name": "Jay", "favorite_number": 0, "favorite_color": "pink"}

{"id": "commute_1", "amount": 3.5}
{"id": "grocery_1", "amount": 25.5}
{"id": "entertainment_1", "amount": 19.2}
{"id": "entertainment_2", "amount": 105}
{"id": "commute_1", "amount": 15}
```

Records after filtering:

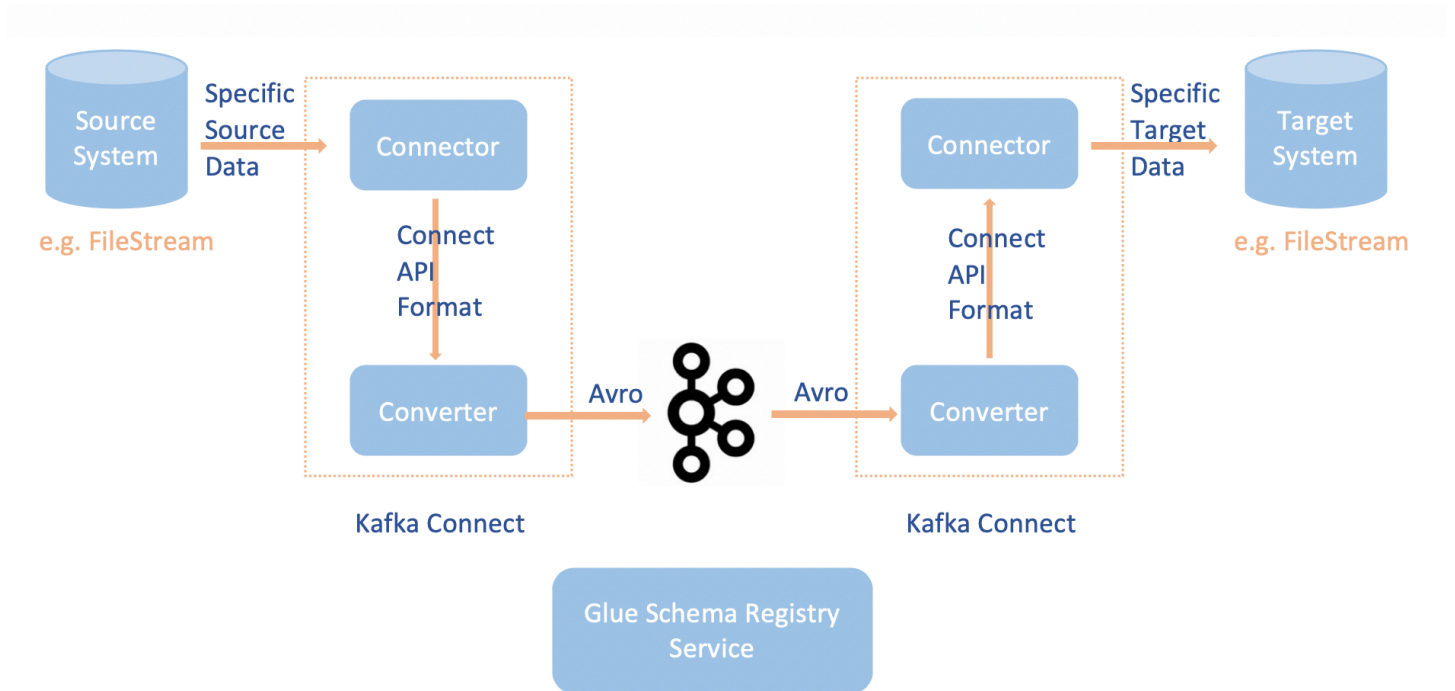

```
{"name": "Sansa", "favorite_number": 99, "favorite_color": "white"}
{"name": "Harry", "favorite_number": 10, "favorite_color": "black"}
{"name": "Hermione", "favorite_number": 1, "favorite_color": "red"}
{"name": "Ron", "favorite_number": 0, "favorite_color": "pink"}

{"id": "commute_1", "amount": 3.5}
{"id": "grocery_1", "amount": 25.5}
{"id": "entertainment_1", "amount": 19.2}
{"id": "entertainment_2", "amount": 105}
```

## Use case: Apache Kafka Connect

The integration of Apache Kafka Connect with the AWS Glue Schema Registry enables you to get schema information from connectors. The Apache Kafka converters specify the format of data within Apache Kafka and how to translate it into Apache Kafka Connect data. Every Apache Kafka Connect user will need to configure these converters based on the format they want their data in when loaded from or stored into Apache Kafka. In this way, you can define your own converters to translate Apache Kafka Connect data into the type used in the AWS Glue Schema Registry (for

example: Avro) and utilize our serializer to register its schema and do serialization. Then converters are also able to use our deserializer to deserialize data received from Apache Kafka and convert it back into Apache Kafka Connect data. An example workflow diagram is given below.

1. Install the `aws-glue-schema-registry` project by cloning the [Github repository for the AWS Glue Schema Registry](#).

```
git clone git@github.com:aws-labs/aws-glue-schema-registry.git
cd aws-glue-schema-registry
mvn clean install
mvn dependency:copy-dependencies
```

2. If you plan on using Apache Kafka Connect in *Standalone* mode, update **`connect-standalone.properties`** using the instructions below for this step. If you plan on using Apache Kafka Connect in *Distributed* mode, update **`connect-avro-distributed.properties`** using the same instructions.

- a. Add these properties also to the Apache Kafka connect properties file:

```
key.converter.region=aws-region
value.converter.region=aws-region
key.converter.schemaAutoRegistrationEnabled=true
value.converter.schemaAutoRegistrationEnabled=true
key.converter.avroRecordType=GENERIC_RECORD
```

```
value.converter.avroRecordType=GENERIC_RECORD
```

- b. Add the command below to the **Launch mode** section under **kafka-run-class.sh**:

```
-cp $CLASSPATH:"<your AWS GlueSchema Registry base directory>/target/dependency/*"
```

3. Add the command below to the **Launch mode** section under **kafka-run-class.sh**

```
-cp $CLASSPATH:"<your AWS GlueSchema Registry base directory>/target/dependency/*"
```

It should look like this:

```
# Launch mode
if [ "$DAEMON_MODE" = "xtrue" ]; then
  nohup "$JAVA" $KAFKA_HEAP_OPTS $KAFKA_JVM_PERFORMANCE_OPTS $KAFKA_GC_LOG_OPTS
  $KAFKA_JMX_OPTS $KAFKA_LOG4J_OPTS -cp $CLASSPATH:"/Users/johndoe/aws-glue-schema-
  registry/target/dependency/*" $KAFKA_OPTS "$@" > "$CONSOLE_OUTPUT_FILE" 2>&1 < /dev/
  null &
else
  exec "$JAVA" $KAFKA_HEAP_OPTS $KAFKA_JVM_PERFORMANCE_OPTS $KAFKA_GC_LOG_OPTS
  $KAFKA_JMX_OPTS $KAFKA_LOG4J_OPTS -cp $CLASSPATH:"/Users/johndoe/aws-glue-schema-
  registry/target/dependency/*" $KAFKA_OPTS "$@"
fi
```

4. If using bash, run the below commands to set-up your CLASSPATH in your bash\_profile. For any other shell, update the environment accordingly.

```
echo 'export GSR_LIB_BASE_DIR=<>' >> ~/.bash_profile
echo 'export GSR_LIB_VERSION=1.0.0' >> ~/.bash_profile
echo 'export KAFKA_HOME=<your Apache Kafka installation directory>' >> ~/.bash_profile
echo 'export CLASSPATH=$CLASSPATH:$GSR_LIB_BASE_DIR/avro-kafkaconnect-converter/
target/schema-registry-kafkaconnect-converter-$GSR_LIB_VERSION.jar:$GSR_LIB_BASE_DIR/
common/target/schema-registry-common-$GSR_LIB_VERSION.jar:$GSR_LIB_BASE_DIR/
avro-serializer-deserializer/target/schema-registry-serde-$GSR_LIB_VERSION.jar'
>> ~/.bash_profile
source ~/.bash_profile
```

5. (Optional) If you want to test with a simple file source, then clone the file source connector.

```
git clone https://github.com/mmolimar/kafka-connect-fs.git
cd kafka-connect-fs/
```

- a. Under the source connector configuration, edit the data format to Avro, file reader to `AvroFileReader` and update an example Avro object from the file path you are reading from. For example:

```
vim config/kafka-connect-fs.properties
```

```
fs.uris=<path to a sample avro object>  
policy.regex=^.*\.avro$  
file_reader.class=com.github.mmolimar.kafka.connect.fs.file.reader.AvroFileReader
```

- b. Install the source connector.

```
mvn clean package  
echo "export CLASSPATH=\$CLASSPATH:\\"$(find target/ -type f -name '*.jar'| grep  
'\-package' | tr '\n' ':')\\"" >> ~/.bash_profile  
source ~/.bash_profile
```

- c. Update the sink properties under *<your Apache Kafka installation directory>/config/connect-file-sink.properties* update the topic name and out file name.

```
file=<output file full path>  
topics=<my topic>
```

6. Start the Source Connector (in this example it is a file source connector).

```
$KAFKA_HOME/bin/connect-standalone.sh $KAFKA_HOME/config/connect-standalone.properties config/kafka-connect-fs.properties
```

7. Run the Sink Connector (in this example it is a file sink connector).

```
$KAFKA_HOME/bin/connect-standalone.sh $KAFKA_HOME/config/connect-standalone.properties $KAFKA_HOME/config/connect-file-sink.properties
```

For an example Kafka Connect usage, look at the `run-local-tests.sh` script under `integration-tests` folder in the [Github repository for the AWS Glue Schema Registry](#).

## Migration from a third-party schema registry to AWS Glue Schema Registry

The migration from a third-party schema registry to the AWS Glue Schema Registry has a dependency on the existing, current third-party schema registry. If there are records in an Apache Kafka topic which were sent using a third-party schema registry, consumers need the third-party schema registry to deserialize those records. The `AWSKafkaAvroDeserializer` provides the ability to specify a secondary deserializer class which points to the third-party deserializer and is used to deserialize those records.

There are two criteria for retirement of a third-party schema. First, retirement can occur only after records in Apache Kafka topics using the 3rd party schema registry are either no longer required by and for any consumers. Second, retirement can occur by aging out of the Apache Kafka topics, depending on the retention period specified for those topics. Note that if you have topics which have infinite retention, you can still migrate to the AWS Glue Schema Registry but you will not be able to retire the third-party schema registry. As a workaround, you can use an application or Mirror Maker 2 to read from the current topic and produce to a new topic with the AWS Glue Schema Registry.

To migrate from a third-party schema registry to the AWS Glue Schema Registry:

1. Create a registry in the AWS Glue Schema Registry, or use the default registry.
2. Stop the consumer. Modify it to include AWS Glue Schema Registry as the primary deserializer, and the third-party schema registry as the secondary.
  - Set the consumer properties. In this example, the `secondary_deserializer` is set to a different deserializer. The behavior is as follows: the consumer retrieves records from Amazon MSK and first tries to use the `AWSKafkaAvroDeserializer`. If it is unable to read the magic byte that contains the Avro Schema ID for the AWS Glue Schema Registry schema, the `AWSKafkaAvroDeserializer` then tries to use the deserializer class provided in the `secondary_deserializer`. The properties specific to the secondary deserializer also need to be provided in the consumer properties, such as the `schema_registry_url_config` and `specific_avro_reader_config`, as shown below.

```
consumerProps.setProperty(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    StringDeserializer.class.getName());
consumerProps.setProperty(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    AWSKafkaAvroDeserializer.class.getName());
```

```
consumerProps.setProperty(AWSSchemaRegistryConstants.AWS_REGION,
    KafkaClickstreamConsumer.gsrRegion);
consumerProps.setProperty(AWSSchemaRegistryConstants.SECONDARY_DESERIALIZER,
    KafkaAvroDeserializer.class.getName());
consumerProps.setProperty(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "URL for third-party schema registry");
consumerProps.setProperty(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
    "true");
```

3. Restart the consumer.
4. Stop the producer and point the producer to the AWS Glue Schema Registry.
  - a. Set the producer properties. In this example, the producer will use the default-registry and auto register schema versions.

```
producerProps.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    StringSerializer.class.getName());
producerProps.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    AWSKafkaAvroSerializer.class.getName());
producerProps.setProperty(AWSSchemaRegistryConstants.AWS_REGION, "us-east-2");
producerProps.setProperty(AWSSchemaRegistryConstants.AVRO_RECORD_TYPE,
    AvroRecordType.SPECIFIC_RECORD.getName());
producerProps.setProperty(AWSSchemaRegistryConstants.SCHEMA_AUTO_REGISTRATION_SETTING,
    "true");
```

5. (Optional) Manually move existing schemas and schema versions from the current third-party schema registry to the AWS Glue Schema Registry, either to the default-registry in AWS Glue Schema Registry or to a specific non-default registry in AWS Glue Schema Registry. This can be done by exporting schemas from the third-party schema registries in JSON format and creating new schemas in AWS Glue Schema Registry using the AWS Management Console or the AWS CLI.

This step may be important if you need to enable compatibility checks with previous schema versions for newly created schema versions using the AWS CLI and the AWS Management Console, or when producers send messages with a new schema with auto-registration of schema versions turned on.

6. Start the producer.

# Connecting to data

An AWS Glue *connection* is a Data Catalog object that stores login credentials, URI strings, virtual private cloud (VPC) information, and more for a particular data store. AWS Glue crawlers, jobs, and development endpoints use connections in order to access certain types of data stores. You can use connections for both sources and targets, and reuse the same connection across multiple crawler or extract, transform, and load (ETL) jobs.

AWS Glue supports the following connection types:

- Amazon DocumentDB
- Amazon OpenSearch Service, for use with AWS Glue for Spark.
- Amazon Redshift
- Azure Cosmos, for use of Azure Cosmos DB for NoSQL with AWS Glue ETL jobs
- Azure SQL, for use with AWS Glue for Spark.
- Google BigQuery, for use with AWS Glue for Spark.
- JDBC
- Kafka
- MongoDB
- MongoDB Atlas
- Salesforce
- SAP HANA, for use with AWS Glue for Spark.
- Snowflake, for use with AWS Glue for Spark.
- Teradata Vantage, when using AWS Glue for Spark.
- Vertica, for use with AWS Glue for Spark.
- Various Amazon Relational Database Service (Amazon RDS) offerings.
- Network (designates a connection to a data source that is in an Amazon Virtual Private Cloud (Amazon VPC))
- Aurora (supported if the native JDBC driver is being used. Not all driver features can be leveraged)

With AWS Glue Studio, you can also create a connection for a *connector*. A connector is an optional code package that assists with accessing data stores in AWS Glue Studio. For more information, see [Using connectors and connections with AWS Glue Studio](#)

For information about how to connect to on-premises databases, see [How to access and analyze on-premises data stores using AWS Glue](#) at the AWS Big Data Blog website.

**This section includes the following topics to help you use AWS Glue connections:**

- [AWS Glue connection properties](#)
- [Storing connection credentials in AWS Secrets Manager](#)
- [Adding an AWS Glue connection](#)
- [Testing an AWS Glue connection](#)
- [Configuring AWS calls to go through your VPC](#)
- [Connecting to a JDBC data store in a VPC](#)
- [Using a MongoDB or MongoDB Atlas connection](#)
- [Crawling an Amazon S3 data store using a VPC endpoint](#)
- [Troubleshooting connection issues in AWS Glue](#)
- [Tutorial: Using the AWS Glue Connector for Elasticsearch](#)

## AWS Glue connection properties

This topic includes information about properties for AWS Glue connections.

### Topics

- [Required connection properties](#)
- [AWS Glue JDBC connection properties](#)
- [AWS Glue MongoDB and MongoDB Atlas connection properties](#)
- [Salesforce connection properties](#)
- [Snowflake connection](#)
- [Vertica connection](#)
- [SAP HANA connection](#)
- [Azure SQL connection](#)

- [Teradata Vantage connection](#)
- [OpenSearch Service connection](#)
- [Azure Cosmos connection](#)
- [AWS Glue SSL connection properties](#)
- [Apache Kafka connection properties for client authentication](#)
- [Google BigQuery connection](#)
- [Vertica connection](#)

## Required connection properties

When you define a connection on the AWS Glue console, you must provide values for the following properties:

### Connection name

Enter a unique name for your connection.

### Connection type

Choose **JDBC** or one of the specific connection types.

For details about the JDBC connection type, see [the section called “JDBC connection properties”](#)

Choose **Network** to connect to a data source within an Amazon Virtual Private Cloud environment (Amazon VPC).

Depending on the type that you choose, the AWS Glue console displays other required fields. For example, if you choose **Amazon RDS**, you must then choose the database engine.

### Require SSL connection

When you select this option, AWS Glue must verify that the connection to the data store is connected over a trusted Secure Sockets Layer (SSL).

For more information, including additional options that are available when you select this option, see [the section called “SSL connection properties”](#).

### Select MSK cluster (Amazon managed streaming for Apache Kafka (MSK) only)

Specifies an MSK cluster from another AWS account.

## Kafka bootstrap server URLs (Kafka only)

Specifies a comma-separated list of bootstrap server URLs. Include the port number. For example: b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-2.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-3.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094

## AWS Glue JDBC connection properties

AWS Glue can connect to the following data stores through a JDBC connection:

- Amazon Redshift
- Amazon Aurora
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL
- Snowflake, when using AWS Glue crawlers.
- Aurora (supported if the native JDBC driver is being used. Not all driver features can be leveraged)
- Amazon RDS for MariaDB

### Important

Currently, an ETL job can use JDBC connections within only one subnet. If you have multiple data stores in a job, they must be on the same subnet, or accessible from the subnet.

If you choose to bring in your own JDBC driver versions for AWS Glue crawlers, your crawlers will consume resources in AWS Glue jobs and Amazon S3 to ensure your provided drivers are run in your environment. The additional usage of resources will be reflected in your account. Additionally, providing your own JDBC driver does not mean that the crawler is able to leverage all of the driver's features. Drivers are limited to the properties described in [Defining connections in the Data Catalog](#).

The following are additional properties for the JDBC connection type.

## JDBC URL

Enter the URL for your JDBC data store. For most database engines, this field is in the following format. In this format, replace *protocol*, *host*, *port*, and *db\_name* with your own information.

```
jdbc:protocol://host:port/db_name
```

Depending on the database engine, a different JDBC URL format might be required. This format can have slightly different use of the colon (:) and slash (/) or different keywords to specify databases.

For JDBC to connect to the data store, a *db\_name* in the data store is required. The *db\_name* is used to establish a network connection with the supplied username and password. When connected, AWS Glue can access other databases in the data store to run a crawler or run an ETL job.

The following JDBC URL examples show the syntax for several database engines.

- To connect to an Amazon Redshift cluster data store with a dev database:

```
jdbc:redshift://xxx.us-east-1.redshift.amazonaws.com:8192/dev
```

- To connect to an Amazon RDS for MySQL data store with an employee database:

```
jdbc:mysql://xxx-cluster.cluster-xxx.us-east-1.rds.amazonaws.com:3306/  
employee
```

- To connect to an Amazon RDS for PostgreSQL data store with an employee database:

```
jdbc:postgresql://xxx-cluster.cluster-xxx.us-  
east-1.rds.amazonaws.com:5432/employee
```

- To connect to an Amazon RDS for Oracle data store with an employee service name:

```
jdbc:oracle:thin://@xxx-cluster.cluster-xxx.us-  
east-1.rds.amazonaws.com:1521/employee
```

The syntax for Amazon RDS for Oracle can follow the following patterns. In these patterns, replace *host*, *port*, *service\_name*, and *SID* with your own information.

```
jdbc:oracle:thin://@host:port/service_name
```

- `jdbc:oracle:thin://@host:port:SID`
- To connect to an Amazon RDS for Microsoft SQL Server data store with an employee database:

```
jdbc:sqlserver://xxx-cluster.cluster-xxx.us-east-1.rds.amazonaws.com:1433;databaseName=employee
```

The syntax for Amazon RDS for SQL Server can follow the following patterns. In these patterns, replace *server\_name*, *port*, and *db\_name* with your own information.

- `jdbc:sqlserver://server_name:port;database=db_name`
- `jdbc:sqlserver://server_name:port;databaseName=db_name`
- To connect to an Amazon Aurora PostgreSQL instance of the employee database, specify the endpoint for the database instance, the port, and the database name:

```
jdbc:postgresql://employee_instance_1.xxxxxxxxxxxxxx.us-east-2.rds.amazonaws.com:5432/employee
```

- To connect to an Amazon RDS for MariaDB data store with an employee database, specify the endpoint for the database instance, the port, and the database name:

```
jdbc:mysql://xxx-cluster.cluster-xxx.aws-region.rds.amazonaws.com:3306/employee
```

- **⚠ Warning**  
Snowflake JDBC connections are supported only by AWS Glue crawlers. When using the Snowflake connector in AWS Glue jobs, use the Snowflake connection type.

To connect to a Snowflake instance of the sample database, specify the endpoint for the snowflake instance, the user, the database name, and the role name. You can optionally add the warehouse parameter.

```
jdbc:snowflake://account_name.snowflakecomputing.com/?  
user=user_name&db=sample&role=role_name&warehouse=warehouse_name
```

**⚠ Important**

For Snowflake connections over JDBC, the order of parameters in the URL is enforced and must be ordered as `user`, `db`, `role_name`, and `warehouse`.

- To connect to a Snowflake instance of the sample database with AWS private link, specify the snowflake JDBC URL as follows:

```
jdbc:snowflake://account_name.region.privatelink.snowflakecomputing.com/?  
user=user_name&db=sample&role=role_name&warehouse=warehouse_name
```

**Username****ℹ Note**

We recommend that you use an AWS secret to store connection credentials instead of supplying your user name and password directly. For more information, see [Storing connection credentials in AWS Secrets Manager](#).

Provide a user name that has permission to access the JDBC data store.

**Password**

Enter the password for the user name that has access permission to the JDBC data store.

**Port**

Enter the port used in the JDBC URL to connect to an Amazon RDS Oracle instance. This field is only shown when **Require SSL connection** is selected for an Amazon RDS Oracle instance.

**VPC**

Choose the name of the virtual private cloud (VPC) that contains your data store. The AWS Glue console lists all VPCs for the current Region.

**⚠ Important**

When working over a JDBC connection which is hosted off of AWS, such as with data from Snowflake, your VPC should have a NAT gateway which splits traffic into public and private subnets. The public subnet is used for connection to the external source, and the internal subnet is used for processing by AWS Glue. For information on

configuring your Amazon VPC for external connections, read [Connect to the internet or other networks using NAT devices](#) and [Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from AWS Glue](#).

## Subnet

Choose the subnet within the VPC that contains your data store. The AWS Glue console lists all subnets for the data store in your VPC.

## Security groups

Choose the security groups that are associated with your data store. AWS Glue requires one or more security groups with an inbound source rule that allows AWS Glue to connect. The AWS Glue console lists all security groups that are granted inbound access to your VPC. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

## JDBC Driver Class name - optional

Provide the custom JDBC driver class name:

- Postgres – org.postgresql.Driver
- MySQL – com.mysql.jdbc.Driver, com.mysql.cj.jdbc.Driver
- Redshift – com.amazon.redshift.jdbc.Driver, com.amazon.redshift.jdbc42.Driver
- Oracle – oracle.jdbc.driver.OracleDriver
- SQL Server – com.microsoft.sqlserver.jdbc.SQLServerDriver

## JDBC Driver S3 Path - optional

Provide the Amazon S3 location to the custom JDBC driver. This is an absolute path to a .jar file. If you want to provide your own JDBC drivers to connect to your data sources for your crawler-supported databases,

you can specify values for parameters

`customJdbcDriverS3Path` and `customJdbcDriverClassName`.

Using a JDBC driver supplied by a customer is limited to the required [Required connection properties](#).

## AWS Glue MongoDB and MongoDB Atlas connection properties

The following are additional properties for the MongoDB or MongoDB Atlas connection type.

### MongoDB URL

Enter the URL for your MongoDB or MongoDB Atlas data store:

- For MongoDB: `mongodb://host:port/database`. The host can be a hostname, IP address, or UNIX domain socket. If the connection string doesn't specify a port, it uses the default MongoDB port, 27017.
- For MongoDB Atlas: `mongodb+srv://server.example.com/database`. The host can be a hostname that follows corresponds to a DNS SRV record. The SRV format does not require a port and will use the default MongoDB port, 27017.

### Username

#### Note

We recommend that you use an AWS secret to store connection credentials instead of supplying your user name and password directly. For more information, see [Storing connection credentials in AWS Secrets Manager](#).

Provide a user name that has permission to access the JDBC data store.

### Password

Enter the password for the user name that has access permission to the MongoDB or MongoDB Atlas data store.

## Salesforce connection properties

The following are additional properties for the Salesforce connection type.

- `ENTITY_NAME(String)` - (Required) Used for Read/Write. The name of your Object in Salesforce.
- `API_VERSION(String)` - (Required) Used for Read/Write. Salesforce Rest API version you want to use.
- `SELECTED_FIELDS(List<String>)` - Default: empty(SELECT \*). Used for Read. Columns you want to select for the object.

- `FILTER_PREDICATE(String)` - Default: empty. Used for Read. It should be in the Spark SQL format.
- `QUERY(String)` - Default: empty. Used for Read. Full Spark SQL query.
- `PARTITION_FIELD(String)` - Used for Read. Field to be used to partition query.
- `LOWER_BOUND(String)`- Used for Read. An inclusive lower bound value of the chosen partition field.
- `UPPER_BOUND(String)` - Used for Read. An exclusive upper bound value of the chosen partition field.
- `NUM_PARTITIONS(Integer)` - Default: 1. Used for Read. Number of partitions for read.
- `IMPORT_DELETED_RECORDS(String)` - Default: FALSE. Used for read. To get the delete records while querying.
- `WRITE_OPERATION(String)` - Default: INSERT. Used for write. Value should be INSERT, UPDATE, UPSERT, DELETE.
- `ID_FIELD_NAMES(String)` - Default : null. Used only for UPSERT.

## Snowflake connection

The following properties are used to set up a Snowflake connection used in AWS Glue ETL jobs. When crawling Snowflake, use a JDBC connection.

### Snowflake URL

The URL of your Snowflake endpoint. For more information about Snowflake endpoint URLs, see [Connecting to Your Accounts](#) in the Snowflake documentation.

### AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to Snowflake using the `sfUser` and `sfPassword` keys of your secret.

### Snowflake role (optional)

A Snowflake security role AWS Glue will use when connecting.

Use the following properties when configuring a connection to a Snowflake endpoint hosted in Amazon VPC using AWS PrivateLink.

## VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The AWS Glue console lists all VPCs for the current Region.

## Subnet

Choose the subnet within the VPC that contains your data store. The AWS Glue console lists all subnets for the data store in your VPC.

## Security groups

Choose the security groups that are associated with your data store. AWS Glue requires one or more security groups with an inbound source rule that allows AWS Glue to connect. The AWS Glue console lists all security groups that are granted inbound access to your VPC. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

## Vertica connection

Use the following properties to set up a Vertica connection for AWS Glue ETL jobs.

### Vertica Host

The hostname of your Vertica installation.

### Vertica Port

The port your Vertica installation is available through.

### AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to Vertica using the keys of your secret.

Use the following properties when configuring a connection to a Vertica endpoint hosted in Amazon VPC.

## VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The AWS Glue console lists all VPCs for the current Region.

## Subnet

Choose the subnet within the VPC that contains your data store. The AWS Glue console lists all subnets for the data store in your VPC.

## Security groups

Choose the security groups that are associated with your data store. AWS Glue requires one or more security groups with an inbound source rule that allows AWS Glue to connect. The AWS Glue console lists all security groups that are granted inbound access to your VPC. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

## SAP HANA connection

Use the following properties to set up a SAP HANA connection for AWS Glue ETL jobs.

### SAP HANA URL

A SAP JDBC URL.

SAP HANA JDBC URLs are in the form

`jdbc:sap://saphanaHostname:saphanaPort?databaseName=saphanaDBname,ParameterName`

AWS Glue requires the following JDBC URL parameters:

- `databaseName` – A default database in SAP HANA to connect to.

### AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to SAP HANA using the keys of your secret.

Use the following properties when configuring a connection to a SAP HANA endpoint hosted in Amazon VPC:

### VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The AWS Glue console lists all VPCs for the current Region.

## Subnet

Choose the subnet within the VPC that contains your data store. The AWS Glue console lists all subnets for the data store in your VPC.

## Security groups

Choose the security groups that are associated with your data store. AWS Glue requires one or more security groups with an inbound source rule that allows AWS Glue to connect. The AWS Glue console lists all security groups that are granted inbound access to your VPC. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

## Azure SQL connection

Use the following properties to set up a Azure SQL connection for AWS Glue ETL jobs.

### Azure SQL URL

The JDBC URL of an Azure SQL endpoint.

The URL must be in the following format:

```
jdbc:sqlserver://databaseServerName:databasePort;databaseName=azuresqlDBName;
```

AWS Glue requires the following URL properties:

- `databaseName` – A default database in Azure SQL to connect to.

For more information about JDBC URLs for Azure SQL Managed Instances, see the [Microsoft documentation](#).

### AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to Azure SQL using the keys of your secret.

## Teradata Vantage connection

Use the following properties to set up a Teradata Vantage connection for AWS Glue ETL jobs.

## Teradata URL

To connect to a Teradata instance specify the hostname for the database instance and relevant Teradata parameters:

```
jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName=Pa
```

AWS Glue supports the following JDBC URL parameters:

- DATABASE\_NAME – A default database in Teradata to connect to.
- DBS\_PORT – Specifies the Teradata port, if nonstandard.

## AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to Teradata Vantage using the keys of your secret.

Use the following properties when configuring a connection to a Teradata Vantage endpoint hosted in Amazon VPC:

### VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The AWS Glue console lists all VPCs for the current Region.

### Subnet

Choose the subnet within the VPC that contains your data store. The AWS Glue console lists all subnets for the data store in your VPC.

### Security groups

Choose the security groups that are associated with your data store. AWS Glue requires one or more security groups with an inbound source rule that allows AWS Glue to connect. The AWS Glue console lists all security groups that are granted inbound access to your VPC. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

## OpenSearch Service connection

Use the following properties to set up a OpenSearch Service connection for AWS Glue ETL jobs.

## Domain endpoint

An Amazon OpenSearch Service domain endpoint will have the following default form, `https://search-domainName-unstructuredIdContent.region.es.amazonaws.com`. For more information on identifying your domain endpoint, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

## Port

The port open on the endpoint.

## AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to OpenSearch Service using the keys of your secret.

Use the following properties when configuring a connection to a OpenSearch Service endpoint hosted in Amazon VPC:

## VPC

Choose the name of the virtual private cloud (VPC) that contains your data store. The AWS Glue console lists all VPCs for the current Region.

## Subnet

Choose the subnet within the VPC that contains your data store. The AWS Glue console lists all subnets for the data store in your VPC.

## Security groups

Choose the security groups that are associated with your data store. AWS Glue requires one or more security groups with an inbound source rule that allows AWS Glue to connect. The AWS Glue console lists all security groups that are granted inbound access to your VPC. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet.

## Azure Cosmos connection

Use the following properties to set up a Azure Cosmos connection for AWS Glue ETL jobs.

## Azure Cosmos DB Account Endpoint URI

The endpoint used to connect to Azure Cosmos. For more information, see [the Azure documentation](#).

## AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue will connect to Azure Cosmos using the keys of your secret.

## AWS Glue SSL connection properties

The following are details about the **Require SSL connection** property.

If you do not require SSL connection, AWS Glue ignores failures when it uses SSL to encrypt a connection to the data store. See the documentation for your data store for configuration instructions. When you select this option, the job run, crawler, or ETL statements in a development endpoint fail when AWS Glue cannot connect.

### Note

Snowflake supports an SSL connection by default, so this property is not applicable for Snowflake.

This option is validated on the AWS Glue client side. For JDBC connections, AWS Glue only connects over SSL with certificate and host name validation. SSL connection support is available for:

- Oracle Database
- Microsoft SQL Server
- PostgreSQL
- Amazon Redshift
- MySQL (Amazon RDS instances only)
- Amazon Aurora MySQL (Amazon RDS instances only)
- Amazon Aurora PostgreSQL (Amazon RDS instances only)
- Kafka, which includes Amazon Managed Streaming for Apache Kafka
- MongoDB

**Note**

To enable an **Amazon RDS Oracle** data store to use **Require SSL connection**, you must create and attach an option group to the Oracle instance.

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Add an **Option group** to the Amazon RDS Oracle instance. For more information about how to add an option group on the Amazon RDS console, see [Creating an Option Group](#).
3. Add an **Option** to the option group for **SSL**. The **Port** you specify for SSL is later used when you create an AWS Glue JDBC connection URL for the Amazon RDS Oracle instance. For more information about how to add an option on the Amazon RDS console, see [Adding an Option to an Option Group](#) in the *Amazon RDS User Guide*. For more information about the Oracle SSL option, see [Oracle SSL](#) in the *Amazon RDS User Guide*.
4. On the AWS Glue console, create a connection to the Amazon RDS Oracle instance. In the connection definition, select **Require SSL connection**. When requested, enter the **Port** that you used in the Amazon RDS Oracle SSL option.

The following additional optional properties are available when **Require SSL connection** is selected for a connection:

**Custom JDBC certificate in S3**

If you have a certificate that you are currently using for SSL communication with your on-premises or cloud databases, you can use that certificate for SSL connections to AWS Glue data sources or targets. Enter an Amazon Simple Storage Service (Amazon S3) location that contains a custom root certificate. AWS Glue uses this certificate to establish an SSL connection to the database. AWS Glue handles only X.509 certificates. The certificate must be DER-encoded and supplied in base64 encoding PEM format.

If this field is left blank, the default certificate is used.

**Custom JDBC certificate string**

Enter certificate information specific to your JDBC database. This string is used for domain matching or distinguished name (DN) matching. For Oracle Database, this string maps to the `SSL_SERVER_CERT_DN` parameter in the security section of the `tnsnames.ora` file. For Microsoft SQL Server, this string is used as `hostNameInCertificate`.

The following is an example for the Oracle Database `SSL_SERVER_CERT_DN` parameter.

```
cn=sales,cn=OracleContext,dc=us,dc=example,dc=com
```

### **Kafka private CA certificate location**

If you have a certificate that you are currently using for SSL communication with your Kafka data store, you can use that certificate with your AWS Glue connection. This option is required for Kafka data stores, and optional for Amazon Managed Streaming for Apache Kafka data stores. Enter an Amazon Simple Storage Service (Amazon S3) location that contains a custom root certificate. AWS Glue uses this certificate to establish an SSL connection to the Kafka data store. AWS Glue handles only X.509 certificates. The certificate must be DER-encoded and supplied in base64 encoding PEM format.

### **Skip certificate validation**

Select the **Skip certificate validation** check box to skip validation of the custom certificate by AWS Glue. If you choose to validate, AWS Glue validates the signature algorithm and subject public key algorithm for the certificate. If the certificate fails validation, any ETL job or crawler that uses the connection fails.

The only permitted signature algorithms are SHA256withRSA, SHA384withRSA, or SHA512withRSA. For the subject public key algorithm, the key length must be at least 2048.

### **Kafka client keystore location**

The Amazon S3 location of the client keystore file for Kafka client side authentication. Path must be in the form `s3://bucket/prefix/filename.jks`. It must end with the file name and `.jks` extension.

### **Kafka client keystore password (optional)**

The password to access the provided keystore.

### **Kafka client key password (optional)**

A keystore can consist of multiple keys, so this is the password to access the client key to be used with the Kafka server side key.

## **Apache Kafka connection properties for client authentication**

AWS Glue supports the Simple Authentication and Security Layer (SASL) framework for authentication when you create an Apache Kafka connection. The SASL framework supports

various mechanisms of authentication, and AWS Glue offers the SCRAM (user name and password), GSSAPI (Kerberos protocol), and PLAIN protocols.

Use AWS Glue Studio to configure one of the following client authentication methods. For more information, see [Creating connections for connectors](#) in the AWS Glue Studio user guide.

- None - No authentication. This is useful if creating a connection for testing purposes.
- SASL/SCRAM-SHA-512 - Choosing this authentication method will allow you to specify authentication credentials. There are two options available:
  - Use AWS Secrets Manager (recommended) - if you select this option, you can store your user name and password in AWS Secrets Manager and let AWS Glue access them when needed. Specify the secret that stores the SSL or SASL authentication credentials. For more information, see [Storing connection credentials in AWS Secrets Manager](#).
  - Provide a user name and password directly.
- SASL/GSSAPI (Kerberos) - if you select this option, you can select the location of the keytab file, krb5.conf file and enter the Kerberos principal name and Kerberos service name. The locations for the keytab file and krb5.conf file must be in an Amazon S3 location. Since MSK does not yet support SASL/GSSAPI, this option is only available for customer managed Apache Kafka clusters. For more information, see [MIT Kerberos Documentation: Keytab](#).
- SASL/PLAIN - choose this authentication method to specify authentication credentials. There are two options available:
  - Use AWS Secrets Manager (recommended) - if you select this option, you can store your credentials in AWS Secrets Manager and let AWS Glue access the information when needed. Specify the secret that stores the SSL or SASL authentication credentials.
  - Provide username and password directly.
- SSL Client Authentication - if you select this option, you can you can select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

## Google BigQuery connection

The following properties are used to set up a Google BigQuery connection used in AWS Glue ETL jobs. For more information, see [the section called "BigQuery connections"](#).

## AWS Secret

The **Secret name** of a secret in AWS Secrets Manager. AWS Glue ETL jobs will connect to Google BigQuery using the `credentials` key of your secret.

## Vertica connection

The following properties are used to set up a Vertica connection used in AWS Glue ETL jobs. For more information, see [the section called "Vertica connections"](#).

## Storing connection credentials in AWS Secrets Manager

We recommend that you use AWS Secrets Manager to supply connection credentials for your data store. Using Secrets Manager this way lets AWS Glue access your secret at runtime for ETL jobs and crawler runs, and helps keep your credentials secure.

### Prerequisites

To use Secrets Manager with AWS Glue, you must grant your [IAM role for AWS Glue](#) permission to retrieve secret values. The AWS managed policy `AWSGlueServiceRole` doesn't include AWS Secrets Manager permissions. For example IAM policies, see [Example: Permission to retrieve secret values](#) in the *AWS Secrets Manager User Guide*.

Depending on your network setup, you might also need to create a VPC endpoint to establish a private connection between your VPC and Secrets Manager. For more information, see [Using an AWS Secrets Manager VPC endpoint](#).

### To create a secret for AWS Glue

1. Follow the instructions in [Create and manage secrets](#) in the *AWS Secrets Manager User Guide*. The following example JSON shows how to specify your credentials in the **Plaintext** tab when you create a secret for AWS Glue.

```
{
  "username": "EXAMPLE-USERNAME",
  "password": "EXAMPLE-PASSWORD"
}
```

2. Associate your secret with a connection using the AWS Glue Studio interface. For detailed instructions, see [Creating connections for connectors](#) in the *AWS Glue Studio User Guide*.

# Adding an AWS Glue connection

You can connect to data sources in AWS Glue for Spark programmatically. For more information, see [Connection types and options for ETL in AWS Glue for Spark](#)

You can also use the AWS Glue console to add, edit, delete, and test connections. For information about AWS Glue connections, see [Connecting to data](#).

## To add an AWS Glue connection

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Connections**.
3. Choose **Add connection** and then complete the wizard, entering connection properties as described in [the section called “AWS Glue connection properties”](#).

## Connecting to Amazon Redshift in AWS Glue Studio

### Note

You can use AWS Glue for Spark to read from and write to tables in Amazon Redshift databases outside of AWS Glue Studio. To configure Amazon Redshift with AWS Glue jobs programmatically, see [Redshift connections](#).

AWS Glue provides built-in support for Amazon Redshift. AWS Glue Studio provides a visual interface to connect to Amazon Redshift, author data integration jobs, and run them on AWS Glue Studio serverless Spark runtime.

## Topics

- [Creating an Amazon Redshift connection](#)
- [Creating a Amazon Redshift source node](#)
- [Creating an Amazon Redshift target node](#)
- [Advanced options](#)

## Creating an Amazon Redshift connection

### Permissions needed

Additional permissions are needed to use Amazon Redshift clusters and Amazon Redshift serverless environments. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

- redshift:DescribeClusters
- redshift-serverless:ListWorkgroups
- redshift-serverless:ListNamespaces

### Overview

When adding an Amazon Redshift connection, you can choose an existing Amazon Redshift connection or create a new connection when adding a **Data source - Redshift** node in AWS Glue Studio.

AWS Glue supports both Amazon Redshift clusters and Amazon Redshift serverless environments. When you create a connection, Amazon Redshift serverless environments display the **serverless** label next to the connection option.

For more information on how to create a Amazon Redshift connection, see [Moving data to and from Amazon Redshift](#).

## Creating a Amazon Redshift source node

### Permissions needed

AWS Glue Studio jobs using Amazon Redshift data sources require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

The following permissions are needed in order to use an Amazon Redshift connection.

- redshift-data:ListSchemas
- redshift-data:ListTables
- redshift-data:DescribeTable
- redshift-data:ExecuteStatement

- redshift-data:DescribeStatement
- redshift-data:GetStatementResult

## Adding an Amazon Redshift data source

### To add a Data Source – Amazon Redshift node:

1. Choose the Amazon Redshift access type:
  - Direct data connection (recommended) – choose this option if you want to access your Amazon Redshift data directly. This is the recommended option and also the default.
  - Data Catalog tables – choose this option if you have Data Catalog tables that you want to use.
2. If you choose Direct data connection, choose the connection for your Amazon Redshift data source. This assumes that the connection already exists and you can select from existing connections. If you need to create a connection, choose **Create Redshift connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**. Information about the connection are visible, including URL, security groups, subnet, availability zone, description, and created (UTC) and last updated (UTC) timestamps.

3. Choose a Amazon Redshift source option:
  - **Choose a single table** – this is the table that contains the data you want to access from a single Amazon Redshift table.
  - **Enter custom query** – allows you to access a dataset from multiple Amazon Redshift tables based on your custom query.
4. If you chose a single table, choose the Amazon Redshift schema. The list of available schema to choose from is determined by the selected table.

Or, choose **Enter custom query**. Choose this option to access a custom dataset from multiple Amazon Redshift tables. When you choose this option, enter the Amazon Redshift query.

When connecting to an Amazon Redshift serverless environment, add the following permission to the custom query:

```
GRANT SELECT ON ALL TABLES IN <schema> TO PUBLIC
```

You can choose **Infer schema** to read the schema based on the query that you entered. You can also choose **Open Redshift query editor** to enter a Amazon Redshift query. For more information, see [Querying a database using the query editor](#) .

5. In **Performance and security**, choose the Amazon S3 staging directory and IAM role.
  - **Amazon S3 staging directory** – choose the Amazon S3 location for temporarily staging data.
  - **IAM role** – choose the IAM role that can write to the Amazon S3 location you selected.
6. In **Custom Redshift paramters - optional**, enter the parameter and value.

## Creating an Amazon Redshift target node

### Permissions needed

AWS Glue Studio jobs using Amazon Redshift data target require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

The following permissions are needed in order to use an Amazon Redshift connection.

- redshift-data:ListSchemas
- redshift-data:ListTables

### Adding an Amazon Redshift target node

#### To create a a Amazon Redshift target node:

1. Choose an existing Amazon Redshift table as the target, or enter a new table name.
2. When you use the **Data target - Redshift** target node, you can choose from the following options:
  - **APPEND** – If a table already exists, dump all the new data into the table as an insert. If the table doesn't exist, create it and then insert all new data.

Additionally, check the box if you want to update (UPSERT) existing records in the target table. The table must exist first, otherwise the operation will fail.

- **MERGE** – AWS Glue will update or append data to your target table based on the conditions you specify.

 **Note**

To use the merge action in AWS Glue, you must enable Amazon Redshift merge functionality. For instructions on how to enable merge for your Amazon Redshift instance, see [MERGE \(preview\)](#).

Choose options:

- **Choose keys and simple actions** – choose the columns to be used as matching keys between the source data and your target data set.

Specify the following options when matched:

- Update record in your target data set with data from source.
- Delete record in your target data set.

Specify the following options when not matched:

- Insert source data as a new row into your target data set.
- Do nothing.

- **Enter custom MERGE statement** – You can then choose **Validate Merge statement** to verify that the statement is valid or invalid.
- **TRUNCATE** – If a table already exists, truncate the table data by first clearing the contents of the target table. If truncate is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If truncate is not successful, the operation will fail.
- **DROP** – If a table already exists, delete the table metadata and data. If deletion is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If drop is not successful, the operation will fail.
- **CREATE** – Create a new table with the default name. If table name already exist, create a new table with a name postfix of `job_datetime` to the name for uniqueness. This will insert all the data into the new table. If the table exists, the final table name will have the postfix appended. If the table doesn't exist, a table will be created. In either case, a new table will be created.

## Advanced options

See [Using the Amazon Redshift Spark connector on AWS Glue](#).

## Connecting to Azure Cosmos DB in AWS Glue Studio

AWS Glue provides built-in support for Azure Cosmos DB. AWS Glue Studio provides a visual interface to connect to Azure Cosmos DB for NoSQL, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a Azure Cosmos DB connection](#)
- [Creating a Azure Cosmos DB source node](#)
- [Creating a Azure Cosmos DB target node](#)
- [Advanced options](#)

## Creating a Azure Cosmos DB connection

### Prerequisites:

- In Azure, you will need to identify or generate an Azure Cosmos DB Key for use by AWS Glue, `cosmosKey`. For more information, see [Secure access to data in Azure Cosmos DB](#) in the Azure documentation.

### To configure a connection to Azure Cosmos DB:

1. In AWS Secrets Manager, create a secret using your Azure Cosmos DB Key. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, `secretName` for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `spark.cosmos.accountKey` with the value `cosmosKey`.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, `connectionName`, for future use in AWS Glue.
  - When selecting a **Connection type**, select Azure Cosmos DB.

- When selecting an **AWS Secret**, provide *secretName*.

## Creating a Azure Cosmos DB source node

### Prerequisites needed

- A AWS Glue Azure Cosmos DB connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure Cosmos DB for NoSQL container you would like to read from. You will need identification information for the container.

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

### Adding a Azure Cosmos DB data source

#### To add a Data source – Azure Cosmos DB node:

1. Choose the connection for your Azure Cosmos DB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure Cosmos DB connection**. For more information see the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose **Cosmos DB Database Name** – provide the name of the database you want to read from, *cosmosDBName*.
3. Choose **Azure Cosmos DB Container** – provide the name of the container you want to read from, *cosmosContainerName*.
4. Optionally, choose **Azure Cosmos DB Custom Query** – provide a SQL SELECT query to retrieve specific information from Azure Cosmos DB.
5. In **Custom Azure Cosmos properties**, enter parameters and values as needed.

## Creating a Azure Cosmos DB target node

### Prerequisites needed

- A AWS Glue Azure Cosmos DB connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure Cosmos DB table you would like to write to. You will need identification information for the container. **You must create the container before calling the connection method.**

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

### Adding a Azure Cosmos DB data target

#### To add a Data target – Azure Cosmos DB node:

1. Choose the connection for your Azure Cosmos DB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure Cosmos DB connection**. For more information see the previous section, [the section called “Creating a Azure Cosmos DB connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose **Cosmos DB Database Name** – provide the name of the database you want to read from, *cosmosDBName*.
3. Choose **Azure Cosmos DB Container** – provide the name of the container you want to read from, *cosmosContainerName*.
4. In **Custom Azure Cosmos properties**, enter parameters and values as needed.

### Advanced options

You can provide advanced options when creating a Azure Cosmos DB node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called “Azure Cosmos DB connections”](#).

## Connecting to Azure SQL in AWS Glue Studio

AWS Glue provides built-in support for Azure SQL. AWS Glue Studio provides a visual interface to connect to Azure SQL, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a Azure SQL connection](#)
- [Creating a Azure SQL source node](#)
- [Creating a Azure SQL target node](#)
- [Advanced options](#)

### Creating a Azure SQL connection

To connect to Azure SQL from AWS Glue, you will need to create and store your Azure SQL credentials in a AWS Secrets Manager secret, then associate that secret with a Azure SQL AWS Glue connection.

#### To configure a connection to Azure SQL:

1. In AWS Secrets Manager, create a secret using your Azure SQL credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key user with the value *azuresqlUsername*.
  - When selecting **Key/value pairs**, create a pair for the key password with the value *azuresqlPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select Azure SQL.
  - When providing **Azure SQL URL**, provide a JDBC endpoint URL.

The URL must be in the following format:

```
jdbc:sqlserver://databaseServerName:databasePort;databaseName=azuresqlDBName
```

AWS Glue requires the following URL properties:

- `databaseName` – A default database in Azure SQL to connect to.

For more information about JDBC URLs for Azure SQL Managed Instances, see the [Microsoft documentation](#).

- When selecting an **AWS Secret**, provide `secretName`.

## Creating a Azure SQL source node

### Prerequisites needed

- A AWS Glue Azure SQL connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure SQL connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure SQL table you would like to read from, `tableName`.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in `connectionName`, schema and table name through the `dbtable`.

## Adding a Azure SQL data source

### To add a Data source – Azure SQL node:

1. Choose the connection for your Azure SQL data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure SQL connection**. For more information see the previous section, [the section called “Creating a Azure SQL connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Azure SQL Source** option:

- **Choose a single table** – access all data from a single table.
  - **Enter custom query** – access a dataset from multiple tables based on your custom query.
3. If you chose a single table, enter *tableName*.  
  
If you chose **Enter custom query**, enter a TransactSQL SELECT query.
  4. In **Custom Azure SQL properties**, enter parameters and values as needed.

## Creating a Azure SQL target node

### Prerequisites needed

- A AWS Glue Azure SQL connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a Azure SQL connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Azure SQL table you would like to write to, *tableName*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the *dbtable*.

### Adding a Azure SQL data target

#### To add a Data target – Azure SQL node:

1. Choose the connection for your Azure SQL data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Azure SQL connection**. For more information see the previous section, [the section called “Creating a Azure SQL connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Configure **Table name** by providing *tableName*.
3. In **Custom Azure SQL properties**, enter parameters and values as needed.

## Advanced options

You can provide advanced options when creating a Azure SQL node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called “Azure SQL connections”](#).

## Connecting to Google BigQuery in AWS Glue Studio

### Note

You can use AWS Glue for Spark to read from and write to tables in Google BigQuery in AWS Glue 4.0 and later versions. To configure Google BigQuery with AWS Glue jobs programmatically, see [BigQuery connections](#).

AWS Glue Studio provides a visual interface to connect to BigQuery, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a BigQuery connection](#)
- [Creating a BigQuery source node](#)
- [Creating a BigQuery target node](#)
- [Advanced options](#)

## Creating a BigQuery connection

To connect to Google BigQuery from AWS Glue, you will need to create and store your Google Cloud Platform credentials in a AWS Secrets Manager secret, then associate that secret with a Google BigQuery AWS Glue connection.

### To configure a connection to BigQuery:

1. In Google Cloud Platform, create and identify relevant resources:
  - Create or identify a GCP project containing BigQuery tables you would like to connect to.

- Enable the BigQuery API. For more information, see [Use the BigQuery Storage Read API to read table data](#).
2. In Google Cloud Platform, create and export service account credentials:

You can use the BigQuery credentials wizard to expedite this step: [Create credentials](#).

To create a service account in GCP, follow the tutorial available in [Create service accounts](#).

- When selecting **project**, select the project containing your BigQuery table.
- When selecting GCP IAM roles for your service account, add or create a role that would grant appropriate permissions to run BigQuery jobs to read, write or create BigQuery tables.

To create credentials for your service account, follow the tutorial available in [Create a service account key](#).

- When selecting key type, select **JSON**.

You should now have downloaded a JSON file with credentials for your service account. It should look similar to the following:

```
{
  "type": "service_account",
  "project_id": "*****",
  "private_key_id": "*****",
  "private_key": "*****",
  "client_email": "*****",
  "client_id": "*****",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
  "token_uri": "https://oauth2.googleapis.com/token",
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
  "client_x509_cert_url": "*****",
  "universe_domain": "googleapis.com"
}
```

3. base64 encode your downloaded credentials file. On an AWS CloudShell session or similar, you can do this from the command line by running `cat credentialsFile.json | base64 -w 0`. Retain the output of this command, *credentialString*.
4. In AWS Secrets Manager, create a secret using your Google Cloud Platform credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets](#)

[Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

- When selecting **Key/value pairs**, create a pair for the key credentials with the value *credentialString*.
5. In the AWS Glue Data Catalog, create a connection by following the steps in <https://docs.aws.amazon.com/glue/latest/dg/console-connections.html>. After creating the connection, keep the connection name, *connectionName*, for the next step.
    - When selecting a **Connection type**, select Google BigQuery.
    - When selecting an **AWS Secret**, provide *secretName*.
  6. Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
  7. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Creating a BigQuery source node

### Prerequisites needed

- A BigQuery type AWS Glue Data Catalog connection
- An AWS Secrets Manager secret for your Google BigQuery credentials, used by the connection.
- Appropriate permissions on your job to read the secret used by the connection.
- The name and dataset of the table and corresponding Google Cloud project you would like to read.

### Adding a BigQuery data source

#### To add a Data source – BigQuery node:

1. Choose the connection for your BigQuery data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create BigQuery connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Identify what BigQuery data you would like to read, then choose a **BigQuery Source** option

- Choose a single table – allows you to pull all data from a table.
  - Enter a custom query – allows you to customize which data is retrieved by providing a query.
3. Describe the data you would like to read

**(Required)** set **Parent Project** to the project containing your table, or a billing parent project, if relevant.

If you chose a single table, set **Table** to the name of a Google BigQuery table in the following format: [dataset].[table]

If you chose a query, provide it to **Query**. In your query, refer to tables with their fully qualified table name, in the format: [project].[dataset].[tableName].

4. Provide BigQuery properties

If you chose a single table, you do not need to provide additional properties.

If you chose a query, you must provide the following **Custom Google BigQuery properties**:

- Set `viewsEnabled` to true.
- Set `materializationDataset` to a dataset. The GCP principal authenticated by the credentials provided through the AWS Glue connection must be able to create tables in this dataset.

## Creating a BigQuery target node

### Prerequisites needed

- A BigQuery type AWS Glue Data Catalog connection
- An AWS Secrets Manager secret for your Google BigQuery credentials, used by the connection.
- Appropriate permissions on your job to read the secret used by the connection.
- The name and dataset of the table and corresponding Google Cloud project you would like to write to.

## Adding a BigQuery data target

### To add a Data target – BigQuery node:

1. Choose the connection for your BigQuery data target. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create BigQuery connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Identify what BigQuery table you would like to write to, then choose a **Write method**.
  - Direct – writes to BigQuery directly using the BigQuery Storage Write API.
  - Indirect – writes to Google Cloud Storage, then copies to BigQuery.

If you would like to write indirectly, provide a destination GCS location with **Temporary GCS bucket**. You will need to provide additional configuration in your AWS Glue connection. For more information, see [Using indirect write with Google BigQuery](#).

3. Describe the data you would like to read

**(Required)** set **Parent Project** to the project containing your table, or a billing parent project, if relevant.

If you chose a single table, set **Table** to the name of a Google BigQuery table in the following format: [dataset].[table]

## Advanced options

You can provide advanced options when creating a BigQuery node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [BigQuery connection option reference](#) in the AWS Glue developer guide.

## Connecting to MongoDB in AWS Glue Studio

AWS Glue provides built-in support for MongoDB. AWS Glue Studio provides a visual interface to connect to MongoDB, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

## Topics

- [Creating a MongoDB connection](#)
- [Creating a MongoDB source node](#)
- [Creating a MongoDB target node](#)
- [Advanced options](#)

## Creating a MongoDB connection

### Prerequisites:

- If your MongoDB instance is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the MongoDB instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your MongoDB instance and this location. Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

### To configure a connection to MongoDB:

1. Optionally, in AWS Secrets Manager, create a secret using your MongoDB credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `username` with the value *mongodbUser*.  
  
When selecting **Key/value pairs**, create a pair for the key `password` with the value *mongodbPass*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select **MongoDB** or **MongoDB Atlas**.

- When selecting **MongoDB URL** or **MongoDB Atlas URL**, provide the hostname of your MongoDB instance.

A MongoDB URL is provided in the format

`mongodb://mongoHost:mongoPort/mongoDBname.`

A MongoDB Atlas URL is provided in the format `mongodb`

`+srv://mongoHost:mongoPort/mongoDBname.`

Providing the default database for the connection, *mongoDBname* is optional.

- If you chose to create an Secrets Manager secret, choose the AWS Secrets Manager **Credential type**.

Then, in **AWS Secret** provide *secretName*.

- If you choose to provide **Username and password**, provide *mongodbUser* and *mongodbPass*.

3. In the following situations, you may require additional configuration:

- For MongoDB instances hosted on AWS in an Amazon VPC
  - You will need to provide Amazon VPC connection information to the AWS Glue connection that defines your MongoDB security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue MongoDB connection, you will need to perform the following steps before running your AWS Glue job:

- When working with AWS Glue jobs in the visual editor, you must provide Amazon VPC connection information for your job to connect to MongoDB. Identify a suitable location in Amazon VPC and provide it to your AWS Glue MongoDB connection.
- If you chose to create an Secrets Manager secret, grant the IAM role associated with your AWS Glue job permission to read *secretName*.

## Creating a MongoDB source node

### Prerequisites needed

- A AWS Glue MongoDB connection, as described in the previous section, [the section called “Creating a MongoDB connection”](#).
- If you chose to create an Secrets Manager secret, appropriate permissions on your job to read the secret used by the connection.
- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

### Adding a MongoDB data source

#### To add a Data source – MongoDB node:

1. Choose the connection for your MongoDB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create MongoDB connection**. For more information see the previous section, [the section called “Creating a MongoDB connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Database**. Enter *mongodbName*.
3. Choose a **Collection**. Enter *mongodbCollection*.
4. Choose your **Partitioner**, **Partition size (MB)** and **Partition key**. For more information about partition parameters, see [the section called “"connectionType": "mongodb" as source”](#).
5. In **Custom MongoDB properties**, enter parameters and values as needed.

## Creating a MongoDB target node

### Prerequisites needed

- A AWS Glue MongoDB connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a MongoDB connection”](#).

- Appropriate permissions on your job to read the secret used by the connection.
- A MongoDB table you would like to write to, *tableName*.

## Adding a MongoDB data target

### To add a Data target – MongoDB node:

1. Choose the connection for your MongoDB data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create MongoDB connection**. For more information see the previous section, [the section called "Creating a MongoDB connection"](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Database**. Enter *mongodbName*.
3. Choose a **Collection**. Enter *mongodbCollection*.
4. Choose your **Partitioner**, **Partition size (MB)** and **Partition key**. For more information about partition parameters, see [the section called "'connectionType': 'mongodb' as source"](#).
5. Choose **Retry Writes** if desired.
6. In **Custom MongoDB properties**, enter parameters and values as needed.

## Advanced options

You can provide advanced options when creating a MongoDB node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called "MongoDB connection"](#).

## Connecting to OpenSearch Service in AWS Glue Studio

AWS Glue provides built-in support for Amazon OpenSearch Service. AWS Glue Studio provides a visual interface to connect to Amazon OpenSearch Service, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime. This feature is not compatible with OpenSearch Service serverless.

### Topics

- [Creating a OpenSearch Service connection](#)

- [Creating a OpenSearch Service source node](#)
- [Creating a OpenSearch Service target node](#)
- [Advanced options](#)

## Creating a OpenSearch Service connection

### Prerequisites:

- Identify the domain endpoint, *aosEndpoint* and port, *aosPort* you would like to read from, or create the resource by following instructions in the Amazon OpenSearch Service documentation. For more information on creating a domain, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

An Amazon OpenSearch Service domain endpoint will have the following default form, `https://search-domainName-unstructuredIdContent.region.es.amazonaws.com`. For more information on identifying your domain endpoint, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

Identify or generate HTTP basic authentication credentials, *aosUser* and *aosPassword* for your domain.

### To configure a connection to OpenSearch Service:

1. In AWS Secrets Manager, create a secret using your OpenSearch Service credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `opensearch.net.http.auth.user` with the value *aosUser*.
  - When selecting **Key/value pairs**, create a pair for the key `opensearch.net.http.auth.pass` with the value *aosPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select OpenSearch Service.

- When selecting a Domain endpoint, provide *aosEndpoint*.
- When selecting a port, provide *aosPort*.
- When selecting an **AWS Secret**, provide *secretName*.

## Creating a OpenSearch Service source node

### Prerequisites needed

- A AWS Glue OpenSearch Service connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a OpenSearch Service connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A OpenSearch Service index you would like to read from, *aosIndex*.

### Adding a OpenSearch Service data source

#### To add a Data source – OpenSearch Service node:

1. Choose the connection for your OpenSearch Service data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create OpenSearch Service connection**. For more information see the previous section, [the section called “Creating a OpenSearch Service connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Provide **Index**, the index you would like to read.
3. Optionally, provide **Query**, an OpenSearch query to deliver more specific results. For more information about writing OpenSearch queries, consult [the section called “Read from OpenSearch Service”](#).
4. In **Custom OpenSearch Service properties**, enter parameters and values as needed.

## Creating a OpenSearch Service target node

### Prerequisites needed

- A AWS Glue OpenSearch Service connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a OpenSearch Service connection”](#).

- Appropriate permissions on your job to read the secret used by the connection.
- A OpenSearch Service index you would like to write to, *aosIndex*.

## Adding a OpenSearch Service data target

### To add a Data target – OpenSearch Service node:

1. Choose the connection for your OpenSearch Service data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create OpenSearch Service connection**. For more information see the previous section, [the section called “Creating a OpenSearch Service connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Provide **Index**, the index you would like to read.
3. In **Custom OpenSearch Service properties**, enter parameters and values as needed.

## Advanced options

You can provide advanced options when creating a OpenSearch Service node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called “OpenSearch Service connections”](#).

## Connecting to Salesforce in AWS Glue Studio

Salesforce provides customer relationship management (CRM) software that help you with sales, customer service, e-commerce, and more. If you're a Salesforce user, you can connect AWS Glue to your Salesforce account. Then, you can use Salesforce as a data source or destination in your ETL Jobs. Run these jobs to transfer data between Salesforce and AWS services or other supported applications.

### Topics

- [AWS Glue support for Salesforce](#)
- [Policies containing the API operations for creating and using connections](#)
- [Configuring Salesforce](#)
- [Configuring Salesforce connections](#)

- [Reading from Salesforce entities](#)
- [Writing to Salesforce](#)
- [Salesforce connection options](#)
- [Limitations for Salesforce connector](#)
- [Set up the JWT bearer OAuth flow for Salesforce](#)

## AWS Glue support for Salesforce

AWS Glue supports Salesforce as follows:

### Supported as a source?

Yes. You can use AWS Glue ETL jobs to query data from Salesforce.

### Supported as a target?

Yes. You can use AWS Glue ETL to write records into Salesforce.

### Supported Salesforce API versions

The following Salesforce API versions are supported

- v58.0
- v59.0
- v60.0

## Policies containing the API operations for creating and using connections

The following sample policy describes the required AWS IAM permissions for creating and using connections. If you are creating a new role, create a policy that contains the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListConnectionTypes",
        "glue:DescribeConnectionType",
        "glue:RefreshOAuth2Tokens"
      ]
    }
  ]
}
```

```
        "glue:ListEntities",
        "glue:DescribeEntity"
    ],
    "Resource": "*"
}
]
```

You can also use the following IAM policies to allow access:

- [AWSGlueServiceRole](#) – Grants access to resources that various AWS Glue processes require to run on your behalf. These resources include AWS Glue, Amazon S3, IAM, CloudWatch Logs, and Amazon EC2. If you follow the naming convention for resources specified in this policy, AWS Glue processes have the required permissions. This policy is typically attached to roles specified when defining crawlers, jobs, and development endpoints.
- [AWSGlueConsoleFullAccess](#) – Grants full access to AWS Glue resources when an identity that the policy is attached to uses the AWS Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the AWS Glue console.

## Configuring Salesforce

Before you can use AWS Glue to transfer data to or from Salesforce, you must meet these requirements:

### Minimum requirements

The following are minimum requirements:

- You have a Salesforce account.
- Your Salesforce account is enabled for API access. API access is enabled by default for the Enterprise, Unlimited, Developer, and Performance editions.
- Your Salesforce account allows you to install connected apps. If you lack access to this functionality, contact your Salesforce administrator. For more information, see [Connected Apps](#) in the Salesforce help.

If you meet these requirements, you're ready to connect AWS Glue to your Salesforce account. AWS Glue handles the remaining requirements with the AWS managed connected app.

## The AWS managed connected app for Salesforce

The AWS managed connected app helps you create Salesforce connections in fewer steps. In Salesforce, a connected app is a framework that authorizes external applications, like AWS Glue, to access your Salesforce data.

- Create a Salesforce connection by using the AWS Glue console.
- When you configure the connection, set **OAuth grant type** to **Authorization code**.

## Configuring Salesforce connections

To configure a Salesforce connection:

1. In AWS Secrets Manager, create a secret with the following details:
  - a. For the `JWT_TOKEN` grant type - the secret should contain the `JWT_TOKEN` key with its value.
  - b. For the `AuthorizationCode` grant type: for a customer managed connected app the secret should contain the connected app Consumer Secret with `USER_MANAGED_CLIENT_APPLICATION_CLIENT_SECRET` as key. For an AWS Managed connected app, an empty secret or a secret with some temporary value.
  - c. Note: You must create a secret per connection in AWS Glue.
2. In the AWS Glue Data Catalog, create a connection by following the steps below:
  - a. When selecting a **Connection type**, select Salesforce.
  - b. Provide the `INSTANCE_URL` of the Salesforce you want to connect to.
  - c. Provide the Salesforce environment.
  - d. Select the AWS IAM role which AWS Glue can assume and has permissions for following actions:
  - e. Select the `OAuth2` grant type which you want to use for the connections. The grant type determines how AWS Glue communicates with Salesforce to request access to your data. Your choice affects the requirements that you must meet before you create the connection. You can choose either of these types:
    - **JWT\_BEARER Grant Type:** This grant type works well for automation scenarios as it allows a JSON Web Token (JWT) to be created up front with the permissions of a particular user in the Salesforce instance. The creator has control over how long the JWT is valid for. AWS Glue is able to use the JWT to obtain an access token which is used to call Salesforce APIs.

This flow requires that the user has created a connected app in their Salesforce instance which enables issuing JWT-based access tokens for users.

For information on creating a connected app for the JWT bearer OAuth flow, see [OAuth 2.0 JWT bearer flow for server-to-server integration](#). To set up the JWT bearer flow with the Salesforce connected app, see [Set up the JWT bearer OAuth flow for Salesforce](#).

- **AUTHORIZATION\_CODE Grant Type:** This grant type is considered a "three-legged" OAuth as it relies on redirecting users to the third-party authorization server to authenticate the user. It is used when creating connections via the AWS Glue console. The user creating a connection may by default rely on an AWS Glue connected app (AWS Glue managed client application) where they do not need to provide any OAuth related information except for their Salesforce instance URL. The AWS Glue console will redirect the user to Salesforce where the user must login and allow AWS Glue the requested permissions to access their Salesforce instance.

Users may still opt to create their own connected app in Salesforce and provide their own client ID and client secret when creating connections through the AWS Glue console. In this scenario, they will still be redirected to Salesforce to login and authorize AWS Glue to access their resources.

This grant type results in a refresh token and access token. The access token is short lived, and may be refreshed automatically without user interaction using the refresh token.

For information on creating a connected app for the Authorization Code OAuth flow, see [Configure a Connected App for the Authorization Code and Credentials Flow](#).

- f. Select the `secretName` which you want to use for this connection in AWS Glue to put the tokens.
  - g. Select the network options if you want to use your network. Grant the IAM role associated with your AWS Glue job permission to read `secretName`.
3. Grant the IAM role associated with your AWS Glue job permission to read `secretName`.
  4. In your AWS Glue job configuration, provide `connectionName` as an **Additional network connection**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```

    "Effect": "Allow",
    "Action": [
        "secretsmanager:DescribeSecret",
        "secretsmanager:GetSecretValue",
        "secretsmanager:PutSecretValue",
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterface",
        "ec2>DeleteNetworkInterface",
    ],
    "Resource": "*"
}
]
}

```

## Reading from Salesforce entities

### Prerequisite

A Salesforce sObject you would like to read from. You will need the object name such as Account or Case or Opportunity.

### Example:

```

salesforce_read = glueContext.create_dynamic_frame.from_options(
    connection_type="salesforce",
    connection_options={
        "connectionName": "connectionName",
        "ENTITY_NAME": "Account",
        "API_VERSION": "v60.0"
    }
)

```

### Partitioning queries

You can provide the additional Spark options `PARTITION_FIELD`, `LOWER_BOUND`, `UPPER_BOUND`, and `NUM_PARTITIONS` if you want to utilize concurrency in Spark. With these parameters, the original query would be split into `NUM_PARTITIONS` number of sub-queries that can be executed by Spark tasks concurrently.

- `PARTITION_FIELD`: the name of the field to be used to partition the query.
- `LOWER_BOUND`: an **inclusive** lower bound value of the chosen partition field.

For timestamp field, we accept the Spark timestamp format used in Spark SQL queries.

Examples of valid values:

```
"TIMESTAMP \"1707256978123\""  
"TIMESTAMP '2024-02-06 22:02:58.123 UTC'"  
"TIMESTAMP \"2018-08-08 00:00:00 Pacific/Tahiti\""  
"TIMESTAMP \"2018-08-08 00:00:00\""  
"TIMESTAMP \"-123456789\" Pacific/Tahiti"  
"TIMESTAMP \"1702600882\""
```

- UPPER\_BOUND: an **exclusive** upper bound value of the chosen partition field.
- NUM\_PARTITIONS: the number of partitions.

Example:

```
salesforce_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="salesforce",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "Account",  
        "API_VERSION": "v60.0",  
        "PARTITION_FIELD": "SystemModstamp"  
        "LOWER_BOUND": "TIMESTAMP '2021-01-01 00:00:00 Pacific/Tahiti'"  
        "UPPER_BOUND": "TIMESTAMP '2023-01-10 00:00:00 Pacific/Tahiti'"  
        "NUM_PARTITIONS": "10"  
    }  
)
```

## Writing to Salesforce

### Prerequisites

A Salesforce sObject you would like to write to. You will need the object name such as Account or Case or Opportunity.

The Salesforce connector supports four write operations:

- INSERT
- UPSERT

- UPDATE
- DELETE

When using the UPSERT write operation, the `ID_FIELD_NAMES` must be provided to specify the external ID field for the records.

### Example

```
salesforce_write = glueContext.write_dynamic_frame.from_options(  
    frame=frameToWrite,  
    connection_type="salesforce",  
    connection_options={  
        "connectionName": "connectionName",  
        "ENTITY_NAME": "Account",  
        "API_VERSION": "v60.0",  
        "WRITE_OPERATION": "INSERT"  
    }  
)
```

## Salesforce connection options

The following are connection options for Salesforce:

- `ENTITY_NAME(String)` - (Required) Used for Read/Write. The name of your Object in Salesforce.
- `API_VERSION(String)` - (Required) Used for Read/Write. Salesforce Rest API version you want to use.
- `SELECTED_FIELDS(List<String>)` - Default: empty(SELECT \*). Used for Read. Columns you want to select for the object.
- `FILTER_PREDICATE(String)` - Default: empty. Used for Read. It should be in the Spark SQL format.
- `QUERY(String)` - Default: empty. Used for Read. Full Spark SQL query.
- `PARTITION_FIELD(String)` - Used for Read. Field to be used to partition query.
- `LOWER_BOUND(String)`- Used for Read. An inclusive lower bound value of the chosen partition field.
- `UPPER_BOUND(String)` - Used for Read. An exclusive upper bound value of the chosen partition field.
- `NUM_PARTITIONS(Integer)` - Default: 1. Used for Read. Number of partitions for read.

- `IMPORT_DELETED_RECORDS`(String) - Default: FALSE. Used for read. To get the delete records while querying.
- `WRITE_OPERATION`(String) - Default: INSERT. Used for write. Value should be INSERT, UPDATE, UPSERT, DELETE.
- `ID_FIELD_NAMES`(String) - Default : null. Used only for UPSERT.

## Limitations for Salesforce connector

The following are limitations for the Salesforce connector:

- We only support Spark SQL and Salesforce SOQL is not supported.
- Job bookmarks are not supported.

## Set up the JWT bearer OAuth flow for Salesforce

Refer to Salesforce public documentation for enabling server-to-server integration with [OAuth 2.0 JSON Web Tokens](#).

### Creating a cert/key pair of PEM files

Create a cert/key pair of PEM files

```
openssl req -newkey rsa:4096 -new -nodes -x509 -days 3650 -keyout key.pem -out cert.pem
```

### Creating a Salesforce connected app with JWT

1. Log in to [Salesforce](#) and click the settings gear at top right and select **Setup**.
2. On the left, navigate to App Manager. (Platform Tools > Apps > App Manager)
3. Choose **New Connection App**.
4. Provide an app name, let the rest be auto filled.
5. Check the box for **Enable OAuth Settings**.
6. Set a callback URL. It won't be used for JWT, so you can use `https://localhost`.
7. Check the box for **Use Digital Signatures**.
8. Upload the cert.pem file created earlier.
9. Add the required permissions:

- a. Manage user data via APIs (api).
  - b. Access custom permissions (custom\_permissions).
  - c. Access the identity URL service (id, profile, email, address, phone).
  - d. Access unique user identifiers (openid).
  - e. Perform requests at any time (refresh\_token, offline\_access).
10. Check the box for **Issue JSON Web Token (JWT)-based access tokens for named users**.
  11. Choose **Save**.
  12. Choose **Continue**.
  13. Choose **Manage Consumer Details**.
  14. Copy the consumer key (client id).
  15. Copy the consumer secret (client secret).
  16. Click **Cancel**.

### Generating a JSON Web Token (JWT)

1. Convert key pair into pkcs12 (set an export password when prompted).

```
openssl pkcs12 -export -in cert.pem -inkey key.pem -name jwtcert > jwtcert.p12
```

2. Create a Java keystore from pkcs12 (set a destination keystore password when prompted, and provide previous export password for source keystore password).

```
keytool -importkeystore -srckeystore jwtcert.p12 -destkeystore keystore.jks -srcstoretype pkcs12 -alias jwtcert
```

3. Confirm keystore.jks includes jwtcert alias (enter previous destination keystore password when prompted).

```
keytool -keystore keystore.jks -list
```

4. Use the Java class JWTEExample provided in Salesforce documentation to generate the signed token.
  - a. Edit the values in claimArray as necessary:
    - claimArray[0] = client id
    - claimArray[1] = salesforce user id

- `claimArray[2]` = salesforce login url
  - `claimArray[4]` = expiration date in millis since epoch. 3660624000000 is 2085-12-31.
- Replace `path/to/keystore` with correct path to your `keystore.jks`.
  - Replace `keystorepassword` with the destination keystore password you entered
  - Replace `privatekeypassword` with the source keystore password you entered
  - Compile the code. The code depends on the [Apache Commons Codec](#) for base64 encoding.

```
javac -classpath " ../commons-codec-1.16.1.jar" JWTExample.java
```

- Run the code.

```
java -classpath " ./commons-codec-1.16.1.jar" JWTExample
```

- Once the connected app and JWT are created, still the user needs to be authorized for the app. See step 3 in <https://mannharleen.github.io/2020-03-03-salesforce-jwt/> for two approaches.

With the above steps completed, this should output a JSON Web Token (JWT) which can be used to obtain access tokens from Salesforce.

### Example input:

```
export password for pkcs12: awsglue
destination keystore password for jks: awsglue
source keystore password for jks: awsglue

claimArray[0] = "client-id";
claimArray[1] = "my@email.com";
claimArray[2] = "https://login.salesforce.com";
claimArray[3] = "3660624000000";

path to keystore: ./keystore.jks
keystore password: awsglue
privatekey password: awsglue
```

### Example output:

```
eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.eyJzdWIiOiIxMjM0NTY3ODkwIiwibmFtZSI6IkpvaG4gRG91IiwiaWF0Ij0j
```

### Useful links:

- <https://jwt.io/>
- [https://help.salesforce.com/s/articleView?id=sf.remoteaccess\\_oauth\\_jwt\\_flow.htm](https://help.salesforce.com/s/articleView?id=sf.remoteaccess_oauth_jwt_flow.htm)

### JWTExample.java:

```
import org.apache.commons.codec.binary.Base64;
import java.io.*;
import java.security.*;
import java.text.MessageFormat;

public class JWTExample {

    public static void main(String[] args) {

        String header = "{\"alg\":\"RS256\"}";
        String claimTemplate = "'{'\"iss\": \"{0}\", \"sub\": \"{1}\", \"aud\": \"{2}\",
        \"exp\": \"{3}\"}'";

        try {
            StringBuffer token = new StringBuffer();

            //Encode the JWT Header and add it to our string to sign
            token.append(Base64.encodeBase64URLSafeString(header.getBytes("UTF-8")));

            //Separate with a period
            token.append(".");

            //Create the JWT Claims Object
            String[] claimArray = new String[5];
            claimArray[0] = "value";
            claimArray[1] = "my@email.com";
            claimArray[2] = "https://login.salesforce.com";
            claimArray[3] = Long.toString( ( System.currentTimeMillis()/1000 ) + 300);
            MessageFormat claims;
            claims = new MessageFormat(claimTemplate);
            String payload = claims.format(claimArray);

            //Add the encoded claims object
            token.append(Base64.encodeBase64URLSafeString(payload.getBytes("UTF-8")));

            //Load the private key from a keystore
```

```
KeyStore keystore = KeyStore.getInstance("JKS");
keystore.load(new FileInputStream("./keystore.jks"), "awsglue".toCharArray());
PrivateKey privateKey = (PrivateKey) keystore.getKey("jwtcert",
"awsglue".toCharArray());

//Sign the JWT Header + "." + JWT Claims Object
Signature signature = Signature.getInstance("SHA256withRSA");
signature.initSign(privateKey);
signature.update(token.toString().getBytes("UTF-8"));
String signedPayload = Base64.encodeBase64URLSafeString(signature.sign());

//Separate with a period
token.append(".");

//Add the encoded signature
token.append(signedPayload);

System.out.println(token.toString());

} catch (Exception e) {
    e.printStackTrace();
}
}
```

## Connecting to SAP HANA in AWS Glue Studio

AWS Glue provides built-in support for SAP HANA. AWS Glue Studio provides a visual interface to connect to SAP HANA, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a SAP HANA connection](#)
- [Creating a SAP HANA source node](#)
- [Creating a SAP HANA target node](#)
- [Advanced options](#)

## Creating a SAP HANA connection

To connect to SAP HANA from AWS Glue, you will need to create and store your SAP HANA credentials in a AWS Secrets Manager secret, then associate that secret with a SAP HANA AWS Glue connection. You will need to configure network connectivity between your SAP HANA service and AWS Glue.

### Prerequisites:

- If your SAP HANA service is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the SAP HANA service without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your SAP HANA endpoint and this location. Your job will need to establish a TCP connection with your SAP HANA JDBC port. For more information about SAP HANA ports, see the [SAP HANA documentation](#). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

### To configure a connection to SAP HANA:

1. In AWS Secrets Manager, create a secret using your SAP HANA credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key user with the value *saphanaUsername*.
  - When selecting **Key/value pairs**, create a pair for the key password with the value *saphanaPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select SAP HANA.
  - When providing **SAP HANA URL**, provide the URL for your instance.

SAP HANA JDBC URLs are in the form

```
jdbc:sap://saphanaHostname:saphanaPort?databaseName=saphanaDBname,Parameter
```

AWS Glue requires the following JDBC URL parameters:

- *databaseName* – A default database in SAP HANA to connect to.
- When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue SAP HANA connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.

## Creating a SAP HANA source node

### Prerequisites needed

- An AWS Glue SAP HANA connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a SAP HANA connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A SAP HANA table you would like to read from, *tableName*, or query *targetQuery*.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName*.*tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in *connectionName*.

## Adding a SAP HANA data source

### To add a Data source – SAP HANA node:

1. Choose the connection for your SAP HANA data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create SAP HANA connection**. For more information see the previous section, [the section called “Creating a SAP HANA connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **SAP HANA Source** option:
  - **Choose a single table** – access all data from a single table.
  - **Enter custom query** – access a dataset from multiple tables based on your custom query.
3. If you chose a single table, enter *tableName*.  
  
If you chose **Enter custom query**, enter a SQL SELECT query.
4. In **Custom SAP HANA properties**, enter parameters and values as needed.

## Creating a SAP HANA target node

### Prerequisites needed

- A AWS Glue SAP HANA connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a SAP HANA connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A SAP HANA table you would like to write to, *tableName*.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in `connectionName`.

### Adding a SAP HANA data target

#### To add a Data target – SAP HANA node:

1. Choose the connection for your SAP HANA data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create SAP HANA connection**. For more information see the previous section, [the section called “Creating a SAP HANA connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Configure **Table name** by providing *tableName*.
3. In **Custom Teradata properties**, enter parameters and values as needed.

## Advanced options

You can provide advanced options when creating a SAP HANA node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called “SAP HANA connections”](#).

## Connecting to Snowflake in AWS Glue Studio

### Note

You can use AWS Glue for Spark to read from and write to tables in Snowflake in AWS Glue 4.0 and later versions. To configure a Snowflake connection with AWS Glue jobs programmatically, see [Redshift connections](#).

AWS Glue provides built-in support for Snowflake. AWS Glue Studio provides a visual interface to connect to Snowflake, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a Snowflake connection](#)
- [Creating a Snowflake source node](#)
- [Creating a Snowflake target node](#)
- [Advanced options](#)

## Creating a Snowflake connection

When adding a **Data source - Snowflake** node in AWS Glue Studio, you can choose an existing AWS Glue Snowflake connection or create a new connection. You must choose a SNOWFLAKE type connection and not a JDBC type connection configured to connect to Snowflake. Follow the following procedure to create a AWS Glue Snowflake connection:

### To create a Snowflake connection

1. In Snowflake, generate a user, *snowflakeUser* and password, *snowflakePassword*.

2. Determine which Snowflake warehouse this user will interact with, *snowflakeWarehouse*. Either set it as the DEFAULT\_WAREHOUSE for *snowflakeUser* in Snowflake or remember it for the next step.
3. In AWS Secrets Manager, create a secret using your Snowflake credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key sfUser.
  - When selecting **Key/value pairs**, create a pair for *snowflakePassword* with the key sfPassword.
  - When selecting **Key/value pairs**, create a pair for *snowflakeWarehouse* with the key sfWarehouse. This is not needed if a default is set in Snowflake.
4. In the AWS Glue Data Catalog, create a connection by following the steps in [Adding an AWS Glue connection](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select Snowflake.
  - When selecting **Snowflake URL**, provide the hostname of your Snowflake instance. The URL will use a hostname in the form *account\_identifier*.snowflakecomputing.com.
  - When selecting an **AWS Secret**, provide *secretName*.

## Creating a Snowflake source node

### Permissions needed

AWS Glue Studio jobs using Snowflake data sources require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

SNOWFLAKE AWS Glue connections use an AWS Secrets Manager secret to provide credential information. Your job and data preview roles in AWS Glue Studio must have permission to read this secret.

### Adding a Snowflake data source

#### Prerequisites:

- An AWS Secrets Manager secret for your Snowflake credentials
- A Snowflake type AWS Glue Data Catalog connection

### To add a Data Source – Snowflake node:

1. Choose the connection for your Snowflake data source. This assumes that the connection already exists and you can select from existing connections. If you need to create a connection, choose **Create Snowflake connection**. For more information, see [Overview of using connectors and connections](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**. Information about the connection are visible, including URL, security groups, subnet, availability zone, description, and created (UTC) and last updated (UTC) timestamps.

2. Choose a Snowflake source option:
  - **Choose a single table** – this is the table that contains the data you want to access from a single Snowflake table.
  - **Enter custom query** – allows you to access a dataset from multiple Snowflake tables based on your custom query.
3. If you chose a single table, enter the name of a Snowflake schema.

Or, choose **Enter custom query**. Choose this option to access a custom dataset from multiple Snowflake tables. When you choose this option, enter the Snowflake query.

4. In **Performance and security** options (optional),
  - **Enable query pushdown** – choose if you want to offload work to the Snowflake instance.
5. In **Custom Snowflake properties** (optional), enter parameters and values as needed.

## Creating a Snowflake target node

### Permissions needed

AWS Glue Studio jobs using Snowflake data sources require additional permissions. For more information on how to add permissions to ETL jobs, see [Review IAM permissions needed for ETL jobs](#).

SNOWFLAKE AWS Glue connections use an AWS Secrets Manager secret to provide credential information. Your job and data preview roles in AWS Glue Studio must have permission to read this secret.

## Adding a Snowflake data target

### To create a Snowflake target node:

1. Choose an existing Snowflake table as the target, or enter a new table name.
2. When you use the **Data target - Snowflake** target node, you can choose from the following options:
  - **APPEND** – If a table already exists, dump all the new data into the table as an insert. If the table doesn't exist, create it and then insert all new data.
  - **MERGE** – AWS Glue will update or append data to your target table based on the conditions you specify.

Choose options:

- **Choose keys and simple actions** – choose the columns to be used as matching keys between the source data and your target data set.

Specify the following options when matched:

- Update record in your target data set with data from source.
- Delete record in your target data set.

Specify the following options when not matched:

- Insert source data as a new row into your target data set.
- Do nothing.
- **Enter custom MERGE statement** – You can then choose **Validate Merge statement** to verify that the statement is valid or invalid.
- **TRUNCATE** – If a table already exists, truncate the table data by first clearing the contents of the target table. If truncate is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If truncate is not successful, the operation will fail.
- **DROP** – If a table already exists, delete the table metadata and data. If deletion is successful, then insert all data. If the table doesn't exist, create the table and insert all data. If drop is not successful, the operation will fail.

## Advanced options

See [Snowflake connections](#) in the AWS Glue developer guide.

## Connecting to Teradata Vantage in AWS Glue Studio

AWS Glue provides built-in support for Teradata Vantage. AWS Glue Studio provides a visual interface to connect to Teradata, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a Teradata Vantage connection](#)
- [Creating a Teradata source node](#)

- [Advanced options](#)

## Creating a Teradata Vantage connection

To connect to Teradata Vantage from AWS Glue, you will need to create and store your Teradata credentials in an AWS Secrets Manager secret, then associate that secret with a AWS Glue Teradata connection.

### Prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP connection with your Teradata client port. For more information about Teradata ports, see the [Teradata documentation](#).

Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about AWS connectivity, consult [AWS Connectivity Options](#) in the Teradata documentation.

## To configure a AWS Glue Teradata connection:

1. In your Teradata configuration, identify or create a user and password AWS Glue will connect with, *teradataUser* and *teradataPassword*. For more information, consult [Vantage Security Overview](#) in the Teradata documentation.
2. In AWS Secrets Manager, create a secret using your Teradata credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key user with the value *teradataUsername*.
  - When selecting **Key/value pairs**, create a pair for the key password with the value *teradataPassword*.
3. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select Teradata.
  - When providing **JDBC URL**, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format:  
`jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName`

Supported URL parameters include:

  - DATABASE– name of database on host to access by default.
  - DBS\_PORT– the database port, used when running on a nonstandard port.
  - When selecting a **Credential type**, select **AWS Secrets Manager**, then set **AWS Secret** to *secretName*.
4. In the following situations, you may require additional configuration:
  - For Teradata instances hosted on AWS in an Amazon VPC
    - You will need to provide Amazon VPC connection information to the AWS Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

## Creating a Teradata source node

### Prerequisites needed

- An AWS Glue Teradata Vantage connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a Teradata Vantage connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Teradata table you would like to read from, *tableName*, or query *targetQuery*.

### Adding a Teradata data source

#### To add a Data source – Teradata node:

1. Choose the connection for your Teradata data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create a new connection**. For more information see the previous section, [the section called “Creating a Teradata Vantage connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose a **Teradata Source** option:
  - **Choose a single table** – access all data from a single table.
  - **Enter custom query** – access a dataset from multiple tables based on your custom query.
3. If you chose a single table, enter *tableName*.

If you chose **Enter custom query**, enter a SQL SELECT query.

4. In **Custom Teradata properties**, enter parameters and values as needed.

## Creating a Teradata target node

### Prerequisites needed

- A AWS Glue Teradata Vantage connection, configured with an AWS Secrets Manager secret, as described in the previous section, [the section called “Creating a Teradata Vantage connection”](#).
- Appropriate permissions on your job to read the secret used by the connection.
- A Teradata table you would like to write to, *tableName*.

## Adding a Teradata data target

### To add a Data target – Teradata node:

1. Choose the connection for your Teradata data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Teradata connection**. For more information, see [Overview of using connectors and connections](#) .

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Configure **Table name** by providing *tableName*.
3. In **Custom Teradata properties**, enter parameters and values as needed.

## Advanced options

You can provide advanced options when creating a Teradata node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called “Teradata Vantage connections”](#).

## Connecting to Vertica in AWS Glue Studio

AWS Glue provides built-in support for Vertica. AWS Glue Studio provides a visual interface to connect to Vertica, author data integration jobs, and run them on the AWS Glue Studio serverless Spark runtime.

### Topics

- [Creating a Vertica connection](#)
- [Creating a Vertica source node](#)
- [Creating a Vertica target node](#)
- [Advanced options](#)

## Creating a Vertica connection

### Prerequisites:

- An Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database, referred to by *tempS3Path*.

**Note**

When using Vertica in AWS Glue job data previews, temporary files may not be automatically removed from *tempS3Path*. To ensure the removal of temporary files, directly end the data preview session by choosing **End session** in the **Data preview** pane. If you cannot guarantee the data preview session is ended directly, consider setting Amazon S3 Lifecycle configuration to remove old data. We recommend removing data older than 49 hours, based on maximum job runtime plus a margin. For more information about configuring Amazon S3 Lifecycle, see [Managing your storage lifecycle](#) in the Amazon S3 documentation.

- An IAM policy with appropriate permissions to your Amazon S3 path you can associate with your AWS Glue job role.
- If your Vertica instance is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Vertica instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Vertica instance and this location. Your job will need to establish a TCP connection with your Vertica client port, (default 5433). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

**To configure a connection to Vertica:**

1. In AWS Secrets Manager, create a secret using your Vertica credentials, *verticaUsername* and *verticaPassword*. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key user with the value *verticaUsername*.
  - When selecting **Key/value pairs**, create a pair for the key password with the value *verticaPassword*.

2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select Vertica.
  - When selecting **Vertica Host**, provide the hostname of your Vertica installation.
  - When selecting **Vertica Port**, the port your Vertica installation is available through.
  - When selecting an **AWS Secret**, provide *secretName*.
3. In the following situations, you may require additional configuration:
  - For Vertica instances hosted on AWS in an Amazon VPC
    - Provide Amazon VPC connection information to the AWS Glue connection that defines your Vertica security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

You will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permissions to *tempS3Path*.
- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.

## Creating a Vertica source node

### Prerequisites needed

- A Vertica type AWS Glue Data Catalog connection, *connectionName* and a temporary Amazon S3 location, *tempS3Path*, as described in the previous section, [the section called "Creating a Vertica connection"](#).
- A Vertica table you would like to read from, *tableName*, or query *targetQuery*.

### Adding a Vertica data source

#### To add a Data source – Vertica node:

1. Choose the connection for your Vertica data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Vertica**

**connection.** For more information see the previous section, [the section called “Creating a Vertica connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose the **Database** containing your table.
3. Choose the **Staging area in Amazon S3**, enter an S3A URI to *tempS3Path*.
4. Choose the **Vertica Source**.
  - **Choose a single table** – access all data from a single table.
  - **Enter custom query** – access a dataset from multiple tables based on your custom query.
5. If you chose a single table, enter *tableName* and optionally select a **Schema**.

If you chose **Enter custom query**, enter a SQL SELECT query and optionally select a **Schema**.

6. In **Custom Vertica properties**, enter parameters and values as needed.

## Creating a Vertica target node

### Prerequisites needed

- A Vertica type AWS Glue Data Catalog connection, *connectionName* and a temporary Amazon S3 location, *tempS3Path*, as described in the previous section, [the section called “Creating a Vertica connection”](#).

### Adding a Vertica data target

#### To add a Data target – Vertica node:

1. Choose the connection for your Vertica data source. Since you have created it, it should be available in the dropdown. If you need to create a connection, choose **Create Vertica connection**. For more information see the previous section, [the section called “Creating a Vertica connection”](#).

Once you have chosen a connection, you can view the connection properties by clicking **View properties**.

2. Choose the **Database** containing your table.
3. Choose the **Staging area in Amazon S3**, enter an S3A URI to *tempS3Path*.

4. Enter *tableName* and optionally select a **Schema**.
5. In **Custom Vertica properties**, enter parameters and values as needed.

## Advanced options

You can provide advanced options when creating a Vertica node. These options are the same as those available when programming AWS Glue for Spark scripts.

See [the section called “Vertica connections”](#).

## Using connectors and connections with AWS Glue Studio

AWS Glue provides built-in support for the most commonly used data stores (such as Amazon Redshift, Amazon Aurora, Microsoft SQL Server, MySQL, MongoDB, and PostgreSQL) using JDBC connections. AWS Glue also allows you to use custom JDBC drivers in your extract, transform, and load (ETL) jobs. For data stores that are not natively supported, such as SaaS applications, you can use connectors.

A *connector* is an optional code package that assists with accessing data stores in AWS Glue Studio. You can subscribe to several connectors offered in AWS Marketplace.

When creating ETL jobs, you can use a natively supported data store, a connector from AWS Marketplace, or your own custom connectors. If you use a connector, you must first create a connection for the connector. A *connection* contains the properties that are required to connect to a particular data store. You use the connection with your data sources and data targets in the ETL job. Connectors and connections work together to facilitate access to the data stores.

### Topics

- [Overview of using connectors and connections](#)
- [Adding connectors to AWS Glue Studio](#)
- [Available connections](#)
- [Creating connections for connectors](#)
- [Authoring jobs with custom connectors](#)
- [Managing connectors and connections](#)
- [Developing custom connectors](#)

- [Restrictions for using connectors and connections in AWS Glue Studio](#)

## Overview of using connectors and connections

A *connection* contains the properties that are required to connect to a particular data store. When you create a connection, it is stored in the AWS Glue Data Catalog. You choose a connector, and then create a connection based on that connector.

You can subscribe to connectors for non-natively supported data stores in AWS Marketplace, and then use those connectors when you're creating connections. Developers can also create their own connectors, and you can use them when creating connections.

### Note

Connections created using custom or AWS Marketplace connectors in AWS Glue Studio appear in the AWS Glue console with type set to UNKNOWN.

The following steps describe the overall process of using connectors in AWS Glue Studio:

1. Subscribe to a connector in AWS Marketplace, or develop your own connector and upload it to AWS Glue Studio. For more information, see [Adding connectors to AWS Glue Studio](#).
2. Review the connector usage information. You can find this information on the **Usage** tab on the connector product page. For example, if you click the **Usage** tab on this product page, [AWS Glue Connector for Google BigQuery](#), you can see in the **Additional Resources** section a link to a blog about using this connector. Other connectors might contain links to the instructions in the **Overview** section, as shown on the connector product page for [Cloudwatch Logs connector for AWS Glue](#).
3. Create a connection. You choose which connector to use and provide additional information for the connection, such as login credentials, URI strings, and virtual private cloud (VPC) information. For more information, see [Creating connections for connectors](#).
4. Create an IAM role for your job. The job assumes the permissions of the IAM role that you specify when you create it. This IAM role must have the necessary permissions to authenticate with, extract data from, and write data to your data stores.
5. Create an ETL job and configure the data source properties for your ETL job. Provide the connection options and authentication information as instructed by the custom connector provider. For more information, see [Authoring jobs with custom connectors](#).

6. Customize your ETL job by adding transforms or additional data stores, as described in [Visual ETL with AWS Glue Studio](#).
7. If using a connector for the data target, configure the data target properties for your ETL job. Provide the connection options and authentication information as instructed by the custom connector provider. For more information, see [the section called "Authoring jobs with custom connectors"](#).
8. Customize the job run environment by configuring job properties, as described in [Modify the job properties](#).
9. Run the job.

## Adding connectors to AWS Glue Studio

A connector is a piece of code that facilitates communication between your data store and AWS Glue. You can either subscribe to a connector offered in AWS Marketplace, or you can create your own custom connector.

### Topics

- [Subscribing to AWS Marketplace connectors](#)
- [Creating custom connectors](#)

### Subscribing to AWS Marketplace connectors

AWS Glue Studio makes it easy to add connectors from AWS Marketplace.

#### To add a connector from AWS Marketplace to AWS Glue Studio

1. In the AWS Glue Studio console, choose **Connectors** in the console navigation pane.
2. On the **Connectors** page, choose **Go to AWS Marketplace**.
3. In AWS Marketplace, in **Featured products**, choose the connector you want to use. You can choose one of the featured connectors, or use search. You can search on the name or type of connector, and you can use options to refine the search results.

If you want to use one of the featured connectors, choose **View product**. If you used search to locate a connector, then choose the name of the connector.

4. On the product page for the connector, use the tabs to view information about the connector. If you decide to purchase this connector, choose **Continue to Subscribe**.

5. Provide the payment information, and then choose **Continue to Configure**.
6. On the **Configure this software** page, choose the method of deployment and the version of the connector to use. Then choose **Continue to Launch**.
7. On the **Launch this software** page, you can review the **Usage Instructions** provided by the connector provider. When you're ready to continue, choose **Activate connection in AWS Glue Studio**.

After a small amount of time, the console displays the **Create marketplace connection** page in AWS Glue Studio.

8. Create a connection that uses this connector, as described in [Creating connections for connectors](#).

Alternatively, you can choose **Activate connector only** to skip creating a connection at this time. You must create a connection at a later date before you can use the connector.

## Creating custom connectors

You can also build your own connector and then upload the connector code to AWS Glue Studio.

Custom connectors are integrated into AWS Glue Studio through the AWS Glue Spark runtime API. The AWS Glue Spark runtime allows you to plug in any connector that is compliant with the Spark, Athena, or JDBC interface. It allows you to pass in any connection option that is available with the custom connector.

You can encapsulate all your connection properties with [AWS Glue Connections](#) and supply the connection name to your ETL job. Integration with Data Catalog connections allows you to use the same connection properties across multiple calls in a single Spark application or across different applications.

You can specify additional options for the connection. The job script that AWS Glue Studio generates contains a `Datasource` entry that uses the connection to plug in your connector with the specified connection options. For example:

```
Datasource = glueContext.create_dynamic_frame.from_options(connection_type =
"custom.jdbc", connection_options = {"dbTable":"Account","connectionName":"my-custom-
jdbc-
connection"}, transformation_ctx = "DataSource0")
```

## To add a custom connector to AWS Glue Studio

1. Create the code for your custom connector. For more information, see [Developing custom connectors](#).
2. Add support for AWS Glue features to your connector. Here are some examples of these features and how they are used within the job script generated by AWS Glue Studio:
  - **Data type mapping** – Your connector can typecast the columns while reading them from the underlying data store. For example, a `dataTypeMapping` of `{"INTEGER": "STRING"}` converts all columns of type `Integer` to columns of type `String` when parsing the records and constructing the `DynamicFrame`. This helps users to cast columns to types of their choice.

```
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type = "custom.jdbc", connection_options = {"dataTypeMapping":{"INTEGER":"STRING"}", connectionName:"test-connection-jdbc"}, transformation_ctx = "DataSource0")
```

- **Partitioning for parallel reads** – AWS Glue allows parallel data reads from the data store by partitioning the data on a column. You must specify the partition column, the lower partition bound, the upper partition bound, and the number of partitions. This feature enables you to make use of data parallelism and multiple Spark executors allocated for the Spark application.

```
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type = "custom.jdbc", connection_options = {"upperBound":"200", "numPartitions":"4", "partitionColumn":"id", "lowerBound":"0", "connectionName":"test-connection-jdbc"}, transformation_ctx = "DataSource0")
```

- **Use AWS Secrets Manager for storing credentials** –The Data Catalog connection can also contain a `secretId` for a secret stored in AWS Secrets Manager. The AWS secret can securely store authentication and credentials information and provide it to AWS Glue at runtime. Alternatively, you can specify the `secretId` from the Spark script as follows:

```
DataSource = glueContext.create_dynamic_frame.from_options(connection_type = "custom.jdbc", connection_options = {"connectionName":"test-connection-jdbc", "secretId"-> "my-secret-id"}, transformation_ctx = "DataSource0")
```

- **Filtering the source data with row predicates and column projections** – The AWS Glue Spark runtime also allows users to push down SQL queries to filter data at the source with row predicates and column projections. This allows your ETL job to load filtered data faster

from data stores that support push-downs. An example SQL query pushed down to a JDBC data source is: `SELECT id, name, department FROM department WHERE id < 200`.

```
DataSource = glueContext.create_dynamic_frame.from_options(connection_type =
"custom.jdbc", connection_options = {"query":"SELECT id, name, department FROM
department
WHERE id < 200"}, "connectionName":"test-connection-jdbc"}, transformation_ctx =
"DataSource0")
```

- **Job bookmarks** – AWS Glue supports incremental loading of data from JDBC sources. AWS Glue keeps track of the last processed record from the data store, and processes new data records in the subsequent ETL job runs. Job bookmarks use the primary key as the default column for the bookmark key, provided that this column increases or decreases sequentially. For more information about job bookmarks, see [Job Bookmarks](#) in the *AWS Glue Developer Guide*.

```
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
"custom.jdbc", connection_options = {"jobBookmarkKeys":["empno"],
"jobBookmarkKeysSortOrder"
:"asc", "connectionName":"test-connection-jdbc"}, transformation_ctx =
"DataSource0")
```

3. Package the custom connector as a JAR file and upload the file to Amazon S3.
4. Test your custom connector. For more information, see the instructions on GitHub at [Glue Custom Connectors: Local Validation Tests Guide](#).
5. In the AWS Glue Studio console, choose **Connectors** in the console navigation pane.
6. On the **Connectors** page, choose **Create custom connector**.
7. On the **Create custom connector** page, enter the following information:
  - The path to the location of the custom code JAR file in Amazon S3.
  - A name for the connector that will be used by AWS Glue Studio.
  - Your connector type, which can be one of **JDBC**, **Spark**, or **Athena**.
  - The name of the entry point within your custom code that AWS Glue Studio calls to use the connector.
    - For JDBC connectors, this field should be the class name of your JDBC driver.

- For Spark connectors, this field should be the fully qualified data source class name, or its alias, that you use when loading the Spark data source with the `format` operator.
  - (JDBC only) The base URL used by the JDBC connection for the data store.
  - (Optional) A description of the custom connector.
8. Choose **Create connector**.
  9. From the **Connectors** page, create a connection that uses this connector, as described in [Creating connections for connectors](#).

## Available connections

The following connections are available when creating connections for connectors:

- **Amazon Aurora** – a scalable, high-performance relational database engine with built-in security, backup and restore, and in-memory acceleration.
- **Amazon DocumentDB** – a scalable, highly available, and fully managed document database service that supports MongoDB and SQL APIs.
- **Amazon Redshift** – a scalable, highly available, and fully managed document database service that supports MongoDB and SQL APIs.
- **Azure SQL** – a cloud-based relational database service from Microsoft Azure that provides scalable, reliable, and secure data storage and management capabilities.
- **Cosmos DB** – a globally distributed cloud database service from Microsoft Azure that provides scalable, high-performance data storage and querying capabilities.
- **Google BigQuery** – a serverless cloud data warehouse for running fast SQL queries on large datasets.
- **JDBC** – a relational database management system (RDBMS) that uses a Java API for connecting and interacting with data connections.
- **Kafka** – an open-source stream processing platform used for real-time data streaming and messaging.
- **MariaDB** – a community-developed fork of MySQL that offers enhanced performance, scalability, and features.
- **MongoDB** – a cross-platform document-oriented database that provides high scalability, flexibility, and performance.
- **MongoDB Atlas** – a cloud-based database as a service (DBaaS) offering from MongoDB that simplifies the management and scaling of MongoDB deployments.

- **Microsoft SQL Server** – a relational database management system (RDBMS) from Microsoft that provides robust data storage, analysis, and reporting capabilities.
- **MySQL** – an open-source relational database management system (RDBMS) that is widely used in web applications and is known for its reliability and scalability.
- **Network** – a network data source represents a network-accessible resource or service that can be accessed by a data integration platform.
- **OpenSearch** – an OpenSearch data source is an application that OpenSearch can connect to and ingest data from.
- **Oracle** – a relational database management system (RDBMS) from Oracle Corporation that provides robust data storage, analysis, and reporting capabilities.
- **PostgreSQL** – an open-source relational database management system (RDBMS) that provides robust data storage, analysis, and reporting capabilities.
- **Salesforce** – Salesforce provides customer relationship management (CRM) software that help you with sales, customer service, e-commerce, and more. If you're a Salesforce user, you can connect AWS Glue to your Salesforce account. Then, you can use Salesforce as a data source or destination in your ETL jobs. Run these jobs to transfer data between Salesforce and AWS services or other supported applications.
- **SAP HANA** – an in-memory database and analytics platform that provides fast data processing, advanced analytics, and real-time data integration.
- **Snowflake** – a cloud-based data warehouse that provides scalable, high-performance data storage and analytics services.
- **Teradata** – a relational database management system (RDBMS) that provides high-performance data storage, analysis, and reporting capabilities.
- **Vertica** – a columnar-oriented analytical data warehouse designed for big data analytics that offers fast query performance, advanced analytics, and scalability.

## Creating connections for connectors

An AWS Glue connection is a Data Catalog object that stores connection information for a particular data store. Connections store login credentials, URI strings, virtual private cloud (VPC) information, and more. Creating connections in the Data Catalog saves the effort of having to specify all connection details every time you create a job.

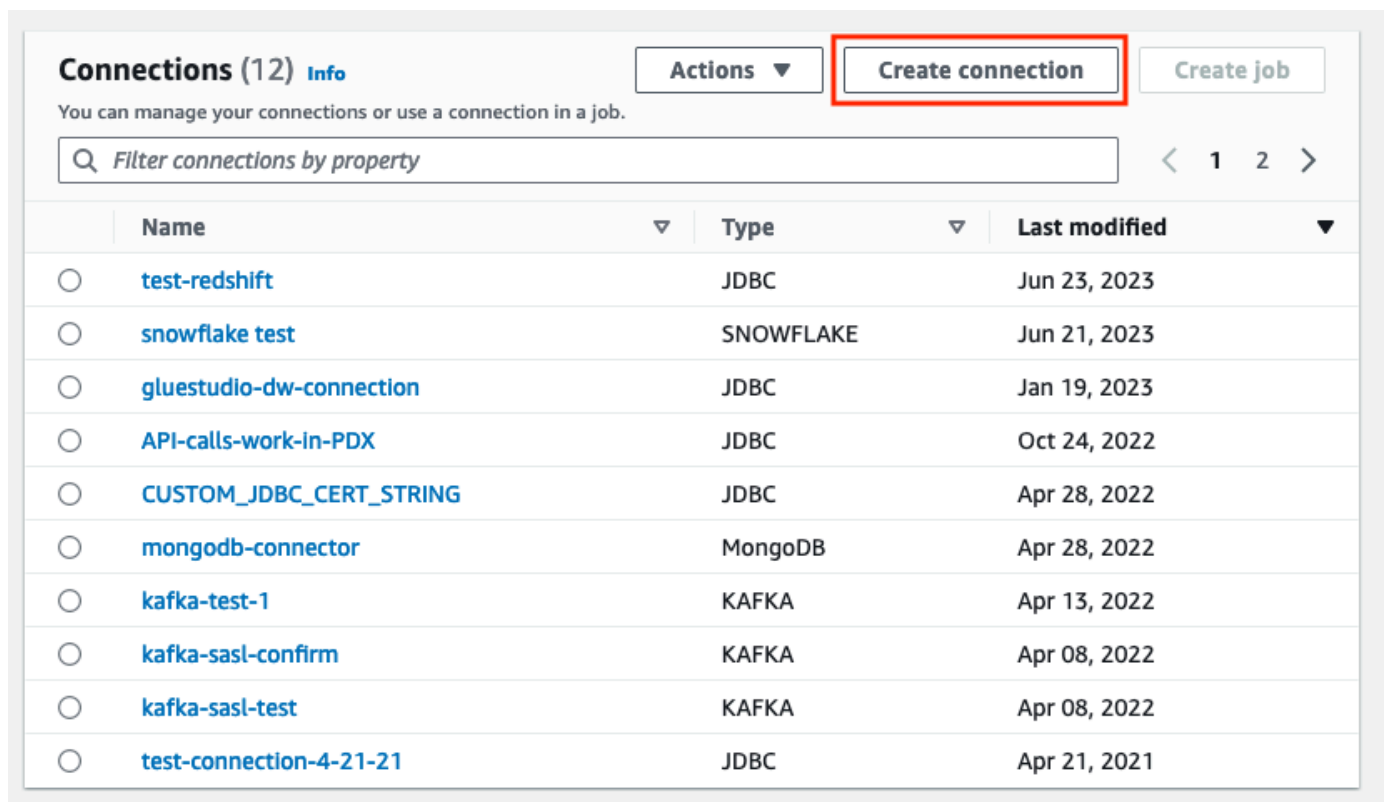

## To create a connection for a connector

1. In the AWS Glue Studio console, choose **Connectors** in the console navigation pane. In the **Connections** section, choose **Create connection**.
2. Choose the data source you want to create a connection for in step 1 of the **Create data connection** wizard. There are several ways to view the available data sources, including:
  - Filter the available data sources by choosing a tab. By default, **All connectors** is selected.
  - Toggle **List** to view the data sources as a list or toggle back to **Grid** to view the available connectors in the grid layout.
  - Use the search bar to narrow the list of data sources. As you type, search matches are displayed and non-matching sources are removed from view.

Once you've chosen the data source, choose **Next**.

3. Configure the connection in Step 2 in the wizard.

Enter the connection details. Depending on the type of connector you selected, you're prompted to enter additional information:

The screenshot shows the AWS Glue Studio console interface for managing connections. At the top, there is a header with 'Connections (12) Info', an 'Actions' dropdown menu, and a 'Create connection' button highlighted with a red box. Below the header is a search bar with the placeholder text 'Filter connections by property' and navigation arrows. The main content is a table listing various connections.

	Name	Type	Last modified
<input type="radio"/>	test-redshift	JDBC	Jun 23, 2023
<input type="radio"/>	snowflake test	SNOWFLAKE	Jun 21, 2023
<input type="radio"/>	gluestudio-dw-connection	JDBC	Jan 19, 2023
<input type="radio"/>	API-calls-work-in-PDX	JDBC	Oct 24, 2022
<input type="radio"/>	CUSTOM_JDBC_CERT_STRING	JDBC	Apr 28, 2022
<input type="radio"/>	mongodb-connector	MongoDB	Apr 28, 2022
<input type="radio"/>	kafka-test-1	KAFKA	Apr 13, 2022
<input type="radio"/>	kafka-sasl-confirm	KAFKA	Apr 08, 2022
<input type="radio"/>	kafka-sasl-test	KAFKA	Apr 08, 2022
<input type="radio"/>	test-connection-4-21-21	JDBC	Apr 21, 2021

4. Choose the data source you want to create a connection for in step 1 of the **Create data connection** wizard. There are several ways to view the available data sources. By default, you will see all available data sources in a grid layout. You can also:
  - Toggle **List** to view the data sources as a list or toggle back to **Grid** to view the available connectors in the grid layout.
  - Use the search bar to narrow the list of data sources. As you type, search matches are displayed and non-matching sources are removed from view.

Once you've chosen the data source, choose **Next**.

5. Configure the connection in Step 2 in the wizard.

Enter the connection details. Depending on the type of connector you selected, you may be required to enter additional connection information. This can include:

- **Connection details** – these fields will change depending on the data source you are connecting to. For example, if you are connecting to Amazon DocumentDB databases, you will enter the Amazon DocumentDB URL. If you are connecting to Amazon Aurora, you will choose the database instance and enter the database name. The following is the Connection details required for Amazon Aurora:

The screenshot shows the 'Configure connection' wizard in AWS Glue. The wizard is in Step 2, 'Configure connection'. The 'Connection details' section is highlighted with a blue box. It contains the following fields and options:

- Database instances:** A dropdown menu with the text 'Choose one JDBC URL' and a refresh button.
- Database name:** A text input field.
- Credential type:** Two radio buttons: 'Username and password' (selected) and 'AWS Secrets Manager'.
- Username:** A text input field.
- Password:** A text input field.

At the bottom right of the wizard, there are three buttons: 'Cancel', 'Previous', and 'Next'.

- Credential type – choose between **Username and password** or **AWS Secrets Manager**. Enter the requested authentication information.
  - For connectors that use JDBC, enter the information required to create the JDBC URL for the data store.
  - If you use a virtual private cloud (VPC), then enter the network information for your VPC.
6. Set the connection properties in step 3 of the wizard. You can add a description and tags as an optional part of this step. Name is required and is prepopulated with a default value. Choose **Next**.
  7. Review the connection source, details, and properties. If you need to make any changes, choose **Edit** for the step in the wizard. When ready, choose, **Create connection** .

Choose **Create connection**.

You are returned to the **Connectors** page, and the informational banner indicates the connection that was created. You can now use the connection in your AWS Glue Studio jobs.

## Creating a Kafka connection

When creating a Kafka connection, selecting **Kafka** from the drop-down menu will display additional settings to configure:

- Kafka cluster details
- Authentication
- Encryption
- Network options

## Configure Kafka cluster details

1. Choose the cluster location. You can choose from an **Amazon managed streaming for Apache Kafka (MSK)** cluster or a **Customer managed Apache Kafka** cluster. For more information on Amazon Managed streaming for Apache Kafka, see [Amazon managed streaming for Apache Kafka \(MSK\)](#).

### Note

Amazon Managed Streaming for Apache Kafka only supports TLS and SASL/SCRAM-SHA-512 authentication methods.

**Kafka cluster details** [Info](#)

Cluster location

Amazon managed streaming for Apache Kafka (MSK)

Customer managed Apache Kafka

Kafka bootstrap server URLs [Info](#)

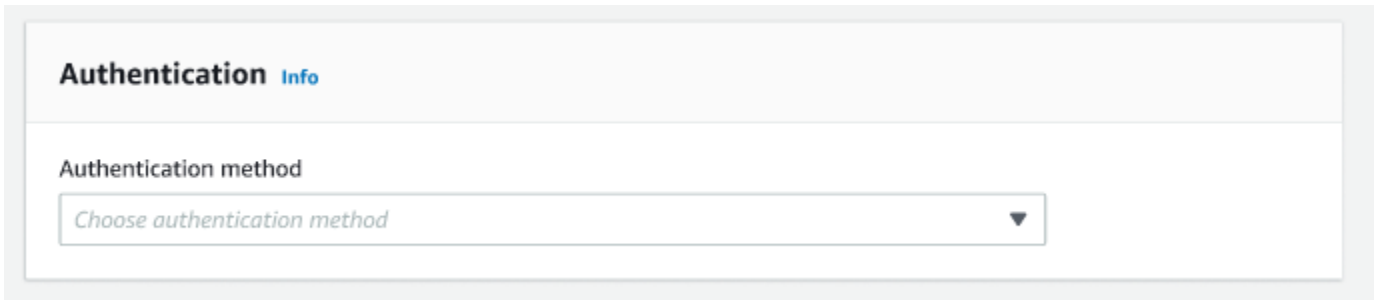

A comma-separated list of bootstrap server URLs. Include the port number.

Example: b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-2.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094, b-3.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094

2. Enter the URLs for your Kafka bootstrap servers. You may enter more than one by separating each server by a comma. Include the port number at the end of the URL by appending `:<port number>`.

For example: `b-1.vpc-test-2.034a88o.kafka-us-east-1.amazonaws.com:9094`

## Select authentication method

**Authentication** [Info](#)

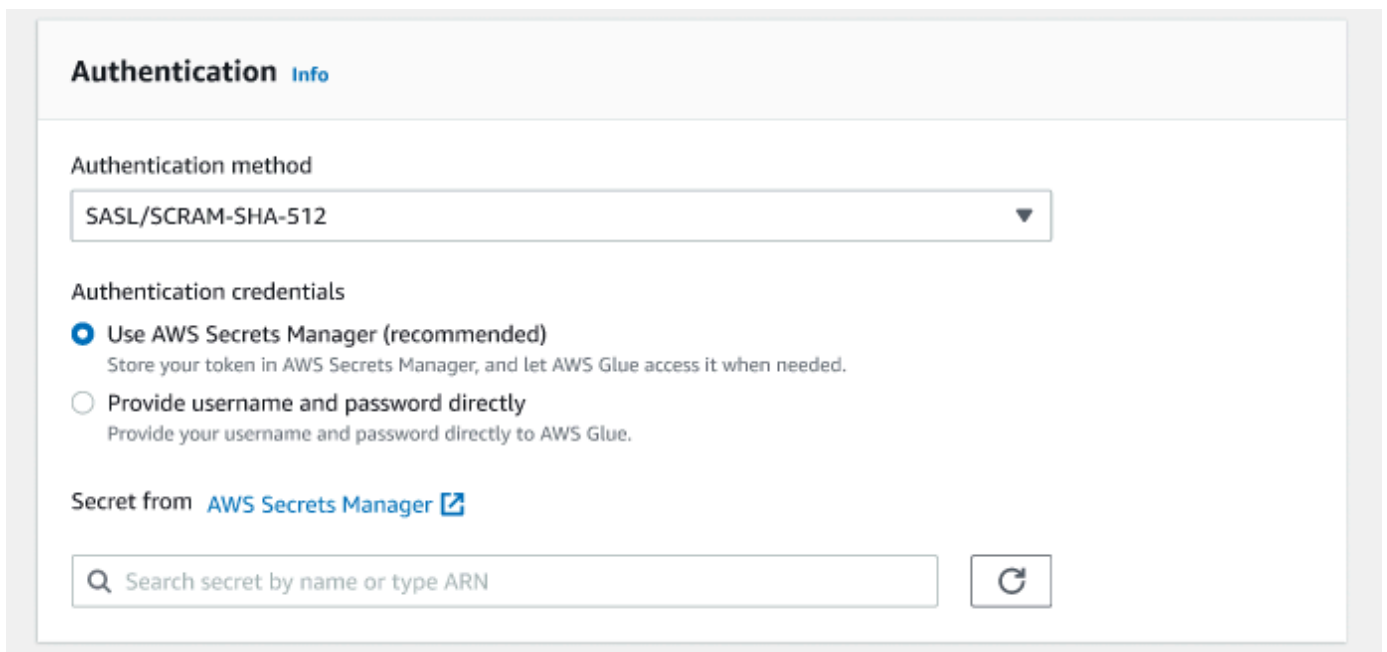

Authentication method

Choose authentication method ▼

AWS Glue supports the Simple Authentication and Security Layer (SASL) framework for authentication. The SASL framework supports various mechanisms of authentication, and AWS Glue offers the SCRAM (username and password), GSSAPI (Kerberos protocol), and PLAIN (username and password) protocols.

When choosing an authentication method from the drop-down menu, the following client authentication methods can be selected:

- None - No authentication. This is useful if you create a connection for testing purposes.
- SASL/SCRAM-SHA-512 - Choose this authentication method to specify authentication credentials. There are two options available:
  - Use AWS Secrets Manager (recommended) - if you select this option, you can store your credentials in AWS Secrets Manager and let AWS Glue access the information when needed. Specify the secret that stores the SSL or SASL authentication credentials.

**Authentication** [Info](#)

SASL/SCRAM-SHA-512 ▼

Authentication credentials

Use AWS Secrets Manager (recommended)  
Store your token in AWS Secrets Manager, and let AWS Glue access it when needed.

Provide username and password directly  
Provide your username and password directly to AWS Glue.

Secret from [AWS Secrets Manager](#) [↗](#)

🔍 Search secret by name or type ARN ↻

- Provide username and password directly.
- SASL/GSSAPI (Kerberos) - if you select this option, you can select the location of the keytab file, krb5.conf file and enter the Kerberos principal name and Kerberos service name. The locations for the keytab file and krb5.conf file must be in an Amazon S3 location. Since MSK does not yet support SASL/GSSAPI, this option is only available for customer managed Apache Kafka clusters. For more information, see [MIT Kerberos Documentation: Keytab](#).
- SASL/PLAIN - Choose this authentication method to specify authentication credentials. There are two options available:
  - Use AWS Secrets Manager (recommended) - if you select this option, you can store your credentials in AWS Secrets Manager and let AWS Glue access the information when needed. Specify the secret that stores the SSL or SASL authentication credentials.
  - Provide username and password directly.
- SSL Client Authentication - if you select this option, you can you can select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

↗

Browse S3

Path must be in the form s3://bucket/prefix/path/. It must end with the file name and .jks extension.

Kafka client keystore password - *optional*

Enter password

Kafka client key password - *optional*

Enter password

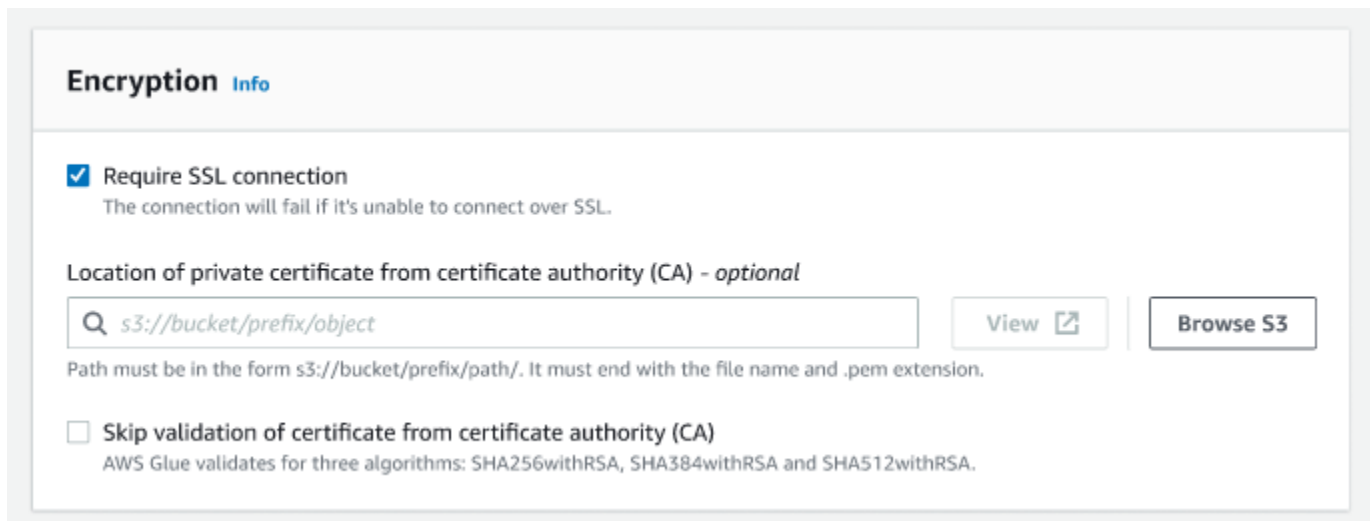

## Configure encryption settings

1. If the Kafka connection requires SSL connection, select the checkbox for **Require SSL connection**. Note that the connection will fail if it's unable to connect over SSL. SSL for

encryption can be used with any of the authentication methods (SASL/SCRAM-SHA-512, SASL/GSSAPI, SASL/PLAIN, or SSL Client Authentication) and is optional.

If the authentication method is set to **SSL client authentication**, this option will be selected automatically and will be disabled to prevent any changes.

2. (Optional). Choose the location of private certificate from certificate authority (CA). Note that the location of the certification must be in an S3 location. Choose **Browse** to choose the file from a connected S3 bucket. The path must be in the form `s3://bucket/prefix/filename.pem`. It must end with the file name and `.pem` extension.
3. You can choose to skip validation of certificate from a certificate authority (CA). Choose the checkbox **Skip validation of certificate from certificate authority (CA)**. If this box is not checked, AWS Glue validates certificates for three algorithms:
  - SHA256withRSA
  - SHA384withRSA
  - SHA512withRSA

**Encryption** [Info](#)

**Require SSL connection**  
The connection will fail if it's unable to connect over SSL.

Location of private certificate from certificate authority (CA) - *optional*

Path must be in the form `s3://bucket/prefix/path/`. It must end with the file name and `.pem` extension.

**Skip validation of certificate from certificate authority (CA)**  
AWS Glue validates for three algorithms: SHA256withRSA, SHA384withRSA and SHA512withRSA.

### (Optional) Network options

The following are optional steps to configure VPC, Subnet and Security groups. If your AWS Glue job needs to run on Amazon EC2 instances in a virtual private cloud (VPC) subnet, you must provide additional VPC-specific configuration information.

1. Choose the VPC (virtual private cloud) that contains your data source.
2. Choose the subnet with your VPC.

3. Choose one or more security groups to allow access to the data store in your VPC subnet. Security groups are associated to the ENI attached to your subnet. You must choose at least one security group with a self-referencing inbound rule for all TCP ports.

### ▼ Network options - *optional*

If your AWS Glue job needs to run on [Amazon Elastic Compute Cloud](#) (EC2) instances in a virtual private cloud (VPC) subnet, you must provide additional VPC-specific configuration information.

#### VPC [Info](#)

Choose the virtual private cloud that contains your data source.

 ▼ 

#### Subnet [Info](#)

Choose the subnet within your VPC.

 ▼

#### Security groups [Info](#)

Choose one or more security groups to allow access to the data store in your VPC subnet. Security groups are associated to the ENI attached to your subnet. You must choose at least one security group with a self-referencing inbound rule for all TCP ports.

 ▼

## Authoring jobs with custom connectors

You can use connectors and connections for both data source nodes and data target nodes in AWS Glue Studio.

### Topics

- [Create jobs that use a connector for the data source](#)
- [Configure source properties for nodes that use connectors](#)
- [Configure target properties for nodes that use connectors](#)

### Create jobs that use a connector for the data source

When you create a new job, you can choose a connector for the data source and data targets.

## To create a job that uses connectors for the data source or data target

1. Sign in to the AWS Management Console and open the AWS Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.
2. On the **Connectors** page, in the **Your connections** resource list, choose the connection you want to use in your job, and then choose **Create job**.

Alternatively, on the AWS Glue Studio **Jobs** page, under **Create job**, choose **Source and target added to the graph**. In the **Source** drop-down list, choose the custom connector that you want to use in your job. You can also choose a connector for **Target**.

The screenshot shows the AWS Glue Studio interface. At the top, it says 'AWS Glue Studio > Jobs'. Below that, the 'Jobs' section is active. The 'Create job' panel is open, with the 'Source and target added to the graph' option selected. The 'Source' dropdown menu is open, displaying a list of connectors: S3 (Read data from S3), Kinesis (Read data from Kinesis), Kafka (Read data from Kafka), RDS (Read data from RDS), Redshift (Read data from Redshift), Cdata Salesforce (My description here), My Snowflake connector (Snowflake connection for our accounts), and Go to AWS Marketplace (Add more sources with Connectors). The 'Target' dropdown is set to 'AWS Glue Data Catalog' (Output data to an AWS Glue Data Catalog table). Below the dropdowns, there are 'Actions' and 'Run job' buttons. At the bottom, a table lists the job details:

Type	Last modified
Glue ETL	08/19/2020, 9:26:29

3. Choose **Create** to open the visual job editor.
4. Configure the data source node, as described in [Configure source properties for nodes that use connectors](#).
5. Continue creating your ETL job by adding transforms, additional data stores, and data targets, as described in [Visual ETL with AWS Glue Studio](#).

- Customize the job run environment by configuring job properties as described in [Modify the job properties](#).
- Save and run the job.

## Configure source properties for nodes that use connectors

After you create a job that uses a connector for the data source, the visual job editor displays a job graph with a data source node configured for the connector. You must configure the data source properties for that node.

### To configure the properties for a data source node that uses a connector

- Choose the connector data source node in the job graph or add a new node and choose the connector for the **Node type**. Then, on the right-side, in the node details panel, choose the **Data source properties** tab, if it's not already selected.

The screenshot displays the AWS Glue Visual Job Editor interface for a job titled "Combine legislator data". The interface includes a top navigation bar with tabs for "Visual", "Script", "Job details", "Runs", and "Schedules". Below this is a toolbar with icons for Source, Transform, Target, Undo, Redo, Remove, and search. The main workspace shows a job graph with several nodes: two "Data source - S3 bucket" nodes (one for "Memberships source ..." and one for "Persons source table"), a "Transform - Join" node, a "Data source - Connection" node for "Organizations table s...", a "Transform - ApplyMapping" node for "Rename Org PK field", and another "Transform - ApplyMapping" node for "Renamed keys for Join". The right-hand side panel is open to the "Data source properties - Connector" tab, showing a "Connection" dropdown set to "MyEsConn" and a "Schema" section with an "Add schema" button. A "Connection options" section is also visible.

- In the **Data source properties** tab, choose the connection that you want to use for this job.

Enter the additional information required for each connection type:

## JDBC

- **Data source input type:** Choose to provide either a table name or a SQL query as the data source. Depending on your choice, you then need to provide the following additional information:
  - **Table name:** The name of the table in the data source. If the data source does not use the term *table*, then supply the name of an appropriate data structure, as indicated by the custom connector usage information (which is available in AWS Marketplace).
  - **Filter predicate:** A condition clause to use when reading the data source, similar to a WHERE clause, which is used to retrieve a subset of the data.
  - **Query code:** Enter a SQL query to use to retrieve a specific dataset from the data source. An example of a basic SQL query is:

```
SELECT column_list FROM  
           table_name WHERE where_clause
```

- **Schema:** Because AWS Glue Studio is using information stored in the connection to access the data source instead of retrieving metadata information from a Data Catalog table, you must provide the schema metadata for the data source. Choose **Add schema** to open the schema editor.

For instructions on how to use the schema editor, see [Editing the schema in a custom transform node](#).

- **Partition column:** (Optional) You can choose to partition the data reads by providing values for **Partition column**, **Lower bound**, **Upper bound**, and **Number of partitions**.

The `lowerBound` and `upperBound` values are used to decide the partition stride, not for filtering the rows in table. All rows in the table are partitioned and returned.

### Note

Column partitioning adds an extra partitioning condition to the query used to read the data. When using a query instead of a table name, you should validate that the query works with the specified partitioning condition. For example:

- If your query format is "SELECT col1 FROM table1", then test the query by appending a WHERE clause at the end of the query that uses the partition column.
- If your query format is "SELECT col1 FROM table1 WHERE col2=val", then test the query by extending the WHERE clause with AND and an expression that uses the partition column.

- **Data type casting:** If the data source uses data types that are not available in JDBC, use this section to specify how a data type from the data source should be converted into JDBC data types. You can specify up to 50 different data type conversions. All columns in the data source that use the same data type are converted in the same way.

For example, if you have three columns in the data source that use the Float data type, and you indicate that the Float data type should be converted to the JDBC String data type, then all three columns that use the Float data type are converted to String data types.

- **Job bookmark keys:** Job bookmarks help AWS Glue maintain state information and prevent the reprocessing of old data. Specify one or more columns as bookmark keys. AWS Glue Studio uses bookmark keys to track data that has already been processed during a previous run of the ETL job. Any columns you use for custom bookmark keys must be strictly monotonically increasing or decreasing, but gaps are permitted.

If you enter multiple bookmark keys, they're combined to form a single compound key. A compound job bookmark key should not contain duplicate columns. If you don't specify bookmark keys, AWS Glue Studio by default uses the primary key as the bookmark key, provided that the primary key is sequentially increasing or decreasing (with no gaps). If the table doesn't have a primary key, but the job bookmark property is enabled, you must provide custom job bookmark keys. Otherwise, the search for primary keys to use as the default will fail and the job run will fail.

- **Job bookmark keys sorting order:** Choose whether the key values are sequentially increasing or decreasing.

## Spark

- **Schema:** Because AWS Glue Studio is using information stored in the connection to access the data source instead of retrieving metadata information from a Data Catalog table, you must provide the schema metadata for the data source. Choose **Add schema** to open the schema editor.

For instructions on how to use the schema editor, see [Editing the schema in a custom transform node](#).

- **Connection options:** Enter additional key-value pairs as needed to provide additional connection information or options. For example, you might enter a database name, table name, a user name, and password.

For example, for OpenSearch, you enter the following key-value pairs, as described in [the section called " Tutorial: Using the AWS Glue Connector for Elasticsearch "](#):

- `es.net.http.auth.user` : *username*
- `es.net.http.auth.pass` : *password*
- `es.nodes` : `https://<Elasticsearch endpoint>`
- `es.port` : 443
- `path` : *<Elasticsearch resource>*
- `es.nodes.wan.only` : true

For an example of the minimum connection options to use, see the sample test script [MinimalSparkConnectorTest.scala](#) on GitHub, which shows the connection options you would normally provide in a connection.

## Athena

- **Table name:** The name of the table in the data source. If you're using a connector for reading from Athena-CloudWatch logs, you would enter the table name `all_log_streams`.
- **Athena schema name:** Choose the schema in your Athena data source that corresponds to the database that contains the table. If you're using a connector for reading from Athena-CloudWatch logs, you would enter a schema name similar to `/aws/glue/name`.

- **Schema:** Because AWS Glue Studio is using information stored in the connection to access the data source instead of retrieving metadata information from a Data Catalog table, you must provide the schema metadata for the data source. Choose **Add schema** to open the schema editor.

For instructions on how to use the schema editor, see [Editing the schema in a custom transform node](#).

- **Additional connection options:** Enter additional key-value pairs as needed to provide additional connection information or options.

For an example, see the README .md file at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/Athena>. In the steps in this document, the sample code shows the minimal required connection options, which are `tableName`, `schemaName`, and `className`. The code example specifies these options as part of the `optionsMap` variable, but you can specify them for your connection and then use the connection.

3. (Optional) After providing the required information, you can view the resulting data schema for your data source by choosing the **Output schema** tab in the node details panel. The schema displayed on this tab is used by any child nodes that you add to the job graph.
4. (Optional) After configuring the node properties and data source properties, you can preview the dataset from your data source by choosing the Data preview tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Configure target properties for nodes that use connectors

If you use a connector for the data target type, you must configure the properties of the data target node.

### To configure the properties for a data target node that uses a connector

1. Choose the connector data target node in the job graph. Then, on the right-side, in the node details panel, choose the **Data target properties** tab, if it's not already selected.
2. In the **Data target properties** tab, choose the connection to use for writing to the target.

Enter the additional information required for each connection type:

## JDBC

- **Connection:** Choose the connection to use with your connector. For information about how to create a connection, see [Creating connections for connectors](#).
- **Table name:** The name of the table in the data target. If the data target does not use the term *table*, then supply the name of an appropriate data structure, as indicated by the custom connector usage information (which is available in AWS Marketplace).
- **Batch size (Optional):** Enter the number of rows or records to insert in the target table in a single operation. The default value is 1000 rows.

## Spark

- **Connection:** Choose the connection to use with your connector. If you did not create a connection previously, choose **Create connection** to create one. For information about how to create a connection, see [Creating connections for connectors](#).
- **Connection options:** Enter additional key-value pairs as needed to provide additional connection information or options. You might enter a database name, table name, a user name, and password.

For example, for OpenSearch, you enter the following key-value pairs, as described in [the section called " Tutorial: Using the AWS Glue Connector for Elasticsearch "](#):

- `es.net.http.auth.user : username`
- `es.net.http.auth.pass : password`
- `es.nodes : https://<Elasticsearch endpoint>`
- `es.port : 443`
- `path : <Elasticsearch resource>`
- `es.nodes.wan.only : true`

For an example of the minimum connection options to use, see the sample test script [MinimalSparkConnectorTest.scala](#) on GitHub, which shows the connection options you would normally provide in a connection.

3. After providing the required information, you can view the resulting data schema for your data source by choosing the **Output schema** tab in the node details panel.

## Managing connectors and connections

You use the **Connections** page in AWS Glue to manage your connectors and connections.

### Topics

- [Viewing connector and connection details](#)
- [Editing connectors and connections](#)
- [Deleting connectors and connections](#)
- [Cancel a subscription for a connector](#)

### Viewing connector and connection details

You can view summary information about your connectors and connections in the **Your connectors** and **Your connections** resource tables on the **Connectors** page. To view detailed information, perform the following steps.

#### To view connector or connection details

1. In the AWS Glue Studio console, choose **Connectors** in the console navigation pane.
2. Choose the connector or connection that you want to view detailed information for.
3. Choose **Actions**, and then choose **View details** to open the detail page for that connector or connection.
4. On the detail page, you can choose to **Edit** or **Delete** the connector or connection.
  - For connectors, you can choose **Create connection** to create a new connection that uses the connector.
  - For connections, you can choose **Create job** to create a job that uses the connection.

### Editing connectors and connections

You use the **Connectors** page to change the information stored in your connectors and connections.

#### To modify a connector or connection

1. In the AWS Glue Studio console, choose **Connectors** in the console navigation pane.
2. Choose the connector or connection that you want to change.

3. Choose **Actions**, and then choose **Edit**.

You can also choose **View details** and on the connector or connection detail page, you can choose **Edit**.

4. On the **Edit connector** or **Edit connection** page, update the information, and then choose **Save**.

## Deleting connectors and connections

You use the **Connectors** page to delete connectors and connections. If you delete a connector, then any connections that were created for that connector should also be deleted.

### To remove connectors from AWS Glue Studio

1. In the AWS Glue Studio console, choose **Connectors** in the console navigation pane.
2. Choose the connector or connection you want to delete.
3. Choose **Actions**, and then choose **Delete**.

You can also choose **View details**, and on the connector or connection detail page, you can choose **Delete**.

4. Verify that you want to remove the connector or connection by entering **Delete**, and then choose **Delete**.

When deleting a connector, any connections that were created for that connector are also deleted.

Any jobs that use a deleted connection will no longer work. You can either edit the jobs to use a different data store, or remove the jobs. For information about how to delete a job, see [Delete jobs](#).

If you delete a connector, this doesn't cancel the subscription for the connector in AWS Marketplace. To remove a subscription for a deleted connector, follow the instructions in [Cancel a subscription for a connector](#) .

### Cancel a subscription for a connector

After you delete the connections and connector from AWS Glue Studio, you can cancel your subscription in AWS Marketplace if you no longer need the connector.

**Note**

If you cancel your subscription to a connector, this does not remove the connector or connection from your account. Any jobs that use the connector and related connections will no longer be able to use the connector and will fail.

Before you unsubscribe or re-subscribe to a connector from AWS Marketplace, you should delete existing connections and connectors associated with that AWS Marketplace product.

**To unsubscribe from a connector in AWS Marketplace**

1. Sign in to the AWS Marketplace console at <https://console.aws.amazon.com/marketplace>.
2. Choose **Manage subscriptions**.
3. On the **Manage subscriptions** page, choose **Manage** next to the connector subscription that you want to cancel.
4. Choose **Actions** and then choose **Cancel subscription**.
5. Select the check box to acknowledge that running instances are charged to your account, and then choose **Yes, cancel subscription**.

**Developing custom connectors**

You can write the code that reads data from or writes data to your data store and formats the data for use with AWS Glue Studio jobs. You can create connectors for Spark, Athena, and JDBC data stores. Sample code posted on GitHub provides an overview of the basic interfaces you need to implement.

You will need a local development environment for creating your connector code. You can use any IDE or even just a command line editor to write your connector. Examples of development environments include:

- A local Scala environment with a local AWS Glue ETL Maven library, as described in [Developing Locally with Scala](#) in the *AWS Glue Developer Guide*.
- IntelliJ IDE, by downloading the IDE from <https://www.jetbrains.com/idea/>.

**Topics**

- [Developing Spark connectors](#)

- [Developing Athena connectors](#)
- [Developing JDBC connectors](#)
- [Examples of using custom connectors with AWS Glue Studio](#)
- [Developing AWS Glue connectors for AWS Marketplace](#)

## Developing Spark connectors

You can create a Spark connector with Spark DataSource API V2 (Spark 2.4) to read data.

### To create a custom Spark connector

Follow the steps in the AWS Glue GitHub sample library for developing Spark connectors, which is located at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/Spark/README.md>.

## Developing Athena connectors

You can create an Athena connector to be used by AWS Glue and AWS Glue Studio to query a custom data source.

### To create a custom Athena connector

Follow the steps in the AWS Glue GitHub sample library for developing Athena connectors, which is located at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/Athena>.

## Developing JDBC connectors

You can create a connector that uses JDBC to access your data stores.

### To create a custom JDBC connector

1. Install the AWS Glue Spark runtime libraries in your local development environment. Refer to the instructions in the AWS Glue GitHub sample library at <https://github.com/aws-samples/aws-glue-samples/tree/master/GlueCustomConnectors/development/GlueSparkRuntime/README.md>.
2. Implement the JDBC driver that is responsible for retrieving the data from the data source. Refer to the [Java Documentation](#) for Java SE 8.

Create an entry point within your code that AWS Glue Studio uses to locate your connector. The **Class name** field should be the full path of your JDBC driver.

3. Use the `GlueContext` API to read data with the connector. Users can add more input options in the AWS Glue Studio console to configure the connection to the data source, if necessary. For a code example that shows how to read from and write to a JDBC database with a custom JDBC connector, see [Custom and AWS Marketplace connectionType values](#).

## Examples of using custom connectors with AWS Glue Studio

You can refer to the following blogs for examples of using custom connectors:

- [Developing, testing, and deploying custom connectors for your data stores with AWS Glue](#)
- Apache Hudi: [Writing to Apache Hudi tables using AWS Glue Custom Connector](#)
- Google BigQuery: [Migrating data from Google BigQuery to Amazon S3 using AWS Glue custom connectors](#)
- Snowflake (JDBC): [Performing data transformations using Snowflake and AWS Glue](#)
- SingleStore: [Building fast ETL using SingleStore and AWS Glue](#)
- Salesforce: [Ingest Salesforce data into Amazon S3 using the CData JDBC custom connector with AWS Glue](#) -
- MongoDB: [Building AWS Glue Spark ETL jobs using Amazon DocumentDB \(with MongoDB compatibility\) and MongoDB](#)
- Amazon Relational Database Service (Amazon RDS): [Building AWS Glue Spark ETL jobs by bringing your own JDBC drivers for Amazon RDS](#)
- MySQL (JDBC): <https://github.com/aws-samples/aws-glue-samples/blob/master/GlueCustomConnectors/development/Spark/SparkConnectorMySQL.scala>

## Developing AWS Glue connectors for AWS Marketplace

As an AWS partner, you can create custom connectors and upload them to AWS Marketplace to sell to AWS Glue customers.

The process for developing the connector code is the same as for custom connectors, but the process of uploading and verifying the connector code is more detailed. Refer to the instructions in [Creating Connectors for AWS Marketplace](#) on the GitHub website.

## Restrictions for using connectors and connections in AWS Glue Studio

When you're using custom connectors or connectors from AWS Marketplace, take note of the following restrictions:

- The testConnection API isn't supported with connections created for custom connectors.
- Data Catalog connection password encryption isn't supported with custom connectors.
- You can't use job bookmarks if you specify a filter predicate for a data source node that uses a JDBC connector.
- Creating a Marketplace connection is not supported outside of the AWS Glue Studio user interface.

## Connecting to data sources using Visual ETL jobs

While creating a new job, you can use connections to connect to data when editing visual ETL jobs in AWS Glue. You can do this by adding source nodes that use connectors to read in data, and target nodes to specify the location for writing out data.

### Topics

- [Modifying properties of a data source node](#)
- [Using Data Catalog tables for the data source](#)
- [Using a connector for the data source](#)
- [Using files in Amazon S3 for the data source](#)
- [Using a streaming data source](#)
- [References](#)

## Modifying properties of a data source node

To specify the data source properties, you first choose a data source node in the job diagram. Then, on the right side in the node details panel, you configure the node properties.

### To modify the properties of a data source node

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram.
3. Choose the **Node properties** tab in the node details panel, and then enter the following information:
  - **Name:** (Optional) Enter a name to associate with the node in the job diagram. This name should be unique among all the nodes for this job.

- **Node type:** The node type determines the action that is performed by the node. In the list of options for **Node type**, choose one of the values listed under the heading **Data source**.
4. Configure the **Data source properties** information. For more information, see the following sections:
    - [Using Data Catalog tables for the data source](#)
    - [Using a connector for the data source](#)
    - [Using files in Amazon S3 for the data source](#)
    - [Using a streaming data source](#)
  5. (Optional) After configuring the node properties and data source properties, you can view the schema for your data source by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
  6. (Optional) After configuring the node properties and data source properties, you can preview the dataset from your data source by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Using Data Catalog tables for the data source

For all data sources except Amazon S3 and connectors, a table must exist in the AWS Glue Data Catalog for the source type that you choose. AWS Glue does not create the Data Catalog table.

### To configure a data source node based on a Data Catalog table

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram.
3. Choose the **Data source properties** tab, and then enter the following information:
  - **S3 source type:** (For Amazon S3 data sources only) Choose the option **Select a Catalog table** to use an existing AWS Glue Data Catalog table.
  - **Database:** Choose the database in the Data Catalog that contains the source table you want to use for this job. You can use the search field to search for a database by its name.

- **Table:** Choose the table associated with the source data from the list. This table must already exist in the AWS Glue Data Catalog. You can use the search field to search for a table by its name.
- **Partition predicate:** (For Amazon S3 data sources only) Enter a Boolean expression based on Spark SQL that includes only the partitioning columns. For example: "(year== '2020' and month== '04' )"
- **Temporary directory:** (For Amazon Redshift data sources only) Enter a path for the location of a working directory in Amazon S3 where your ETL job can write temporary intermediate results.
- **Role associated with the cluster:** (For Amazon Redshift data sources only) Enter a role for your ETL job to use that contains permissions for Amazon Redshift clusters. For more information, see [the section called "Data source and data target permissions"](#).

## Using a connector for the data source

If you select a connector for the **Node type**, follow the instructions at [Authoring jobs with custom connectors](#) to finish configuring the data source properties.

## Using files in Amazon S3 for the data source

If you choose Amazon S3 as your data source, then you can choose either:

- A Data Catalog database and table.
- A bucket, folder, or file in Amazon S3.

If you use an Amazon S3 bucket as your data source, AWS Glue detects the schema of the data at the specified location from one of the files, or by using the file you specify as a sample file. Schema detection occurs when you use the **Infer schema** button. If you change the Amazon S3 location or the sample file, then you must choose **Infer schema** again to perform the schema detection using the new information.

### To configure a data source node that reads directly from files in Amazon S3

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram for an Amazon S3 source.
3. Choose the **Data source properties** tab, and then enter the following information:

- **S3 source type:** (For Amazon S3 data sources only) Choose the option **S3 location**.
- **S3 URL:** Enter the path to the Amazon S3 bucket, folder, or file that contains the data for your job. You can choose **Browse S3** to select the path from the locations available to your account.
- **Recursive:** Choose this option if you want AWS Glue to read data from files in child folders at the S3 location.

If the child folders contain partitioned data, AWS Glue doesn't add any partition information that's specified in the folder names to the Data Catalog. For example, consider the following folders in Amazon S3:

```
S3://sales/year=2019/month=Jan/day=1
S3://sales/year=2019/month=Jan/day=2
```

If you choose **Recursive** and select the `sales` folder as your S3 location, then AWS Glue reads the data in all the child folders, but doesn't create partitions for year, month or day.

- **Data format:** Choose the format that the data is stored in. You can choose JSON, CSV, or Parquet. The value you select tells the AWS Glue job how to read the data from the source file.

#### Note

If you don't select the correct format for your data, AWS Glue might infer the schema correctly, but the job won't be able to correctly parse the data from the source file.

You can enter additional configuration options, depending on the format you choose.

- **JSON** (JavaScript Object Notation)
  - **JsonPath:** Enter a JSON path that points to an object that is used to define a table schema. JSON path expressions always refer to a JSON structure in the same way as XPath expressions are used in combination with an XML document. The "root member object" in the JSON path is always referred to as `$`, even if it's an object or array. The JSON path can be written in dot notation or bracket notation.

For more information about the JSON path, see [JsonPath](#) on the GitHub website.

- **Records in source files can span multiple lines:** Choose this option if a single record can span multiple lines in the CSV file.
- **CSV (comma-separated values)**
  - **Delimiter:** Enter a character to denote what separates each column entry in the row, for example, ; or ,.
  - **Escape character:** Enter a character that is used as an escape character. This character indicates that the character that immediately follows the escape character should be taken literally, and should not be interpreted as a delimiter.
  - **Quote character:** Enter the character that is used to group separate strings into a single value. For example, you would choose **Double quote (")** if you have values such as "This is a single value" in your CSV file.
  - **Records in source files can span multiple lines:** Choose this option if a single record can span multiple lines in the CSV file.
  - **First line of source file contains column headers:** Choose this option if the first row in the CSV file contains column headers instead of data.
- **Parquet (Apache Parquet columnar storage)**

There are no additional settings to configure for data stored in Parquet format.

- **Partition predicate:** To partition the data that is read from the data source, enter a Boolean expression based on Spark SQL that includes only the partitioning columns. For example: "(year=='2020' and month=='04')"
- **Advanced options:** Expand this section if you want AWS Glue to detect the schema of your data based on a specific file.
  - **Schema inference:** Choose the option **Choose a sample file from S3** if you want to use a specific file instead of letting AWS Glue choose a file.
  - **Auto-sampled file:** Enter the path to the file in Amazon S3 to use for inferring the schema.

If you're editing a data source node and change the selected sample file, choose **Reload schema** to detect the schema by using the new sample file.

4. Choose the **Infer schema** button to detect the schema from the sources files in Amazon S3. If you change the Amazon S3 location or the sample file, you must choose **Infer schema** again to infer the schema using the new information.

## Using a streaming data source

You can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources in Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

### To configure properties for a streaming data source

1. Go to the visual graph editor for a new or saved job.
2. Choose a data source node in the graph for Kafka or Kinesis Data Streams.
3. Choose the **Data source properties** tab, and then enter the following information:

#### Kinesis

- **Kinesis source type:** Choose the option **Stream details** to use direct access to the streaming source or choose **Data Catalog table** to use the information stored there instead.

If you choose **Stream details**, specify the following additional information.

- **Location of data stream:** Choose whether the stream is associated with the current user, or if it is associated with a different user.
- **Region:** Choose the AWS Region where the stream exists. This information is used to construct the ARN for accessing the data stream.
- **Stream ARN:** Enter the Amazon Resource Name (ARN) for the Kinesis data stream. If the stream is located within the current account, you can choose the stream name from the drop-down list. You can use the search field to search for a data stream by its name or ARN.
- **Data format:** Choose the format used by the data stream from the list.

AWS Glue automatically detects the schema from the streaming data.

If you choose **Data Catalog table**, specify the following additional information.

- **Database:** (Optional) Choose the database in the AWS Glue Data Catalog that contains the table associated with your streaming data source. You can use the search field to search for a database by its name.
- **Table:** (Optional) Choose the table associated with the source data from the list. This table must already exist in the AWS Glue Data Catalog. You can use the search field to search for a table by its name.

- **Detect schema:** Choose this option to have AWS Glue detect the schema from the streaming data, rather than using the schema information in a Data Catalog table. This option is enabled automatically if you choose the **Stream details** option.
- **Starting position:** By default, the ETL job uses the **Earliest** option, which means it reads data starting with the oldest available record in the stream. You can instead choose **Latest**, which indicates the ETL job should start reading from just after the most recent record in the stream.
- **Window size:** By default, your ETL job processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data that arrives later than expected. You can modify this window size to increase timeliness or aggregation accuracy.

AWS Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

- **Connection options:** Expand this section to add key-value pairs to specify additional connection options. For information about what options you can specify here, see ["connectionType": "kinesis"](#) in the *AWS Glue Developer Guide*.

## Kafka

- **Apache Kafka source:** Choose the option **Stream details** to use direct access to the streaming source or choose **Data Catalog table** to use the information stored there instead.

If you choose **Data Catalog table**, specify the following additional information.

- **Database:** (Optional) Choose the database in the AWS Glue Data Catalog that contains the table associated with your streaming data source. You can use the search field to search for a database by its name.
- **Table:** (Optional) Choose the table associated with the source data from the list. This table must already exist in the AWS Glue Data Catalog. You can use the search field to search for a table by its name.
- **Detect schema:** Choose this option to have AWS Glue detect the schema from the streaming data, rather than storing the schema information in a Data Catalog table. This option is enabled automatically if you choose the **Stream details** option.

If you choose **Stream details**, specify the following additional information.

- **Connection name:** Choose the AWS Glue connection that contains the access and authentication information for the Kafka data stream. You must use a connection with Kafka streaming data sources. If a connection doesn't exist, you can use the AWS Glue console to create a connection for your Kafka data stream.
- **Topic name:** Enter the name of the topic to read from.
- **Data format:** Choose the format to use when reading data from the Kafka event stream.
- **Starting position:** By default, the ETL job uses the **Earliest** option, which means it reads data starting with the oldest available record in the stream. You can instead choose **Latest**, which indicates the ETL job should start reading from just after the most recent record in the stream.
- **Window size:** By default, your ETL job processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data that arrives later than expected. You can modify this window size to increase timeliness or aggregation accuracy.

AWS Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

- **Connection options:** Expand this section to add key-value pairs to specify additional connection options. For information about what options you can specify here, see ["connectionType": "kafka"](#) in the *AWS Glue Developer Guide*.

#### Note

Data previews are not currently supported for streaming data sources.

## Adding a JDBC connection using your own JDBC drivers

You can use your own JDBC driver when using a JDBC connection. When the default driver utilized by the AWS Glue crawler is unable to connect to a database, you can use your own JDBC Driver. For example, if you want to use SHA-256 with your Postgres database, and older postgres drivers do not support this, you can use your own JDBC driver.

### Supported datasources

Supported datasources	Unsupported datasources
MySQL	Snowflake
Postgres	
Oracle	
Redshift	
SQL Server	
Aurora*	

\*Supported if the native JDBC driver is being used. Not all driver features can be leveraged.

### Adding a JDBC driver to a JDBC connection

#### Note

If you choose to bring in your own JDBC driver versions, AWS Glue crawlers will consume resources in AWS Glue jobs and Amazon S3 buckets to ensure your provided driver are run in your environment. The additional usage of resources will be reflected in your account. The cost for AWS Glue crawlers and jobs is under the AWS Glue category in billing.

Additionally, providing your own JDBC driver does not mean that the crawler is able to leverage all of the driver's features.

**To add your own JDBC driver to a JDBC connection:**

1. Add the JDBC driver file to an Amazon S3 location. You can create a bucket and/or folder or use an existing bucket and/or folder.
2. In the AWS Glue console, choose **Connections** in the left-hand menu under **Data Catalog**, then create a new connection.
3. Complete the fields for **Connection properties** and choose JDBC for **Connection type**.
4. In **Connection access**, enter the **JDBC URL** and **JDBC Driver Class name** – *optional*. The driver class name must be for a datasource supported by AWS Glue crawlers.

### Connection access

**JDBC URL**  
Use the JDBC protocol to access Amazon Redshift, Amazon RDS, and publicly accessible databases.

JDBC syntax for most database engines is jdbc:protocol://host:port/databasename.

**JDBC Driver Class name - optional**

Type a custom JDBC driver class name for the crawler to connect to the data source.

**JDBC Driver S3 Path - optional**

Browse for or enter an existing S3 path to a .jar file.

Please note that if you choose to bring in your own JDBC driver versions to be used with Glue Crawlers, the Glue Crawlers will consume resources in Glue Jobs and S3 to ensure your provided driver are run in your environment. The additional usage of resources will be reflected in your account.

**Credential type**

Username and password  
 Secret

**Username**

**Password**

- Choose the Amazon S3 path where the JDBC driver is located in the **JDBC Driver Amazon S3 Path – optional** field.
- Complete the fields for Credential type if entering a username and password or secret. When complete, choose **Create connection**.

**Note**

Testing connection is not supported currently. When crawling the data source with a JDBC driver you provided, the crawler skips this step.

- Add the newly created connection to a crawler. In the AWS Glue console, choose **Crawlers** in the left-hand menu under **Data Catalog**, then create a new crawler.

8. In the **Add crawler** wizard, in Step 2 choose **Add a data source**.

### Add data source ✕

**Data source**  
Choose the source of data to be crawled.

JDBC ▼

**Connection**  
Select a connection to access the data sources below.

mysql-connection068fd134-c2f1-4234-ad6b-345968e73be8 ▼ ↻

Clear selection

Add new connection ↗

**Include path**

public/%

You can substitute the percent (%) character for a schema or table. For databases that support schemas, enter MyDatabase/MySchema/% to match all tables in MySchema within MyDatabase. Oracle Database and MySQL don't support schema in the path; instead, enter MyDatabase/%. For Oracle database without SSL, MyDatabase can be either the system identifier (SID) or the service name (SERVICE\_NAME). For Oracle database with SSL, MyDatabase must be the service name (SERVICE\_NAME).

**Additional metadata - optional**

▼

Select additional metadata properties for the crawler to crawl.

Exclude tables matching pattern

Cancel

Add a JDBC data source

9. Choose **JDBC** as the data source and choose the the connection that was created in the previous steps. Complete
10. In order to use your own JDBC driver with a AWS Glue crawler, add the following permissions to the role used by the crawler:
- Grant permissions for the following job actions: CreateJob, DeleteJob, GetJob, GetJobRun, StartJobRun.
  - Grant permissions for IAM actions: iam:PassRole

- Grant permissions for Amazon S3 actions: `s3:DeleteObjects`, `s3:GetObject`, `s3:ListBucket`, `s3:PutObject`.
- Grant service principal access to bucket/folder in the IAM policy.

Example IAM policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:ListBucket",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::bucket-name/driver-parent-folder/driver.jar",
        "arn:aws:s3:::bucket-name"
      ]
    }
  ]
}
```

11. If you are using a VPC, you must allow access to the AWS Glue endpoint by creating the interface endpoint and add it to your route table. For more information, see [Creating an interface VPC endpoint for AWS Glue](#)
12. If you are using encryption in your Data Catalog, create the AWS KMS interface endpoint and add it to your route table. For more information, see [Creating a VPC endpoint for AWS KMS](#).

## Testing an AWS Glue connection

As a best practice, before you use an AWS Glue connection in an ETL job, use the AWS Glue console to test the connection. AWS Glue uses the parameters in your connection to confirm that it can

access your data store and reports any errors. For information about AWS Glue connections, see [Connecting to data](#).

### To test an AWS Glue connection

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data Catalog**, choose **Connections**. You can also choose **Data connections** above **Data Catalog** in the navigation pane.
3. In **Connections**, select the check box next to the desired connection, and then choose **Actions**. In the drop-down menu, choose **Test connection**.
4. In the **Test connection** dialog box, select a role or choose **Create IAM role** to go to the AWS Identity and Access Management (IAM) console to create a new role. The role must have permissions on the data store.
5. Choose **Confirm**.

The test begins and can take several minutes to complete. If the test fails, choose **Troubleshoot** to view the steps to resolve the issue.

6. Choose **Logs** to view the logs in CloudWatch. You must have the required IAM permissions to view the logs. For more information, see [AWS Managed \(Predefined\) Policies for CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

## Configuring AWS calls to go through your VPC

The special job parameter `disable-proxy-v2` allows you to route your calls to services such as Amazon S3, CloudWatch, and AWS Glue through your VPC. By default, AWS Glue uses a local proxy to send traffic through the AWS Glue VPC to download scripts and libraries from Amazon S3, to send requests to CloudWatch for publishing logs and metrics, and to send requests to AWS Glue for accessing data catalogs. This proxy allows the job to function normally even if your VPC doesn't configure a proper route to other AWS services, such as Amazon S3, CloudWatch, and AWS Glue. AWS Glue now offers a parameter for you to turn off this behavior. For more information, see [Job parameters used by AWS Glue](#). AWS Glue will continue to use local proxy for publishing CloudWatch logs of your AWS Glue jobs.

**Note**

- This feature is supported for AWS Glue jobs with AWS Glue version 2.0 and above. When using this feature, you need to ensure that your VPC has configured a route to Amazon S3 through a NAT or service VPC endpoint.
- The deprecated job parameter `disable-proxy` only routes your calls to Amazon S3 for downloading scripts and libraries through your VPC. It's recommended to use the new parameter `disable-proxy-v2` instead.

**Example usage**

Create an AWS Glue job with `disable-proxy-v2`:

```
aws glue create-job \  
  --name no-proxy-job \  
  --role GlueDefaultRole \  
  --command "Name=glueetl,ScriptLocation=s3://my-bucket/glue-script.py" \  
  --connections Connections="traffic-monitored-connection" \  
  --default-arguments '{"--disable-proxy-v2" : "true"}'
```

## Connecting to a JDBC data store in a VPC

Typically, you create resources inside Amazon Virtual Private Cloud (Amazon VPC) so that they cannot be accessed over the public internet. By default, AWS Glue can't access resources inside a VPC. To enable AWS Glue to access resources inside your VPC, you must provide additional VPC-specific configuration information that includes VPC subnet IDs and security group IDs. AWS Glue uses this information to set up [elastic network interfaces](#) that enable your function to connect securely to other resources in your private VPC.

When using a VPC endpoint, add it to your route table. For more information, see [Creating an interface VPC endpoint for AWS Glue](#) and [Prerequisites](#).

When using encryption in Data Catalog, create the KMS interface endpoint and add it to your route table. For more information, see [Creating a VPC endpoint for AWS KMS](#).

## Accessing VPC Data Using elastic network interfaces

When AWS Glue connects to a JDBC data store in a VPC, AWS Glue creates an elastic network interface (with the prefix `Glue_`) in your account to access your VPC data. You can't delete this network interface as long as it's attached to AWS Glue. As part of creating the elastic network interface, AWS Glue associates one or more security groups to it. To enable AWS Glue to create the network interface, security groups that are associated with the resource must allow inbound access with a source rule. This rule contains a security group that is associated with the resource. This gives the elastic network interface access to your data store with the same security group.

To allow AWS Glue to communicate with its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC and not open it to all networks. The default security group for your VPC might already have a self-referencing inbound rule for `ALL Traffic`.

You can create rules in the Amazon VPC console. To update rule settings via the AWS Management Console, navigate to the VPC console (<https://console.aws.amazon.com/vpc/>), and select the appropriate security group. Specify the inbound rule for `ALL TCP` to have as its source the same security group name. For more information about security group rules, see [Security Groups for Your VPC](#).

Each elastic network interface is assigned a private IP address from the IP address range in the subnets that you specify. The network interface is not assigned any public IP addresses. AWS Glue requires internet access (for example, to access AWS services that don't have VPC endpoints). You can configure a network address translation (NAT) instance inside your VPC, or you can use the Amazon VPC NAT gateway. For more information, see [NAT Gateways](#) in the *Amazon VPC User Guide*. You can't directly use an internet gateway attached to your VPC as a route in your subnet route table because that requires the network interface to have public IP addresses.

The VPC network attributes `enableDnsHostnames` and `enableDnsSupport` must be set to `true`. For more information, see [Using DNS with your VPC](#).

### Important

Don't put your data store in a public subnet or in a private subnet that doesn't have internet access. Instead, attach it only to private subnets that have internet access through a NAT instance or an Amazon VPC NAT gateway.

## Elastic network interface properties

To create the elastic network interface, you must supply the following properties:

### VPC

The name of the VPC that contains your data store.

### Subnet

The subnet in the VPC that contains your data store.

### Security groups

The security groups that are associated with your data store. AWS Glue associates these security groups with the elastic network interface that is attached to your VPC subnet. To allow AWS Glue components to communicate and also prevent access from other networks, at least one chosen security group must specify a self-referencing inbound rule for all TCP ports.

For information about managing a VPC with Amazon Redshift, see [Managing Clusters in an Amazon Virtual Private Cloud \(VPC\)](#).

For information about managing a VPC with Amazon Relational Database Service (Amazon RDS), see [Working with an Amazon RDS DB Instance in a VPC](#).

## Using a MongoDB or MongoDB Atlas connection

After you create a connection for MongoDB or MongoDB Atlas, you can use the connection in your ETL job. You create a table in the AWS Glue Data Catalog and specify the MongoDB or MongoDB Atlas connection for the `connection` attribute of the table.

AWS Glue stores your connection `url` and credentials in the MongoDB connection. The connection URI formats are as follows:

- For MongoDB: `mongodb://host:port/database`. The host can be a hostname, IP address, or UNIX domain socket. If the connection string doesn't specify a port, it uses the default MongoDB port, 27017.
- For MongoDB Atlas: `mongodb+srv://server.example.com/database`. The host can be a hostname that follows corresponds to a DNS SRV record. The SRV format does not require a port and will use the default MongoDB port, 27017.

Additionally, you can specify options in your job script. For more information, see [the section called “MongoDB connection”](#).

## Crawling an Amazon S3 data store using a VPC endpoint

For security, auditing, or control purposes you may want your Amazon S3 data store or Amazon S3 backed Data Catalog tables to only be accessed through an Amazon Virtual Private Cloud environment (Amazon VPC). This topic describes how to create and test a connection to the Amazon S3 data store or Amazon S3 backed Data Catalog tables in a VPC endpoint using the Network connection type.

Perform the following tasks to run a crawler on the data store:

- [the section called “Prerequisites”](#)
- [the section called “Creating the connection to Amazon S3”](#)
- [the section called “Testing the connection to Amazon S3”](#)
- [the section called “Creating a crawler for an Amazon S3 data store”](#)
- [the section called “Running a crawler”](#)

### Prerequisites

Check that you have met these prerequisites for setting up your Amazon S3 data store or Amazon S3 backed Data Catalog tables to be accessed through an Amazon Virtual Private Cloud environment (Amazon VPC).

- A configured VPC. For example: vpc-01685961063b0d84b. For more information, see [Getting started with Amazon VPC](#) in the *Amazon VPC User Guide*.
- An Amazon S3 endpoint attached to the VPC. For example: vpc-01685961063b0d84b. For more information, see [Endpoints for Amazon S3](#) in the *Amazon VPC User Guide*.

Name	VPC ID	State	IPv4 CIDR	IPv6	DHCP options set	Main Route table	Main Network ACL	Tenancy	Default VPC

Destination	Target	Status	Propagate														
192.168.1.0/24	local	active	No														
pl-7ba54012 (com.amazonaws.us-east-2.s3, 52.219.80.0/20, 3.5.128.0/22, 3.5.132.0/23, 52.219.96.0/20, 52.92.76.0/22)	<a href="#">vpce-0ec5da4d265227786</a>	active	No														

- A network ACL attached to the VPC allows the traffic.
- A security group attached to the VPC allows the traffic.

## Creating the connection to Amazon S3

Typically, you create resources inside Amazon Virtual Private Cloud (Amazon VPC) so that they cannot be accessed over the public internet. By default, AWS Glue can't access resources inside a VPC. To enable AWS Glue to access resources inside your VPC, you must provide additional VPC-

specific configuration information that includes VPC subnet IDs and security group IDs. To create a Network connection you need to specify the following information:

- A VPC ID
- A subnet within the VPC
- A security group

To set up a Network connection:

1. Choose **Add connection** in the navigation pane of the AWS Glue console.
2. Enter the connection name, choose **Network** as the connection type. Choose **Next**.

**Add connection** ✕

## Testing the connection to Amazon S3

Once you have created your Network connection, you can test the connectivity to your Amazon S3 data store in a VPC endpoint.

The following errors may occur when testing a connection:

- **INTERNET CONNECTION ERROR:** indicates an Internet connection issue
- **INVALID BUCKET ERROR:** indicates a problem with the Amazon S3 bucket
- **S3 CONNECTION ERROR:** indicates a failure to connect to Amazon S3
- **INVALID CONNECTION TYPE:** indicates the Connection type does not have the expected value, NETWORK
- **INVALID CONNECTION TEST TYPE:** indicates a problem with the type of network connection test
- **INVALID TARGET:** indicates that the Amazon S3 bucket has not been specified properly

To test a Network connection:

1. Select the **Network** connection in the AWS Glue console.
2. Choose **Test connection**.
3. Choose the IAM role that you created in the previous step and specify an Amazon S3 Bucket.

#### 4. Choose **Test connection** to start the test. It might take few moments to show the result.

The screenshot shows the 'Test connection' dialog in the AWS Glue console. The dialog has a title bar with a close button (X). Below the title, it says 'Test connection from your VPC and subnet to data stores and Amazon S3.' There are two main sections: 'IAM role' and 'Include path'. The 'IAM role' section has a dropdown menu showing 'AWSGlueServiceRole-glue' and a refresh icon. Below it, a note says 'Ensure that this role has permission to access your data store.' and a link 'Create IAM role.'. The 'Include path' section has a text input field containing 's3://crawlertestfiles' and a folder icon. Below these sections is a list of S3 buckets, each with a plus icon and a radio button. The bucket 'crawlertestfiles' is selected. At the bottom right of the dialog is a blue button labeled 'Test connection'.

If you receive an error, check the following:

- The correct privileges are provided to the role selected.
- The correct Amazon S3 bucket is provided.
- The security groups and Network ACL allow the required incoming and outgoing traffic.
- The VPC you specified is connected to an Amazon S3 VPC endpoint.

Once you have successfully tested the connection, you can create a crawler.

## Creating a crawler for an Amazon S3 data store

You can now create a crawler that specifies the Network connection you've created. For more details on creating a crawler, see [Configuring a crawler](#).

1. Start by choosing **Crawlers** in the navigation pane on the AWS Glue console.
2. Choose **Add crawler**.
3. Specify the crawler name and choose **Next**.
4. When asked for the data source, choose **S3**, and specify the Amazon S3 bucket prefix and the connection you created earlier.

**Add crawler**
✕

- ✔ **Crawler info**
- TestNetworkConnecti  
on

9. Finish the remaining setup.

## Creating a crawler for Amazon S3 backed Data Catalog tables

You can now create a crawler that specifies the Network connection you've created and a Catalog source type. For more details on creating a crawler, see [Configuring a crawler](#).

1. Start by choosing **Crawlers** in the navigation pane on the AWS Glue console.
2. Choose **Add crawler**.
3. Specify the crawler name and choose **Next**.
4. When asked for the crawler source type, choose **Existing catalog tables**, and specify the existing catalog tables to crawl from the list of available tables.

The screenshot shows the 'Add crawler' wizard in the AWS Glue console, specifically the 'Choose catalog tables' step. The interface is divided into a sidebar on the left and a main content area on the right.

**Sidebar:** Contains a list of steps: 'Crawler info' (test), 'Crawler source type' (Existing catalog tables), 'Catalog tables', 'IAM Role', 'Schedule', 'Output', and 'Review all steps'. The 'Crawler source type' step is currently selected.

**Main Content Area:** Titled 'Choose catalog tables'. It features two tables:

- Selected tables:** A table with columns 'Name', 'Database', 'Location', and 'Classification'. It currently shows 'No items selected'.
- Available tables:** A table with columns 'Name', 'Database', 'Location', and 'Classification'. It contains three rows of data:
 

Name	Database	Location	Classification
s3_event_crawl_demo	test-sampling-db	s3://s3-event-crawl-demo/	json
test_int5100_idf_20210310094002_0800_obfusca...	test-large-xml	s3://crawltickets/TEST_INT5100_IDF_20210310...	Unknown
test_int5100_idf_20210310094002_0800_obfusca...	test-cx-whitelist	s3://crawltickets/TEST_INT5100_IDF_20210310...	xml

At the bottom of the main content area, there is a 'Connection' dropdown menu with the text 'Select a connection' and a blue 'Add connection' button.

5. Choose IAM role. The IAM role must allow access to the AWS Glue service and the Amazon S3 bucket. For more information, see [the section called "Configuring a crawler"](#).
6. Define the schedule for the crawler.
7. Choose an existing database in the Data Catalog, or create a new database entry.
8. Finish the remaining setup and review your steps.

**Add crawler**
✕

- ✔ **Crawler info**  
test
- ✔ **Crawler source type**  
Existing catalog tables
- ✔ **Catalog tables**  
test\_int5100\_idf\_20...

Connections

**Crawlers**

A crawler connects to a data store, progresses through a prioritized list of classifiers to determine the schema for your data, and then creates metadata tables in your data catalog.

Crawler **TestNetworkConnection** was created to run on demand. [Run it now?](#) ✕

[User preferences](#)

## Troubleshooting

For troubleshooting related to Amazon S3 buckets using a VPC gateway, see [Why can't I connect to an S3 bucket using a gateway VPC endpoint?](#)

## Troubleshooting connection issues in AWS Glue

When an AWS Glue crawler or a job uses connection properties to access a data store, you might encounter errors when you try to connect. AWS Glue uses private IP addresses in the subnet when it creates elastic network interfaces in your specified virtual private cloud (VPC) and subnet. Security groups specified in the connection are applied on each of the elastic network interfaces.

Check to see whether security groups allow outbound access and if they allow connectivity to the database cluster.

In addition, Apache Spark requires bidirectional connectivity among driver and executor nodes. One of the security groups needs to allow ingress rules on all TCP ports. You can prevent it from being open to the world by restricting the source of the security group to itself with a self-referencing security group.

Here are some typical actions you can take to troubleshoot connection problems:

- Check the port address of your connection.
- Check the user name and password string in your connection or secret.
- For a JDBC data store, verify that it allows incoming connections.
- Verify that your data store can be accessed within your VPC.
- If you store your connection credentials using AWS Secrets Manager, make sure that your IAM role for AWS Glue has permission to access your secret. For more information, see [Example: Permission to retrieve secret values](#) in the *AWS Secrets Manager User Guide*. Depending on your network setup, you might also need to create a VPC endpoint to establish a private connection between your VPC and Secrets Manager. For more information, see [Using an AWS Secrets Manager VPC endpoint](#).

## Tutorial: Using the AWS Glue Connector for Elasticsearch

Elasticsearch is a popular open-source search and analytics engine for use cases such as log analytics, real-time application monitoring, and clickstream analysis. You can use OpenSearch as a data store for your extract, transform, and load (ETL) jobs by configuring the AWS Glue Connector for Elasticsearch in AWS Glue Studio. This connector is available for free from [AWS Marketplace](#).

### Note

The [AWS Marketplace Elasticsearch Spark Connector](#) has been deprecated. Please use the [AWS Glue Connector for Elasticsearch](#) instead.

In this tutorial, we will show how to connect to your Amazon OpenSearch Service nodes with a minimal number of steps.

### Topics

- [Prerequisites](#)
- [Step 1: \(Optional\) Create an AWS secret for your OpenSearch cluster information](#)
- [Step 2: Subscribe to the connector](#)
- [Step 3: Activate the connector in AWS Glue Studio and create a connection](#)
- [Step 4: Configure an IAM role for your ETL job](#)
- [Step 5: Create a job that uses the OpenSearch connection](#)
- [Step 6: Run the job](#)

## Prerequisites

To use this tutorial, you must have the following:

- Access to AWS Glue Studio
- Access to an OpenSearch cluster in the AWS Cloud
- (Optional) Access to AWS Secrets Manager.

## Step 1: (Optional) Create an AWS secret for your OpenSearch cluster information

To safely store and use your connection credential, save your credential in AWS Secrets Manager. The secret you create will be used later in the tutorial by the connection. The credential key-value pairs will be fed into the AWS Glue Connector for Elasticsearch as normal connection options.

For more information about creating secrets, see [Creating and Managing Secrets with AWS Secrets Manager](#) in the *AWS Secrets Manager User Guide*.

### To create an AWS secret

1. Sign in to the [AWS Secrets Manager console](#).
2. On either the service introduction page or the **Secrets** list page, choose **Store a new secret**.
3. On the **Store a new secret** page, choose **Other type of secret**. This option means that you must supply the structure and details of your secret.
4. Add a **Key** and **Value** pair for the OpenSearch cluster user name. For example:

```
es.net.http.auth.user: username
```

5. Choose **+ Add row**, and enter another key-value pair for the password. For example:  
`es.net.http.auth.pass: password`
6. Choose **Next**.
7. Enter a secret name. For example: **my-es-secret**. You can optionally include a description.  
Record the secret name, which is used later in this tutorial, and then choose **Next**.
8. Choose **Next** again, and then choose **Store** to create the secret.

## Next step

### [Step 2: Subscribe to the connector](#)

## Step 2: Subscribe to the connector

The AWS Glue Connector for Elasticsearch is available for free from [AWS Marketplace](#).

### To subscribe to the AWS Glue Connector for Elasticsearch on AWS Marketplace

1. If you have not already configured your AWS account to use License Manager, do the following:
  - a. Open the AWS License Manager console at <https://console.aws.amazon.com/license-manager>.
  - b. Choose **Create customer managed license**.
  - c. In the **IAM permissions (one-time setup)** window, choose **I grant AWS License Manager the required permissions**, and then choose **Grant permissions**.

If you do not see this window, then you have already configured the necessary permissions.

2. Open the AWS Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.
3. In the AWS Glue Studio console, expand the menu icon () and then choose **Connectors** in the navigation pane.
4. On the **Connectors** page, choose **Go to AWS Marketplace**.
5. In AWS Marketplace, in the **Search AWS Glue Studio products** section, enter **AWS Glue Connector for Elasticsearch** in the search field, and then press Enter.
6. Choose the name of the connector, **AWS Glue Connector for Elasticsearch**.

7. On the product page for the connector, use the tabs to view information about the connector. When you're ready to continue, choose **Continue to Subscribe**.
8. Review the terms of use for the software. Click **Accept Terms**.
9. When the subscription process completes, you will see a notification: "Thank you for subscribing to this product! You can now configure your software." Above the banner will be the button **Continue to Configuration**. Choose **Continue to Configuration**.
10. Choose the Fulfillment option on the **Configure this software** page. You can either choose between AWS Glue 1.0/2.0 or AWS Glue 3.0. Then, choose **Continue to Launch**.

## Next step

[Step 3: Activate the connector in AWS Glue Studio and create a connection](#)

## Step 3: Activate the connector in AWS Glue Studio and create a connection

After you choose **Continue to Launch**, you see the **Launch this software** page in AWS Marketplace. After you use the link to activate the connector in AWS Glue Studio, you create a connection.

### To deploy the connector and create a connection in AWS Glue Studio

1. On the **Launch this software** page in the AWS Marketplace console, choose **Usage Instructions**, and then choose the link in the window that appears.

Your browser is redirected to the AWS Glue Studio console **Create marketplace connection** page.

2. Enter a name for the connection. For example: **my-es-connection**.
3. In the **Connection access** section, for **Connection credential type**, choose **User name and password**.
4. For the **AWS secret**, enter the name of your secret. For example: **my-es-secret**.
5. In the **Network options** section, enter the VPC information to connect to OpenSearch cluster.
6. Choose **Create connection and activate connector**.

## Next step

[Step 4: Configure an IAM role for your ETL job](#)

## Step 4: Configure an IAM role for your ETL job

When you create the AWS Glue ETL job, you specify an AWS Identity and Access Management (IAM) role for the job to use. The role must grant access to all resources used by the job, including Amazon S3 (for any sources, targets, scripts, driver files, and temporary directories), and also AWS Glue Data Catalog objects.

The assumed IAM role for the AWS Glue ETL job must also have access to the secret that was created in the previous section. By default, the AWS managed role `AWSGlueServiceRole` does not have access to the secret. To set up access control for your secrets, see [Authentication and Access Control for AWS Secrets Manager](#) and [Limiting Access to Specific Secrets](#).

### To configure an IAM role for your ETL job

1. Configure the permissions described in [the section called “Review IAM permissions needed for ETL jobs”](#).
2. Configure the additional permissions needed when using connectors with AWS Glue Studio, as described in [the section called “Permissions required for using connectors”](#).

### Next step

[Step 5: Create a job that uses the OpenSearch connection](#)

## Step 5: Create a job that uses the OpenSearch connection

After creating a role for your ETL job, you can create a job in AWS Glue Studio that uses the connection and connector for Open Spark ElasticSearch.

If your job runs within a Amazon Virtual Private Cloud (Amazon VPC), make sure the VPC is configured correctly. For more information, see [the section called “Configure a VPC for your ETL job”](#).

### To create a job that uses the Elasticsearch Spark Connector

1. In AWS Glue Studio, choose **Connectors**.
2. In the **Your connections** list, select the connection you just created and choose **Create job**.
3. In the visual job editor, choose the Data source node. On the right, on the **Data source properties - Connector** tab, configure additional information for the connector.

- a. Choose **Add schema** and enter the schema of the data set in the data source. Connections do not use tables stored in the Data Catalog, which means that AWS Glue Studio doesn't know the schema of the data. You must manually provide this schema information. For instructions on how to use the schema editor, see [the section called "Editing the schema in a custom transform node"](#).
- b. Expand **Connection options**.
- c. Choose **Add new option** and enter the information needed for the connector that was not entered in the AWS secret:
  - **es.nodes:** `https://<OpenSearch domain endpoint>`
  - **es.port:** 443
  - **path:** test
  - **es.nodes.wan.only:** true

For an explanation of these connection options, refer to: <https://www.elastic.co/guide/en/elasticsearch/hadoop/current/configuration.html>.

4. Add a target node to the graph.

Your data target can be Amazon S3, or it can use information from an AWS Glue Data Catalog or a connector to write data in a different location. For example, you can use a Data Catalog table to write to a database in Amazon RDS, or you can use a connector as your data target to write to data stores that are not natively supported in AWS Glue.

If you choose a connector for your data target, you must choose a connection created for that connector. Also, if required by the connector provider, you must add options to provide additional information to the connector. If you use a connection that contains information for an AWS secret, then you don't need to provide the user name and password authentication in the connection options.

5. Optionally, add additional data sources and one or more transform nodes as described in [the section called "Editing AWS Glue managed data transform nodes"](#).
6. Configure the job properties as described in [the section called "Modify the job properties"](#), starting with step 3, and save the job.

## Next step

### [Step 6: Run the job](#)

## Step 6: Run the job

After you save your job, you can run the job to perform the ETL operations.

### To run the job you created for the AWS Glue Connector for Elasticsearch

1. Using the AWS Glue Studio console, on the visual editor page, choose **Run**.
2. In the success banner, choose **Run Details**, or you can choose the **Runs** tab of the visual editor to view information about the job run.

# Building AWS Glue jobs with interactive sessions

Data engineers can author AWS Glue jobs faster and more easily than before using interactive sessions in AWS Glue.

## Topics

- [Overview of AWS Glue interactive sessions](#)
- [Getting started with AWS Glue interactive sessions](#)
- [Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks](#)
- [Getting started with AWS Glue for Ray interactive sessions \(preview\)](#)
- [Interactive sessions with IAM](#)
- [Converting a script or notebook into an AWS Glue job](#)
- [AWS Glue interactive sessions for streaming](#)
- [Developing and testing AWS Glue job scripts locally](#)
- [Development endpoints](#)

## Overview of AWS Glue interactive sessions

With AWS Glue interactive sessions, you can rapidly build, test, and run data preparation and analytics applications. Interactive sessions provides a programmatic and visual interface for building and testing extract, transform, and load (ETL) scripts for data preparation. Interactive sessions run Apache Spark analytics applications and provide on-demand access to a remote Spark runtime environment. AWS Glue transparently manages serverless Spark for these interactive sessions.

Interactive sessions are flexible, so you build and test your applications from the environment of your choice. You can create and work with interactive sessions through the AWS Command Line Interface and the API. You can use Jupyter-compatible notebooks to visually author and test your notebook scripts. Interactive sessions provide an open-source Jupyter kernel that integrates almost anywhere that Jupyter does, including integrating with IDEs such as PyCharm, IntelliJ, and VS Code. This enables you to author code in your local environment and run it seamlessly on the interactive sessions backend.

Using the interactive sessions API, customers can programmatically run applications that use Apache Spark analytics without having to manage Spark infrastructure. You can run one or more Spark statements within a single interactive session.

Interactive sessions therefore provide a faster, cheaper, more-flexible way to build and run data preparation and analytics applications. To learn how to use interactive sessions, see the documentation in this section. [Magics supported by AWS Glue](#)

## Limitations

- Job bookmarks are not supported in interactive sessions.
- Creating notebook jobs using the AWS Command Line Interface is not supported.

## Getting started with AWS Glue interactive sessions

These sections describe how to run AWS Glue interactive sessions locally.

### Prerequisites for setting up interactive sessions locally

The following are prerequisites for installing interactive sessions:

- Supported Python versions are 3.6 - 3.10+.
- See sections below for MacOS/Linux and Windows instructions.

### Installing Jupyter and AWS Glue interactive sessions Jupyter kernels

Use the following to install the kernel locally.

The command, `install-glue-kernels`, installs the jupyter kernelspec for both pyspark and spark kernels and also installs logos in the right directory.

```
pip3 install --upgrade jupyter boto3 aws-glue-sessions
```

```
install-glue-kernels
```

## Running Jupyter

To run Jupyter Notebook, complete the following steps.

1. Run the following command to launch Jupyter Notebook.

```
jupyter notebook
```

2. Choose **New**, and then choose one of the AWS Glue kernels to begin coding against AWS Glue.

## Configuring session credentials and region

### MacOS/Linux instructions

AWS Glue interactive sessions requires the same IAM permissions as AWS Glue Jobs and Dev Endpoints. Specify the role used with interactive sessions in one of two ways:

1. With the `%iam_role` and `%region` magics
2. With an additional line in `~/.aws/config`

### Configuring a session role with magic

In the first cell, type `%iam_role <YourGlueServiceRole>` in the first cell executed.

### Configuring a session role with `~/.aws/config`

AWS Glue Service Role for interactive sessions can either be specified in the notebook itself or stored alongside the AWS CLI config. If you have a role you typically use with AWS Glue Jobs this will be that role. If you do not have a role you use for AWS Glue jobs, please follow this guide, [Configuring IAM permissions for AWS Glue](#), to set one up.

To set this role as the default role for interactive sessions:

1. With a text editor, open `~/.aws/config`.
2. Look for the profile you use for AWS Glue. If you don't use a profile, use the `[Default]` profile.
3. Add a line in the profile for the role you intend to use like `glue_role_arn=<AWSGlueServiceRole>`.

4. [Optional]: If your profile does not have a default region set, I recommend adding one with `region=us-east-1`, replacing `us-east-1` with your desired region.
5. Save the config.

For more information, see [Interactive sessions with IAM](#).

## Windows instructions

AWS Glue interactive sessions requires the same IAM permissions as AWS Glue Jobs and Dev Endpoints. Specify the role used with interactive sessions in one of two ways:

1. With the `%iam_role` and `%region` magics
2. With an additional line in `~/.aws/config`

### Configuring a session role with magic

In the first cell, type `%iam_role <YourGlueServiceRole>` in the first cell executed.

### Configuring a session role with `~/.aws/config`

AWS Glue Service Role for interactive sessions can either be specified in the notebook itself or stored alongside the AWS CLI config. If you have a role you typically use with AWS Glue Jobs this will be that role. If you do not have a role you use for AWS Glue jobs, please follow this guide, [Setting up IAM permissions for AWS Glue](#), to set one up.

To set this role as the default role for interactive sessions:

1. With a text editor, open `~/.aws/config`.
2. Look for the profile you use for AWS Glue. If you don't use a profile, use the `[Default]` profile.
3. Add a line in the profile for the role you intend to use like `glue_role_arn=<AWSGlueServiceRole>`.
4. [Optional]: If your profile does not have a default region set, I recommend adding one with `region=us-east-1`, replacing `us-east-1` with your desired region.
5. Save the config.

For more information, see [Interactive sessions with IAM](#).

## Upgrading from the interactive sessions preview

The kernel was upgraded with new names when it was released with version 0.27. To clean up preview versions of the kernels run the following from a terminal or PowerShell.

### Note

If you are a part of any other AWS Glue preview that requires a custom service model, removing the kernel will remove the custom service model.

```
# Remove Old Glue Kernels
jupyter kernelspec remove glue_python_kernel
jupyter kernelspec remove glue_scala_kernel

# Remove Custom Model
cd ~/.aws/models
rm -rf glue/
```

## Using interactive sessions with SageMaker Studio

AWS Glue Interactive Sessions is an on-demand, serverless, Apache Spark runtime environment that data scientists and engineers can use to rapidly build, test, and run data preparation and analytics applications. You can initiate an AWS Glue interactive session by starting a Amazon SageMaker Studio Classic notebook.

For more information, see [Prepare Data using AWS Glue interactive sessions](#) .

## Using interactive sessions with Microsoft Visual Studio Code

### Prerequisites

- Install AWS Glue interactive sessions and verify it works with Jupyter Notebook.
- Download and install Visual Studio Code with Jupyter. For details, see [Jupyter Notebook in VS Code](#).

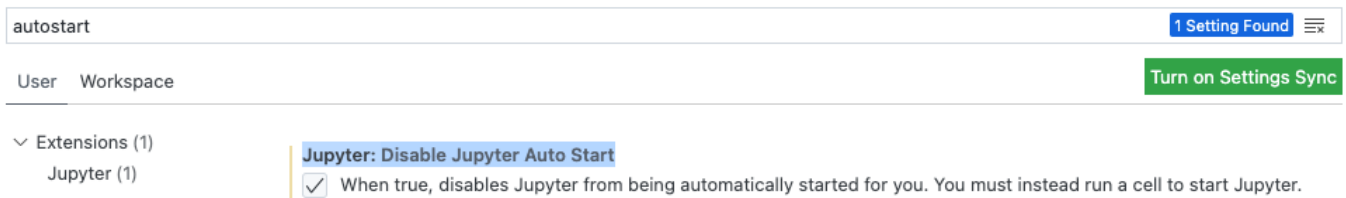

## To get started with interactive sessions with VSCode

### 1. Disable Jupyter AutoStart in VS Code.

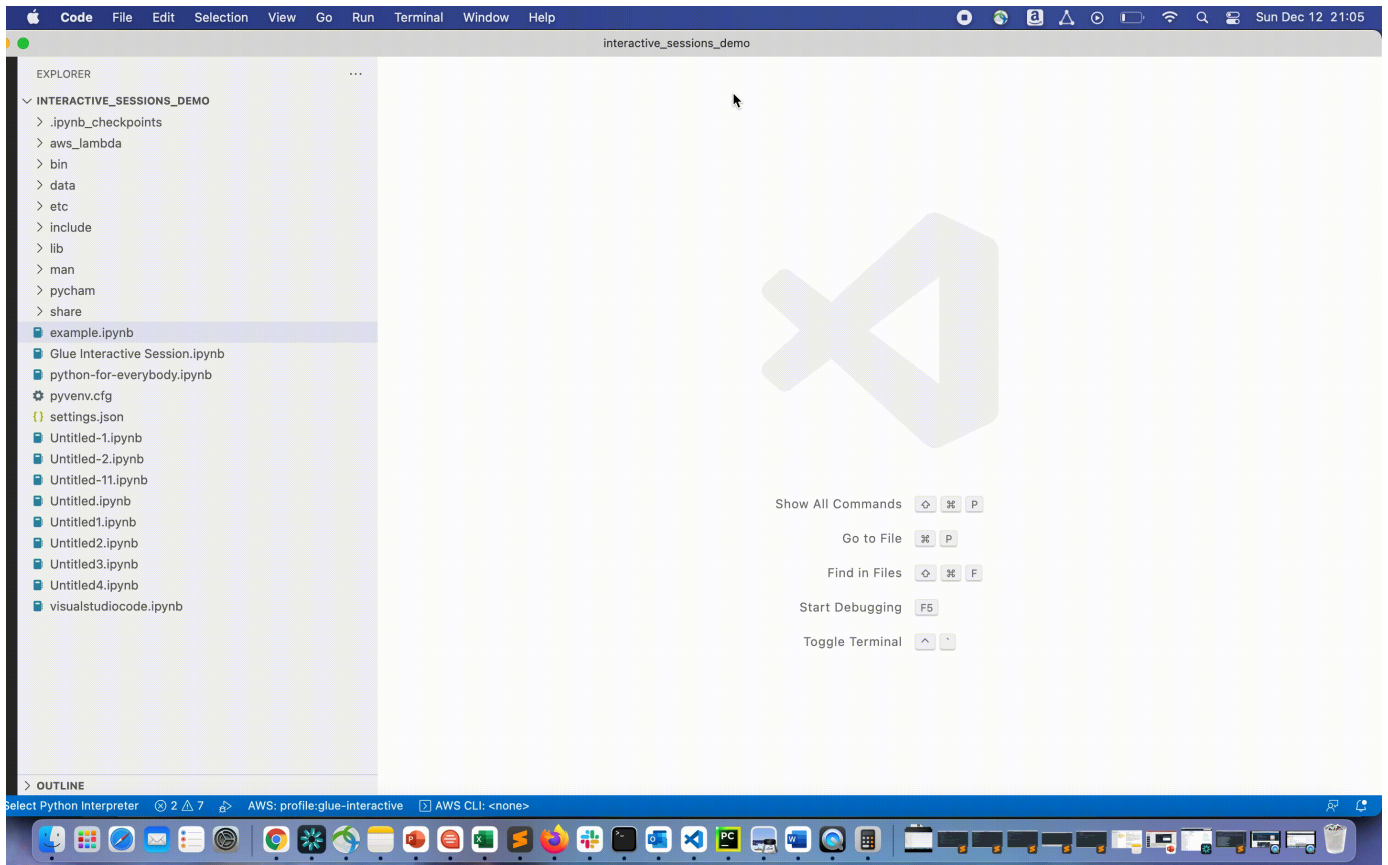

In Visual Studio Code, Jupyter kernels will auto-start which will prevent your magics from taking effect as the session will already be started. To disable **Auto Start** on Windows, go to **File > Preferences > Extensions > Jupyter > right-click on Jupyter then choose Extension Settings**.

On MacOS, go to **Code > Settings > Extensions > Jupyter > right-click on Jupyter then choose Extension Settings**.

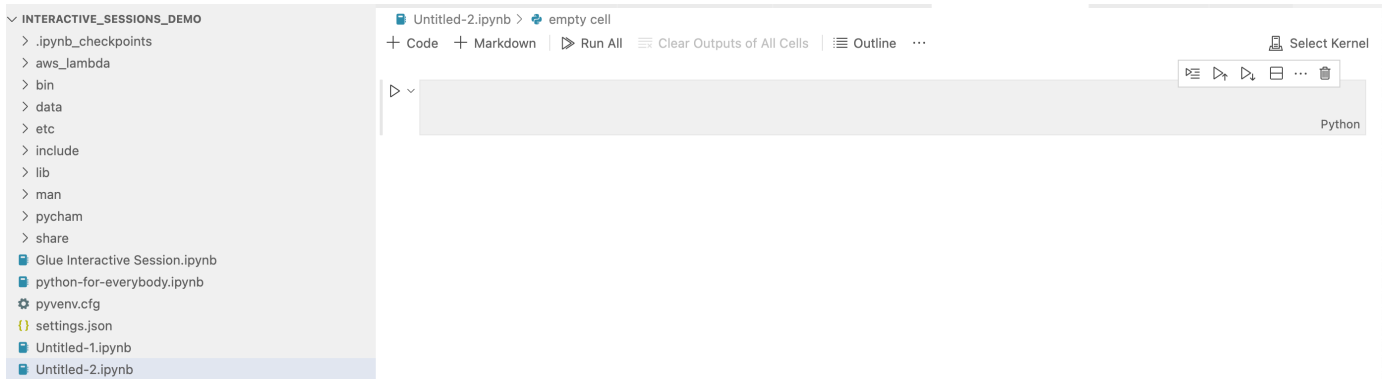

Scroll down until you see **Jupyter: Disable Jupyter Auto Start**. Check the box "When true, disables Jupyter from being automatically started for you. You must instead run a cell to start Jupyter."

### 2. Go to File > New File > Save to save this file with name of your choice as an .ipynb extension or select **jupyter** under **select a language** and save the file.

3. Double-click on the file. The Jupyter shell will display and a notebook will be opened.

4. On Windows, when you first create a file, by default no kernel is selected. Click on **Select Kernel** and a list of available kernels is displayed. Choose **Glue PySpark**.

On MacOS, If you do not see the **Glue PySpark** kernel, try the following steps:

1. Run a local Jupyter session to obtain the URL.

For example, run the following command to launch Jupyter Notebook.

```
jupyter notebook
```

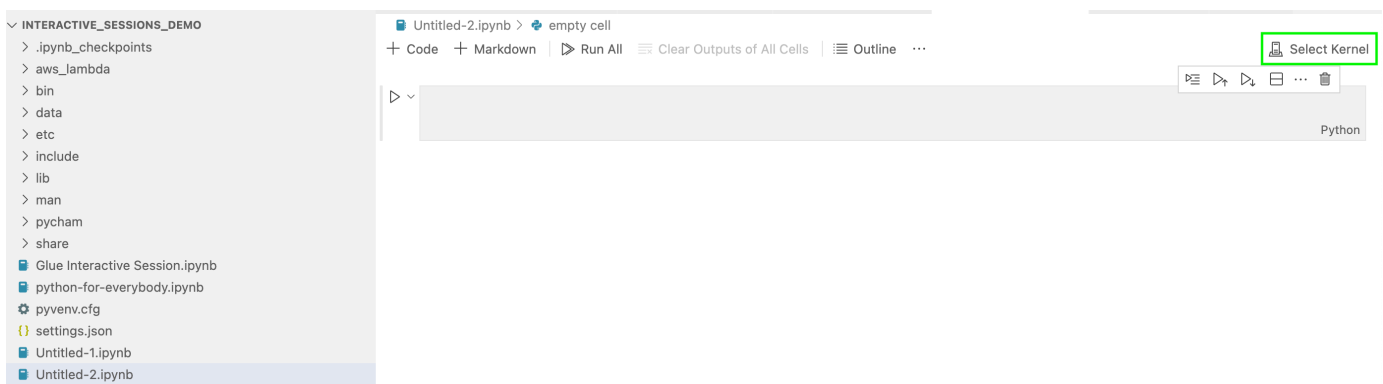

When the notebook first runs, you will see a URL that looks like `http://localhost:8888/?token=3398XXXXXXXXXXXXXXXXXX`.

Copy the URL.

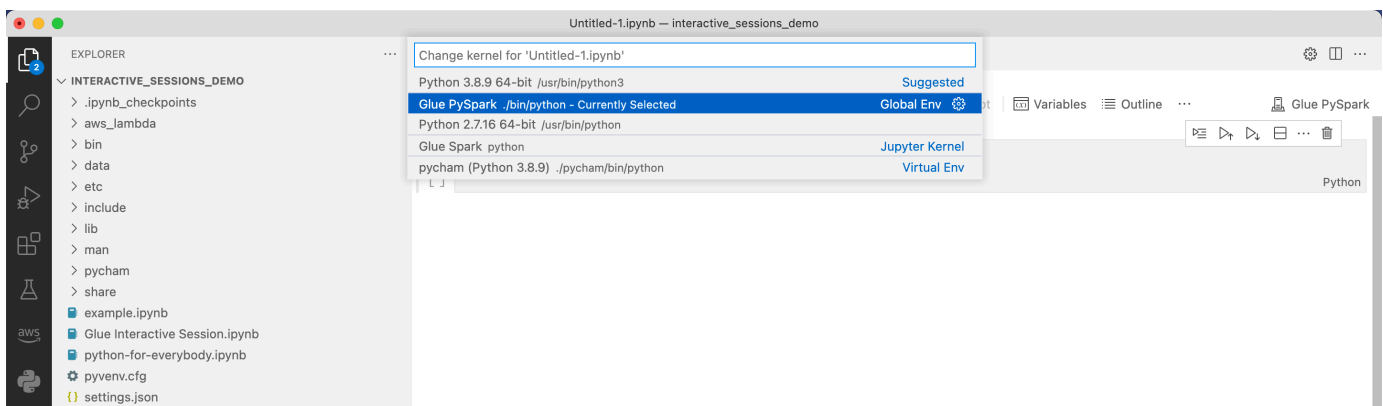

- In VS Code, click the current kernel, then **Select Another Kernel...**, then select **Existing Jupyter Server...** Paste the URL you copied from the step above.

If you receive an error message, see the [VS Code Jupyter wiki](#).

- If successful, this will set the kernel to **Glue PySpark**.

Choose the **Glue PySpark** or **Glue Spark** kernel (for Python and Scala respectively).

If you don't see **AWS Glue PySpark** and **AWS Glue Spark** kernels in the drop-down list, please ensure you have installed the AWS Glue kernel in the step above, or that your `python.defaultInterpreterPath` setting in Visual Studio Code is correct. For more information, see [python.defaultInterpreterPath setting description](#).

5. Create an AWS Glue Interactive Session. Proceed to create a session in the same manner as you did in Jupyter Notebook. Specify any magics at the top of your first cell and run a statement of code.

## Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks

### Introduction to Jupyter Magics

Jupyter Magics are commands that can be run at the beginning of a cell or as a whole cell body. Magics start with % for line-magics and %% for cell-magics. Line-magics such as %region and %connections can be run with multiple magics in a cell, or with code included in the cell body like the following example.

```
%region us-east-2
%connections my_rds_connection
dy_f = glue_context.create_dynamic_frame.from_catalog(database='rds_tables',
table_name='sales_table')
```

Cell magics must use the entire cell and can have the command span multiple lines. An example of %%sql is below.

```
%%sql
select * from rds_tables.sales_table
```

### Magics supported by AWS Glue interactive sessions for Jupyter

The following are magics that you can use with AWS Glue interactive sessions for Jupyter notebooks.

#### Sessions magics

Name	Type	Description
%help	n/a	Return a list of descriptions and input types for all magic commands.

Name	Type	Description
<code>%profile</code>	String	Specify a profile in your AWS configuration to use as the credentials provider.
<code>%region</code>	String	Specify the AWS Region; in which to initialize a session. Default from <code>~/.aws/configure</code> .  Example: <code>%region us-west-1</code>
<code>%idle_timeout</code>	Int	The number of minutes of inactivity after which a session will timeout after a cell has been executed. The default idle timeout value for Spark ETL sessions is the default timeout, 2880 minutes (48 hours). For other session types, consult documentation for that session type.  Example: <code>%idle_timeout 3000</code>
<code>%session_id</code>	n/a	Return the session ID for the running session.
<code>%session_id_prefix</code>	String	Define a string that will precede all session IDs in the format <code>[session_id_prefix]-[session_id]</code> . If a session ID is not provided, a random UUID will be generated. This magic is not supported when you run a Jupyter Notebook in AWS Glue Studio.  Example: <code>%session_id_prefix 001</code>
<code>%status</code>		Return the status of the current AWS Glue session including its duration, configuration and executing user / role.
<code>%stop_session</code>		Stop the current session.

Name	Type	Description
<code>%list_sessions</code>		Lists all currently running sessions by name and ID.
<code>%session_type</code>	String	Sets the session type to one of Streaming, ETL, or Ray.  Example: <code>%session_type Streaming</code>
<code>%glue_version</code>	String	The version of AWS Glue to be used by this session.  Example: <code>%glue_version 3.0</code>

### Magics for selecting job types

Name	Type	Description
<code>%streaming</code>	String	Changes the session type to AWS Glue Streaming.
<code>%etl</code>	String	Changes the session type to AWS Glue ETL.
<code>%glue_ray</code>	String	Changes the session type to AWS Glue for Ray. See <a href="#">Magics supported by AWS Glue Ray interactive sessions</a> .

### AWS Glue for Spark config magics

The `%%configure` magic is a json-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be specified here or through individual magics.

Name	Type	Description
<code>%%configure</code>	Dictionary	<p>Specify a JSON-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be specified here or through individual magics.</p> <p>For a list of parameters and examples on how to use <code>%%configure</code>, see the table below: <b>Using <code>%%configure</code></b>.</p>
<code>%iam_role</code>	String	<p>Specify an IAM role ARN to execute your session with. Default from <code>~/.aws/configure</code>.</p> <p>Example: <code>%iam_role AWSGlueServiceRole</code></p>
<code>%number_of_workers</code>	Int	<p>The number of workers of a defined <code>worker_type</code> that are allocated when a job runs. <code>worker_type</code> must be set too. The default <code>number_of_workers</code> is 5.</p> <p>Example: <code>%number_of_workers 2</code></p>
<code>%additional_python_modules</code>	List	<p>Comma separated list of additional Python modules to include in your cluster (can be from PyPI or S3).</p> <p>Example: <code>%additional_python_modules pandas, numpy</code></p>
<code>%%tags</code>	String	<p>Adds tags to a session. Specify the tags within curly brackets <code>{ }</code>. Each tag name pair is enclosed in parentheses <code>" "</code> and separated by a comma <code>(,)</code>.</p> <div style="border: 1px solid #ccc; border-radius: 10px; padding: 5px; margin-top: 10px;"> <pre>%%tags</pre> </div>

Name	Type	Description
		<pre data-bbox="915 212 1344 281">{"billing":"Data-Platform", "team":"analytics"}</pre> <p data-bbox="894 386 1425 464">Use the %status magic to view tags associated with the session.</p> <pre data-bbox="915 527 1027 554">%status</pre> <pre data-bbox="915 638 1425 1423">Session ID: &lt;sessionId&gt; Status: READY Role: &lt;example-role&gt; CreatedOn: 2023-05-26 11:12:17. 056000-07:00 GlueVersion: 3.0 Job Type: glueetl Tags: {'owner':'example-owner', 'team':'analytics', 'billing': 'Data-Platform'} Worker Type: G.4X Number of Workers: 5 Region: us-west-2 Applying the following default arguments: --glue_kernel_version 0.38.0 --enable-glue-datacatalog true Arguments Passed: ['--glue_ kernel_version: 0.38.0', '-- enable-glue-datacatalog: true']</pre>

Name	Type	Description
%%assume_role	Dictionary	<p>Specify a json-formatted dictionary or an IAM role ARN string to create a session for cross-account access.</p> <p>Example with ARN:</p> <pre data-bbox="894 472 1507 751">%%assume_role {   'arn:aws:iam::XXXXXXXXXXXX: role/AWSGlueServiceRole' }</pre> <p>Example with credentials:</p> <pre data-bbox="894 863 1507 1264">%%assume_role {{   "aws_access_key_id" =   "XXXXXXXXXXXX",   "aws_secret_access_key" =   "XXXXXXXXXXXX",   "aws_session_token" =   "XXXXXXXXXXXX" }}</pre>

## %%configure cell magic arguments

The %%configure magic is a json-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be specified here or through individual magics. See below for examples for arguments supported by the %%configure cell magic. Use the -- prefix for run arguments specified for the job. Example:

```
%%configure
{
  "--user-jars-first": "true",
  "--enable-glue-datacatalog": "false"
}
```

For more information on job parameters, see [Job parameters](#).

## Session Configuration

Parameter	Type	Description
<code>max_retries</code>	Int	The maximum number of times to retry this job if it fails.  <pre>%%configure {   "max_retries": "0" }</pre>
<code>max_concurrent_runs</code>	Int	The maximum number of concurrent runs allowed for a job.  Example:  <pre>%%configure {   "max_concurrent_runs": "3" }</pre>

## Session parameters

Parameter	Type	Description
<code>--enable-spark-ui</code>	Boolean	Enable Spark UI to monitor and debug AWS Glue ETL jobs.  <pre>%%configure {   "--enable-spark-ui": "true" }</pre>

Parameter	Type	Description
<code>--spark-event-logs-path</code>	String	<p>Specifies an Amazon S3 path. When using the Spark UI monitoring feature.</p> <p>Example:</p> <pre>%%configure {   "--spark-event-logs-path":   "s3://path/to/event/logs/" }</pre>
<code>--scriptLocation</code>	String	<p>Specifies the S3 path to a script that executes a job.</p> <p>Example:</p> <pre>%%configure {   "--scriptLocation": "s3://new- folder-here" }</pre>
<code>--SECURITY_CONFIGURATION</code>	String	<p>The name of a AWS Glue security configuration</p> <p>Example:</p> <pre>%%configure {   "--SECURITY_CONFIGURATION": <i>security-configuration-name</i> , }</pre>

Parameter	Type	Description
<code>--job-language</code>	String	<p>The script programming language. Accepts a value of 'scala' or 'python'. Default is 'python'.</p> <p>Example:</p> <pre>%%configure {   "--job-language": "scala" }</pre>
<code>--class</code>	String	<p>The Scala class that serves as the entry point for your Scala script. Default is null.</p> <p>Example:</p> <pre>%%configure {   "--class": "className" }</pre>
<code>--user-jars-first</code>	Boolean	<p>Prioritizes the customer's extra JAR files in the classpath. Default is null.</p> <p>Example:</p> <pre>%%configure {   "--user-jars-first": "true" }</pre>

Parameter	Type	Description
<code>--use-postgres-driver</code>	Boolean	<p>Prioritizes the Postgres JDBC driver in the class path to avoid a conflict with the Amazon Redshift JDBC driver. Default is null.</p> <p>Example:</p> <pre>%%configure {   "--use-postgres-driver": "true" }</pre>
<code>--extra-files</code>	List(string)	<p>The Amazon S3 paths to additional files, such as configuration files that AWS Glue copies to the working directory of your script before executing it.</p> <p>Example:</p> <pre>%%configure {   "--extra-files": "s3://path/to/ additional/files/" }</pre>

Parameter	Type	Description
<code>--job-bookmark-option</code>	String	<p>Controls the behavior of a job bookmark. Accepts a value of 'job-bookmark-enable', 'job-bookmark-disable' or 'job-bookmark-pause'. Default is 'job-bookmark-disable'.</p> <p>Example:</p> <pre>%%configure {   "--job-bookmark-option": "job-bookmark-enable" }</pre>
<code>--temp-dir</code>	String	<p>Specifies an Amazon S3 path to a bucket that can be used as a temporary directory for the job. Default is null.</p> <p>Example:</p> <pre>%%configure {   "--temp-dir": "s3://path/to/temp/dir" }</pre>

Parameter	Type	Description
<code>--enable-s3-parquet-optimized-committer</code>	Boolean	<p>Enables the EMRFS Amazon S3-optimized committer for writing Parquet data into Amazon S3. Default is 'true'.</p> <p>Example:</p> <pre>%%configure {   "--enable-s3-parquet-optimized-committer": "false" }</pre>
<code>--enable-rename-algorithm-v2</code>	Boolean	<p>Sets the EMRFS rename algorithm version to version 2. Default is 'true'.</p> <p>Example:</p> <pre>%%configure {   "--enable-rename-algorithm-v2": "true" }</pre>
<code>--enable-glue-data-catalog</code>	Boolean	<p>Enables you to use the AWS Glue Data Catalog as an Apache Spark Hive metastore.</p> <p>Example:</p> <pre>%%configure {   "--enable-glue-datacatalog": "true" }</pre>

Parameter	Type	Description
<code>--enable-metrics</code>	Boolean	<p>Enables the collection of metrics for job profiling for job run. Default is 'false'.</p> <p>Example:</p> <pre>%%configure {   "--enable-metrics": "true" }</pre>
<code>--enable-continuous-cloudwatch-log</code>	Boolean	<p>Enables real-time continuous logging for AWS Glue jobs. Default is 'false'.</p> <p>Example:</p> <pre>%%configure {   "--enable-continuous-cloudw atch-log": "true" }</pre>
<code>--enable-continuous-log-filter</code>	Boolean	<p>Specifies a standard filter or no filter when you create or edit a job enabled for continuous logging. Default is 'true'.</p> <p>Example:</p> <pre>%%configure {   "--enable-continuous-log-fi lter": "true" }</pre>

Parameter	Type	Description
<code>--continuous-log-stream-prefix</code>	String	<p>Specifies a custom Amazon CloudWatch log stream prefix for a job enabled for continuous logging. Default is null.</p> <p>Example:</p> <pre>%%configure {   "--continuous-log-stream-prefix": "prefix" }</pre>
<code>--continuous-log-conversionPattern</code>	String	<p>Specifies a custom conversion log pattern for a job enabled for continuous logging. Default is null.</p> <p>Example:</p> <pre>%%configure {   "--continuous-log-conversionPattern": "pattern" }</pre>

Parameter	Type	Description
--conf	String	<p>Controls Spark config parameters. It is for advanced use cases. Use --conf before each parameter. Example:</p> <pre>%%configure {   "--conf": "spark.hadoop.hive .metastore.glue.catalogid=1 23456789012 --conf hive.meta store.client.factory.class= com.amazonaws.glue.catalog. metastore.AWSGlueDataCatalo gHiveClientFactory --conf hive.metastore.schema.verif ication=false" }</pre>

## Spark jobs (ETL & streaming) magics

Name	Type	Description
%worker_type	String	Standard, G.1X, or G.2X. number_of_workers must be set too. The default worker_type is G.1X.
%connections	List	<p>Specify a comma-separated list of connections to use in the session.</p> <p>Example:</p> <pre>%connections my_rds_connection dy_f = glue_context.create_dynamic _frame.from_catalog(databas</pre>

Name	Type	Description
		<pre>e='rds_tables', table_name='sales_table')</pre>
<code>%extra_py_files</code>	List	Comma separated list of additional Python files from Amazon S3.
<code>%extra_jars</code>	List	Comma-separated list of additional jars to include in the cluster.
<code>%spark_conf</code>	String	Specify custom spark configurations for your session. For example, <code>%spark_conf spark.serializer=org.apache.spark.serializer.KryoSerializer</code> .

## Magics for Ray jobs

Name	Type	Description
<code>%min_workers</code>	Int	The minimum number of workers that are allocated to a Ray job. Default: 1.  Example: <code>%min_workers 2</code>
<code>%object_memory_head</code>	Int	The percentage of free memory on the instance head node after a warm start. Minimum: 0. Maximum: 100.  Example: <code>%object_memory_head 100</code>
<code>%object_memory_worker</code>	Int	The percentage of free memory on the instance worker nodes after a warm start. Minimum: 0. Maximum: 100.

Name	Type	Description
		Example: <code>%object_memory_worker 100</code>

## Action magics

Name	Type	Description
<code>%%sql</code>	String	<p>Run SQL code. All lines after the initial <code>%sql</code> magic will be passed as part of the SQL code.</p> <p>Example: <code>%%sql select * from rds_tables.sales_table</code></p>
<code>%matplotlib</code>	Matplotlib figure	<p>Visualize your data using the matplotlib library.</p> <p>Example:</p> <pre>import matplotlib.pyplot as plt  # Set X-axis and Y-axis values x = [5, 2, 8, 4, 9] y = [10, 4, 8, 5, 2]  # Create a bar chart plt.bar(x, y)  # Show the plot %matplotlib plt</pre>
<code>%plotly</code>	Plotly figure	<p>Visualize your data using the plotly library.</p> <p>Example:</p>

Name	Type	Description
		<pre>import plotly.express as px  #Create a graphical figure fig = px.line(x=["a","b","c"],              y=[1,3,2], title="sample              figure")  #Show the figure %plotly fig</pre>

## Naming sessions

AWS Glue interactive sessions are AWS resources and require a name. Names should be unique for each session and may be restricted by your IAM administrators. For more information, see [Interactive sessions with IAM](#). The Jupyter kernel automatically generates unique session names for you. However sessions can be named manually in two ways:

1. Using the AWS Command Line Interface config file located at `~/.aws/config`. See [Setting Up AWS Config with the AWS Command Line Interface](#).
2. Using the `%session_id_prefix` magics. See [Magics supported by AWS Glue interactive sessions for Jupyter](#).

A session name is generated as follows:

- When the prefix and session\_id are provided: the session name will be {prefix}-{UUID}.
- When nothing is provided: the session name will be {UUID}.

Prefixing session names allows you to recognize your session when listing it in the AWS CLI or console.

## Specifying an IAM role for interactive sessions

You must specify an AWS Identity and Access Management (IAM) role to use with AWS Glue ETL code that you run with interactive sessions.

The role requires the same IAM permissions as those required to run AWS Glue jobs. See [Create an IAM role for AWS Glue](#) for more information on creating a role for AWS Glue jobs and interactive sessions.

IAM roles can be specified in two ways:

- Using the AWS Command Line Interface config file located at `~/.aws/config` (Recommended). For more information, see [Configuring sessions with `~/.aws/config`](#).

**Note**

When the `%profile` magic is used, the configuration for `glue_iam_role` of that profile is honored.

- Using the `%iam_role` magic. For more information, see [Magics supported by AWS Glue interactive sessions for Jupyter](#).

## Configuring sessions with named profiles

AWS Glue interactive sessions uses the same credentials as the AWS Command Line Interface or boto3, and interactive sessions honors and works with named profiles like the AWS CLI found in `~/.aws/config` (Linux and MacOS) or `%USERPROFILE%\\.aws\config` (Windows). For more information, see [Using named profiles](#).

Interactive sessions takes advantage of named profiles by allowing the AWS Glue Service Role and Session ID Prefix to be specified in a profile. To configure a profile role, add a line for the `iam_role` key and/or `session_id_prefix` to your named profile as shown below. The `session_id_prefix` does not require quotes. For example, if you want to add a `session_id_prefix`, enter the value of the `session_id_prefix=myprefix`.

```
[default]
region=us-east-1
aws_access_key_id=AKIAIOSFODNN7EXAMPLE
aws_secret_access_key=wJalrXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY
glue_iam_role=arn:aws:iam::<AccountID>:role/<GlueServiceRole>
session_id_prefix=<prefix_for_session_names>

[user1]
region=eu-west-1
```

```
aws_access_key_id=AKIAI44QH8DHBEXAMPLE
aws_secret_access_key=je7MtGbClwBF/2Zp9Utk/h3yCo8nvbEXAMPLEKEY
glue_iam_role=arn:aws:iam::<AccountID>:role/<GlueServiceRoleUser1>
session_id_prefix=<prefix_for_session_names_for_user1>
```

If you have a custom method of generating credentials, you can also configure your profile to use the `credential_process` parameter in your `~/.aws/config` file. For example:

```
[profile developer]
region=us-east-1
credential_process = "/Users/Dave/generate_my_credentials.sh" --username helen
```

You can find more details about sourcing credentials through the `credential_process` parameter here: [Sourcing credentials with an external process](#).

If a region or `iam_role` are not set in the profile that you are using, you must specify them using the `%region` and `%iam_role` magics in the first cell that you run.

## Getting started with AWS Glue for Ray interactive sessions (preview)

### Warning

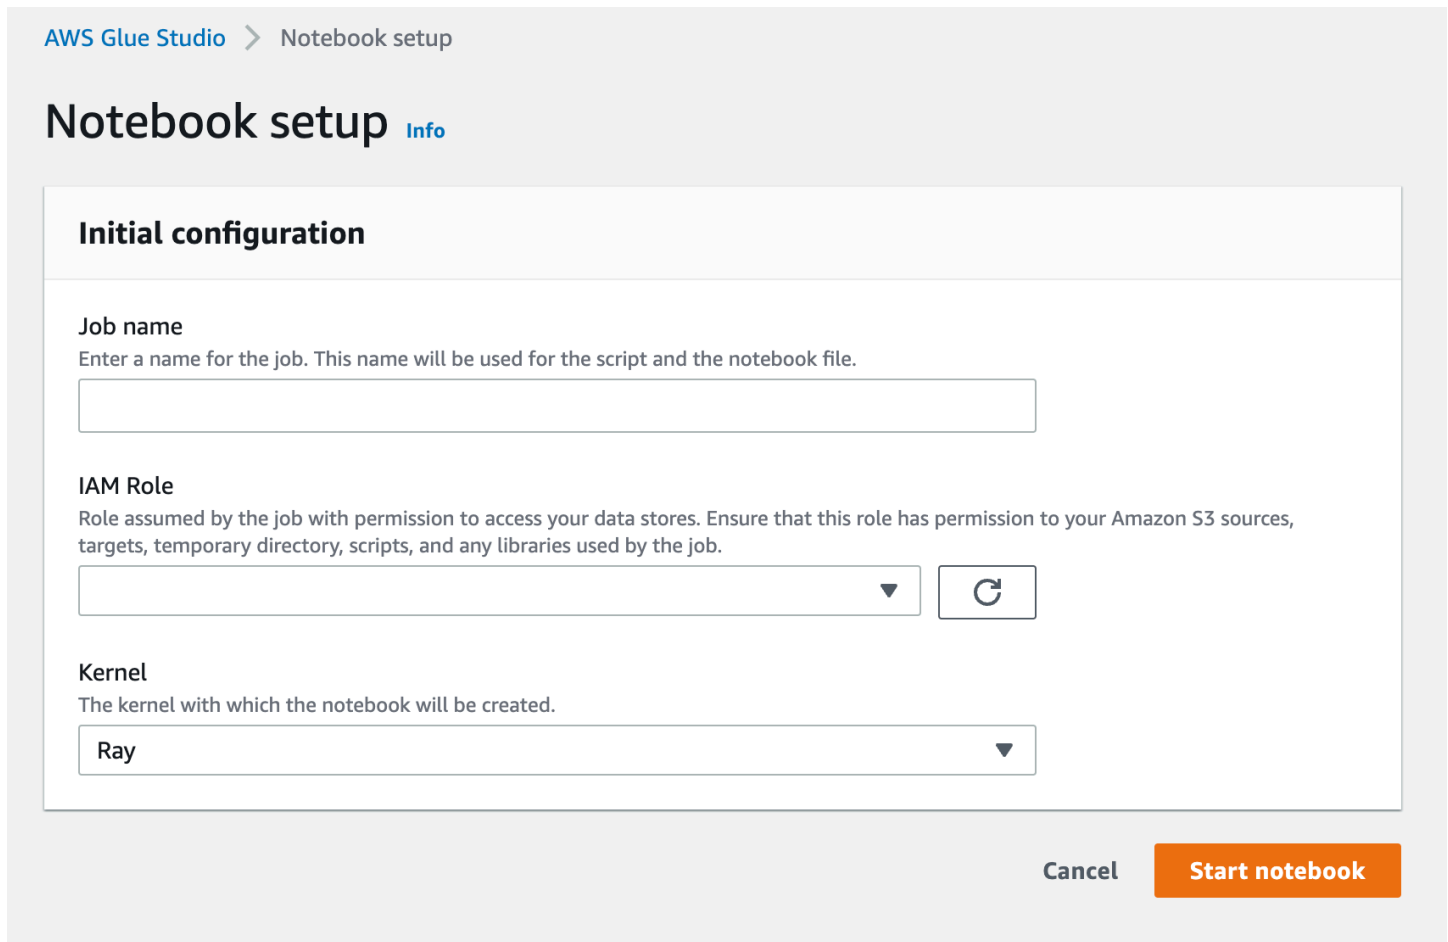

**The preview of AWS Glue for Ray interactive sessions is ending on April 30, 2024.** Following this date, you will no longer be able to create new interactive sessions on AWS Glue for Ray.

### Note

AWS Glue for Ray is available in US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Tokyo), and Europe (Ireland).

## Ray interactive sessions in the AWS Glue Studio Console

In the **Jobs** page in the AWS Glue Studio Console, select the existing **Jupyter Notebook** option. This will open a **Notebook setup** page where you can select your **Kernel**. Select the **Ray** kernel to begin a Ray interactive session. For more information about interactive sessions and how they are used, see [the section called “Getting started with AWS Glue interactive sessions”](#).

AWS Glue Studio > Notebook setup

### Notebook setup [Info](#)

**Initial configuration**

**Job name**  
Enter a name for the job. This name will be used for the script and the notebook file.

**IAM Role**  
Role assumed by the job with permission to access your data stores. Ensure that this role has permission to your Amazon S3 sources, targets, temporary directory, scripts, and any libraries used by the job.

**Kernel**  
The kernel with which the notebook will be created.

## Ray interactive sessions using the Jupyter Kernel

To use the Ray Kernel outside of the AWS Glue Studio Console, you will need to install the `aws-glue-sessions` package, which we publish on PyPI. For more information about using the kernel package, see the [the section called “Getting started with AWS Glue interactive sessions”](#) documentation.

To update or install the kernel, run `pip install --upgrade aws-glue-sessions`. You will need version `.37+` to use the Ray kernel.

Ray interactive sessions have access to the same libraries and versions of Ray as Ray jobs. In preview, all Ray interactive sessions will use Ray 2.4.0.

## Ray interactive session timeout defaults

- **Timeout** (for session) default: 8 hours.
- **Idle Timeout** default: 1 hour.

## Magics supported by AWS Glue Ray interactive sessions

Magics for the AWS Glue Jupyter kernel when it powers Ray interactive sessions are similar to those for the Spark sessions. For reference, see [the section called “Configuring AWS Glue interactive sessions for Jupyter and AWS Glue Studio notebooks”](#).

### Sessions magics

Sessions magics are mostly the same as prior to the AWS Glue for Ray preview. For more information about session magics outside of this preview, see [the section called “Magics supported by AWS Glue interactive sessions for Jupyter”](#). We introduce a new magic to set the session type to AWS Glue for Ray.

Name	Type	Description
<code>%glue_ray</code>	String	Changes the session type to AWS Glue for Ray.

### AWS Glue config magics

Magics to configure AWS Glue in an interactive session may be different between session types. Currently, we only support this subset of existing magics when using AWS Glue for Ray.

#### Warning

##### **Known Issue: `additional_python_modules`**

In the Ray interactive sessions preview, use of the `additional_python_modules` magic will cause problems when saving your notebook. To configure python modules for Ray

sessions, use the `%%configure` magic to set the `pip-install` parameter defined in [the section called “Ray job parameters”](#).

Name	Type	Description
<code>%%configure</code>	Dictionary	Specify a JSON-formatted dictionary consisting of all configuration parameters for a session. Each parameter can be specified here or through individual magics.
<code>%iam_role</code>	String	Specify an IAM role ARN to execute your session with. Default from <code>~/.aws/configure</code>
<code>%number_of_workers</code>	int	The number of workers of a defined <code>worker_type</code> that are allocated when a job runs. <code>worker_type</code> must be set too.
<code>%worker_type</code>	String	In the AWS Glue for Ray preview, the only supported worker type is Z.2X.
<code>%additional_python_modules</code>	List	Comma separated list of additional Python modules to include in your cluster (can be from Pypi or S3).

## Action magics

AWS Glue Ray sessions do not support any action magics.

## Interactive sessions with IAM

These sections describe security considerations for AWS Glue interactive sessions.

### Topics

- [IAM principals used with interactive sessions](#)

- [Setting up a client principal](#)
- [Setting up a runtime role](#)
- [Make your session private with TagOnCreate](#)
- [IAM policy considerations](#)

## IAM principals used with interactive sessions

You use two IAM principals used with AWS Glue interactive sessions.

- **Client principal:** The client principal (either a user or a role) authorizes API operations for interactive sessions from an AWS Glue client that's configured with the principal's identity-based credentials. For example, this could be an IAM role that you typically use to access the AWS Glue console. This could also be a role given to a user in IAM whose credentials are used for the AWS Command Line Interface, or an AWS Glue client used by the interactive sessions Jupyter kernel.
- **Runtime role:** The runtime role is an IAM role that the client principal passes to interactive sessions API operations. AWS Glue uses this role to run statements in your session. For example, this role could be the one used for running AWS Glue ETL jobs.

For more information, see [Setting up a runtime role](#).

## Setting up a client principal

You must attach an identity policy to the client principal to allow it to call the interactive sessions API. This role must have `iam:PassRole` access to the execution role that you would pass to the interactive sessions API, such as `CreateSession`. For example, you can attach the **AWSGlueConsoleFullAccess** managed policy to an IAM role which allows users in your account with the policy attached to access all the sessions created in your account (such as runtime statement or cancel statement).

If you would like to protect your session and make it private only to certain IAM roles, such as ones associated with the user who created the session then you can use AWS Glue Interactive Session's Tag Based Authorization Control called `TagOnCreate`. For more information, see [Make your session private with TagOnCreate](#) on how an owner tag-based scoped down managed policy can make your session private with `TagOnCreate`. For more information on identity-based policies, see [Identity-based policies for AWS Glue](#).

## Setting up a runtime role

You must pass an IAM role to the `CreateSession` API operation in order to allow AWS Glue to assume and run statements in interactive sessions. The role should have the same IAM permissions as those required to run a typical AWS Glue job. For example, you can create a service role using the **`AWSGlueServiceRole`** policy that allows AWS Glue to call AWS services on your behalf. If you use the AWS Glue console, it will automatically create a service role on your behalf or use an existing one. You can also create your own IAM role and attach your own IAM policy to allow similar permissions.

If you would like to protect your session and make it private only to the user who created the session then you can use AWS Glue Interactive Session's Tag Based Authorization Control called `TagOnCreate`. For more information, see [Make your session private with TagOnCreate](#) on how an owner tag-based scoped down managed policy can make your session private with `TagOnCreate`. For more information on identity-based policies, see [Identity-based policies for AWS Glue](#). If you are creating the execution role by yourself from the IAM console and you want to make your service private with `TagOnCreate` feature then follow the steps below.

1. Create an IAM role with role type set to `Glue`.
2. Attach this AWS Glue managed policy: `AwsGlueSessionUserRestrictedServiceRole`
3. Prefix the role name with the policy name `AwsGlueSessionUserRestrictedServiceRole`. For example, you can create a role with name `AwsGlueSessionUserRestrictedServiceRole-myrole` and attach AWS Glue managed policy `AwsGlueSessionUserRestrictedServiceRole`.
4. Attach a trust policy like following to allow AWS Glue to assume the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Action": [
        "sts:AssumeRole"
      ]
    }
  ]
}
```

```
]
}
```

For an interactive sessions Jupyter kernel, you can specify the `iam_role` key in your AWS Command Line Interface profile. For more information, see [Configuring sessions with ~/.aws/config](#). If you're interacting with interactive sessions using an AWS Glue notebook, then you can pass the execution role in the `%iam_role` magic in the first cell that you run.

## Make your session private with TagOnCreate

AWS Glue interactive sessions supports tagging and Tag Based Authorization (TBAC) for interactive sessions as a named resource. In addition to TBAC using `TagResource` and `UntagResource` APIs, AWS Glue interactive sessions supports the `TagOnCreate` feature to 'tag' a session with a given tag only during session creation with `CreateSession` operation. This also means those tags will be removed on `DeleteSession`, aka `UntagOnDelete`.

`TagOnCreate` offers a powerful security mechanism to make your session private to the creator of the session. For example, you can attach an IAM policy with "owner" `RequestTag` and value of `${aws:userId}` to a client principal (such as a user) in order to allow creating a session only if an "owner" tag with matching value of the callers `userId` is provided as `userId` tag in `CreateSession` request. This policy allows AWS Glue interactive sessions to create a session resource and tag the session with the `userId` tag only during session creation time. In addition to it you can scope down the access (like running statements) to your session only to the creator (aka owner tag with value `${aws:userId}`) of the session by attaching an IAM policy with "owner" `ResourceTag` to the execution role you passed in during `CreateSession`.

In order to make it easier for you to use `TagOnCreate` feature to make a session private to the session creator, AWS Glue provides specialized managed policies and service roles.

If you want to create a AWS Glue Interactive Session using an IAM `AssumeRole` principal (that is, using credential vended by assuming an IAM role) and you want to make the session private to the creator, then use policies similar to the **`AWSGlueSessionUserRestrictedNotebookPolicy`** and **`AWSGlueSessionUserRestrictedNotebookServiceRole`** respectively. These policies allow AWS Glue to use `${aws:PrincipalTag}` to extract the owner tag value. This requires you to pass a `userId` tag with value `${aws:userId}` as `SessionTag` in the assume role credential. See [ID session tags](#). If you are using an Amazon EC2 instance with an instance profile vending the credential and you want to create a session or interact with the session from within the Amazon EC2 instance, then you would require to pass a `userId` tag with value `${aws:userId}` as `SessionTag` in the assume role credential.

For example, If you are creating a session using an IAM AssumeRole principal credential and you want to make your service private with TagOnCreate feature then follow the steps below.

1. Create a runtime role yourself from the IAM console. Please attach this AWS Glue managed policy *AwsGlueSessionUserRestrictedNotebookServiceRole* and prefix the role name with the policy name *AwsGlueSessionUserRestrictedNotebookServiceRole*. For example, you can create a role with name *AwsGlueSessionUserRestrictedNotebookServiceRole-myrole* and attach AWS Glue managed policy *AwsGlueSessionUserRestrictedNotebookServiceRole*.
2. Attach a trust policy like below to allow AWS Glue to assume the above role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "glue.amazonaws.com"
        ]
      },
      "Action": [
        "sts:AssumeRole"
      ]
    }
  ]
}
```

3. Create another role named with a prefix *AwsGlueSessionUserRestrictedNotebookPolicy* and attach the AWS Glue managed policy *AwsGlueSessionUserRestrictedNotebookPolicy* to make the session private. In addition to the managed policy please attach the following inline policy to allow iam:PassRole to the role you created in step 1.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
    }
  ],
}
```

```

    "Resource": [
      "arn:aws:iam::*:role/
      AwsGlueSessionUserRestrictedNotebookServiceRole*"
    ],
    "Condition": {
      "StringLike": {
        "iam:PassedToService": [
          "glue.amazonaws.com"
        ]
      }
    }
  }
]
}

```

4. Attach a trust policy like following to the above IAM AWS Glue to assume the role.

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {
      "Service": [
        "glue.amazonaws.com"
      ]
    },
    "Action": [
      "sts:AssumeRole",
      "sts:TagSession"
    ]
  }]
}

```

#### Note

Optionally, you can use a single role (for example, notebook role) and attach both of the above managed policies *AwsGlueSessionUserRestrictedNotebookServiceRole* and *AwsGlueSessionUserRestrictedNotebookPolicy*. Also attach the additional inline policy

to allow `iam:passrole` of your role to AWS Glue. And finally attach the above trust policy to allow `sts:AssumeRole` and `sts:TagSession`.

## **AWSGlueSessionUserRestrictedNotebookPolicy**

The **AWSGlueSessionUserRestrictedNotebookPolicy** provides access to create a AWS Glue Interactive Session from a notebook only if a tag key "owner" and value matching the AWS user id of the principal (user or Role). For more information, see [Where you can use policy variables](#) . This policy is attached to the principal (User or role) that creates AWS Glue Interactive Session notebooks from AWS Glue Studio. This policy also permits sufficient access to the AWS Glue Studio notebook to interact with the AWS Glue Studio Interactive Session resources that are created with the "owner" tag value matching the AWS user ID of the principal. This policy denies permission to change or remove "owner" tag from a AWS Glue session resource after the session is created.

## **AWSGlueSessionUserRestrictedNotebookServiceRole**

The **AWSGlueSessionUserRestrictedNotebookServiceRole** provides sufficient access to the AWS Glue Studio notebook to interact with the AWS Glue Interactive Session resources that are created with the "owner" tag value matching the AWS user ID of the principal (user or role) of the notebook creator. For more information, see [Where you can use policy variables](#) . This service-role policy is attached to the role that is passed as magic to a notebook or passed as execution role to the `CreateSession` API. This policy also permits to create a AWS Glue Interactive Session from a notebook only if a tag key "owner" and value matching the AWS user ID of the principal. This policy denies permission to change or remove "owner" tag from an AWS Glue session resource after the session is created. This policy also includes permissions for writing and reading from Amazon S3 buckets, writing CloudWatch logs, creating and deleting tags for Amazon EC2 resources used by AWS Glue.

## **Make your session private with user policies**

You can attach the **AWSGlueSessionUserRestrictedPolicy** to IAM roles attached to each of the users in your account to restrict them from creating a session only with an owner tag with a value matching their own `${aws:userId}`. Instead of using the **AWSGlueSessionUserRestrictedNotebookPolicy** and **AWSGlueSessionUserRestrictedNotebookServiceRole** you need to use policies similar to the **AWSGlueSessionUserRestrictedPolicy** and **AWSGlueSessionUserRestrictedServiceRole** respectively. For more information, see [Using-identity based policies](#) . This policy scopes down the

access to a session only to the creator, the `${aws:userId}` of the user who created the session with an owner tag bearing their own `${aws:userId}`. If you have created the execution role yourself using the IAM console by following the steps in [Setting up a runtime role](#), then in addition to attaching the **AwsGlueSessionUserRestrictedPolicy** managed policy, also attach the following inline policy to each of the users in your account to allow `iam:PassRole` for the execution role you created earlier.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "iam:PassRole"
    ],
    "Resource": [
      "arn:aws:iam::*:role/AwsGlueSessionUserRestrictedServiceRole*"
    ],
    "Condition": {
      "StringLike": {
        "iam:PassedToService": [
          "glue.amazonaws.com"
        ]
      }
    }
  ]
}
```

### **AWSGlueSessionUserRestrictedPolicy**

The **AWSGlueSessionUserRestrictedPolicy** provides access to create an AWS Glue Interactive Session using the `CreateSession` API only if a tag key "owner" and value matching their AWS user ID is provided. This identity policy is attached to the user that invokes the `CreateSession` API. This policy also permits to interact with the AWS Glue Interactive Session resources that were created with a "owner" tag and value matching their AWS user id. This policy denies permission to change or remove "owner" tag from a AWS Glue session resource after the session is created.

### **AWSGlueSessionUserRestrictedServiceRole**

The **AWSGlueSessionUserRestrictedServiceRole** provides full access to all AWS Glue resources except for sessions and allows users to create and use only the interactive sessions that are associated with the user. This policy also includes other permissions needed by AWS Glue to

manage Glue resources in other AWS services. The policy also allows adding tags to AWS Glue resources in other AWS services.

## IAM policy considerations

Interactive sessions are IAM resources in AWS Glue. Because they are IAM resources, access and interaction to a session is governed by IAM policies. Based on the IAM policies attached to a client principal or execution role configured by an admin, a client principal (user or role) will be able to create new sessions and interact with its own sessions and other sessions.

If an admin has attached an IAM policy such as `AWSGlueConsoleFullAccess` or `AWSGlueServiceRole` that allows access to all AWS Glue resources in that account, a client principal will be able to collaborate with each other. For example, one user will be able to interact with sessions that are created by other users if policies allow this.

If you'd like to configure a policy tailored to your specific needs, see [IAM documentation about configuring resources for a policy](#). For example, in order to isolate sessions that belong to an user, you can use the `TagOnCreate` feature supported by AWS Glue Interactive sessions. See [Make your session private with TagOnCreate](#).

Interactive sessions supports limiting session creation based on certain VPC conditions. See [Control policies that control settings using condition keys](#).

## Converting a script or notebook into an AWS Glue job

There are two ways you can convert a script or notebook into an AWS Glue job:

- Use **nbconvert** to convert your Jupyter `.ipynb` notebook document file into a `.py` file. For more information, see [nbconvert: Convert Notebooks to other formats](#).
- Upload the file to AWS Glue Studio Notebooks.
  - In the AWS Glue Studio console, choose **Jobs** from the navigation menu.
  - In the **Create job** section, choose **Jupyter Notebook**.
  - In the **Options** section, choose **Upload and edit an existing notebook**.
  - Select **Choose file** to upload an `.ipynb` file.

# AWS Glue interactive sessions for streaming

## Switching streaming session type

Use the AWS Glue interactive sessions configuration magic, `%streaming`, to define the job you are running and initialize a streaming interactive session.

## Sampling input stream for interactive development

One tool we have derived to help enhance the interactive experience in AWS Glue interactive sessions is the addition of a new method under `GlueContext` to obtain a snapshot of a stream in a static `DynamicFrame`. `GlueContext` allows you to inspect, interact and implement your workflow.

With the `GlueContext` class instance, you will be able to locate the method `getSampleStreamingDynamicFrame`. Required arguments for this method are:

- `dataFrame`: The Spark Streaming `DataFrame`
- `options`: See available options below

Available options include :

- **windowSize**: This is also called Microbatch Duration. This parameter will determine how long a streaming query will wait after previous batch was triggered. This parameter value must be smaller than `pollingTimeInMs`.
- **pollingTimeInMs**: The total length of time the method will run. It will fire off at least one micro batch to obtain sample records from the input stream.
- **recordPollingLimit**: This parameter helps you limit the total number of records you will poll from the stream.
- (Optional) You can also use `writeStreamFunction` to apply this custom function to every record sampling function. See below for examples in Scala and Python.

### Scala

```
val sampleBatchFunction = (batchDF: DataFrame, batchId: Long) => {  
  //Optional but  
  you can replace your own forEachBatch function here  
}
```

```
val jsonString: String = s""""{"pollingTimeInMs": "10000", "windowSize": "5
seconds}""""
val dynFrame = glueContext.getSampleStreamingDynamicFrame(YOUR_STREAMING_DF,
  JsonOptions(jsonString), sampleBatchFunction)
dynFrame.show()
```

## Python

```
def sample_batch_function(batch_df, batch_id):
    //Optional but you can replace your own forEachBatch function here
    options = {
        "pollingTimeInMs": "10000",
        "windowSize": "5 seconds",
    }
    glue_context.getSampleStreamingDynamicFrame(YOUR_STREAMING_DF, options,
        sample_batch_function)
```

### Note

When the sampled `DynFrame` is empty, it could be caused by a few reasons:

- The Streaming source is set to "Latest" and no new data has been ingested during the sampling period.
- The polling time is not enough to process the records it ingested. Data won't show up unless the whole batch has been processed.

## Running streaming applications in interactive sessions

In AWS Glue interactive sessions, you can run a the AWS Glue streaming application like how you would create a streaming application in the AWS Glue Console. Since interactive sessions is session-based, encountering exceptions in the runtime does not cause the session to stop. We now have the added benefit of developing your batch function iteratively. For example:

```
def batch_function(data_frame, batch_id):
    log.info(data_frame.count())
    invalid_method_call()
```

```
glueContext.forEachBatch(frame=streaming_df, batch_function = batch_function, options =
  {**})
```

In the example above, we included an invalid usage of a method and unlike regular AWS Glue jobs which will exit the entire application, the user's coding context and definitions are fully preserved and the session is still operational. There is no need to bootstrap a new cluster and rerun all the preceding transformation. This allows you to focus on quickly iterating your batch function implementations to obtain desirable outcomes.

It is important to note that Interactive Session evaluates each statement in a blocking manner so that the session will only execute one statement at a time. Since streaming queries are continuous and never ending, sessions with active streaming queries won't be able to handle any follow up statements unless they are interrupted. You can issue the interruption command directly from Jupyter Notebook and our kernel will handle the cancellation for you.

Take the following sequence of statements which are waiting for execution as an example:

Statement 1:

```
val number = df.count()
#Spark Action with deterministic result
Result: 5
```

Statement 2:

```
streamingQuery.start().awaitTermination()
#Spark Streaming Query that will be executing continuously
Result: Constantly updated with each microbatch
```

Statement 3:

```
val number2 = df.count()
#This will not be executed as previous statement will be running indefinitely
```

## Developing and testing AWS Glue job scripts locally

When you develop and test your AWS Glue for Spark job scripts, there are multiple available options:

- AWS Glue Studio console

- Visual editor
- Script editor
- AWS Glue Studio notebook
- Interactive sessions
  - Jupyter notebook
- Docker image
  - Local development
  - Remote development
- AWS Glue Studio ETL library
  - Local development

You can choose any of the above options based on your requirements.

If you prefer no code or less code experience, the AWS Glue Studio visual editor is a good choice.

If you prefer an interactive notebook experience, AWS Glue Studio notebook is a good choice. For more information, see [Using Notebooks with AWS Glue Studio and AWS Glue](#). If you want to use your own local environment, interactive sessions is a good choice. For more information, see [Using interactive sessions with AWS Glue](#).

If you prefer local/remote development experience, the Docker image is a good choice. This helps you to develop and test AWS Glue for Spark job scripts anywhere you prefer without incurring AWS Glue cost.

If you prefer local development without Docker, installing the AWS Glue ETL library directory locally is a good choice.

## Developing using AWS Glue Studio

The AWS Glue Studio visual editor is a graphical interface that makes it easy to create, run, and monitor extract, transform, and load (ETL) jobs in AWS Glue. You can visually compose data transformation workflows and seamlessly run them on AWS Glue's Apache Spark-based serverless ETL engine. You can inspect the schema and data results in each step of the job. For more information, see the [AWS Glue Studio User Guide](#).

## Developing using interactive sessions

Interactive sessions allow you to build and test applications from the environment of your choice. For more information, see [Using interactive sessions with AWS Glue](#).

## Developing using a Docker image

### Note

The instructions in this section have not been tested on Microsoft Windows operating systems.

For local development and testing on Windows platforms, see the blog [Building an AWS Glue ETL pipeline locally without an AWS account](#)

For a production-ready data platform, the development process and CI/CD pipeline for AWS Glue jobs is a key topic. You can flexibly develop and test AWS Glue jobs in a Docker container. AWS Glue hosts Docker images on Docker Hub to set up your development environment with additional utilities. You can use your preferred IDE, notebook, or REPL using AWS Glue ETL library. This topic describes how to develop and test AWS Glue version 4.0 jobs in a Docker container using a Docker image.

The following Docker images are available for AWS Glue on Docker Hub.

- For AWS Glue version 4.0: `amazon/aws-glue-libs:glue_libs_4.0.0_image_01`
- For AWS Glue version 3.0: `amazon/aws-glue-libs:glue_libs_3.0.0_image_01`
- For AWS Glue version 2.0: `amazon/aws-glue-libs:glue_libs_2.0.0_image_01`

These images are for `x86_64`. It is recommended that you test on this architecture. However, it may be possible to rework a local development solution on unsupported base images.

This example describes using `amazon/aws-glue-libs:glue_libs_4.0.0_image_01` and running the container on a local machine. This container image has been tested for an AWS Glue version 3.3 Spark jobs. This image contains the following:

- Amazon Linux
- AWS Glue ETL library ([aws-glue-libs](#))
- Apache Spark 3.3.0

- Spark history server
- Jupyter Lab
- Livy
- Other library dependencies (the same set as the ones of AWS Glue job system)

Complete one of the following sections according to your requirements:

- Set up the container to use spark-submit
- Set up the container to use REPL shell (PySpark)
- Set up the container to use Pytest
- Set up the container to use Jupyter Lab
- Set up the container to use Visual Studio Code

## Prerequisites

Before you start, make sure that Docker is installed and the Docker daemon is running. For installation instructions, see the Docker documentation for [Mac](#) or [Linux](#). The machine running the Docker hosts the AWS Glue container. Also make sure that you have at least 7 GB of disk space for the image on the host running the Docker.

For more information about restrictions when developing AWS Glue code locally, see [Local development restrictions](#).

## Configuring AWS

To enable AWS API calls from the container, set up AWS credentials by following steps. In the following sections, we will use this AWS named profile.

1. Set up the AWS CLI, configuring a named profile. For more information about AWS CLI configuration, see [Configuration and credential file settings](#) in the AWS CLI documentation.
2. Run the following command in a terminal:

```
PROFILE_NAME="<your_profile_name>"
```

You may also need to set the `AWS_REGION` environment variable to specify the AWS Region to send requests to.

## Setting up and running the container

Setting up the container to run PySpark code through the `spark-submit` command includes the following high-level steps:

1. Pull the image from Docker Hub.
2. Run the container.

### Pulling the image from Docker Hub

Run the following command to pull the image from Docker Hub:

```
docker pull amazon/aws-glue-libs:glue_libs_4.0.0_image_01
```

### Running the container

You can now run a container using this image. You can choose any of following based on your requirements.

#### **spark-submit**

You can run an AWS Glue job script by running the `spark-submit` command on the container.

1. Write the script and save it as `sample1.py` under the `/local_path_to_workspace` directory. Sample code is included as the appendix in this topic.

```
$ WORKSPACE_LOCATION=/local_path_to_workspace
$ SCRIPT_FILE_NAME=sample.py
$ mkdir -p ${WORKSPACE_LOCATION}/src
$ vim ${WORKSPACE_LOCATION}/src/${SCRIPT_FILE_NAME}
```

2. Run the following command to execute the `spark-submit` command on the container to submit a new Spark application:

```
$ docker run -it -v ~/.aws:/home/glue_user/.aws -v $WORKSPACE_LOCATION:/
home/glue_user/workspace/ -e AWS_PROFILE=$PROFILE_NAME -e DISABLE_SSL=true
--rm -p 4040:4040 -p 18080:18080 --name glue_spark_submit amazon/aws-glue-
libs:glue_libs_4.0.0_image_01 spark-submit /home/glue_user/workspace/src/
$SCRIPT_FILE_NAME
...22/01/26 09:08:55 INFO DAGScheduler: Job 0 finished: fromRDD at
DynamicFrame.scala:305, took 3.639886 s
```

```
root
|-- family_name: string
|-- name: string
|-- links: array
| |-- element: struct
| | |-- note: string
| | |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
| |-- element: struct
| | |-- scheme: string
| | |-- identifier: string
|-- other_names: array
| |-- element: struct
| | |-- lang: string
| | |-- note: string
| | |-- name: string
|-- sort_name: string
|-- images: array
| |-- element: struct
| | |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
| |-- element: struct
| | |-- type: string
| | |-- value: string
|-- death_date: string
...

```

3. (Optionally) Configure `spark-submit` to match your environment. For example, you can pass your dependencies with the `--jars` configuration. For more information, consult [Launching Applications with spark-submit](#) in the Spark documentation.

## REPL shell (Pyspark)

You can run REPL (read-eval-print loops) shell for interactive development.

Run the following command to execute the PySpark command on the container to start the REPL shell:

```
$ docker run -it -v ~/.aws:/home/glue_user/.aws -e AWS_PROFILE=$PROFILE_NAME -e
  DISABLE_SSL=true --rm -p 4040:4040 -p 18080:18080 --name glue_pyspark amazon/aws-glue-
  libs:glue_libs_4.0.0_image_01 pyspark
...
  ____  _
 /  _/  _/  _/  _/  _/  _/
 _\  \  \  \  \  \  \  \  \
 /_  /  .__/\  ,/_/_/  /_\  \  version 3.1.1-amzn-0
 /_/_/

Using Python version 3.7.10 (default, Jun 3 2021 00:02:01)
Spark context Web UI available at http://56e99d000c99:4040
Spark context available as 'sc' (master = local[*], app id = local-1643011860812).
SparkSession available as 'spark'.
>>>
```

## Pytest

For unit testing, you can use pytest for AWS Glue Spark job scripts.

Run the following commands for preparation.

```
$ WORKSPACE_LOCATION=/local_path_to_workspace
$ SCRIPT_FILE_NAME=sample.py
$ UNIT_TEST_FILE_NAME=test_sample.py
$ mkdir -p ${WORKSPACE_LOCATION}/tests
$ vim ${WORKSPACE_LOCATION}/tests/${UNIT_TEST_FILE_NAME}
```

Run the following command to execute pytest on the test suite:

```
$ docker run -it -v ~/.aws:/home/glue_user/.aws -v $WORKSPACE_LOCATION:/home/glue_user/
  workspace/ -e AWS_PROFILE=$PROFILE_NAME -e DISABLE_SSL=true --rm -p 4040:4040 -p
  18080:18080 --name glue_pytest amazon/aws-glue-libraries:glue_libs_4.0.0_image_01 -c
  "python3 -m pytest"
starting org.apache.spark.deploy.history.HistoryServer,

## Jupyter Lab

You can start Jupyter for interactive development and ad-hoc queries on notebooks.

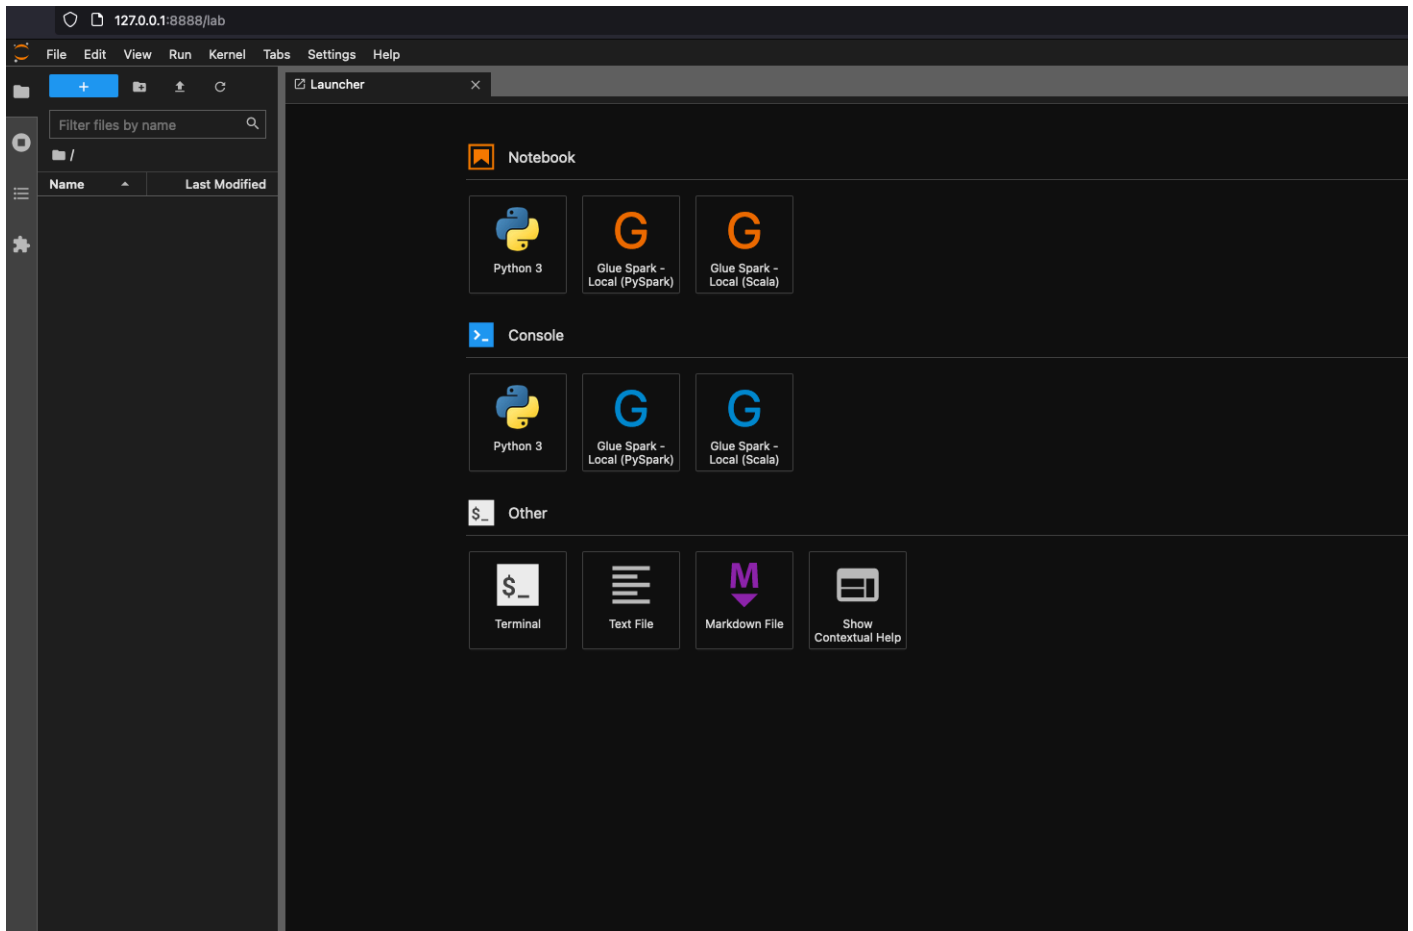

1. Run the following command to start Jupyter Lab:

```

$ JUPYTER_WORKSPACE_LOCATION=/local_path_to_workspace/jupyter_workspace/
$ docker run -it -v ~/.aws:/home/glue_user/.aws -v $JUPYTER_WORKSPACE_LOCATION:/
home/glue_user/workspace/jupyter_workspace/ -e AWS_PROFILE=$PROFILE_NAME -e
DISABLE_SSL=true --rm -p 4040:4040 -p 18080:18080 -p 8998:8998 -p 8888:8888 --name
glue_jupyter_lab amazon/aws-glue-libs:glue_libs_4.0.0_image_01 /home/glue_user/
jupyter/jupyter_start.sh
...
[I 2022-01-24 08:19:21.368 ServerApp] Serving notebooks from local directory: /home/
glue_user/workspace/jupyter_workspace
[I 2022-01-24 08:19:21.368 ServerApp] Jupyter Server 1.13.1 is running at:
[I 2022-01-24 08:19:21.368 ServerApp] http://faa541f8f99f:8888/lab
[I 2022-01-24 08:19:21.368 ServerApp] or http://127.0.0.1:8888/lab
[I 2022-01-24 08:19:21.368 ServerApp] Use Control-C to stop this server and shut down
all kernels (twice to skip confirmation).

```

2. Open <http://127.0.0.1:8888/lab> in your web browser in your local machine, to see the Jupyter lab UI.

3. Choose **Glue Spark Local (PySpark)** under **Notebook**. You can start developing code in the interactive Jupyter notebook UI.

## Setting up the container to use Visual Studio Code

Prerequisites:

1. Install Visual Studio Code.
2. Install [Python](#).
3. Install [Visual Studio Code Remote - Containers](#)
4. Open the workspace folder in Visual Studio Code.
5. Choose **Settings**.
6. Choose **Workspace**.
7. Choose **Open Settings (JSON)**.
8. Paste the following JSON and save it.

```
{
  "python.defaultInterpreterPath": "/usr/bin/python3",
  "python.analysis.extraPaths": [
    "/home/glue_user/aws-glue-libs/PyGlue.zip:/home/glue_user/spark/python/lib/
py4j-0.10.9-src.zip:/home/glue_user/spark/python/"
  ]
}
```

```
}
```

## Steps:

### 1. Run the Docker container.

```
$ docker run -it -v ~/.aws:/home/glue_user/.aws -v $WORKSPACE_LOCATION:/home/glue_user/workspace/ -e AWS_PROFILE=$PROFILE_NAME -e DISABLE_SSL=true --rm -p 4040:4040 -p 18080:18080 --name glue_pyspark amazon/aws-glue-libs:glue_libs_4.0.0_image_01 pyspark
```

### 2. Start Visual Studio Code.

### 3. Choose **Remote Explorer** on the left menu, and choose `amazon/aws-glue-libs:glue_libs_4.0.0_image_01`.

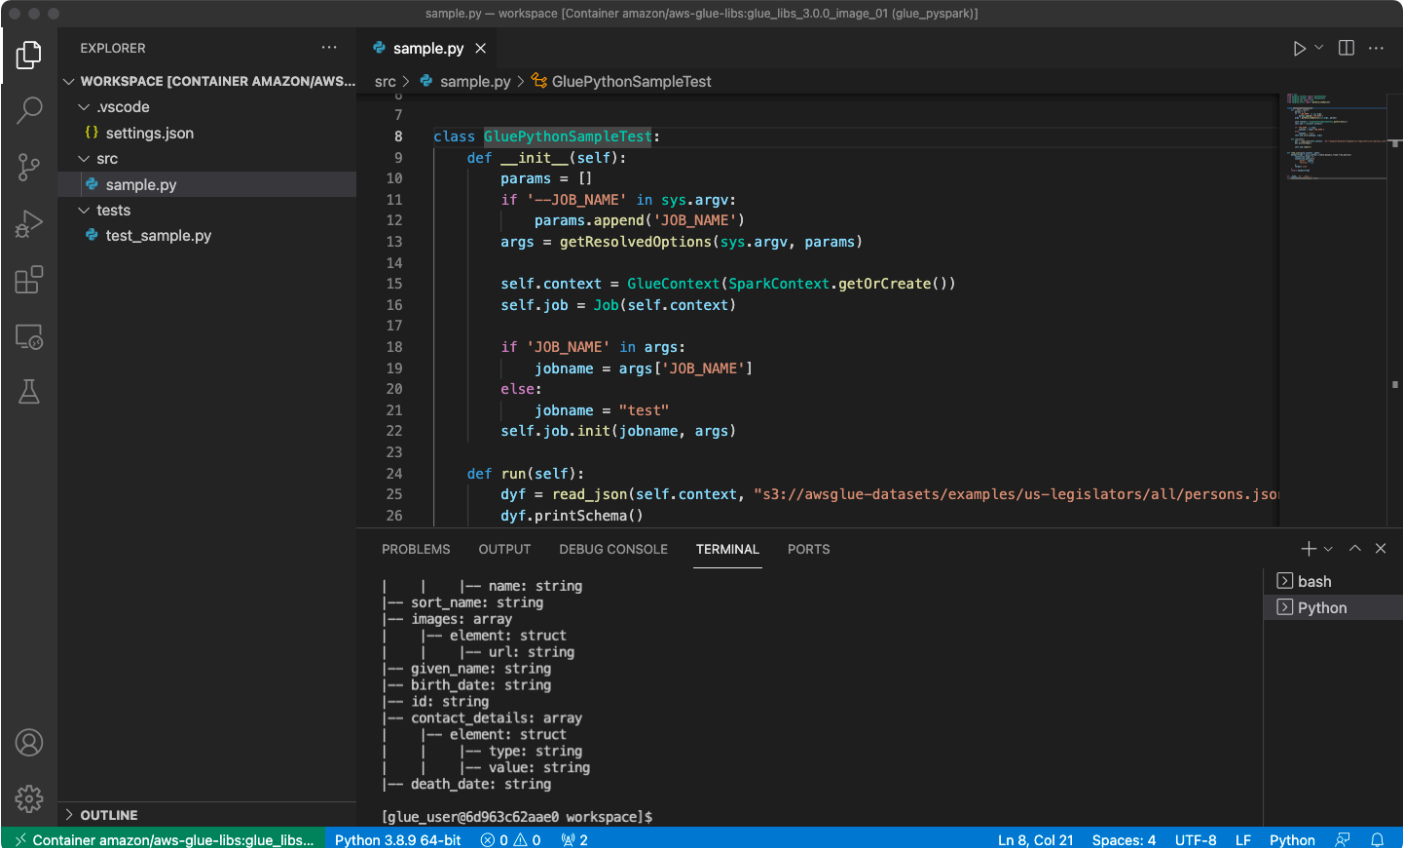

### 4. Right click and choose **Attach to Container**. If a dialog is shown, choose **Got it**.

### 5. Open `/home/glue_user/workspace/`.

### 6. Create a Glue PySpark script and choose **Run**.

You will see the successful run of the script.

```

## Appendix: AWS Glue job sample code for testing

This appendix provides scripts as AWS Glue job sample code for testing purposes.

sample.py: Sample code to utilize the AWS Glue ETL library with an Amazon S3 API call

```

import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

class GluePythonSampleTest:
    def __init__(self):
        params = []
        if '--JOB_NAME' in sys.argv:
            params.append('JOB_NAME')
        args = getResolvedOptions(sys.argv, params)

```

```
self.context = GlueContext(SparkContext.getOrCreate())
self.job = Job(self.context)

if 'JOB_NAME' in args:
    jobname = args['JOB_NAME']
else:
    jobname = "test"
self.job.init(jobname, args)

def run(self):
    dyf = read_json(self.context, "s3://awsglue-datasets/examples/us-legislators/
all/persons.json")
    dyf.printSchema()

    self.job.commit()

def read_json(glue_context, path):
    dynamicframe = glue_context.create_dynamic_frame.from_options(
        connection_type='s3',
        connection_options={
            'paths': [path],
            'recurse': True
        },
        format='json'
    )
    return dynamicframe

if __name__ == '__main__':
    GluePythonSampleTest().run()
```

The above code requires Amazon S3 permissions in AWS IAM. You need to grant the IAM managed policy `arn:aws:iam::aws:policy/AmazonS3ReadOnlyAccess` or an IAM custom policy which allows you to call `ListBucket` and `GetObject` for the Amazon S3 path.

`test_sample.py`: Sample code for unit test of `sample.py`.

```
import pytest
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions
```

```
import sys
from src import sample

@pytest.fixture(scope="module", autouse=True)
def glue_context():
    sys.argv.append('--JOB_NAME')
    sys.argv.append('test_count')

    args = getResolvedOptions(sys.argv, ['JOB_NAME'])
    context = GlueContext(SparkContext.getOrCreate())
    job = Job(context)
    job.init(args['JOB_NAME'], args)

    yield(context)

    job.commit()

def test_counts(glue_context):
    dyf = sample.read_json(glue_context, "s3://awsglue-datasets/examples/us-
legislators/all/persons.json")
    assert dyf.toDF().count() == 1961
```

## Developing using the AWS Glue ETL library

The AWS Glue ETL library is available in a public Amazon S3 bucket, and can be consumed by the Apache Maven build system. This enables you to develop and test your Python and Scala extract, transform, and load (ETL) scripts locally, without the need for a network connection. Local development with the Docker image is recommended, as it provides an environment properly configured for the use of this library.

Local development is available for all AWS Glue versions, including AWS Glue version 0.9, 1.0, 2.0, and later. For information about the versions of Python and Apache Spark that are available with AWS Glue, see the [Glue version job property](#).

The library is released with the Amazon Software license (<https://aws.amazon.com/asl>).

### Local development restrictions

Keep the following restrictions in mind when using the AWS Glue Scala library to develop locally.

- Avoid creating an assembly jar ("fat jar" or "uber jar") with the AWS Glue library because it causes the following features to be disabled:
  - [Job bookmarks](#)
  - AWS Glue Parquet writer ([Using the Parquet format in AWS Glue](#))
  - FillMissingValues transform ([Scala](#) or [Python](#))

These features are available only within the AWS Glue job system.

- The [FindMatches transform](#) is not supported with local development.
- The [vectorized SIMD CSV reader](#) is not supported with local development.
- The property [customJdbcDriverS3Path](#) for loading JDBC driver from S3 path is not supported with local development. Alternatively you can download the JDBC driver in your local and load from there.
- The [Glue Data Quality](#) is not supported with local development.

## Developing locally with Python

Complete some prerequisite steps and then use AWS Glue utilities to test and submit your Python ETL script.

### Prerequisites for local Python development

Complete these steps to prepare for local Python development:

1. Clone the AWS Glue Python repository from GitHub (<https://github.com/aws-labs/aws-glue-libs>).
2. Do one of the following:
  - For AWS Glue version 0.9, check out branch `glue-0.9`.
  - For AWS Glue versions 1.0, check out branch `glue-1.0`. All versions above AWS Glue 0.9 support Python 3.
  - For AWS Glue versions 2.0, check out branch `glue-2.0`.
  - For AWS Glue versions 3.0, check out branch `glue-3.0`.
  - For AWS Glue version 4.0, check out the `master` branch.
3. Install Apache Maven from the following location: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-common/apache-maven-3.6.0-bin.tar.gz>.
4. Install the Apache Spark distribution from one of the following locations:

- For AWS Glue version 0.9: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-0.9/spark-2.2.1-bin-hadoop2.7.tgz>
  - For AWS Glue version 1.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-1.0/spark-2.4.3-bin-hadoop2.8.tgz>
  - For AWS Glue version 2.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-2.0/spark-2.4.3-bin-hadoop2.8.tgz>
  - For AWS Glue version 3.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-3.0/spark-3.1.1-amzn-0-bin-3.2.1-amzn-3.tgz>
  - For AWS Glue version 4.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-4.0/spark-3.3.0-amzn-1-bin-3.3.3-amzn-0.tgz>
5. Export the SPARK\_HOME environment variable, setting it to the root location extracted from the Spark archive. For example:
- For AWS Glue version 0.9: `export SPARK_HOME=/home/$USER/spark-2.2.1-bin-hadoop2.7`
  - For AWS Glue version 1.0 and 2.0: `export SPARK_HOME=/home/$USER/spark-2.4.3-bin-hadoop2.8`
  - For AWS Glue version 3.0: `export SPARK_HOME=/home/$USER/spark-3.1.1-amzn-0-bin-3.2.1-amzn-3`
  - For AWS Glue version 4.0: `export SPARK_HOME=/home/$USER/spark-3.3.0-amzn-1-bin-3.3.3-amzn-0`

## Running your Python ETL script

With the AWS Glue jar files available for local development, you can run the AWS Glue Python package locally.

Use the following utilities and frameworks to test and run your Python script. The commands listed in the following table are run from the root directory of the [AWS Glue Python package](#).

Utility	Command	Description
AWS Glue Shell	<code>./bin/gluepyspark</code>	Enter and run Python scripts in a shell that integrates with AWS Glue ETL libraries.

Utility	Command	Description
AWS Glue Submit	<code>./bin/gluesparksubmit</code>	Submit a complete Python script for execution.
Pytest	<code>./bin/gluepytest</code>	Write and run unit tests of your Python code. The <code>pytest</code> module must be installed and available in the <code>PATH</code> . For more information, see the <a href="#">pytest documentation</a> .

## Developing locally with Scala

Complete some prerequisite steps and then issue a Maven command to run your Scala ETL script locally.

### Prerequisites for local Scala development

Complete these steps to prepare for local Scala development.

#### Step 1: Install software

In this step, you install software and set the required environment variable.

1. Install Apache Maven from the following location: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-common/apache-maven-3.6.0-bin.tar.gz>.
2. Install the Apache Spark distribution from one of the following locations:
  - For AWS Glue version 0.9: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-0.9/spark-2.2.1-bin-hadoop2.7.tgz>
  - For AWS Glue version 1.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-1.0/spark-2.4.3-bin-hadoop2.8.tgz>
  - For AWS Glue version 2.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-2.0/spark-2.4.3-bin-hadoop2.8.tgz>
  - For AWS Glue version 3.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-3.0/spark-3.1.1-amzn-0-bin-3.2.1-amzn-3.tgz>
  - For AWS Glue version 4.0: <https://aws-glue-etl-artifacts.s3.amazonaws.com/glue-4.0/spark-3.3.0-amzn-1-bin-3.3.3-amzn-0.tgz>

3. Export the SPARK\_HOME environment variable, setting it to the root location extracted from the Spark archive. For example:

- For AWS Glue version 0.9: `export SPARK_HOME=/home/$USER/spark-2.2.1-bin-hadoop2.7`
- For AWS Glue version 1.0 and 2.0: `export SPARK_HOME=/home/$USER/spark-2.4.3-bin-spark-2.4.3-bin-hadoop2.8`
- For AWS Glue version 3.0: `export SPARK_HOME=/home/$USER/spark-3.1.1-amzn-0-bin-3.2.1-amzn-3`
- For AWS Glue version 4.0: `export SPARK_HOME=/home/$USER/spark-3.3.0-amzn-1-bin-3.3.3-amzn-0`

## Step 2: Configure your Maven project

Use the following `pom.xml` file as a template for your AWS Glue Scala applications. It contains the required dependencies, repositories, and plugins elements. Replace the Glue version string with one of the following:

- 4.0.0 for AWS Glue version 4.0
- 3.0.0 for AWS Glue version 3.0
- 1.0.0 for AWS Glue version 1.0 or 2.0
- 0.9.0 for AWS Glue version 0.9

```
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://
maven.apache.org/maven-v4_0_0.xsd">

  </plugins>
</build>
</project>
```

## Running your Scala ETL script

Run the following command from the Maven project root directory to run your Scala ETL script.

```
mvn exec:java -Dexec.mainClass="mainClass" -Dexec.args="--JOB-NAME jobName"
```

Replace *mainClass* with the fully qualified class name of the script's main class. Replace *jobName* with the desired job name.

## Configuring a test environment

For examples of configuring a local test environment, see the following blog articles:

- [Building an AWS Glue ETL pipeline locally without an AWS account](#)
- [Developing AWS Glue ETL jobs locally using a container](#)

If you want to use development endpoints or notebooks for testing your ETL scripts, see [Developing scripts using development endpoints](#).

### Note

Development endpoints are not supported for use with AWS Glue version 2.0 jobs. For more information, see [Running Spark ETL Jobs with Reduced Startup Times](#).

## Development endpoints

### Note

**The console experience for dev endpoints has been removed as of March 31, 2023.** Creating, updating, and monitoring dev endpoints is still available via the [Development endpoints API](#) and [AWS Glue CLI](#).

We strongly recommend migrating from dev endpoints to interactive sessions for the reasons listed below. For required actions on how to migrate from dev endpoints to interactive sessions, see [Migrating from dev endpoints to interactive sessions](#).

Description	Dev endpoints	Interactive sessions
Glue version support	Supports AWS Glue version 0.9 and 1.0	Supports AWS Glue version 2.0 and later
Dev endpoints are not available in the Asia Pacific (Jakarta) (ap-southeast-3 ), Middle East (UAE) (me-central-1 ), Europe (Spain) (eu-south-2 ), Europe (Zurich) (eu-central-2 ), or other new regions going forward	Interactive sessions are not currently available in the Middle East (UAE) (me-central-1 ) region, but may be made available later	

Description	Dev endpoints	Interactive sessions
Access method to the Spark cluster	Supports SSH, REPL shell, Jupyter notebook, IDE (e.g. PyCharm)	supports AWS Glue Studio notebook, Jupyter notebook, various IDEs (for example, Visual Studio Code, PyCharm), and SageMaker notebook
Time to first query	Requires 10-15 minutes to setup a Spark cluster	Can take up to 1 minute to set up an ephemeral Spark cluster
Price model	<p>AWS charges for development endpoints based on the time that the endpoint is provisioned and the number of DPUs. Development endpoints do not time out. There is a 10-minute minimum billing duration for each provisioned development endpoint. Additionally, AWS charges for Jupyter notebook on Amazon EC2 instances, and SageMaker notebooks when you configure them with dev endpoints.</p>	<p>AWS charges for interactive sessions based on the time that the session is active and the number of DPUs. Interactive sessions have configurable idle timeouts. AWS Glue Studio notebooks provide a built-in interface for interactive sessions and are offered at no additional cost. There is a 1-minute minimum billing duration for each interactive session. AWS Glue Studio notebooks provide a built-in interface for interactive sessions and are offered at no additional cost</p>
Console experience	Only available via the CLI and API	Available through the AWS Glue console, CLI, and APIs

## Migrating from dev endpoints to interactive sessions

Use the following checklist to determine the appropriate method to migrate from dev endpoints to interactive sessions.

## Does your script depend on AWS Glue 0.9 or 1.0 specific features (for example, HDFS, YARN, etc.)?

If the answer is yes, see [Migrating AWS Glue jobs to AWS Glue version 3.0.](#) to learn how to migrate from Glue 0.9 or 1.0 to Glue 3.0 and later.

## Which method do you use to access your dev endpoint?

If you use this method	Then do this
SageMaker notebook, Jupyter notebook, or JupyterLab	Migrate to <a href="#">AWS Glue Studio notebook</a> by downloading .ipynb files on Jupyter and create a new AWS Glue Studio notebook job by uploading the .ipynb file. Alternatively, you can also use <a href="#">SageMaker Studio</a> and select the AWS Glue kernel.
Zeppelin notebook	Convert the notebook to a Jupyter notebook manually by copying and pasting code or automatically using a third-party converter such as ze2nb. Then, use the notebook in AWS Glue Studio notebook or SageMaker Studio.
IDE	See <a href="#">Author AWS Glue jobs with PyCharm using AWS Glue interactive sessions</a> , or <a href="#">Using interactive sessions with Microsoft Visual Studio Code</a> .
REPL	Install the <a href="#">aws-glue-session package</a> locally, then run the following command: <ul style="list-style-type: none"> <li>• For Python: <code>jupyter console --kernel glue_pyspark</code></li> <li>• For Scala: <code>jupyter console --kernel glue_spark</code></li> </ul>
SSH	No corresponding option on interactive sessions. Alternatively, you can use a Docker

If you use this method	Then do this
	image. To learn more, see <a href="#">Developing using a Docker image</a> .

The following sections provide information on using dev endpoints to develop jobs in AWS Glue version 1.0.

## Topics

- [Developing scripts using development endpoints](#)
- [Managing notebooks](#)

## Developing scripts using development endpoints

### Note

Development Endpoints are only supported for versions of AWS Glue prior to 2.0. For an interactive environment where you can author and test ETL scripts, use [Notebooks on AWS Glue Studio](#).

AWS Glue can create an environment—known as a *development endpoint*—that you can use to iteratively develop and test your extract, transform, and load (ETL) scripts. You can create, edit, and delete development endpoints using the AWS Glue console or API.

## Managing your development environment

When you create a development endpoint, you provide configuration values to provision the development environment. These values tell AWS Glue how to set up the network so that you can access the endpoint securely and the endpoint can access your data stores.

You can then create a notebook that connects to the endpoint, and use your notebook to author and test your ETL script. When you're satisfied with the results of your development process, you can create an ETL job that runs your script. With this process, you can add functions and debug your scripts in an interactive manner.

Follow the tutorials in this section to learn how to use your development endpoint with notebooks.

## Topics

- [Development endpoint workflow](#)
- [How AWS Glue development endpoints work with SageMaker notebooks](#)
- [Adding a development endpoint](#)
- [Accessing your development endpoint](#)
- [Tutorial: Set up a Jupyter notebook in JupyterLab to test and debug ETL scripts](#)
- [Tutorial: Use a SageMaker notebook with your development endpoint](#)
- [Tutorial: Use a REPL shell with your development endpoint](#)
- [Tutorial: Set up PyCharm professional with a development endpoint](#)
- [Advanced configuration: sharing development endpoints among multiple users](#)

## Development endpoint workflow

To use an AWS Glue development endpoint, you can follow this workflow:

1. Create a development endpoint using the API. The endpoint is launched in a virtual private cloud (VPC) with your defined security groups.
2. The API polls the development endpoint until it is provisioned and ready for work. When it's ready, connect to the development endpoint using one of the following methods to create and test AWS Glue scripts.
  - Create an SageMaker notebook in your account. For more information about how to create a notebook, see [the section called "Authoring code with AWS Glue Studio notebooks"](#).
  - Open a terminal window to connect directly to a development endpoint.
  - If you have the professional edition of the JetBrains [PyCharm Python IDE](#), connect it to a development endpoint and use it to develop interactively. If you insert pydevd statements in your script, PyCharm can support remote breakpoints.
3. When you finish debugging and testing on your development endpoint, you can delete it.

## How AWS Glue development endpoints work with SageMaker notebooks

One of the common ways to access your development endpoints is to use [Jupyter](#) on SageMaker notebooks. The Jupyter notebook is an open-source web application which is widely used in

visualization, analytics, machine learning, etc. An AWS Glue SageMaker notebook provides you a Jupyter notebook experience with AWS Glue development endpoints. In the AWS Glue SageMaker notebook, the Jupyter notebook environment is pre-configured with [SparkMagic](#), an open source Jupyter plugin to submit Spark jobs to a remote Spark cluster. [Apache Livy](#) is a service that allows interaction with a remote Spark cluster over a REST API. In the AWS Glue SageMaker notebook, SparkMagic is configured to call the REST API against a Livy server running on an AWS Glue development endpoint.

The following text flow explains how each component works:

*AWS Glue SageMaker notebook: (Jupyter # SparkMagic) # (network) # AWS Glue development endpoint: (Apache Livy # Apache Spark)*

Once you run your Spark script written in each paragraph on a Jupyter notebook, the Spark code is submitted to the Livy server via SparkMagic, then a Spark job named "livy-session-N" runs on the Spark cluster. This job is called a Livy session. The Spark job will run while the notebook session is alive. The Spark job will be terminated when you shutdown the Jupyter kernel from the notebook, or when the session is timed out. One Spark job is launched per notebook (.ipynb) file.

You can use a single AWS Glue development endpoint with multiple SageMaker notebook instances. You can create multiple notebook files in each SageMaker notebook instance. When you open an each notebook file and run the paragraphs, then a Livy session is launched per notebook file on the Spark cluster via SparkMagic. Each Livy session corresponds to single Spark job.

### Default behavior for AWS Glue development endpoints and SageMaker notebooks

The Spark jobs run based on the [Spark configuration](#). There are multiple ways to set the Spark configuration (for example, Spark cluster configuration, SparkMagic's configuration, etc.).

By default, Spark allocates cluster resources to a Livy session based on the Spark cluster configuration. In the AWS Glue development endpoints, the cluster configuration depends on the worker type. Here's a table which explains the common configurations per worker type.

	Standard	G.1X	G.2X
spark.driver.memory	5G	10G	20G

	Standard	G.1X	G.2X
<code>spark.executor.memory</code>	5G	10G	20G
<code>spark.executor.cores</code>	4	8	16
<code>spark.dynamicAllocation.enabled</code>	TRUE	TRUE	TRUE

The maximum number of Spark executors is automatically calculated by combination of DPU (or `NumberOfWorkers`) and worker type.

	Standard	G.1X	G.2X
The number of max Spark executors	$(\text{DPU} - 1) * 2 - 1$	$(\text{NumberOfWorkers} - 1)$	$(\text{NumberOfWorkers} - 1)$

For example, if your development endpoint has 10 workers and the worker type is G.1X, then you will have 9 Spark executors and the entire cluster will have 90G of executor memory since each executor will have 10G of memory.

Regardless of the specified worker type, Spark dynamic resource allocation will be turned on. If a dataset is large enough, Spark may allocate all the executors to a single Livy session since `spark.dynamicAllocation.maxExecutors` is not set by default. This means that other Livy sessions on the same dev endpoint will wait to launch new executors. If the dataset is small, Spark will be able to allocate executors to multiple Livy sessions at the same time.

**Note**

For more information about how resources are allocated in different use cases and how you set a configuration to modify the behavior, see [Advanced configuration: sharing development endpoints among multiple users](#).

## Adding a development endpoint

Use development endpoints to iteratively develop and test your extract, transform, and load (ETL) scripts in AWS Glue. Working with development endpoints is only available through the AWS Command Line Interface.

1. In a command line window, enter a command similar to the following.

```
aws glue create-dev-endpoint --endpoint-name "endpoint1" --role-arn
"arn:aws:iam::account-id:role/role-name" --number-of-nodes "3" --glue-version
"1.0" --arguments '{"GLUE_PYTHON_VERSION": "3"}' --region "region-name"
```

This command specifies AWS Glue version 1.0. Because this version supports both Python 2 and Python 3, you can use the `arguments` parameter to indicate the desired Python version. If the `glue-version` parameter is omitted, AWS Glue version 0.9 is assumed. For more information about AWS Glue versions, see the [Glue version job property](#).

For information about additional command line parameters, see [create-dev-endpoint](#) in the *AWS CLI Command Reference*.

2. (Optional) Enter the following command to check the development endpoint status. When the status changes to READY, the development endpoint is ready to use.

```
aws glue get-dev-endpoint --endpoint-name "endpoint1"
```

## Accessing your development endpoint

When you create a development endpoint in a virtual private cloud (VPC), AWS Glue returns only a private IP address. The public IP address field is not populated. When you create a non-VPC development endpoint, AWS Glue returns only a public IP address.

If your development endpoint has a **Public address**, confirm that it is reachable with the SSH private key for the development endpoint, as in the following example.

```
ssh -i dev-endpoint-private-key.pem glue@public-address
```

Suppose that your development endpoint has a **Private address**, your VPC subnet is routable from the public internet, and its security groups allow inbound access from your client. In this case, follow these steps to attach an *Elastic IP address* to a development endpoint to allow access from the internet.

### Note

If you want to use Elastic IP addresses, the subnet that is being used requires an internet gateway associated through the route table.

## To access a development endpoint by attaching an Elastic IP address

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Dev endpoints**, and navigate to the development endpoint details page. Record the **Private address** for use in the next step.
3. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
4. In the navigation pane, under **Network & Security**, choose **Network Interfaces**.
5. Search for the **Private DNS (IPv4)** that corresponds to the **Private address** on the AWS Glue console development endpoint details page.

You might need to modify which columns are displayed on your Amazon EC2 console. Note the **Network interface ID** (ENI) for this address (for example, `eni-12345678`).

6. On the Amazon EC2 console, under **Network & Security**, choose **Elastic IPs**.
7. Choose **Allocate new address**, and then choose **Allocate** to allocate a new Elastic IP address.
8. On the **Elastic IPs** page, choose the newly allocated **Elastic IP**. Then choose **Actions, Associate address**.
9. On the **Associate address** page, do the following:
  - For **Resource type**, choose **Network interface**.
  - In the **Network interface** box, enter the **Network interface ID** (ENI) for the private address.

- Choose **Associate**.

10. Confirm that the newly associated Elastic IP address is reachable with the SSH private key that is associated with the development endpoint, as in the following example.

```
ssh -i dev-endpoint-private-key.pem glue@elastic-ip
```

For information about using a bastion host to get SSH access to the development endpoint's private address, see the AWS Security Blog post [Securely Connect to Linux Instances Running in a Private Amazon VPC](#).

## Tutorial: Set up a Jupyter notebook in JupyterLab to test and debug ETL scripts

In this tutorial, you connect a Jupyter notebook in JupyterLab running on your local machine to a development endpoint. You do this so that you can interactively run, debug, and test AWS Glue extract, transform, and load (ETL) scripts before deploying them. This tutorial uses Secure Shell (SSH) port forwarding to connect your local machine to an AWS Glue development endpoint. For more information, see [Port forwarding](#) on Wikipedia.

### Step 1: Install JupyterLab and Sparkmagic

You can install JupyterLab by using `conda` or `pip`. `conda` is an open-source package management system and environment management system that runs on Windows, macOS, and Linux. `pip` is the package installer for Python.

If you're installing on macOS, you must have Xcode installed before you can install Sparkmagic.

1. Install JupyterLab, Sparkmagic, and the related extensions.

```
$ conda install -c conda-forge jupyterlab
$ pip install sparkmagic
$ jupyter nbextension enable --py --sys-prefix widgetsnbextension
$ jupyter labextension install @jupyter-widgets/jupyterlab-manager
```

2. Check the sparkmagic directory from Location.

```
$ pip show sparkmagic | grep Location
Location: /Users/username/.pyenv/versions/anaconda3-5.3.1/lib/python3.7/site-
packages
```

3. Change your directory to the one returned for Location, and install the kernels for Scala and PySpark.

```
$ cd /Users/username/.pyenv/versions/anaconda3-5.3.1/lib/python3.7/site-packages
$ jupyter-kernelspec install sparkmagic/kernels/sparkkernel
$ jupyter-kernelspec install sparkmagic/kernels/pysparkkernel
```

4. Download a sample config file.

```
$ curl -o ~/.sparkmagic/config.json https://raw.githubusercontent.com/jupyter-
incubator/sparkmagic/master/sparkmagic/example_config.json
```

In this configuration file, you can configure Spark-related parameters like `driverMemory` and `executorCores`.

## Step 2: Start JupyterLab

When you start JupyterLab, your default web browser is automatically opened, and the URL `http://localhost:8888/lab/workspaces/{workspace_name}` is shown.

```
$ jupyter lab
```

## Step 3: Initiate SSH port forwarding to connect to your development endpoint

Next, use SSH local port forwarding to forward a local port (here, 8998) to the remote destination that is defined by AWS Glue (`169.254.76.1:8998`).

1. Open a separate terminal window that gives you access to SSH. In Microsoft Windows, you can use the BASH shell provided by [Git for Windows](#), or you can install [Cygwin](#).
2. Run the following SSH command, modified as follows:
  - Replace *private-key-file-path* with a path to the `.pem` file that contains the private key corresponding to the public key that you used to create your development endpoint.
  - If you're forwarding a different port than 8998, replace 8998 with the port number that you're actually using locally. The address `169.254.76.1:8998` is the remote port and isn't changed by you.
  - Replace *dev-endpoint-public-dns* with the public DNS address of your development endpoint. To find this address, navigate to your development endpoint in the AWS Glue

console, choose the name, and copy the **Public address** that's listed on the **Endpoint details** page.

```
ssh -i private-key-file-path -NTL 8998:169.254.76.1:8998 glue@dev-endpoint-public-dns
```

You will likely see a warning message like the following:

```
The authenticity of host 'ec2-xx-xxx-xxx-xx.us-west-2.compute.amazonaws.com
(xx.xxx.xxx.xx)'
can't be established. ECDSA key fingerprint is SHA256:4e97875Brt+1wKzRko
+Jf15np21X7aTP3BcFnHYLEts.
Are you sure you want to continue connecting (yes/no)?
```

Enter **yes** and leave the terminal window open while you use JupyterLab.

3. Check that SSH port forwarding is working with the development endpoint correctly.

```
$ curl localhost:8998/sessions
{"from":0,"total":0,"sessions":[]}
```

#### Step 4: Run a simple script fragment in a notebook paragraph

Now your notebook in JupyterLab should work with your development endpoint. Enter the following script fragment into your notebook and run it.

1. Check that Spark is running successfully. The following command instructs Spark to calculate 1 and then print the value.

```
spark.sql("select 1").show()
```

2. Check if AWS Glue Data Catalog integration is working. The following command lists the tables in the Data Catalog.

```
spark.sql("show tables").show()
```

3. Check that a simple script fragment that uses AWS Glue libraries works.

The following script uses the `persons_json` table metadata in the AWS Glue Data Catalog to create a `DynamicFrame` from your sample data. It then prints out the item count and the schema of this data.

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create a Glue context
glueContext = GlueContext(SparkContext.getOrCreate())

# Create a DynamicFrame using the 'persons_json' table
persons_DyF = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="persons_json")

# Print out information about *this* data
print("Count: ", persons_DyF.count())
persons_DyF.printSchema()
```

The output of the script is as follows.

```
Count: 1961
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- name: string
|   |   |-- lang: string
```

```
|-- sort_name: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

## Troubleshooting

- During the installation of JupyterLab, if your computer is behind a corporate proxy or firewall, you might encounter HTTP and SSL errors due to custom security profiles managed by corporate IT departments.

The following is an example of a typical error that occurs when conda can't connect to its own repositories:

```
CondaHTTPError: HTTP 000 CONNECTION FAILED for url <https://repo.anaconda.com/pkg/main/win-64/current_repodata.json>
```

This might happen because your company can block connections to widely used repositories in Python and JavaScript communities. For more information, see [Installation Problems](#) on the JupyterLab website.

- If you encounter a *connection refused* error when trying to connect to your development endpoint, you might be using a development endpoint that is out of date. Try creating a new development endpoint and reconnecting.

## Tutorial: Use a SageMaker notebook with your development endpoint

In AWS Glue, you can create a development endpoint and then create a SageMaker notebook to help develop your ETL and machine learning scripts. A SageMaker notebook is a fully managed machine learning compute instance running the Jupyter Notebook application.

1. In the AWS Glue console, choose **Dev endpoints** to navigate to the development endpoints list.
2. Select the check box next to the name of a development endpoint that you want to use, and on the **Action** menu, choose **Create SageMaker notebook**.
3. Fill out the **Create and configure a notebook** page as follows:
  - a. Enter a notebook name.
  - b. Under **Attach to development endpoint**, verify the development endpoint.
  - c. Create or choose an AWS Identity and Access Management (IAM) role.

Creating a role is recommended. If you use an existing role, ensure that it has the required permissions. For more information, see [the section called “Step 6: Create an IAM policy for SageMaker notebooks”](#).

- d. (Optional) Choose a VPC, a subnet, and one or more security groups.
  - e. (Optional) Choose an AWS Key Management Service encryption key.
  - f. (Optional) Add tags for the notebook instance.
4. Choose **Create notebook**. On the **Notebooks** page, choose the refresh icon at the upper right, and continue until the **Status** shows Ready.
  5. Select the check box next to the new notebook name, and then choose **Open notebook**.
  6. Create a new notebook: On the **jupyter** page, choose **New**, and then choose **Sparkmagic (PySpark)**.

Your screen should now look like the following:

7. (Optional) At the top of the page, choose **Untitled**, and give the notebook a name.
8. To start a Spark application, enter the following command into the notebook, and then in the toolbar, choose **Run**.

```
spark
```

After a short delay, you should see the following response:

```
In [1]: spark
Starting Spark application
```

ID	YARN Application ID	Kind	State	Spark UI	Driver log	Current session?
0	application_1576209965005_0001	pyspark	idle	<a href="#">Link</a>	<a href="#">Link</a>	✓

```
SparkSession available as 'spark'.
<pyspark.sql.session.SparkSession object at 0x7f3d54913550>
```

9. Create a dynamic frame and run a query against it: Copy, paste, and run the following code, which outputs the count and schema of the `persons_json` table.

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import *
glueContext = GlueContext(SparkContext.getOrCreate())
persons_DyF = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="persons_json")
print ("Count: ", persons_DyF.count())
persons_DyF.printSchema()
```

## Tutorial: Use a REPL shell with your development endpoint

In AWS Glue, you can create a development endpoint and then invoke a REPL (Read–Evaluate–Print Loop) shell to run PySpark code incrementally so that you can interactively debug your ETL scripts before deploying them.

In order to use a REPL on a development endpoint, you need to have authorization to SSH to the endpoint.

1. On your local computer, open a terminal window that can run SSH commands, and paste in the edited SSH command. Run the command.

Assuming that you accepted AWS Glue version 1.0 with Python 3 for the development endpoint, the output will look like this:

```
Python 3.6.8 (default, Aug  2 2019, 17:42:44)
[GCC 4.8.5 20150623 (Red Hat 4.8.5-28)] on linux
Type "help", "copyright", "credits" or "license" for more information.
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding in [jar:file:/usr/share/aws/glue/etl/jars/glue-assembly.jar!/
org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/usr/lib/spark/jars/slf4j-log4j12-1.7.16.jar!/
org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
Setting default log level to "WARN".
To adjust logging level use sc.setLogLevel(newLevel). For SparkR, use
setLogLevel(newLevel).
2019-09-23 22:12:23,071 WARN [Thread-5] yarn.Client (Logging.scala:logWarning(66))
- Neither spark.yarn.jars nor spark.yarn.archive is set, falling back to uploading
libraries under SPARK_HOME.
2019-09-23 22:12:26,562 WARN [Thread-5] yarn.Client (Logging.scala:logWarning(66))
- Same name resource file:///usr/lib/spark/python/lib/pyspark.zip added multiple
times to distributed cache

times to distributed cache.
2019-09-23 22:12:26,581 WARN [Thread-5] yarn.Client (Logging.scala:logWarning(66))
- Same path resource file:///usr/share/aws/glue/libs/pyspark.zip added multiple
times to distributed cache.
Welcome to

  ____
 /  __ \  _  /  _  /  _  /
-\  \ \ /  \ /  \ /  \ /
/_  /  .  \ /  \ /  \ /  \  version 2.4.3
  /  \

Using Python version 3.6.8 (default, Aug  2 2019 17:42:44)
SparkSession available as 'spark'.
>>>
```

2. Test that the REPL shell is working correctly by typing the statement, `print(spark.version)`. As long as that displays the Spark version, your REPL is now ready to use.
3. Now you can try executing the following simple script, line by line, in the shell:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import *
glueContext = GlueContext(SparkContext.getOrCreate())
persons_DyF = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="persons_json")
print ("Count: ", persons_DyF.count())
persons_DyF.printSchema()
```

## Tutorial: Set up PyCharm professional with a development endpoint

This tutorial shows you how to connect the [PyCharm Professional](#) Python IDE running on your local machine to a development endpoint so that you can interactively run, debug, and test AWS Glue ETL (extract, transfer, and load) scripts before deploying them. The instructions and screen captures in the tutorial are based on PyCharm Professional version 2019.3.

To connect to a development endpoint interactively, you must have PyCharm Professional installed. You can't do this using the free edition.

### Note

The tutorial uses Amazon S3 as a data source. If you want to use a JDBC data source instead, you must run your development endpoint in a virtual private cloud (VPC). To connect with SSH to a development endpoint in a VPC, you must create an SSH tunnel. This tutorial does not include instructions for creating an SSH tunnel. For information on using SSH to connect to a development endpoint in a VPC, see [Securely Connect to Linux Instances Running in a Private Amazon VPC](#) in the AWS security blog.

## Topics

- [Connecting PyCharm professional to a development endpoint](#)
- [Deploying the script to your development endpoint](#)

- [Configuring a remote interpreter](#)
- [Running your script on the development endpoint](#)

## Connecting PyCharm professional to a development endpoint

1. Create a new pure-Python project in PyCharm named legislators.
2. Create a file named `get_person_schema.py` in the project with the following content:

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

def main():
    # Create a Glue context
    glueContext = GlueContext(SparkContext.getOrCreate())

    # Create a DynamicFrame using the 'persons_json' table
    persons_DyF =
glueContext.create_dynamic_frame.from_catalog(database="legislators",
table_name="persons_json")

    # Print out information about this data
    print("Count: ", persons_DyF.count())
    persons_DyF.printSchema()

if __name__ == "__main__":
    main()
```

3. Do one of the following:
  - For AWS Glue version 0.9, download the AWS Glue Python library file, `PyGlue.zip`, from <https://s3.amazonaws.com/aws-glue-jes-prod-us-east-1-assets/etl/python/PyGlue.zip> to a convenient location on your local machine.
  - For AWS Glue version 1.0 and later, download the AWS Glue Python library file, `PyGlue.zip`, from <https://s3.amazonaws.com/aws-glue-jes-prod-us-east-1-assets/etl-1.0/python/PyGlue.zip> to a convenient location on your local machine.
4. Add `PyGlue.zip` as a content root for your project in PyCharm:

- In PyCharm, choose **File, Settings** to open the **Settings** dialog box. (You can also press **Ctrl+Alt+S**.)
- Expand the `legislators` project and choose **Project Structure**. Then in the right pane, choose **+ Add Content Root**.
- Navigate to the location where you saved `PyGlue.zip`, select it, then choose **Apply**.

The **Settings** screen should look something like the following:

Leave the **Settings** dialog box open after you choose **Apply**.

5. Configure deployment options to upload the local script to your development endpoint using SFTP (this capability is available only in PyCharm Professional):
  - In the **Settings** dialog box, expand the **Build, Execution, Deployment** section. Choose the **Deployment** subsection.
  - Choose the **+** icon at the top of the middle pane to add a new server. Set its **Type** to SFTP and give it a name.
  - Set the **SFTP host** to the **Public address** of your development endpoint, as listed on its details page. (Choose the name of your development endpoint in the AWS Glue console to display the details page). For a development endpoint running in a VPC, set **SFTP host** to the host address and local port of your SSH tunnel to the development endpoint.

- Set the **User name** to `glue`.
- Set the **Auth type** to **Key pair (OpenSSH or Putty)**. Set the **Private key file** by browsing to the location where your development endpoint's private key file is located. Note that PyCharm only supports DSA, RSA and ECDSA OpenSSH key types, and does not accept keys in Putty's private format. You can use an up-to-date version of `ssh-keygen` to generate a key-pair type that PyCharm accepts, using syntax like the following:

```
ssh-keygen -t rsa -f <key_file_name> -C "<your_email_address>"
```

- Choose **Test connection**, and allow the connection to be tested. If the connection succeeds, choose **Apply**.

The **Settings** screen should now look something like the following:

Again, leave the **Settings** dialog box open after you choose **Apply**.

## 6. Map the local directory to a remote directory for deployment:

- In the right pane of the **Deployment** page, choose the middle tab at the top, labeled **Mappings**.
- In the **Deployment Path** column, enter a path under `/home/glue/scripts/` for deployment of your project path. For example: `/home/glue/scripts/legislators`.

- Choose **Apply**.

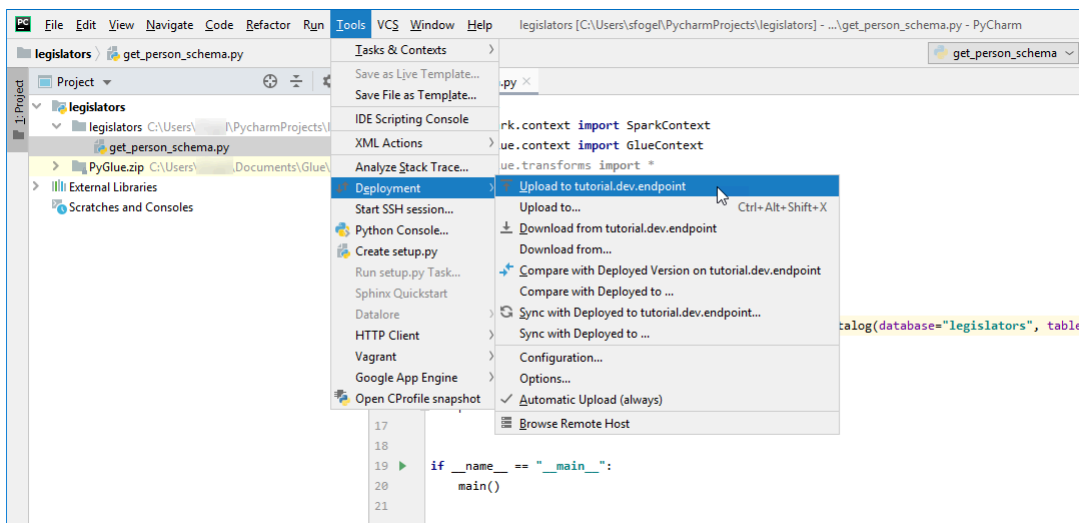

The **Settings** screen should now look something like the following:

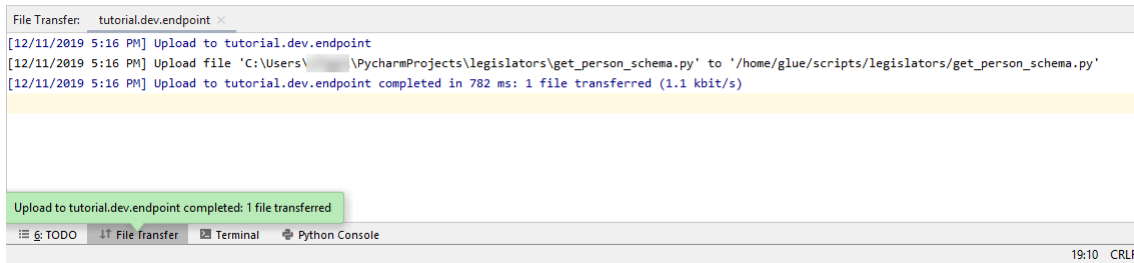

Choose **OK** to close the **Settings** dialog box.

## Deploying the script to your development endpoint

1. Choose **Tools, Deployment**, and then choose the name under which you set up your development endpoint, as shown in the following image:

After your script has been deployed, the bottom of the screen should look something like the following:

```
File Transfer: tutorial.dev.endpoint x
[12/11/2019 5:16 PM] Upload to tutorial.dev.endpoint
[12/11/2019 5:16 PM] Upload file 'C:\Users\... \PycharmProjects\legislators\get_person_schema.py' to '/home/glue/scripts/legislators/get_person_schema.py'
[12/11/2019 5:16 PM] Upload to tutorial.dev.endpoint completed in 782 ms: 1 file transferred (1.1 kbit/s)

Upload to tutorial.dev.endpoint completed: 1 file transferred
```

2. On the menu bar, choose **Tools, Deployment, Automatic Upload (always)**. Ensure that a check mark appears next to **Automatic Upload (always)**.

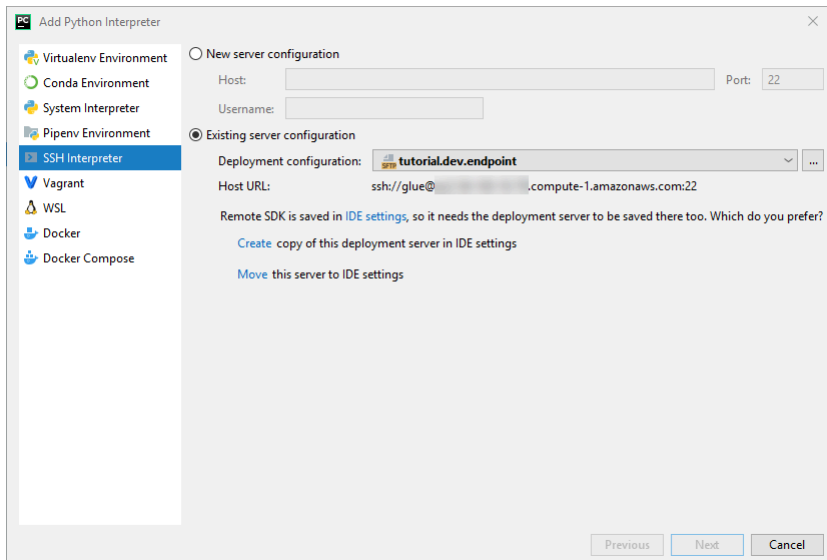

When this option is enabled, PyCharm automatically uploads changed files to the development endpoint.

## Configuring a remote interpreter

Configure PyCharm to use the Python interpreter on the development endpoint.

1. From the **File** menu, choose **Settings**.
2. Expand the project **legislators** and choose **Project Interpreter**.
3. Choose the gear icon next to the **Project Interpreter** list, and then choose **Add**.
4. In the **Add Python Interpreter** dialog box, in the left pane, choose **SSH Interpreter**.
5. Choose **Existing server configuration**, and in the **Deployment configuration** list, choose your configuration.

Your screen should look something like the following image.

6. Choose **Move this server to IDE settings**, and then choose **Next**.
7. In the **Interpreter** field, change the path to `/usr/bin/gluepython` if you are using Python 2, or to `/usr/bin/gluepython3` if you are using Python 3. Then choose **Finish**.

## Running your script on the development endpoint

To run the script:

- In the left pane, right-click the file name and choose **Run '<filename>'**.

After a series of messages, the final output should show the count and the schema.

```
Count: 1961
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
```

```
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

Process finished with exit code 0

You are now set up to debug your script remotely on your development endpoint.

## Advanced configuration: sharing development endpoints among multiple users

This section explains how you can take advantage of development endpoints with SageMaker notebooks in typical use cases to share development endpoints among multiple users.

### Single-tenancy configuration

In single tenant use-cases, to simplify the developer experience and to avoid contention for resources it is recommended that you have each developer use their own development endpoint sized for the project they are working on. This also simplifies the decisions related to worker type and DPU count leaving them up to the discretion of the developer and project they are working on.

You won't need to take care of resource allocation unless you runs multiple notebook files concurrently. If you run code in multiple notebook files at the same time, multiple Livy sessions will be launched concurrently. To segregate Spark cluster configurations in order to run multiple Livy sessions at the same time, you can follow the steps which are introduced in multi tenant use-cases.

For example, if your development endpoint has 10 workers and the worker type is `G.1X`, then you will have 9 Spark executors and the entire cluster will have 90G of executor memory since each executor will have 10G of memory.

Regardless of the specified worker type, Spark dynamic resource allocation will be turned on. If a dataset is large enough, Spark may allocate all the executors to a single Livy session since `spark.dynamicAllocation.maxExecutors` is not set by default. This means that other Livy sessions on the same dev endpoint will wait to launch new executors. If the dataset is small, Spark will be able to allocate executors to multiple Livy sessions at the same time.

### Note

For more information about how resources are allocated in different use cases and how you set a configuration to modify the behavior, see [Advanced configuration: sharing development endpoints among multiple users](#).

## Multi-tenancy configuration

### Note

Please note, development endpoints are intended to emulate the AWS Glue ETL environment as a single-tenant environment. While multi-tenant use is possible, it is an advanced use-case and it is recommended most users maintain a pattern of single-tenancy for each development endpoint.

In multi tenant use-cases, you might need to take care of resource allocation. The key factor is the number of concurrent users who use a Jupyter notebook at the same time. If your team works in a "follow-the-sun" workflow and there is only one Jupyter user at each time zone, then the number of concurrent users is only one, so you won't need to be concerned with resource allocation. However, if your notebook is shared among multiple users and each user submits code in an ad-hoc basis, then you will need to consider the below points.

To partition Spark cluster resources among multiple users, you can use SparkMagic configurations. There are two different ways to configure SparkMagic.

## (A) Use the %%configure -f directive

If you want to modify the configuration per Livy session from the notebook, you can run the %%configure -f directive on the notebook paragraph.

For example, if you want to run Spark application on 5 executors, you can run the following command on the notebook paragraph.

```
%%configure -f
{"numExecutors":5}
```

Then you will see only 5 executors running for the job on the Spark UI.

We recommend limiting the maximum number of executors for dynamic resource allocation.

```
%%configure -f
{"conf":{"spark.dynamicAllocation.maxExecutors":"5"}}
```

## (B) Modify the SparkMagic config file

SparkMagic works based on the [Livy API](#). SparkMagic creates Livy sessions with configurations such as driverMemory, driverCores, executorMemory, executorCores, numExecutors, conf, etc. Those are the key factors that determine how much resources are consumed from the entire Spark cluster. SparkMagic allows you to provide a config file to specify those parameters which are sent to Livy. You can see a sample config file in this [Github repository](#).

If you want to modify configuration across all the Livy sessions from a notebook, you can modify /home/ec2-user/.sparkmagic/config.json to add session\_config .

To modify the config file on a SageMaker notebook instance, you can follow these steps.

1. Open a SageMaker notebook.
2. Open the Terminal kernel.
3. Run the following commands:

```
sh-4.2$ cd .sparkmagic
sh-4.2$ ls
config.json logs
sh-4.2$ sudo vim config.json
```

For example, you can add these lines to `/home/ec2-user/.sparkmagic/config.json` and restart the Jupyter kernel from the notebook.

```
"session_configs": {
  "conf": {
    "spark.dynamicAllocation.maxExecutors": "5"
  }
},
```

## Guidelines and best practices

To avoid this kind of resource conflict, you can use some basic approaches like:

- Have a larger Spark cluster by increasing the `NumberOfWorkers` (scaling horizontally) and upgrading the `workerType` (scaling vertically)
- Allocate fewer resources per user (fewer resources per Livy session)

Your approach will depend on your use case. If you have a larger development endpoint, and there is not a huge amount of data, the possibility of a resource conflict will decrease significantly because Spark can allocate resources based on a dynamic allocation strategy.

As described above, the number of Spark executors can be automatically calculated based on a combination of DPU (or `NumberOfWorkers`) and worker type. Each Spark application launches one driver and multiple executors. To calculate you will need the `NumberOfWorkers = NumberOfExecutors + 1`. The matrix below explains how much capacity you need in your development endpoint based on the number of concurrent users.

Number of concurrent notebook users	Number of Spark executors you want to allocate per user	Total <code>NumberOfWorkers</code> for your dev endpoint
3	5	18
10	5	60
50	5	300

If you want to allocate fewer resources per user, the `spark.dynamicAllocation.maxExecutors` (or `numExecutors`) would be the easiest parameter to configure as a Livy session parameter. If you set the below configuration in `/home/ec2-user/.sparkmagic/config.json`, then SparkMagic will assign a maximum of 5 executors per Livy session. This will help segregating resources per Livy session.

```
"session_configs": {
  "conf": {
    "spark.dynamicAllocation.maxExecutors": "5"
  }
},
```

Suppose there is a dev endpoint with 18 workers (G.1X) and there are 3 concurrent notebook users at the same time. If your session config has `spark.dynamicAllocation.maxExecutors=5` then each user can make use of 1 driver and 5 executors. There won't be any resource conflicts even when you run multiple notebook paragraphs at the same time.

### Trade-offs

With this session config `"spark.dynamicAllocation.maxExecutors": "5"`, you will be able to avoid resource conflict errors and you do not need to wait for resource allocation when there are concurrent user accesses. However, even when there are many free resources (for example, there are no other concurrent users), Spark cannot assign more than 5 executors for your Livy session.

### Other notes

It is a good practice to stop the Jupyter kernel when you stop using a notebook. This will free resources and other notebook users can use those resources immediately without waiting for kernel expiration (auto-shutdown).

### Common issues

Even when following the guidelines, you may experience certain issues.

### Session not found

When you try to run a notebook paragraph even though your Livy session has been already terminated, you will see the below message. To activate the Livy session, you need to restart the Jupyter kernel by choosing **Kernel > Restart** in the Jupyter menu, then run the notebook paragraph again.

```
An error was encountered:  
Invalid status code '404' from http://localhost:8998/sessions/13 with error payload:  
"Session '13' not found."
```

## Not enough YARN resources

When you try to run a notebook paragraph even though your Spark cluster does not have enough resources to start a new Livy session, you will see the below message. You can often avoid this issue by following the guidelines, however, there might be a possibility that you face this issue. To workaroud the issue, you can check if there are any unneeded, active Livy sessions. If there are unneeded Livy sessions, you will need to terminate them to free the cluster resources. See the next section for details.

```
Warning: The Spark session does not have enough YARN resources to start.  
The code failed because of a fatal error:  
    Session 16 did not start up in 60 seconds..
```

Some things to try:

- a) Make sure Spark has enough available resources for Jupyter to create a Spark context.
- b) Contact your Jupyter administrator to make sure the Spark magics library is configured correctly.
- c) Restart the kernel.

## Monitoring and debugging

This section describes techniques for monitoring resources and sessions.

### Monitoring and debugging cluster resource allocation

You can watch the Spark UI to monitor how many resources are allocated per Livy session, and what are the effective Spark configurations on the job. To activate the Spark UI, see [Enabling the Apache Spark Web UI for Development Endpoints](#).

(Optional) If you need a real-time view of the Spark UI, you can configure an SSH tunnel against the Spark history server running on the Spark cluster.

```
ssh -i <private-key.pem> -N -L 8157:<development endpoint public address>:18080  
glue@<development endpoint public address>
```

You can then open `http://localhost:8157` on your browser to view the Spark UI.

## Free unneeded Livy sessions

Review these procedures to shut down any unneeded Livy sessions from a notebook or a Spark cluster.

### (a). Terminate Livy sessions from a notebook

You can shut down the kernel on a Jupyter notebook to terminate unneeded Livy sessions.

### (b). Terminate Livy sessions from a Spark cluster

If there are unneeded Livy sessions which are still running, you can shut down the Livy sessions on the Spark cluster.

As a pre-requisite to perform this procedure, you need to configure your SSH public key for your development endpoint.

To log in to the Spark cluster, you can run the following command:

```
$ ssh -i <private-key.pem> glue@<development endpoint public address>
```

You can run the following command to see the active Livy sessions:

```
$ yarn application -list
20/09/25 06:22:21 INFO client.RMPProxy: Connecting to ResourceManager at
ip-255-1-106-206.ec2.internal/172.38.106.206:8032

## Managing notebooks

### Note

Development Endpoints are only supported for versions of AWS Glue prior to 2.0. For an interactive environment where you can author and test ETL scripts, use [Notebooks on AWS Glue Studio](#).

A notebook enables interactive development and testing of your ETL (extract, transform, and load) scripts on a development endpoint. AWS Glue provides an interface to SageMaker Jupyter notebooks. With AWS Glue, you create and manage SageMaker notebooks. You can also open SageMaker notebooks from the AWS Glue console.

In addition, you can use Apache Spark with SageMaker on AWS Glue development endpoints which support SageMaker (but not AWS Glue ETL jobs). SageMaker Spark is an open source Apache Spark library for SageMaker. For more information, see [Using Apache Spark with Amazon SageMaker](#).

### Important

Managing SageMaker notebooks with AWS Glue development endpoints is available in the following AWS Regions:

Region	Code
US East (Ohio)	us-east-2
US East (N. Virginia)	us-east-1
US West (N. California)	us-west-1
US West (Oregon)	us-west-2
Asia Pacific (Tokyo)	ap-northeast-1

Region	Code
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2

## Building visual ETL jobs with AWS Glue Studio

An AWS Glue job encapsulates a script that connects to your source data, processes it, and then writes it out to your data target. Typically, a job runs extract, transform, and load (ETL) scripts. Jobs can run scripts designed for Apache Spark and Ray runtime environments. Jobs can also run general-purpose Python scripts (Python shell jobs.) AWS Glue *triggers* can start jobs based on a schedule or event, or on demand. You can monitor job runs to understand runtime metrics such as completion status, duration, and start time.

You can use scripts that AWS Glue generates or you can provide your own. With a source schema and target location or schema, the AWS Glue Studio code generator can automatically create an Apache Spark API (PySpark) script. You can use this script as a starting point and edit it to meet your goals.

AWS Glue can write output files in several data formats. Each job type may support different output formats. For some data formats, common compression formats can be written.

## Signing in to the AWS Glue console

A job in AWS Glue consists of the business logic that performs extract, transform, and load (ETL) work. You can create jobs in the **ETL** section of the AWS Glue console.

To view existing jobs, sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>. Then choose the **Jobs** tab in AWS Glue. The **Jobs** list displays the location of the script that is associated with each job, when the job was last modified, and the current job bookmark option.

While creating a new job, or after you have saved your job, you can use can AWS Glue Studio to modify your ETL jobs. You can do this by editing the nodes in the visual editor or by editing the job script in developer mode. You can also add and remove nodes in the visual editor to create more complicated ETL jobs.

## Next steps for creating a job in AWS Glue Studio

You use the visual job editor to configure nodes for your job. Each node represents an action, such as reading data from the source location or applying a transform to the data. Each node you add to your job has properties that provide information about either the data location or the transform.

The next steps for creating and managing your jobs are:

- [Visual ETL with AWS Glue Studio](#)
- [View the job script](#)
- [Modify the job properties](#)
- [Save the job](#)
- [Start a job run](#)
- [View information for recent job runs](#)
- [Accessing the job monitoring dashboard](#)

## Visual ETL with AWS Glue Studio

You can use the simple visual interface in AWS Glue Studio to create your ETL jobs. You use the **Jobs** page to create new jobs. You can also use a script editor or notebook to work directly with code in the AWS Glue Studio ETL job script.

On the **Jobs** page, you can see all the jobs that you have created either with AWS Glue Studio or AWS Glue. You can view, manage, and run your jobs on this page.

Also see the [blog tutorial](#) on another example of how to create ETL jobs with AWS Glue Studio.

## Starting jobs in AWS Glue Studio

AWS Glue allows you to create a job through a visual interface, an interactive code notebook, or with a script editor. You can start a job by clicking on any of the options or create a new job based on a sample job.

Sample jobs create a job with the tool of your choice. For example, sample jobs allow you to create a visual ETL job that joins CSV files into a catalog table, create a job in an interactive code notebook with AWS Glue for Ray or AWS Glue for Spark when working with pandas, or create a job in an interactive code notebook with SparkSQL.

## Creating a job in AWS Glue Studio from scratch

1. Sign in to the AWS Management Console and open the AWS Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.

2. Choose **ETL jobs** from the navigation pane.
3. In the **Create job** section, select a configuration option for your job.

The screenshot shows the 'Create job' interface in AWS Glue Studio. It is divided into two main sections: 'Create job' and 'Example jobs'.

**Create job** section:

- Visual ETL:** Author in a visual interface focused on data flow. (Highlighted with an orange button)
- Notebook:** Author using an interactive code notebook.
- Script editor:** Author code with a script editor.

**Example jobs** section (with a 'Create sample job' button):

- Visual ETL job with a join:** Read three CSV files, combine the data, change the data types, then write the data to Amazon S3 and catalog it for querying later.
- Ray sample notebook - New:** Use the Ray framework for parallel processing in Python. Read many parquet files from S3, explore and filter the data, then save it to a CSV.
- Spark Pandas sample notebook:** Explore and visualize data using the popular Pandas framework combined with Spark.
- Spark SQL sample notebook:** Use SQL to get started quickly with Apache Spark. Access data via the AWS Glue Data Catalog and transform it using familiar commands.

Options to create a job from scratch:

- **Visual ETL** – author in a visual interface focused on data flow
- **Author using an Interactive code notebook** – interactively author jobs in a notebook interface based on Jupyter Notebooks

When you select this option, you must provide additional information before creating a notebook authoring session. For more information about how to specify this information, see [Getting started with notebooks in AWS Glue Studio](#).

- **Author code with a script editor** – For those familiar with programming and writing ETL scripts, choose this option to create a new Spark ETL job. Choose the engine (Python shell, Ray, Spark (Python), or Spark (Scala)). Then, choose **Start fresh** or **Upload script**, uploading an existing script from a local file. If you choose to use the script editor, you can't use the visual job editor to design or edit your job.

A Spark job is run in an Apache Spark environment managed by AWS Glue. By default, new scripts are coded in Python. To write a new Scala script, see [Creating and editing Scala scripts in AWS Glue Studio](#).

## Creating a job in AWS Glue Studio from an example job

You can choose to create a job from an example job. In the **Example jobs** section, choose a sample job, then choose **Create sample job**. Creating a sample job from one of the options provides a quick template you can work from.

1. Sign in to the AWS Management Console and open the AWS Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.
2. Choose **ETL jobs** from the navigation pane.
3. Select an option create a job from a sample job:
  - **Visual ETL job to join multiple sources** – Read three CSV files, combine the data, change the data types, then write the data to Amazon S3 and catalog it for querying later.
  - **Spark notebook using Pandas** – Explore and visualize data using the popular Pandas framework combined with Spark.
  - **Spark notebook using SQL** – Use SQL to get started quickly with Apache Spark. Access data through the AWS Glue Data Catalog and transform it using familiar commands.
4. Choose **Create sample job**.

## Job editor features

The job editor provides the following features for creating and editing jobs.

- A visual diagram of your job, with a node for each job task: Data source nodes for reading the data; transform nodes for modifying the data; data target nodes for writing the data.

You can view and configure the properties of each node in the job diagram. You can also view the schema and sample data for each node in the job diagram. These features help you to verify that your job is modifying and transforming the data in the right way, without having to run the job.

- A Script viewing and editing tab, where you can modify the code generated for your job.
- A Job details tab, where you can configure a variety of settings to customize the environment in which your AWS Glue ETL job runs.
- A Runs tab, where you can view the current and previous runs of the job, view the status of the job run, and access the logs for the job run.
- A Data quality tab, where you can apply data quality rules to your job.
- A Schedules tab, where you can configure the start time for you job, or set up a recurring job runs.
- A Version Control tab, where you can configure a Git service to use with your job.

## Using schema previews in the visual job editor

While creating or editing your job, you can use the **Output schema** tab to view the schema for your data.

Before you can see the schema, the job editor needs permissions to access the data source. You can specify an IAM role on the Job details tab of the editor or on the **Output schema** tab for a node. If the IAM role has all the necessary permissions to access the data source, you can then view the schema on the **Output schema** tab for a node.

## Using data previews in the visual job editor

Data previews help you create and test your job using a sample of your data without having to repeatedly run the job. By using data preview, you can:

- Test an IAM role to make sure you have access to your data sources or data targets.
- Check that the transform is modifying the data in the intended way. For example, if you use a Filter transform, you can make sure that the filter is selecting the right subset of data.
- Check your data. If your dataset contains columns with values of multiple types, the data preview shows a list of tuples for these columns. Each tuple contains the data type and its value.

While creating or editing your job, you can use the **Data preview** tab beneath the job canvas to view a sample of your data. A new data preview session will start automatically when the role is already configured on the job or a default IAM role has been set up in the account. If a role has not been previously configured, you can start a session by selecting the role.

**Data preview** | **Output schema** 🔍 🔍

Start a data preview session

**IAM role**  
To start a data preview session, choose an IAM role for this job. Changing the role will end an existing data preview session.

Admin  
No description available. ▼

[Create IAM role.](#)

▶ **Additional Settings**

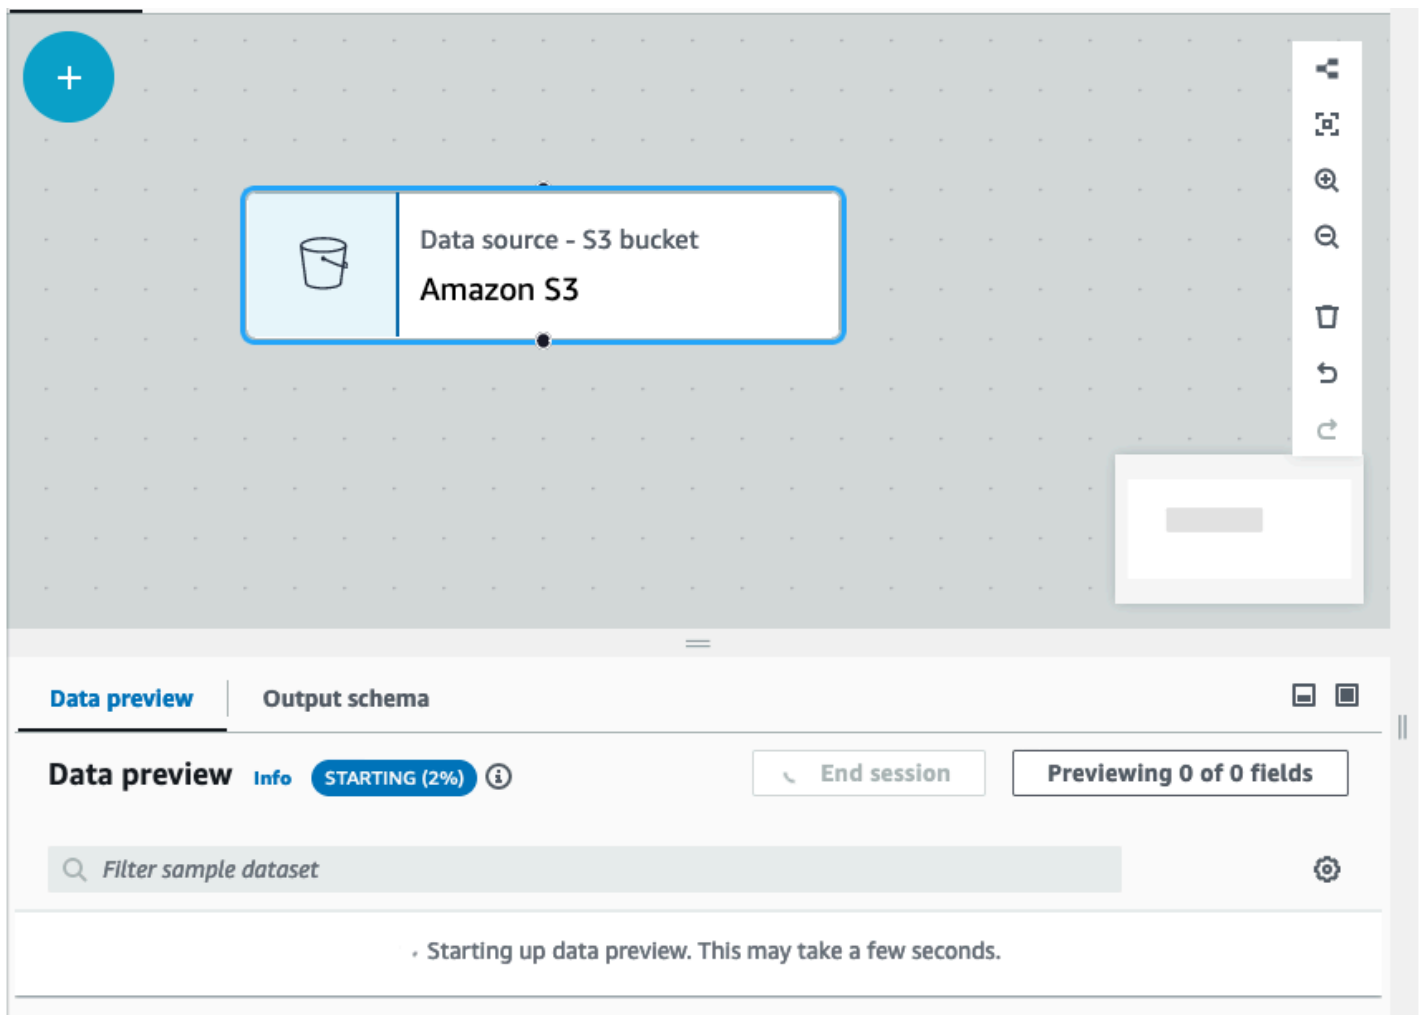

**Start session**

**Note**

The role you choose for the data preview session will also be used for the job.

You can see the status and the progress of your session as well as the session details by clicking the info icon.

When the session is ready, AWS Glue Studio will load the data for the node you selected. You can view the **% complete** as it progresses.

The screenshot displays the AWS Glue Studio interface. At the top, a blue circular button with a white plus sign is visible. Below it, a data source node is shown, labeled "Data source - S3 bucket" and "Amazon S3", with a bucket icon. A vertical toolbar on the right contains icons for undo, redo, search, and other actions. The bottom section of the interface is divided into two tabs: "Data preview" (selected) and "Output schema". The "Data preview" tab shows a status bar with "Data preview" in bold, an "Info" icon, a "STARTING (2%)" progress indicator, and an "End session" button. To the right, a button indicates "Previewing 0 of 0 fields". Below the status bar is a search input field labeled "Filter sample dataset" and a settings gear icon. At the bottom, a message states: "Starting up data preview. This may take a few seconds."

As you author your visual job, AWS Glue Studio will automatically update the schema for the selected node when you toggle **Infer schema from session** in the **Output schema** tab.

The screenshot displays the AWS Glue console interface. At the top, a job diagram shows a 'Transform - SQL Query' node highlighted with a blue border and a green checkmark. Below the diagram, the 'Output schema' tab is active, showing a table with three columns: 'firstname', 'lastname', and 'title', all of type 'string'. To the right, the configuration pane for the selected node is visible. It includes a dropdown for 'Choose one or more parent node', a list of input sources (Amazon S3), and a section for 'SQL aliases' with 'myDataSource' entered. The 'SQL query' section contains a text area with the following query:

```
1 select firstname, lastname, title from myDataSource
2
```

To configure your data preview preferences:

Choose the settings icon (a gear symbol) to configure your preferences for data previews. These settings apply to all nodes in the job diagram. You can:

- Choose to wrap the text from one line to the next. This option is enabled by default
- Change the number of rows (default to 200)
- Choose an IAM role or create an IAM role if needed
- Choose to automatically start a new session when you author a job. This provisions a new interactive session when authoring jobs. **This setting applies at the account level.** Once set, it will apply to all users in your account when editing any job.
- Choose to automatically infer schema. Output schemas will be automatically inferred for the selected node
- Choose to automatically import AWS Glue libraries. This is useful as it will prevent data preview from restarting new sessions when adding new transforms that require a session restart

## Preferences ✕

**Wrap lines**  
Enable to wrap lines of table cell content, disable to truncate text.

**Number of rows**  
Enter the amount of entries to sample from the dataset.

**IAM role**  
To start a data preview session, choose an IAM role for this job. Changing the role will end an existing data preview session.

Admin  
No description available. ▼

[Create IAM role.](#) 

**Automatically start data preview sessions**  
Data preview will automatically start new interactive sessions when entering the visual job editor enabling you to preview data more efficiently.  
**⚠ This setting applies to all users in your account.**

**Infer schema from session**  
Output schemas will be automatically inferred based on the result of the datapreview execution

**Automatically import glue libraries**  
Some ETL transform require extra libraries to be imported in the datapreview session, enabling this option will automatically import them to your sessions in order to prevent session from restarting during your job authoring. Note: the IAM role require read permission to Glue S3 bucket to prevent failures.

**Cancel** **Confirm**

Additional features include the ability to:

- Choose the **Previewing x of y fields** button to select which columns (fields) to preview. When you preview your data using the default settings, the job editor shows the first 5 columns of your dataset. You can change this to show all or none (not recommended).

- Scroll through the data preview window both horizontally and vertically.
- Use the maximize button to expand the Data preview tab to over-ly the job graph to better view the data and data structures. Similarly, use the minimize button to minimize the Data preview tab. You can also grab the handle pane and drag up to expand the **Data preview** tab.

The screenshot displays the AWS Glue console interface. At the top, there are navigation tabs: Visual, Script, Job details, Runs, Data quality New, Schedules, and Version Control. Below these is a job graph with a 'Data source - S3 bucket Amazon S3' node and a 'Data target - Snowflake' node. A red box highlights the 'Data preview' tab in the bottom right corner of the job graph area. Below the job graph, the 'Data preview' window is open, showing a table of venue data. The 'Data preview' tab is selected, and the 'Output schema' tab is also visible. The 'Data preview' window shows a table with columns: venueid, venue name, venue city, venue state, and venue seats. The table contains three rows of data. The 'Data preview' window also has a search bar, a 'Filter sample dataset' button, and a 'READY' status indicator. The 'End session' button is visible in the top right corner of the preview window.

venueid	venue name	venue city	venue state	venue seats
1	Toyota Park	Bridgeview	IL	0
2	Columbus Crew Stadium	Columbus	OH	0
3	RFK Stadium	Washington	DC	0

- Use **End session** to stop the data preview. When you stop the session, you can choose a new IAM role, and set additional settings (such as turn on or off settings to automatically start a new session, infer schema, or import AWS Glue libraries, and start the session again).

## Restrictions when using data previews

When using data previews, you might encounter the following restrictions or limitations.

- The first time you choose the Data preview tab you must choose IAM role. This role must have the necessary permissions to access the data and other resources needed to create the data previews.

- After you provide an IAM role, it takes a while before the data is available for viewing. For datasets with less than 1 GB of data, it can take up to one minute. If you have a large dataset, you should use partitions to improve the loading time. Loading data directly from Amazon S3 has the best performance.
- If you have a very large dataset, and it takes more than 15 minutes to query the data for the data preview, the request will time out. Data previews have a 30 minute IDLE timeout. To alleviate this, reduce the dataset size to use data previews.
- By default, you see the first 50 columns in the Data preview tab. If the columns have no data values, you will get a message that there is no data to display. You can increase the number of rows sampled, or selected different columns to see data values.
- Data previews are currently not supported for streaming data sources, or for data sources that use custom connectors.
- Errors on one node effect the entire job. If any one node has an error with data previews, the error will show up on all nodes until you correct it.
- If you change a data source for the job, then the child nodes of that data source might need to be updated to match the new schema. For example, if you have an ApplyMapping node that modifies a column, and the column does not exist in the replacement data source, you will need to update the ApplyMapping transform node.
- If you view the Data preview tab for a SQL query transform node, and the SQL query uses an incorrect field name, the Data preview tab shows an error.

## Script code generation

When you use the visual editor to create a job, the ETL code is automatically generated for you. AWS Glue Studio creates a functional and complete job script, and saves it in an Amazon S3 location.

There are two forms of code generated by AWS Glue Studio: the original, or Classic version, and a newer, streamlined version. By default, the new code generator is used to create the job script. You can generate a job script using classic code generator on the **Script** tab by choosing the **Generate classic script** toggle button.

Some of the differences in the new version of the generated code include:

- Large comment blocks are no longer added to the script

- Output structures in the code use the node name that you specify in the visual editor. In the class script, the output structures are simply named `DataSource0`, `DataSource1`, `Transform0`, `Transform1`, `DataSink0`, `DataSink1`, and so on.
- Long commands are split across multiple lines to remove the need to scroll across the page to see the entire command.

New features in AWS Glue Studio require the new version of code generation, and will not work with the classic code script. You are prompted to update these jobs when you attempt to run them.

## Editing AWS Glue managed data transform nodes

AWS Glue Studio provides two types of transforms:

- **AWS Glue-native transforms** - available to all users and are managed by AWS Glue.
- **Custom visual transforms** - allows you to upload your own transforms to use in AWS Glue Studio

## AWS Glue managed data transform nodes

AWS Glue Studio provides a set of built-in transforms that you can use to process your data. Your data passes from one node in the job diagram to another in a data structure called a `DynamicFrame`, which is an extension to an Apache Spark SQL `DataFrame`.

In the pre-populated diagram for a job, between the data source and data target nodes is the **Change Schema** transform node. You can configure this transform node to modify your data, or you can use additional transforms.

The following built-in transforms are available with AWS Glue Studio:

- **[ChangeSchema](#)**: Map data property keys in the data source to data property keys in the data target. You can rename keys, modify the data types for keys, and choose which keys to drop from the dataset.
- **[SelectFields](#)**: Choose the data property keys that you want to keep.
- **[DropFields](#)**: Choose the data property keys that you want to drop.
- **[RenameField](#)**: Rename a single data property key.
- **[Spigot](#)**: Write samples of the data to an Amazon S3 bucket.

- **[Join](#)**: Join two datasets into one dataset using a comparison phrase on the specified data property keys. You can use inner, outer, left, right, left semi, and left anti joins.
- **[Union](#)**: Combine rows from more than one data source that have the same schema.
- **[SplitFields](#)**: Split data property keys into two `DynamicFrames`. Output is a collection of `DynamicFrames`: one with selected data property keys, and one with the remaining data property keys.
- **[SelectFromCollection](#)**: Choose one `DynamicFrame` from a collection of `DynamicFrames`. The output is the selected `DynamicFrame`.
- **[FillMissingValues](#)**: Locate records in the dataset that have missing values and add a new field with a suggested value that is determined by imputation
- **[Filter](#)**: Split a dataset into two, based on a filter condition.
- **[Drop Null Fields](#)**: Removes columns from the dataset if all values in the column are 'null'.
- **[Drop Duplicates](#)**: Removes rows from your data source by choosing to match entire rows or specify keys.
- **[SQL](#)**: Enter SparkSQL code into a text entry field to use a SQL query to transform the data. The output is a single `DynamicFrame`.
- **[Aggregate](#)**: Performs a calculation (such as average, sum, min, max) on selected fields and rows, and creates a new field with the newly calculated value(s).
- **[Flatten](#)**: Extract fields inside structs into top level fields.
- **[UUID](#)**: Add a column with a Universally Unique Identifier for each row.
- **[Identifier](#)**: Add a column with a numeric identifier for each row.
- **[To timestamp](#)**: Convert a column to timestamp type.
- **[Format timestamp](#)**: Convert a timestamp column to a formatted string.
- **[Conditional Router transform](#)**: Apply multiple conditions to incoming data. Each row of the incoming data is evaluated by a group filter condition and processed into its corresponding group.
- **[Concatenate Columns transform](#)**: Build a new string column using the values of other columns with an optional spacer.
- **[Split String transform](#)**: Break up a string into an array of tokens using a regular expression to define how the split is done.
- **[Array To Columns transform](#)**: Extract some or all the elements of a column of type array into new columns.

- **[Add Current Timestamp transform](#)**: Mark the rows with the time on which the data was processed. This is useful for auditing purposes or to track latency in the data pipeline.
- **[Pivot Rows to Columns transform](#)**: Aggregate a numeric column by rotating unique values on selected columns which become new columns. If multiple columns are selected, the values are concatenated to name the new columns.
- **[Unpivot Columns To Rows transform](#)**: Convert columns into values of new columns generating a row for each unique value.
- **[Autobalance Processing transform](#)**: Redistribute the data better among the workers. This is useful where the data is unbalanced or as it comes from the source doesn't allow enough parallel processing on it.
- **[Derived Column transform](#)**: Define a new column based on a math formula or SQL expression in which you can use other columns in the data, as well as constants and literals.
- **[Lookup transform](#)**: Add columns from a defined catalog table when the keys match the defined lookup columns in the data.
- **[Explode Array or Map Into Rows transform](#)**: Extract values from a nested structure into individual rows that are easier to manipulate.
- **[Record matching transform](#)**: Invoke an existing Record Matching machine learning data classification transform.
- **[Remove null rows transform](#)**: Remove from the dataset rows that have all columns as null, or empty.
- **[Parse JSON column transform](#)**: Parse a string column containing JSON data and convert it to a struct or an array column, depending if the JSON is an object or an array, respectively.
- **[Extract JSON path transform](#)**: Extract new columns from a JSON string column.
- **[Extract string fragments from a regular expression](#)**: Extract string fragments using a regular expression and create new column out of it, or multiple columns if using regex groups.
- **[Custom transform](#)**: Enter code into a text entry field to use custom transforms. The output is a collection of `DynamicFrames`.

## Using a data preparation recipe in AWS Glue Studio

AWS Glue Studio allows you to use a AWS Glue DataBrew recipe in a visual workflow. This allows a customer's AWS Glue DataBrew recipes to be run in a AWS Glue job along with other AWS Glue Studio nodes.

In DataBrew, a recipe is a set of data transformation steps. DataBrew recipes prescribes how to transform data that have already been read and doesn't describe where and how to read data, as well as how and where to write data. This is configured in Source and Target nodes in AWS Glue Studio. For more information on recipes, see [Creating and using AWS Glue DataBrew recipes](#).

The **Data Preparation Recipe** node is available from the Resource panel. You can connect the **Data Preparation Recipe** node to another node in the visual workflow, whether it is a Data source node or another transformation node. After choosing a AWS Glue DataBrew recipe and version, the applied steps in the recipe are visible in the node properties tab.

### Prerequisites

- You have a AWS Glue DataBrew recipe created in AWS Glue DataBrew.
- You have the required IAM permissions as described in the section below.

### IAM permissions for AWS Glue DataBrew

This topic provides information to help you understand the actions and resources that you an IAM administrator can use in an AWS Identity and Access Management (IAM) policy for the Data Preparation Recipe transform.

For additional information about security in AWS Glue, see [Access Management](#).

The following table lists the permissions that a user needs in order to perform specific operations to use the Data Preparation Recipe transform.

### Data Preparation Recipe transform actions

Action	Description
<code>databrew:ListRecipes</code>	Grants permission to retrieve AWS Glue DataBrew recipes.
<code>databrew:ListRecipeVersions</code>	Grants permission to retrieve AWS Glue DataBrew recipe versions.
<code>databrew:DescribeRecipe</code>	Grants permission to retrieve AWS Glue DataBrew recipe description.

The role you're using for accessing this functionality should have a policy that allows several AWS Glue DataBrew. You can achieve this by either using `AWSGlueConsoleFullAccess` policy that includes necessary actions or add the following inline policy to your role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "databrew:ListRecipes",
        "databrew:ListRecipeVersions",
        "databrew:DescribeRecipe"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

To use the Data Preparation Recipe transform, you must add the `IAM:PassRole` action to the permissions policy.

### Additional required permissions

Action	Description
<code>iam:PassRole</code>	Grants permission for IAM to allow the user to pass the approved roles.

Without these permissions the following error occurs:

```
"errorCode": "AccessDenied"
"errorMessage": "User: arn:aws:sts::account_id:assumed-role/AWSGlueServiceRole is not
authorized to perform: iam:PassRole on resource: arn:aws:iam::account_id:role/service-
role/AWSGlueServiceRole
because no identity-based policy allows the iam:PassRole action"
```

## Limitations

- Not all AWS Glue DataBrew recipes are supported by AWS Glue. Some recipes will not be able to be run in AWS Glue Studio.
  - Recipes with UNION and JOIN transforms are not supported, however, AWS Glue Studio already has "Join" and "Union" transform nodes which can be used before or after a Data Preparation Recipe node instead.
- **Data Preparation Recipe** nodes are supported for jobs starting with AWS Glue version 4.0. This version will be auto-selected after a **Data Preparation Recipe** node is added to the job.
- **Data Preparation Recipe** nodes require Python. This is automatically set when the **Data Preparation Recipe** node is added to the job.
- When using **Data Preview**, you will need to restart your data preview session after adding a **Data Preparation Recipe** node to your job.

## How to use AWS Glue DataBrew recipes in AWS Glue Studio

To use AWS Glue DataBrew recipes in AWS Glue Studio, begin with creating recipes in AWS Glue DataBrew. If you have recipes you want to use, you can skip this step.

### To create a AWS Glue DataBrew recipe in AWS Glue DataBrew:

1. Author a recipe in AWS Glue DataBrew. For more information, see [Getting started with AWS Glue DataBrew](#).
2. Save your recipe.
3. Publish your recipe. This will publish your recipe as version 1.0.

### To use a Data Preparation Recipe node in AWS Glue Studio:

You can use more than one **Data Preparation Recipe** node in a visual ETL job. To do this, add a **Data Preparation Recipe** node by following the steps below and add another Data Preparation Recipe node to the job. For example, a workflow might follow this pattern:

- Data source 1 > recipe 1 > output 1
- Data source 2 > recipe 2 > output 2
- output 1, output 2 > JOIN

1. Start a AWS Glue job in AWS Glue Studio with a datasource.
2. Add the **Data Preparation Recipe** node to your datasource.
3. Filter for recipe by name by typing in the recipe name in the search field.
4. Choose the published version. Only published versions are available.
5. Finish authoring the job by adding other transformations nodes as needed and add Data target node(s) to save the job output.
6. Make necessary configuration changes in the **Job details** tab, like naming your job and adjusting allocated capacity as needed, and save the job.
7. Run the job by choosing **Run** from the **Actions** drop-down menu.

### To change schema if the data source is Amazon S3 and the data format is CSV:

If all the columns in a CSV file are initially loaded as string data type in AWS Glue Studio, you need to ensure that the column data type is compatible with the rest of the steps in the AWS Glue DataBrew recipe.

AWS Glue DataBrew recipes only prescribes how to transform data that have already been read. It doesn't describe where and how to read data.

1. Add a **Change Schema** node before the **Multi-step** recipe node.
2. Click the **Change Schema** node and change the schema to be the same as the column data types in AWS Glue DataBrew by selecting the new data type in the Transform for columns as needed.

**Transform**

### To change schema if the data source is headerless:

AWS Glue DataBrew recipes only prescribes how to transform data that have already been read. It doesn't describe where and how to read data.

When loading header-less datasets in AWS Glue Studio, the default header names are different than what are loaded in AWS Glue DataBrew.

1. In the ETL job, add a **Change Schema** node before the **Data Preparation Recipe** node.
2. Choose the **Change Schema** node and change the column names to the same names used in the AWS Glue DataBrew recipe.

## Using Change Schema to remap data property keys

A *Change Schema* transform remaps the source data property keys into the desired configured for the target data. In a Change Schema transform node, you can:

- Change the name of multiple data property keys.
- Change the data type of the data property keys, if the new data type is supported and there is a transformation path between the two data types.
- Choose a subset of data property keys by indicating which data property keys you want to drop.

You can add additional *Change Schema* nodes to the job diagram as needed – for example, to modify additional data sources or following a *Join* transform.

### Note

The *Change Schema* transform is not case-sensitive.

## To add a Change Schema transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Change Schema** to add a new transform to your job diagram, if needed.
2. In the node properties panel, enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node properties panel.
4. Modify the input schema:
  - To rename a data property key, enter the new name of the key in the **Target key** field.
  - To change the data type for a data property key, choose the new data type for the key from the **Data type** list.

- To remove a data property key from the target schema, choose the **Drop** check box for that key.
- (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
  - (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Using Drop Duplicates

The Drop Duplicates transform removes rows from your data source by giving you two options. You can choose to remove the duplicate row that are completely the same, or you can choose to choose the fields to match and remove only those rows based on your chosen fields.

For example, in this data set, you have duplicate rows where all the values in some of the rows are exactly the same as another row, and some of the values in rows are the same or different.

Row	Name	Email	Age	State	Note
1	Joy	joy@gmail	33	NY	
2	Tim	tim@gmail	45	OH	
3	Rose	rose@gmail	23	NJ	
4	Tim	tim@gmail	42	OH	
5	Rose	rose@gmail	23	NJ	
6	Tim	tim@gmail	42	OH	this is a duplicate row and matches completely

Row	Name	Email	Age	State	Note
					on all values as row #4
7	Rose	rose@gmail	23	NJ	This is a duplicate row and matches completely on all values as row #5

If you choose to match entire rows, rows 6 and 7 will be removed from the data set. The data set is now:

Row	Name	Email	Age	State
1	Joy	joy@gmail	33	NY
2	Tim	tim@gmail	45	OH
3	Rose	rose@gmail	23	NJ
4	Tim	tim@gmail	42	OH
5	Rose	rose@gmail	23	NJ

If you chose to specify keys, you can choose to remove rows that match on 'name' and 'email'. This gives you finer control of what is a 'duplicate row' for your data set. By specifying 'name' and 'email', the data set is now:

Row	Name	Email	Age	State
1	Joy	joy@gmail	33	NY
2	Tim	tim@gmail	45	OH
3	Rose	rose@gmail	23	NJ

Some things to keep in mind:

- In order for rows to be recognized as a duplicate, values are case sensitive. All values in rows need to have the same casing - this applies to either option you choose (Match entire rows or Specify keys).
- All values are read in as strings.
- The **Drop Duplicates** transform utilizes the Spark `dropDuplicates` command.
- When using the **Drop Duplicates** transform, the first row is kept and other rows are dropped.
- The **Drop Duplicates** transform does not change the schema of the dataframe. If you choose to specify keys, all fields are kept in the resulting dataframe.

## Using SelectFields to remove most data property keys

You can create a subset of data property keys from the dataset using the *SelectFields* transform. You indicate which data property keys you want to keep and the rest are removed from the dataset.

### Note

The *SelectFields* transform is case sensitive. Use *ApplyMapping* if you need a case-insensitive way to select fields.

## To add a SelectFields transform node to your job diagram

1. (Optional) Open the Resource panel, and then choose **SelectFields** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node details panel.
4. Under the heading **SelectFields**, choose the data property keys in the dataset that you want to keep. Any data property keys not selected are dropped from the dataset.

You can also choose the check box next to the column heading **Field** to automatically choose all the data property keys in the dataset. Then you can deselect individual data property keys to remove them from the dataset.

5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Using DropFields to keep most data property keys

You can create a subset of data property keys from the dataset using the *DropFields* transform. You indicate which data property keys you want to remove from the dataset and the rest of the keys are retained.

### Note

The *DropFields* transform is case sensitive. Use *Change Schema* if you need a case-insensitive way to select fields.

## To add a DropFields transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **DropFields** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node details panel.
4. Under the heading **DropFields**, choose the data property keys to drop from the data source.

You can also choose the check box next to the column heading **Field** to automatically choose all the data property keys in the dataset. Then you can deselect individual data property keys so they are retained in the dataset.

5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Renaming a field in the dataset

You can use the *RenameField* transform to change the name for an individual property key in the dataset.

### Note

The *RenameField* transform is case sensitive. Use *ApplyMapping* if you need a case-insensitive transform.

### Tip

If you use the *Change Schema* transform, you can rename multiple data property keys in the dataset with a single transform.

## To add a *RenameField* transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **RenameField** to add a new transform to your job diagram, if needed.

2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Under the heading **Data field**, choose a property key from the source data and then enter a new name in the **New field name** field.
5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Using Spigot to sample your dataset

To test the transformations performed by your job, you might want to get a sample of the data to check that the transformation works as intended. The *Spigot* transform writes a subset of records from the dataset to a JSON file in an Amazon S3 bucket. The data sampling method can be either a specific number of records from the beginning of the file or a probability factor used to pick records.

### To add a Spigot transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Spigot** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab in the node details panel.
4. Enter an Amazon S3 path or choose **Browse S3** to choose a location in Amazon S3. This is the location where the job writes the JSON file that contains the data sample.

5. Enter information for the sampling method. You can specify a value for **Number of records** to write starting from the beginning of the dataset and a **Probability threshold** (entered as a decimal value with a maximum value of 1) of picking any given record.

For example, to write the first 50 records from the dataset, you would set **Number of records** to 50 and **Probability threshold** to 1 (100%).

## Joining datasets

The *Join* transform allows you to combine two datasets into one. You specify the key names in the schema of each dataset to compare. The output `DynamicFrame` contains rows where keys meet the join condition. The rows in each dataset that meet the join condition are combined into a single row in the output `DynamicFrame` that contains all the columns found in either dataset.

### To add a Join transform node to your job diagram

1. If there is only one data source available, you must add a new data source node to the job diagram.
2. Choose one of the source nodes for the join. Open the Resource panel and then choose **Join** to add a new transform to your job diagram.
3. On the **Node properties** tab, enter a name for the node in the job diagram.
4. In the **Node properties** tab, under the heading **Node parents**, add a parent node so that there are two datasets providing inputs for the join. The parent can be a data source node or a transform node.

#### Note

A join can have only two parent nodes.

5. Choose the **Transform** tab.

If you see a message indicating that there are conflicting key names, you can either:

- Choose **Resolve it** to automatically add an *ApplyMapping* transform node to your job diagram. The *ApplyMapping* node adds a prefix to any keys in the dataset that have the same name as a key in the other dataset. For example, if you use the default value of **right**, then any keys in the right dataset that have the same name as a key in the left dataset will be renamed to `(right)key name`.

- Manually add a transform node earlier in the job diagram to remove or rename the conflicting keys.
6. Choose the type of join in the **Join type** list.
    - **Inner join:** Returns a row with columns from both datasets for every match based on the join condition. Rows that don't satisfy the join condition aren't returned.
    - **Left join:** All rows from the left dataset and only the rows from the right dataset that satisfy the join condition.
    - **Right join:** All rows from the right dataset and only the rows from the left dataset that satisfy the join condition.
    - **Outer join:** All rows from both datasets.
    - **Left semi join:** All rows from the left dataset that have a match in the right dataset based on the join condition.
    - **Left anti join:** All rows in the left dataset that don't have a match in the right dataset based on join condition.
  7. On the **Transform** tab, under the heading **Join conditions**, choose **Add condition**. Choose a property key from each dataset to compare. Property keys on the left side of the comparison operator are referred to as the left dataset and property keys on the right are referred to as the right dataset.

For more complex join conditions, you can add additional matching keys by choosing **Add condition** more than once. If you accidentally add a condition, you can choose the delete icon (  ) to remove it.

8. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
9. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

For an example of the join output schema, consider a join between two datasets with the following property keys:

```
Left: {id, dept, hire_date, salary, employment_status}
Right: {id, first_name, last_name, hire_date, title}
```

The join is configured to match on the `id` and `hire_date` keys using the `=` comparison operator.

Because both datasets contain `id` and `hire_date` keys, you chose **Resolve it** to automatically add the prefix **right** to the keys in the right dataset.

The keys in the output schema would be:

```
{id, dept, hire_date, salary, employment_status,
(right)id, first_name, last_name, (right)hire_date, title}
```

## Using Union to combine rows

You use the Union transform node when you want to combine rows from more than one data source that have the same schema.

There are two types of Union transformations:

1. ALL – when applying ALL, the resulting union does not remove duplicate rows.
2. DISTINCT – when applying DISTINCT, the resulting union removes duplicate rows.

## Unions vs. Joins

You use Union to combine rows. You use Join to combine columns.

## Using the Union transform in the Visual ETL canvas

1. Add more than one data source to perform a union transform. To add a data source, open the Resource Panel, then choose the data source from the Sources tab. Before using the Union transformation, you must ensure that all data sources involved in the union have the same schema and structure.
2. When you have at least two data sources that you want to combine using the Union transform, create the Union transform by adding it to the canvas. Open the Resource Panel on the canvas and search for 'Union'. You can also choose the Transforms tab in the Resource Panel and scroll down until you find the Union transform, then choose **Union**.

3. Select the Union node on the job canvas. In the Node properties window, choose the parent nodes to connect to the Union transform.
4. AWS Glue checks for compatibility to make sure that the Union transform can be applied to all data sources. If the schema for the data sources are the same, the operation will be allowed. If the data sources do not have the same schema, an invalid error message is displayed: "The input schemas of this union are not the same. Consider using ApplyMapping to match the schemas." To fix this, choose Use **ApplyMapping**.
5. Choose the Union type.
  1. All – By default, the All Union type is selected; this will result in duplicate rows if there are any in the data combination.
  2. Distinct – Choose Distinct if you want duplicate rows to be removed from the resulting data combination.

## Using SplitFields to split a dataset into two

The *SplitFields* transform allows you to choose some of the data property keys in the input dataset and put them into one dataset and the unselected keys into a separate dataset. The output from this transform is a collection of `DynamicFrames`.

### Note

You must use a *SelectFromCollection* transform to convert the collection of `DynamicFrames` into a single `DynamicFrame` before you can send the output to a target location.

The *SplitFields* transform is case sensitive. Add an *ApplyMapping* transform as a parent node if you need case-insensitive property key names.

### To add a SplitFields transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **SplitFields** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.

3. Choose the **Transform** tab.
4. Choose which property keys you want to put into the first dataset. The keys that you do not choose are placed in the second dataset.
5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.
7. Configure a *SelectFromCollection* transform node to process the resulting datasets.

## Overview of *SelectFromCollection* transform

Certain transforms have multiple datasets as their output instead of a single dataset, for example, *SplitFields*. The *SelectFromCollection* transform selects one dataset (`DynamicFrame`) from a collection of datasets (an array of `DynamicFrames`). The output for the transform is the selected `DynamicFrame`.

You must use this transform after you use a transform that creates a collection of `DynamicFrames`, such as:

- Custom code transforms
- *SplitFields*

If you don't add a *SelectFromCollection* transform node to your job diagram after any of these transforms, you will get an error for your job.

The parent node for this transform must be a node that returns a collection of `DynamicFrames`. If you choose a parent for this transform node that returns a single `DynamicFrame`, such as a *Join* transform, your job returns an error.

Similarly, if you use a *SelectFromCollection* node in your job diagram as the parent for a transform that expects a single `DynamicFrame` as input, your job returns an error.

**Node parents**

Select which node(s) will provide inputs for this one

Split Fields ×  
 SplitFields - Transform

⚠ Parent node **Split Fields** outputs a collection, but node **Drop Fields** does not accept a collection.

## Using `SelectFromCollection` to choose which dataset to keep

Use the `SelectFromCollection` transform to convert a collection of `DynamicFrames` into a single `DynamicFrame`.

### To add a `SelectFromCollection` transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **SelectFromCollection** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Under the heading **Frame index**, choose the array index number that corresponds to the `DynamicFrame` you want to select from the collection of `DynamicFrames`.

For example, if the parent node for this transform is a `SplitFields` transform, on the **Output schema** tab of that node you can see the schema for each `DynamicFrame`. If you want to keep the `DynamicFrame` associated with the schema for **Output 2**, you would select **1** for the value of **Frame index**, which is the second value in the list.

Only the `DynamicFrame` that you choose is included in the output.

5. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
6. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to

access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Find and fill missing values in a dataset

You can use the *FillMissingValues* transform to locate records in the dataset that have missing values and add a new field with a value determined by imputation. The input data set is used to train the machine learning (ML) model that determines what the missing value should be. If you use incremental data sets, then each incremental set is used as the training data for the ML model, so the results might not be as accurate.

### To use a *FillMissingValues* transform node in your job diagram

1. (Optional) Open the Resource panel and then choose **FillMissingValues** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. For **Data field**, choose the column or field name from the source data that you want to analyze for missing values.
5. (Optional) In the **New field name** field, enter a name for the field added to each record that will hold the estimated replacement value for the analyzed field. If the analyzed field doesn't have a missing value, the value in the analyzed field is copied into the new field.

If you don't specify a name for the new field, the default name is the name of the analyzed column with `_filled` appended. For example, if you enter **Age** for **Data field** and don't specify a value for **New field name**, a new field named **Age\_filled** is added to each record.

6. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
7. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to

access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Filtering keys within a dataset

Use the *Filter* transform to create a new dataset by filtering records from the input dataset based on a regular expression. Rows that don't satisfy the filter condition are removed from the output.

- For string data types, you can filter rows where the key value matches a specified string.
- For numeric data types, you can filter rows by comparing the key value to a specified value using the comparison operators `<`, `>`, `=`, `!=`, `<=`, and `>=`.

If you specify multiple filter conditions, the results are combined using an AND operator by default, but you can choose OR instead.

The *Filter* transform is case sensitive. Add an *ApplyMapping* transform as a parent node if you need case-insensitive property key names.

### To add a Filter transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Filter** to add a new transform to your job diagram, if needed.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent isn't already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. Choose the **Transform** tab.
4. Choose either **Global AND** or **Global OR**. This determines how multiple filter conditions are combined. All conditions are combined using either AND or OR operations. If you have only a single filter conditions, then you can choose either one.
5. Choose the **Add condition** button in the **Filter condition** section to add a filter condition.

In the **Key** field, choose a property key name from the dataset. In the **Operation** field, choose the comparison operator. In the **Value** field, enter the comparison value. Here are some examples of filter conditions:

- `year >= 2018`
- `State matches 'CA*'`

When you filter on string values, make sure that the comparison value uses a regular expression format that matches the script language selected in the job properties (Python or Scala).

6. Add additional filter conditions, as needed.
7. (Optional) After configuring the transform node properties, you can view the modified schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.
8. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Using DropNullFields to remove fields with null values

Use the *DropNullFields* transform to remove fields from the dataset if all values in the field are 'null'. By default, AWS Glue Studio will recognize null objects, but some values such as empty strings, strings that are "null", -1 integers or other placeholders such as zeros, are not automatically recognized as nulls.

### To use the DropNullFields

1. Add a DropNullFields node to the job diagram.
2. On the **Node properties** tab, choose additional values that represent a null value. You can choose to select none or all of the values:

Node properties
Transform
Output schema
Data preview
✕

**DropNullFields** Info

Remove fields or columns where all the values are the null objects.

Choose additional values that represent a null value below.

Empty String (" " or "")

"null" String

-1 Integer

**Add custom null values**

Specify custom null values by entering the value and choosing the datatype.

String
▼

✕

Add new value

- Empty String (" " or "") - fields that contain empty strings will be removed
  - "null string" - fields that contain the string with the word 'null' will be removed
  - -1 integer - fields that contain a -1 (negative one) integer will be removed
3. If needed, you can also specify custom null values. These are null values that may be unique to your dataset. To add a custom null value, choose **Add new value**.
  4. Enter the custom null value. For example, this can zero, or any value that is being used to represent a null in the dataset.
  5. Choose the data type in the drop-down field. Data types can either be String or Integer.

i **Note**

Custom null values and their data types must match exactly in order for the fields to be recognized as null values and the fields removed. Partial matches where only the custom null value matches but the data type does not will not result in the fields being removed.

## Using a SQL query to transform data

You can use a **SQL** transform to write your own transform in the form of a SQL query.

A SQL transform node can have multiple datasets as inputs, but produces only a single dataset as output. It contains a text field, where you enter the Apache SparkSQL query. You can assign aliases to each dataset used as input, to help simplify the SQL query. For more information about the SQL syntax, see the [Spark SQL documentation](#).

### Note

If you use a Spark SQL transform with a data source located in a VPC, add an AWS Glue VPC endpoint to the VPC that contains the data source. For more information about configuring development endpoints, see [Adding a Development Endpoint](#), [Setting Up Your Environment for Development Endpoints](#), and [Accessing Your Development Endpoint](#) in the *AWS Glue Developer Guide*.

### To use a SQL transform node in your job diagram

1. (Optional) Add a transform node to the job diagram, if needed. Choose **Spark SQL** for the node type.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, or if you want multiple inputs for the SQL transform, choose a node from the **Node parents** list to use as the input source for the transform. Add additional parent nodes as needed.
3. Choose the **Transform** tab in the node details panel.
4. The source datasets for the SQL query are identified by the names you specified in the **Name** field for each node. If you do not want to use these names, or if the names are not suitable for a SQL query, you can associate a name to each dataset. The console provides default aliases, such as MyDataSource.

The screenshot displays the AWS Glue console interface. At the top, there are tabs for 'Visual', 'Script', 'Job details', 'Runs', and 'Schedules'. Below these are icons for 'Source', 'Transform', 'Target', 'Undo', 'Redo', and 'Remove'. The main workspace shows a workflow with three nodes connected by arrows: a 'Data source - S3 bucket' node with the text 'This is a really long n...', a 'Transform - SQL Code' node with the text 'SQL query', and a 'Data target - S3 bucket' node with the text 'Revised flight data'. On the right, the 'Node properties' pane is open to the 'Transform' tab. It includes an 'Associate an alias with each input source' section with an 'Info' link and a note: 'Enter valid SQL table names to associate with DynamicFrames.' Below this are 'Input sources' and 'Spark SQL aliases' fields. The 'Input sources' field contains 'This is a really long name' and the 'Spark SQL aliases' field contains 'myDataSource'. The 'Code block' section has a note: 'Enter SQL code to add to your job.' and contains a code editor with the following SQL query:

```
1 select * from myDataSource
2
```

For example, if a parent node for the SQL transform node is named `Rename Org PK field`, you might associate the name `org_table` with this dataset. This alias can then be used in the SQL query in place of the node name.

5. In the text entry field under the heading **Code block**, paste or enter the SQL query. The text field displays SQL syntax highlighting and keyword suggestions.
6. With the SQL transform node selected, choose the **Output schema** tab, and then choose **Edit**. Provide the columns and data types that describe the output fields of the SQL query.

Specify the schema using the following actions in the **Output schema** section of the page:

- To rename a column, place the cursor in the **Key** text box for the column (also referred to as a *field* or *property key*) and enter the new name.
- To change the data type for a column, select the new data type for the column from the drop-down list.
- To add a new top-level column to the schema, choose the Overflow ( ... ) button, and then choose **Add root key**. New columns are added at the top of the schema.
- To remove a column from the schema, choose the delete icon ( ☒ ) to the far right of the Key name.

7. When you finish specifying the output schema, choose **Apply** to save your changes and exit the schema editor. If you do not want to save your changes, choose **Cancel** to edit the schema editor.
8. (Optional) After configuring the node properties and transform properties, you can preview the modified dataset by choosing the **Data preview** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. There is a cost associated with using this feature, and billing starts as soon as you provide an IAM role.

## Using Aggregate to perform summary calculations on selected fields

### To use the Aggregate transform

1. Add the Aggregate node to the job diagram.
2. On the **Node properties** tab, choose fields to group together by selecting the drop-down field (optional). You can select more than one field at a time or search for a field name by typing in the search bar.

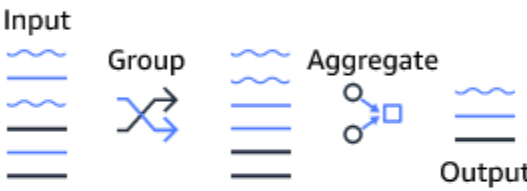

When fields are selected, the name and datatype are shown. To remove a field, choose 'X' on the field.

Node properties | **Transform** 1 | Output schema | 

Data preview

▼ **Aggregate** [Info](#)

This transform first groups your rows by fields you choose, and then computes the aggregated value for fields you choose by specific function (e.g., sum, average, max).

#### Fields to group by - *optional*

Select the fields you would like to group your rows by, so the aggregation would be done for each unique group.

Choose one or more fields ▼

**Aggregate another column**

 Add an aggregation.

3. Choose **Aggregate another column**. It is required to select at least one field.

Field to aggregate      Aggregation function [Info](#)

Choose a field ▼      Choose a function ▼      

**Aggregate another column**

4. Choose a field in the **Field to aggregate** drop-down.
5. Choose the aggregation function to apply to the chosen field:

- avg - calculates the average
- countDistinct - calculates the number of unique non-null values
- count - calculates the number of non-null values
- first - returns the first value that satisfies the 'group by' criteria
- last - returns the last value that satisfies the 'group by' criteria
- kurtosis - calculates the the sharpness of the peak of a frequency-distribution curve
- max - returns the highest value that satisfies the 'group by' criteria
- min - returns the lowest value that satisfies the 'group by' criteria
- skewness - measure of the asymmetry of the probability distribution of a normal distribution
- stddev\_pop - calculates the population standard deviation and returns the square root of the population variance
- sum - the sum of all values in the group
- sumDistinct - the sum of distinct values in the group
- var\_samp - the sample variance of the group (ignores nulls)
- var\_pop - the population variance of the group (ignores nulls)

## Flatten nested structs

*Flatten* the fields of nested structs in the data, so they become top level fields. The new fields are named using the field name prefixed with the names of the struct fields to reach it, separated by dots.

For example, if the data has a field of type Struct named “phone\_numbers”, which among other fields has one of type “Struct” named “home\_phone” with two fields: “country\_code” and “number”. Once flattened, these two fields will become top level fields named: “phone\_numbers.home\_phone.country\_code” and “phone\_numbers.home\_phone.number” respectively.

### To add a *Flatten* transform node in your job diagram

1. Open the Resource panel and then choose the **Transforms** tab, then **Flatten** to add a new transform to your job diagram. You can also use the search bar by entering 'Flatten', then clicking the Flatten node. The node selected at the time of adding the node will be its parent.

The screenshot shows the AWS Glue console interface for an 'Untitled job'. At the top, there are tabs for 'Visual', 'Script', 'Job details', 'Runs', 'Data quality New', 'Schedules', and 'Version Control'. A '+ Add nodes' panel is open, displaying a search bar with 'flatten' and a list of nodes. The 'Flatten' node is highlighted, with a description: 'Flatten struct fields into top level fields'. Below the list, there are options for 'Amazon S3', 'Amazon Kinesis', 'Apache Kafka', and 'Relational DB'. A 'Data preview' section at the bottom contains a message: 'To see a transformed sample of your data at each node, start a data preview session. Data previews use 2 DPU. Choose "End session" or navigate away from the job to end billing for the session. [Learn more](#)'. A 'Start data preview session' button is also visible.

2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can limit the maximum nesting level to flatten. For instance, setting that value to 1 means that only top-level structs will be flattened. Setting the max to 2 will flatten the top level and the structs directly under it.

## Add a UUID column

When you add a *UUID* (Universally Unique Identified) column, each row will be assigned a unique 36-character string.

### To add a *UUID* transform node in your job diagram

1. Open the Resource panel and then choose **UUID** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.

2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can customize the name of the new column. By default it will be named "uuid".

## Add an identifier column

Assign a numeric *Identifier* for each row in the dataset.

### To add an *Identifier* transform node in your job diagram

1. Open the Resource panel and then choose **Identifier** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can customize the name of the new column. By default, it will be named "id".
4. (Optional) If the job processes and stores data incrementally, you want to avoid the same ids to be reused between job runs.

On the **Transform** tab, mark the **unique** checkbox option. It will include the job timestamp in the identifier, making it unique between multiple runs. To allow for the larger number, the column instead of type long will be a decimal.

## Convert a column to timestamp type

You can use the transform *To timestamp* to change the data type of a numeric or string column into timestamp, so that it can be stored with that data type or applied to other transforms that require a timestamp.

### To add a *To timestamp* transform node in your job diagram

1. Open the Resource panel and then choose **To timestamp** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.

2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, enter the name of the column to be converted.
4. On the **Transform** tab, define how to parse the column selected by choosing the type.

If the value is a number, it can be expressed in seconds (Unix/Python timestamp), milliseconds or microseconds, choose the corresponding option.

If the value is a formatted string, choose the "iso" type, the string needs to conform to one of the variants of the ISO format, for example: "2022-11-02T14:40:59.915Z".

If you don't know the type at this point or different rows use different types, then you can choose "autodetect" and the system will make its best guess, with a small performance cost.

5. (Optional) On the **Transform** tab, instead of converting the selected column, you can create a new one and keep the original by entering a name for the new column.

## Convert a timestamp column to a formatted string

Format a timestamp column into a string based on a pattern. You can use *Format timestamp* to get date and time as a string with the desired format. You can define the format using [Spark date syntax](#) as well as most of the [Python date codes](#).

For example, if you want your date string to be formatted like "2023-01-01 00:00", you can define such format using the Spark syntax as "yyyy-MM-dd HH:mm" or the equivalent Python date codes as "%Y-%m-%d %H:%M"

### To add a *Format timestamp* transform node in your job diagram

1. Open the Resource panel and then choose **Format timestamp** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, enter the name of the column to be converted.
4. On the **Transform** tab, enter the **Timestamp format** pattern to use, expressed using [Spark date syntax](#) or [Python date codes](#).

5. (Optional) On the **Transform** tab, instead of converting the selected column, you can create a new one and keep the original by entering a name for the new column.

## Creating a Conditional Router transformation

The Conditional Router transform allows you to apply multiple conditions to incoming data. Each row of the incoming data is evaluated by a group filter condition and processed into its corresponding group. If a row meets more than one group filter condition, the transform passes the row to multiple groups. If a row does not meet any condition, it can either be dropped or routed to a default output group.

This transform is similar to the filter transform, but useful for users who want to test the same input data on multiple conditions.

### To add a Conditional Router transform:

1. Choose a node where you will perform the conditional router transformation. This can be a source node or another transform.
2. Choose **Action**, then use the search bar to find and choose 'Conditional Router'. A **Conditional Router** transform is added along with two output nodes. One output node, 'Default group', contains records which do not meet any of the conditions defined in the other output node(s). The default group cannot be edited.

You can add additional output groups by choosing **Add group**. For each output group, you can name the group and add filter conditions and a logical operator.

Node properties | **Transform** | Output schema | Data preview ✕

Add group

### output\_group\_1

Remove group

Define a set of conditions a record has to meet in order to be routed to the output group.

**Group name**  
The name of this output group, as it would appear in your job. Letters, numbers, \_ and - are allowed.

**Logical operator**

**AND**  
Trigger only when ALL conditions are met.

**OR**  
Trigger when at least one of the conditions is met.

**Filter condition** [Info](#)  
Specify your filter condition by choosing the key, operator, and entering a value.

Start by adding a filter condition.

Add condition

### Default group

Records which do not meet any of the conditions defined above will be routed here.

3. Rename the output group name by entering a new name for the group. AWS Glue Studio will automatically name your groups for you (for example, 'output\_group\_1').
4. Choose a logical operator (**AND**, **OR**) and add a **Filter condition** by specifying the **Key**, **Operation**, and **Value**. Logical operators allow you to implement more than one filter condition and perform the logical operator on each filter condition you specify.

When specifying the key, you can choose from available keys in your schema. You can then choose the available operation depending on the type of key you selected. For example, if the key type is 'string', then the available operation to choose from is 'matches'.

### Filter condition Info

Specify your filter condition by choosing the key, operator, and entering a value.

Key	Operation	Value	
year ▼	= ▼	2023	
<b>Add condition</b>			

- Enter the value in the **Value** field. To add additional filter conditions, choose **Add condition**. To remove filter conditions, choose the trash can icon.

## Using the Concatenate Columns transform to append columns

The Concatenate transform allows you to build a new string column using the values of other columns with an optional spacer. For example, if we define a concatenated column “date” as the concatenation of “year”, “month” and “day” (in that order) with “-” as the spacer, we would get:

day	month	year	date
01	01	2020	2020-01-01
02	01	2020	2020-01-02
03	01	2020	2020-01-03
04	01	2020	2020-01-04

### To add a Concatenate transform:

- Open the Resource panel. Then choose **Concatenate Columns** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
- (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.

3. On the **Transform** tab, enter the name of the column that will hold the concatenated string as well as the columns to concatenate. The order in which you check the columns in the dropdown will be the order used.

Node properties
Transform
Output schema
Data preview
✕

Name of the concatenated column  
Name of the string column that will be generated

List of column named separated by comma or spaces  
The fields listed will be concatenated on that order

Array new column Name - *optional*  
String to place between the concatenated fields, by default there is no spacer.

Null value - *optional*  
The string to use when a column value is null, for example: 'NULL' or 'NA', by default an empty string will be used

4. **Spacer - optional** – Enter a string to place between the concatenated fields. By default, there is no spacer.
5. **Null value - optional** – Enter a string to use when a column value is null. By default, in the cases where columns have the value 'NULL' or 'NA', an empty string is used.

## Using the Split String transform to break up a string column

The Split String transform allows you to break up a string into an array of tokens using a regular expression to define how the split is done. You can then keep the column as an array type or apply an **Array To Columns** transform after this one, to extract the array values onto top level fields, assuming that each token has a meaning we know beforehand. Also, if the order of the tokens is irrelevant (for instance, a set of categories), you can use the **Explode** transform to generate a separate row for each value.

For example, you can split a the column “categories” using a comma as a pattern to add a column “categories\_arr”.

product_id	categories	categories_arr
1	sports,winter	[sports, winter]
2	garden,tools	[garden, tools]
3	videogames	[videogames]
4	game,boardgame,social	[game, boardgame, social]

### To add a Split String transform:

1. Open the Resource panel and then choose Split String to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the Node properties tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the column to split and enter the pattern to use to split the string. In most cases you can just enter the character(s) unless it has a special meaning as a regular expression and needs to be escaped. The characters that need escaping are: \ . [ ] { } ( ) < > \* + - = ! ? ^ \$ | by adding a backslash in front of the character. For instance if you want to separate by a dot ('.') you need to enter \. However, a comma doesn't have a special meaning and can just be specified as is: , .

Node properties
Transform
Output schema
Data preview

**Column to split**  
Column whose string will be split into an string array

**Splitting regular expression**  
Regex defining the separator token, examples: ';', '\|' (pipe needs to be escaped) or '\s+' (whitespace split)

**Array column Name - *optional***  
Name to use for the column with the extracted array resulting of the split. If not specified, instead of a new column the existing one is replaced

4. (Optional) If you want to keep the original string column, then you can enter a name for a new array column, this way keeping both the original string column and the new tokenized array column.

## Using the Array To Columns transform to extract the elements of an array into top level columns

The Array To Columns transform allows you extract some or all the elements of a column of type array into new columns. The transform will fill the new columns as much as possible if the array has enough values to extract, optionally taking the elements in the positions specified.

For instance, if you have an array column “subnet”, which was the result of applying the “Split String” transform on a ip v4 subnet, you can extract the first and forth positions into new columns “first\_octect” and “forth\_octect”. The output of the transform in this example would be (notice the last two rows have shorter arrays than expected):

subnet	first_octect	fourth_octect
[54, 240, 197, 238]	54	238
[192, 168, 0, 1]	192	1

subnet	first_octect	fourth_octect
[192, 168]	192	
[]		

### To add a Array To Columns transform:

1. Open the Resource panel and then choose **Array To Columns** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the array column to extract and enter the list of new columns for the tokens extracted.

Node properties
Transform
Output schema
Data preview

**Array type column**

Column of type array from which the new columns are extracted

**Output columns**

The names (separated by commas) of the columns to create out of the array fields. The data type will be the same as the array. For each row, the transform will try to fill them as much as possible using the array elements, the rest will be NULL

**Array indexes to use - optional**

List of array positions (starting from 1 and separated by commas), indicating which columns to take to fill the columns. Only need to set this if you want to skip some positions of the array

4. (Optional) If you don't want to take the array tokens in order to assign to columns, you can specify the indexes to take which will be assigned to the list of columns in the same order specified. For instance if the output columns are "column1, column2, column3" and the

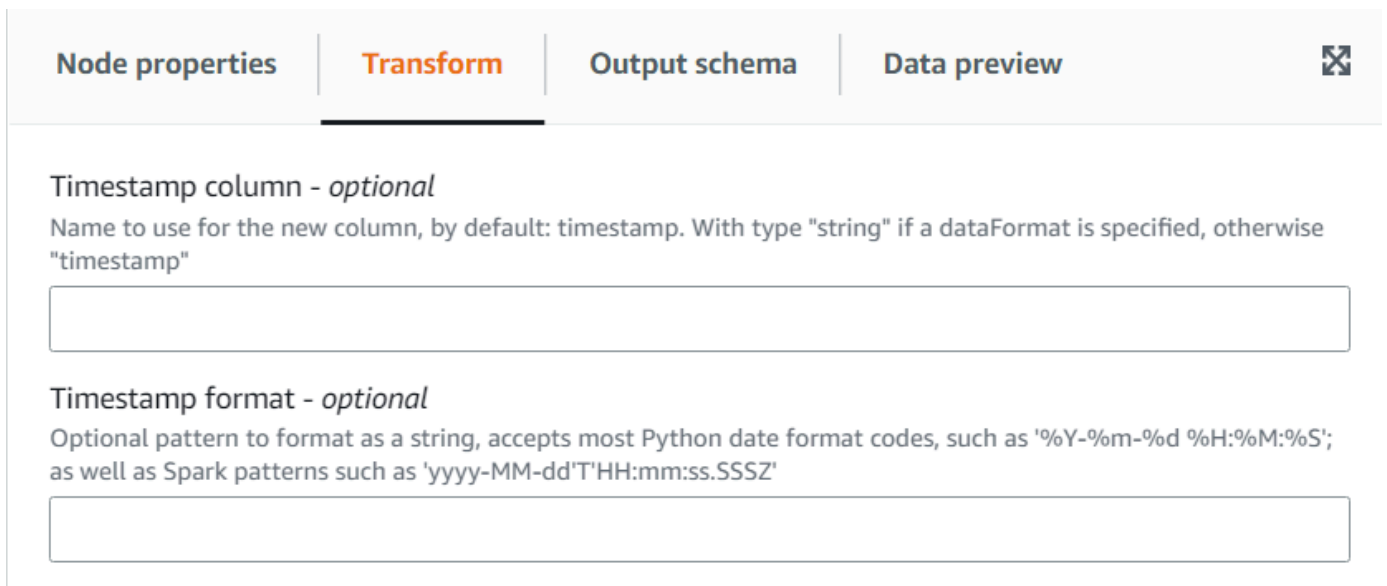

indexes "4, 1, 3", the fourth element of the array will go to column1, the first to column2 and the third to column3 (if the array is shorter than the index number, a NULL value will be set).

## Using the Add Current Timestamp transform

The **Add Current Timestamp** transform allows you to mark the rows with the time on which the data was processed. This is useful for auditing purposes or to track latency in the data pipeline. You can add this new column as a timestamp data type or a formatted string.

### To add a Add Current Timestamp transform:

1. Open the Resource panel and then choose **Add Current Timestamp** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.

The screenshot shows the configuration interface for the 'Add Current Timestamp' transform. At the top, there are four tabs: 'Node properties', 'Transform' (which is selected and highlighted in orange), 'Output schema', and 'Data preview'. Below the tabs, there are two optional configuration fields:

- Timestamp column - optional**: A text input field with a placeholder text: "Name to use for the new column, by default: timestamp. With type 'string' if a dataFormat is specified, otherwise 'timestamp'".
- Timestamp format - optional**: A text input field with a placeholder text: "Optional pattern to format as a string, accepts most Python date format codes, such as '%Y-%m-%d %H:%M:%S'; as well as Spark patterns such as 'yyyy-MM-dd'T'HH:mm:ss.SSSZ'".

3. (Optional) On the **Transform** tab, enter a custom name for the new column and a format if you rather the column to be a formatted date string.

## Using the Pivot Rows to Columns transform

The **Pivot Rows to Columns** transform allows you to aggregate a numeric column by rotating unique values on selected columns which become new columns (if multiple columns are selected, the values are concatenated to name the new columns). That way rows are consolidated while

having more columns with partial aggregations for each unique value. For example, if you have this dataset of sales by month and country (sorted to be easier to illustrate):

year	month	country	amount
2020	Jan	uk	32
2020	Jan	de	42
2020	Jan	us	64
2020	Feb	uk	67
2020	Feb	de	4
2020	Feb	de	7
2020	Feb	us	6
2020	Feb	us	12
2020	Jan	us	90

If you pivot **amount** and **country** as the aggregation columns, new columns are created from the original **country** column. In the table below, you have new columns for **de**, **uk**, and **us** instead of the **country** column.

year	month	de	uk	us
2020	Jan	42	32	64
2020	Jan	11	67	18
2021	Jan			90

If instead you want to pivot both the month and county, you get a column for each combination of the values of those columns:

year	Jan_de	Jan_uk	Jan_us	Feb_de	Feb_uk	Feb_us
2020	42	32	64	11	67	18
2021			90			

### To add a Pivot Rows To Columns transform:

1. Open the Resource panel and then choose **Pivot Rows To Columns** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the numeric column which will be aggregated to produce the values for the new columns, the aggregation function to apply and the column(s) to convert its unique values into new columns.

Node properties
Transform
Output schema
Data preview
⌵

**Aggregation column**  
Numeric column on which the aggregation function is applied

**Aggregation**  
The Spark function to apply to the aggregation column.

**Columns to convert**  
List of columns whose values will become new columns. If multiple columns are specified, the values are concatenated using underscore.

Choose options
⌵

## Using the Unpivot Columns To Rows transform

The **Unpivot** transform allows you convert columns into values of new columns generating a row for each unique value. It's the opposite of pivot but note that it's not equivalent since it cannot separate rows with identical values that were aggregated or split combinations into the original columns (you can do that later using a Split transform). For example, if you have the following table:

year	month	de	uk	us
2020	Jan	42	32	64
2020	Feb	11	67	18
2021	Jan			90

You can unpivot the columns: "de", "uk" and "us" into a column "country" with the value "amount", and get the following (sorted here for illustration purposes):

year	month	country	amount
2020	Jan	uk	32
2020	Jan	de	42
2020	Jan	us	64
2020	Feb	uk	67
2020	Feb	de	11
2020	Feb	us	18
2021	Jan	us	90

Notice the columns that have a NULL value ("de" and "uk" of Jan 2021) don't get generated by default. You can enable that option to get:

year	month	country	amount
2020	Jan	uk	32
2020	Jan	de	42
2020	Jan	us	64
2020	Feb	uk	67
2020	Feb	de	11
2020	Feb	us	18
2021	Jan	us	90
2021	Jan	de	
2021	Jan	uk	

### To add a Unpivot Columns to Rows transform:

1. Open the Resource panel and then choose **Unpivot Columns to Rows** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, enter the new columns to be created to hold the names and values of the columns chosen to unpivot.

<b>Node properties</b>	<b>Transform</b>	<b>Output schema</b>	<b>Data preview</b>	
------------------------	------------------	----------------------	---------------------	---

**Unpivot names column**  
Column to create out of the source columns names

**Unpivot values column**  
Column to create out of values of the old columns

**Columns to unpivot into the new value column**  
List of columns whose name will become values of the new column

## Using the Autobalance Processing transform to optimize your runtime

The **Autobalance Processing** transform redistributes the data among the workers for better performance. This helps in cases where the data is unbalanced or as it comes from the source doesn't allow enough parallel processing on it. This is common where the source is gzipped or is JDBC. The redistribution of data has a modest performance cost, so the optimization might not always compensate that effort if the data was already well balanced. Underneath, the transform uses Apache Spark repartition to randomly reassign data among a number of partitions optimal for the cluster capacity. For advanced users, it's possible to enter a number of partitions manually. In addition, it can be used to optimize the writing of partitioned tables by reorganizing the data based on specified columns. This results in output files that are more consolidated.

1. Open the Resource panel and then choose **Autobalance Processing** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. (Optional) On the **Transform** tab, you can enter a number of partitions. In general, it's recommended that you let the system decide this value, however you can tune the multiplier or enter a specific value if you need to control this. If you are going to save the data

partitioned by columns, you can choose the same columns as repartition columns. This way it will minimize the number of files on each partition and avoid having many files per partitions, which would hinder the performance of the tools querying that data.

Node properties
Transform
Output schema
Data preview

**Number of partitions - optional**  
 Number of partitions on which to randomly distribute the data. If the number ends with the x letter then it means it's a multiple of the number of cores in the cluster. By default: 2x

**Repartition columns - optional**  
 Instead of randomly reassign the data to partitions, assign data with the same values of the columns specified to the same partition.

Choose options
▼

## Using the Derived Column transform to combine other columns

The **Derived Column** transform allows you to define a new column based on a math formula or SQL expression in which you can use other columns in the data, as well as constants and literals. For instance, to derive a "percentage" column from the columns "success" and "count", you can enter the SQL expression: "success \* 100 / count || '%'".

Example result:

success	count	percentage
14	100	14%
6	20	3%
3	40	7.5%

### To add a Derived Column transform:

1. Open the Resource panel and then choose **Derived Column** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.

2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, enter the name of the column and the expression for its content.

Node properties	<b>Transform</b>	Output schema	Data preview	
-----------------	------------------	---------------	--------------	---

Name of the derived column  
Name to use for the new column or replace an existing one

SQL Expression  
A SQL expression that defines the column, which can be derived from other existing columns and use operators to modify or combine them. For instance, to derive a percentage from the columns "success" and "count", you can enter: "success \* 100 / count"

## Using the Lookup transform to add matching data from a catalog table

The **Lookup** transform allows you to add columns from a defined catalog table when the keys match the defined lookup columns in the data. This is equivalent to doing a left outer join between the data and the lookup table using as condition matching columns.

### To add a Lookup transform:

1. Open the Resource panel and then choose **Lookup** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, enter the fully qualified catalog table name to use to perform the lookups. For example, if your database is "mydb" and your table "mytable" then enter "mydb.mytable". Then enter the criteria to find a match in the lookup table, if the lookup key is composed. Enter the list of key columns separated by commas. If one or more of the key columns don't have the same name then you need to define the match mapping.

For example, if the data columns are “user\_id” and “region” and in the users table the corresponding columns are named “id” and “region”, then in the **Columns to match** field, enter: “user\_id=id, region”. You could do region=region but it’s not needed since they are the same.

4. Finally, enter the columns to bring from the row matched in the lookup table to incorporate them into the data. If no match was found those columns will be set to NULL.

### Note

Underneath the **Lookup** transform, it is using a left join in order to be efficient. If the lookup table has a composite key, ensure the columns to match are setup to match all the key columns so that only one match can occur. Otherwise, multiple lookup rows will match and this will result in extra rows added for each of those matches.

Node properties	Transform	Output schema	Data preview	
<p><b>AWS Glue Data Catalog table</b>            Qualified name of the catalog table to use for the lookup, specifying the database and table name separated by a dot</p> <input type="text"/>				
<p><b>Lookup key columns to match</b>            Columns in the lookup table to match separated by commas; if the column names don't match, you can specify the mapping between the data and the lookup table separating the names with an equals sign =</p> <input type="text"/>				
<p><b>Lookup columns to take</b>            Columns in the lookup table to add to the data when a match is found in the lookup table</p> <input type="text"/>				

## Using the Explode Array or Map Into Rows transform

The **Explode** transform allows you to extract values from a nested structure into individual rows that are easier to manipulate. In the case of an array, the transform will generate a row for each value of the array, replicating the values for the other columns in the row. In the case of a map,

the transform will generate a row for each entry with the key and value as columns plus any other columns in the row.

For example, if we have this dataset which has a “category” array column with multiple values.

product_id	category
1	[sports, winter]
2	[garden, tools]
3	[videogames]
4	[game, boardgame, social]
5	[]

If you explode the 'category' column into a column with the same name, you will override the column. You can select that you want NULLs included to get the following (ordered for illustration purposes):

product_id	category
1	sports
1	winter
2	garden
2	tool
3	videogames
4	game
4	boardgame
4	social
5	

## To add a Explode Array Or Map Into Rows transform:

1. Open the Resource panel and then choose **Explode Array Or Map Into Rows** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. (Optional) On the **Node properties** tab, you can enter a name for the node in the job diagram. If a node parent is not already selected, then choose a node from the Node parents list to use as the input source for the transform.
3. On the **Transform** tab, choose the column to explode (it must be an array or map type). Then enter a name for the column for the items of the array or the names of the columns for the keys and values if you are exploding a map.
4. (Optional) On the **Transform** tab, by default if the column to explode is NULL or has an empty structure, it will be omitted on the exploded dataset. If you want to keep the row (with the new columns as NULL) then check "Include NULLs".

Node properties	<b>Transform</b>	Output schema	Data preview	
-----------------	------------------	---------------	--------------	---

**Column to explode**  
A column of type array or map

**New column name**  
The name of the column to put the array values or the dictionary keys

**Values column - optional**  
If exploding a dictionary, you can specify a name for a column to contain the values. Default name: "value"

**Include NULLs - optional**  
If selected, NULL values will also generate a new rows, otherwise the row with a NULL value is omitted

## Using the Record Matching transform to invoke an existing data classification transform

This transform invokes an existing Record Matching machine learning data classification transform.

The transform evaluates the current data against the trained model based on labels. A column "match\_id" is added to assign each row to a group of items that are considered equivalent based on the algorithm training. For more information, see [Record matching with Lake Formation FindMatches](#).

### Note

The version of AWS Glue used by the visual job must match the version that AWS Glue used to create the Record Matching transform.

id	title	venue	year	source	match_id
journals_sigmod_Liu02	Editor's Notes	SIGMOD Record	2002	DBLP	25769803776
journals_sigmod_Hammer02	Report on the ACM Fourth International Workshop on Data Warehousing and OLAP (DOLAP 2001)	null	2002	DBLP	25769803777
journals_sigmod_Konig-RiesMMPPRSVW02	Report on the NSF Workshop on Building an Infrastructure for Mobile and Wireless Systems	null	2002	DBLP	68719476736

## To add a Record Matching transform node to your job diagram

1. Open the Resource panel, and then choose **Record Matching** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.

- In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
- On the **Transform** tab, enter the ID taken from the **Machine learning transforms** page:

AWS Glue > ML transforms

**Machine learning transforms (1)** [Info](#)  
Clean all your data using machine learning transforms.

Q

	Transform name ▲	ID	Status ▼	Label count ▼
<input type="radio"/>	Test	tfm-3d291b652cec092a79aeda5062f2c96e7c528474	<input checked="" type="checkbox"/> Ready for use	352

- (Optional) On the **Transform** tab, you can check the option to add the confidence scores. At the cost of extra computing, the model will estimate a confidence score for each match as an additional column.

## Removing null rows

This transform removes from the dataset rows that have all columns as null. In addition, you can extend this criteria to include empty fields, so as to keep rows where at least one column is non empty.

### To add a Remove Null Rows transform node to your job diagram

- Open the Resource panel, and then choose **Remove Null Rows** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
- In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
- (Optional) On the **Transform** tab, check the **Extended** option if you want to require rows not just to not be null but also not empty, this way empty strings, arrays or maps will be considered nulls for the purpose of this transform.

## Parsing a string column containing JSON data

This transform parses a string column containing JSON data and convert it to a struct or an array column, depending if the JSON is an object or an array, respectively. Optionally you can keep both the parsed and original column.

The JSON schema can be provided or inferred (in the case of JSON objects), with optional sampling.

### To add a Parse JSON Column transform node to your job diagram

1. Open the Resource panel, and then choose **Parse JSON Column** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, select the column containing the JSON string.
4. (Optional) On the **Transform** tab, enter the schema that the JSON data follows using SQL syntax, for instance: "field1 STRING, field2 INT" in the case of an object or "ARRAY<STRING>" in the case of an array.

If the case of an array the schema is required but in the case of an object, if the schema is not specified it will be inferred using the data. To reduce the impact of inferring the schema (especially on a large dataset), you can avoid reading the whole data twice by entering a **Ratio of samples to use to infer schema**. If the value is lower than 1, the corresponding ratio of random samples is used to infer the schema. If the data is reliable and the object is consistent between rows, you can use a small ratio such as 0.1 to improve performance.

5. (Optional) On the **Transform** tab, you can enter a new column name if you want to keep both the original string column and the parsed column.

## Extracting a JSON path

This transform extracts new columns from a JSON string column. This transform is useful when you only need a few data elements and don't want to import the entire JSON content into the table schema.

## To add an Extract JSON Path transform node to your job diagram

1. Open the Resource panel, and then choose **Extract JSON Path** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, select the column containing the JSON string. Enter one or more JSON path expressions separated by commas, each one referencing how to extract a value out of the JSON array or object. For instance, if the JSON column contained an objects with properties "prop\_1" and "prop2" you could extract both specifying their names "prop\_1, prop\_2".

If the JSON field has special characters, for instance to extract the property from this JSON `{ "a . a": 1 }` you could use the path `$[ ' a . a ' ]`. The exception is the comma because it is reserved to separate paths. Then enter the corresponding column names for each path, separated by commas.

4. (Optional) On the **Transform** tab, you can check to drop the JSON column once extracted, this makes sense when you don't need the rest of the JSON data once you have extracted the parts you need.

## Extracting string fragments using a regular expression

This transform extracts string fragments using a regular expression and creates a new column out of it, or multiple columns if using regex groups.

### To add a Regex Extractor transform node to your job diagram

1. Open the Resource panel, and then choose **Regex Extractor** to add a new transform to your job diagram. The node selected at the time of adding the node will be its parent.
2. In the node properties panel, you can enter a name for the node in the job diagram. If a node parent isn't already selected, choose a node from the **Node parents** list to use as the input source for the transform.
3. On the **Transform** tab, enter the regular expression and the column on which it needs to be applied. Then enter the name of the new column on which to store the matching string. The new column will be null only if the source column is null, if the regex doesn't match the column will be empty.

If the regex uses groups, there has to be a corresponding column name separated by comma but you can skip groups by leaving the column name empty.

For example, if you have a column "purchase\_date" with a string using both long and short ISO date formats, then you want to extract the year, month, day and hour, when available. Notice the hour group is optional, otherwise in the rows where not available, all the extracted groups would be empty strings (because the regex didn't match). In this case, we don't want the group to make the time optional but the inner one, so we leave the name empty and it doesn't get extracted (that group would include the T character).

## Creating a custom transformation

If you need to perform more complicated transformations on your data, or want to add data property keys to the dataset, you can add a **Custom code** transform to your job diagram. The Custom code node allows you to enter a script that performs the transformation.

When using custom code, you must use a schema editor to indicate the changes made to the output through the custom code. When editing the schema, you can perform the following actions:

- Add or remove data property keys
- Change the data type of data property keys
- Change the name of data property keys
- Restructure a nested property key

You must use a *SelectFromCollection* transform to choose a single `DynamicFrame` from the result of your Custom transform node before you can send the output to a target location.

Use the following tasks to add a custom transform node to your job diagram.

## Adding a custom code transform node to the job diagram

### To add a custom transform node to your job diagram

1. (Optional) Open the Resource panel and then choose **Custom transform** to add a custom transform to your job diagram.
2. On the **Node properties** tab, enter a name for the node in the job diagram. If a node parent is not already selected, or if you want multiple inputs for the custom transform, then choose a node from the **Node parents** list to use as the input source for the transform.

### Entering code for the custom transform node

You can type or copy code into an input field. The job uses this code to perform the data transformation. You can provide a code snippet in either Python or Scala. The code should take one or more `DynamicFrames` as input and returns a collection of `DynamicFrames`.

### To enter the script for a custom transform node

1. With the custom transform node selected in the job diagram, choose the **Transform** tab.
2. In the text entry field under the heading **Code block**, paste or enter the code for the transformation. The code that you use must match the language specified for the job on the **Job details** tab.

When referring to the input nodes in your code, AWS Glue Studio names the `DynamicFrames` returned by the job diagram nodes sequentially based on the order of creation. Use one of the following naming methods in your code:

- Classic code generation – Use functional names to refer to the nodes in your job diagram.
  - Data source nodes: `DataSource0`, `DataSource1`, `DataSource2`, and so on.
  - Transform nodes: `Transform0`, `Transform1`, `Transform2`, and so on.
- New code generation – Use the name specified on the **Node properties** tab of a node, appended with `'_node1'`, `'_node2'`, and so on. For example, `S3bucket_node1`, `ApplyMapping_node2`, `S3bucket_node2`, `MyCustomNodeName_node1`.

For more information about the new code generator, see [Script code generation](#).

The following examples show the format of the code to enter in the code box:

## Python

The following example takes the first `DynamicFrame` received, converts it to a `DataFrame` to apply the native filter method (keeping only records that have over 1000 votes), then converts it back to a `DynamicFrame` before returning it.

```
def FilterHighVoteCounts (glueContext, dfc) -> DynamicFrameCollection:
    df = dfc.select(list(dfc.keys())[0]).toDF()
    df_filtered = df.filter(df["vote_count"] > 1000)
    dyf_filtered = DynamicFrame.fromDF(df_filtered, glueContext, "filter_votes")
    return(DynamicFrameCollection({"CustomTransform0": dyf_filtered}, glueContext))
```

## Scala

The following example takes the first `DynamicFrame` received, converts it to a `DataFrame` to apply the native filter method (keeping only records that have over 1000 votes), then converts it back to a `DynamicFrame` before returning it.

```
object FilterHighVoteCounts {
    def execute(glueContext : GlueContext, input : Seq[DynamicFrame]) :
    Seq[DynamicFrame] = {
        val frame = input(0).toDF()
        val filtered = DynamicFrame(frame.filter(frame("vote_count") > 1000),
        glueContext)
        Seq(filtered)
    }
}
```

## Editing the schema in a custom transform node

When you use a custom transform node, AWS Glue Studio cannot automatically infer the output schemas created by the transform. You use the schema editor to describe the schema changes implemented by the custom transform code.

A custom code node can have any number of parent nodes, each providing a `DynamicFrame` as input for your custom code. A custom code node returns a collection of `DynamicFrames`. Each `DynamicFrame` that is used as input has an associated schema. You must add a schema that describes each `DynamicFrame` returned by the custom code node.

### Note

When you set your own schema on a custom transform, AWS Glue Studio does not inherit schemas from previous nodes. To update the schema, select the Custom transform node, then choose the Data preview tab. Once the preview is generated, choose 'Use Preview Schema'. The schema will then be replaced by the schema using the preview data.

## To edit the output schemas for a custom transform node

1. With the custom transform node selected in the job diagram, in the node details panel, choose the **Output schema** tab.
2. Choose **Edit** to make changes to the schema.

If you have nested data property keys, such as an array or object, you can choose the **Expand-Rows** icon

( )

on the top right of each schema panel to expand the list of child data property keys. After you choose this icon, it changes to the **Collapse-Rows** icon

( ),

which you can choose to collapse the list of child property keys.

3. Modify the schema using the following actions in the section on the right side of the page:
  - To rename a property key, place the cursor in the **Key** text box for the property key, then enter the new name.
  - To change the data type for a property key, use the list to choose the new data type for the property key.
  - To add a new top-level property key to the schema, choose the **Overflow** ( ) icon to the left of the **Cancel** button, and then choose **Add root key**.
  - To add a child property key to the schema, choose the **Add-Key** icon () with the parent key. Enter a name for the child key and choose the data type.
  - To remove a property key from the schema, choose the **Remove** icon () to the far right of the key name.

4. If your custom transform code uses multiple `DynamicFrames`, you can add additional output schemas.

- To add a new, empty schema, choose the **Overflow**

( ... )

icon, and then choose **Add output schema**.

- To copy an existing schema to a new output schema, make sure the schema you want to copy is displayed in the schema selector. Choose the **Overflow**

( ... )

icon, and then choose **Duplicate**.

If you want to remove an output schema, make sure the schema you want to copy is displayed in the schema selector. Choose the **Overflow**

( ... )

icon, and then choose **Delete**.

5. Add new root keys to the new schema or edit the duplicated keys.

6. When you are modifying the output schemas, choose the **Apply** button to save your changes and exit the schema editor.

If you do not want to save your changes, choose the **Cancel** button.

## Configure the custom transform output

A custom code transform returns a collection of `DynamicFrames`, even if there is only one `DynamicFrame` in the result set.

### To process the output from a custom transform node

1. Add a *SelectFromCollection* transform node, which has the custom transform node as its parent node. Update this transform to indicate which dataset you want to use. See [Using SelectFromCollection to choose which dataset to keep](#) for more information.
2. Add additional *SelectFromCollection* transforms to the job diagram if you want to use additional `DynamicFrames` produced by the custom transform node.

Consider a scenario in which you add a custom transform node to split a flight dataset into multiple datasets, but duplicate some of the identifying property keys in each output schema,

such as the flight date or flight number. You add a *SelectFromCollection* transform node for each output schema, with the custom transform node as its parent.

3. (Optional) You can then use each *SelectFromCollection* transform node as input for other nodes in the job, or as a parent for a data target node.

## AWS Glue custom visual transforms

Custom visual transforms allow you to create transforms and make them available for use in AWS Glue Studio jobs. Custom visual transforms enable ETL developers, who may not be familiar with coding, to search and use a growing library of transforms using the AWS Glue Studio interface.

You can create a custom visual transform, then upload it to Amazon S3 to make available for use through the visual editor in AWS Glue Studio to work with these jobs.

### Topics

- [Getting started with custom visual transforms](#)
- [Step 1. Create a JSON config file](#)
- [Step 2. Implement the transform logic](#)
- [Step 3. Validate and troubleshoot custom visual transforms in AWS Glue Studio](#)
- [Step 4. Update custom visual transforms as needed](#)
- [Step 5. Use custom visual transforms in AWS Glue Studio](#)
- [Usage examples](#)
- [Examples of custom visual scripts](#)
- [Video](#)

### Getting started with custom visual transforms

To create a custom visual transform, you go through the following steps.

- Step 1. Create a JSON config file
- Step 2. Implement the transform logic
- Step 3. Validate the custom visual transform
- Step 4. Update the custom visual transform as needed
- Step 5. Use the custom visual transform in AWS Glue Studio

Get started by setting up the Amazon S3 bucket and continue to **Step 1. Create a JSON config file.**

## Prerequisites

Customer-supplied transforms reside within a customer AWS account. That account owns the transforms and therefore has all permissions to view (search and use), edit, or delete them.

In order to use a custom transform in AWS Glue Studio, you will need to create and upload two files to the Amazon S3 assets bucket in that AWS account:

- **Python file** – contains the transform function
- **JSON file** – describes the transform. This is also known as the config file that is required to define the transform.

In order to pair the files together, use the same name for both. For example:

- myTransform.json
- myTransform.py

Optionally, you can give your custom visual transform a custom icon by providing a **SVG file** containing the icon. In order to pair the files together, use the same name for the icon:

- myTransform.svg

AWS Glue Studio will automatically match them using their respective file names. File names cannot be the same for any existing module.

## Recommended convention for transform file name

AWS Glue Studio will import your file as module (for example, `import myTransform`) in your job script. Therefore, your file name must follow the same naming rules set for python variable names (identifiers). Specifically, they must start with either a letter or an underscore and then be composed entirely of letters, digits, and/or underscores.

### Note

Ensure your transform file name is not conflicting with existing loaded python modules (for example, `sys`, `array`, `copy` etc.) to avoid unexpected runtime issues.

## Setting up the Amazon S3 bucket

Transforms you create are stored in Amazon S3 and is owned by your AWS account. You create new custom visual transforms by simply uploading files (json and py) to the Amazon S3 assets folder where all job scripts are currently stored (for example, `s3://aws-glue-assets-<accountid>-<region>/transforms`). If using a custom icon, upload it as well. By default, AWS Glue Studio will read all .json files from the /transforms folder in the same S3 bucket.

### Step 1. Create a JSON config file

A JSON config file is required to define and describe your custom visual transform. The schema for the config file is as follows.

#### JSON file structure

##### Fields

- `name`: `string` – (required) the transform system name used to identify transforms. Follow the same naming rules set for python variable names (identifiers). Specifically, they must start with either a letter or an underscore and then be composed entirely of letters, digits, and/or underscores.
- `displayName`: `string` – (optional) the name of the transform displayed in the AWS Glue Studio visual job editor. If no `displayName` is specified, the name is used as the name of the transform in AWS Glue Studio.
- `description`: `string` – (optional) the transform description is displayed in AWS Glue Studio and is searchable.
- `functionName`: `string` – (required) the Python function name is used to identify the function to call in the Python script.
- `path`: `string` – (optional) the full Amazon S3 path to the Python source file. If not specified, AWS Glue uses file name matching to pair the .json and .py files together. For example, the name of the JSON file, `myTransform.json`, will be paired to the Python file, `myTransform.py`, on the same Amazon S3 location.
- `parameters`: Array of `TransformParameter` object – (optional) the list of parameters to be displayed when you configure them in the AWS Glue Studio visual editor.

#### TransformParameter fields

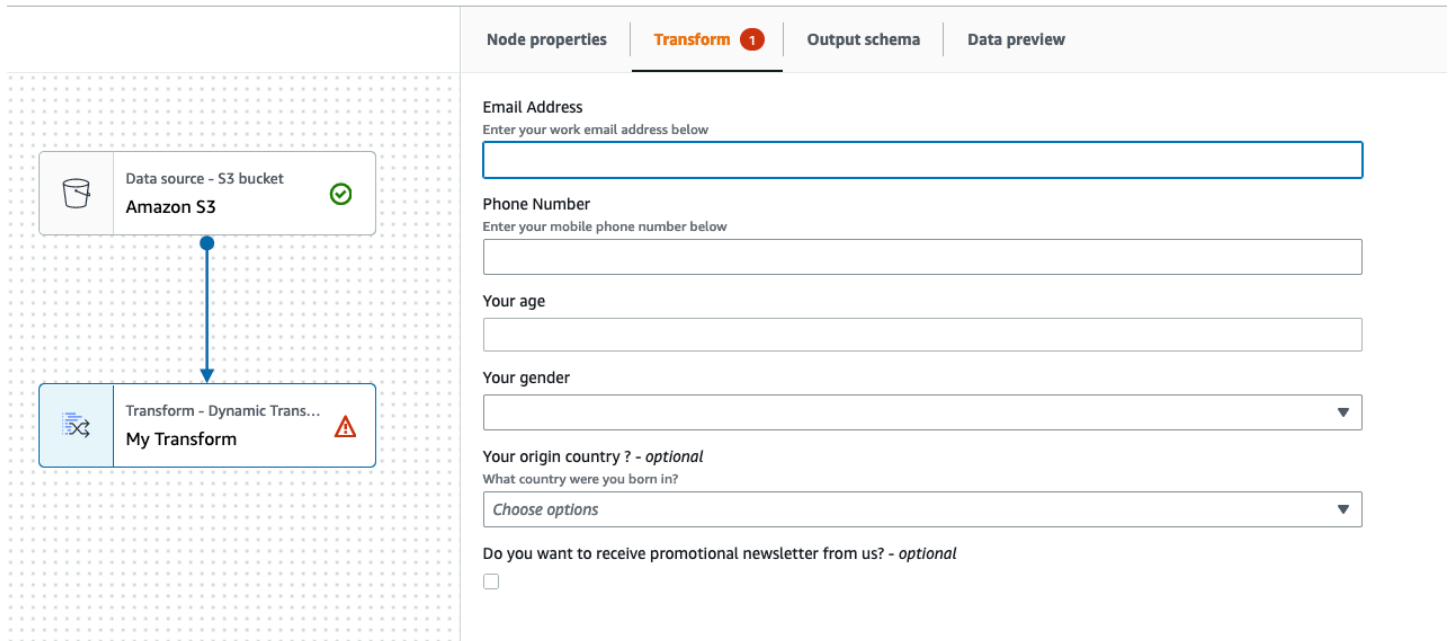

- **name:** `string` – (required) the parameter name that will be passed to the python function as a named argument in the job script. Follow the same naming rules set for python variable names (identifiers). Specifically, they must start with either a letter or an underscore and then be composed entirely of letters, digits, and/or underscores.
- **displayName:** `string` – (optional) the name of the transform displayed in the AWS Glue Studio visual job editor. If no `displayName` is specified, the name is used as the name of the transform in AWS Glue Studio.
- **type:** `string` – (required) the parameter type accepting common Python data types. Valid values: `'str' | 'int' | 'float' | 'list' | 'bool'`.
- **isOptional:** `boolean` – (optional) determines whether the parameter is optional. By default all parameters are required.
- **description:** `string` — (optional) description is displayed in AWS Glue Studio to help the user configure the transform parameter.
- **validationType:** `string` – (optional) defines the way this parameter is validated. Currently, it only supports regular expressions. By default, the validation type is set to `RegularExpression`.
- **validationRule:** `string` – (optional) regular expression used to validate form input before submit when `validationType` is set to `RegularExpression`. Regular expression syntax must be compatible with [RegExp EcmaScript specifications](#).
- **validationMessage:** `string` – (optional) the message to display when validation fails.
- **listOptions:** An array of `TransformParameterListOption` object OR a `string` or the `string` value `'column'` – (optional) options to display in Select or Multiselect UI control. Accepting a list of comma separated value or a strongly type JSON object of type `TransformParameterListOption`. It can also dynamically populate the list of columns from the parent node schema by specifying the `string` value `"column"`.
- **listType:** `string` – (optional) Define options types for `type = 'list'`. Valid values: `'str' | 'int' | 'float' | 'list' | 'bool'`. Parameter type accepting common python data types.

### TransformParameterListOption fields

- **value:** `string | int | float | bool` – (required) option value.
- **label:** `string` – (optional) option label displayed in the select dropdown.

## Transform parameters in AWS Glue Studio

By default, parameters are required unless mark as `isOptional` in the `.json` file. In AWS Glue Studio, parameters are displayed in the **Transform** tab. The example shows user-defined parameters such as Email Address, Phone Number, Your age, Your gender and Your origin country.

The screenshot displays the AWS Glue Studio interface. On the left, a visual workflow shows a 'Data source - S3 bucket Amazon S3' node connected to a 'Transform - Dynamic Trans... My Transform' node. On the right, the 'Transform' tab is active, showing a list of parameters for the transform job:

- Email Address**: Enter your work email address below. (Text input field)
- Phone Number**: Enter your mobile phone number below. (Text input field)
- Your age**: (Text input field)
- Your gender**: (Dropdown menu)
- Your origin country? - optional**: What country were you born in? (Dropdown menu with 'Choose options' selected)
- Do you want to receive promotional newsletter from us? - optional**: (Checkbox, currently unchecked)

You can enforce some validations in AWS Glue Studio using regular expressions in the `json` file by specifying the `validationRule` parameter and specifying a validation message in `validationMessage`.

```
"validationRule": "^\\((?\\d{3})\\)?[- ]?(\\d{3})[- ]?(\\d{4})$",
"validationMessage": "Please enter a valid US number"
```

### Note

Since validation occurs in the browser, your regular expression syntax must be compatible with [RegExp EcmaScript specifications](#). Python syntax is not supported for these regular expressions.

Adding validation will prevent the user from saving the job with incorrect user input. AWS Glue Studio displays the validation message as displayed in the example:

Node properties | **Transform** 1 | Output schema | Data preview

Email Address  
Enter your work email address below

wrongEmail.com

⚠ Please enter a valid email address

Parameters are displayed in AWS Glue Studio based on the parameter configuration.

- When type is any of the following: `str`, `int` or `float`, a text input field is displayed. For example, the screenshot shows input fields for 'Email Address' and 'Your age' parameters.

Email Address  
Enter your work email address below

|

Your age

|

- When type is `bool`, a checkbox is displayed.

Do you want to receive promotional newsletter from us?

- When type is `str` and `listOptions` is provided, a single select list is displayed.

Your gender

Male	▲
Male	✓
Female	
Other	

- When type is `list` and `listOptions` and `listType` are provided, a multi-select list is displayed.

### Country recently visited - *optional*

What countries did you visit in the past 2 years?

Choose options ▲

- Iceland
- India
- Indor India
- Iran
- Iraq
- Ireland
- Israel
- Italy
- Jamaica
- Japan

### Displaying a column selector as parameter

If the configuration requires the user to choose a column from the schema, you can display a column selector so the user isn't required to type the column name. By setting the `listOptions` field to "column", AWS Glue Studio dynamically displays a column selector based on the parent node output schema. AWS Glue Studio can display either a single or multiple column selector.

The following example uses the schema:

Node properties	Data source properties - S3	Output schema	Data preview
<b>Schema</b> <span style="float: right; border: 1px solid black; padding: 2px 5px;">Edit</span>			
Key	Data type	Partition	
CustomerID	string	-	
Title	string	-	
FirstName	string	-	
LastName	string	-	
EmailAddress	string	-	
Phone	string	-	
CompanyName	string	-	

## To define your Custom Visual Transform parameter to display a single column:

1. In your JSON file, for the `parameters` object, set the `listOptions` value to "column". This allows a user to choose a column from a pick list in AWS Glue Studio.

```
{
  "name": "mb_to_timestamp",
  "displayName": "MB Convert column to timestamp",
  "description": "Convert a timestamp string or a system epoch column into a new timestamp type column.",
  "functionName": "mb_to_timestamp",
  "parameters": [
    {
      "name": "colName",
      "displayName": "Name of the column with the time",
      "type": "str",
      "listOptions": "column",
      "description": "Column with an epoch or string to be converted"
    }
  ]
}
```

2. You can also allow multiple columns selection by defining the parameter as:
  - `listOptions`: "column"
  - `type`: "list"

```
{
  "name": "mb_to_timestamp",
  "displayName": "MB Convert column to timestamp",
  "description": "Convert a timestamp string or a system epoch column into a new timestamp type column.",
  "functionName": "mb_to_timestamp",
  "parameters": [
    {
      "name": "colNames",
      "displayName": "Name of the column with the time",
      "type": "list",
      "listOptions": "column",
      "listType": "str",
      "description": "Column with an epoch or string to be converted"
    }
  ]
}
```

Node properties | **Transform** | Output schema | Data preview

Name of the column with the time  
Column with an epoch or string to be converted

Choose options

- CustomerID  
string
- Title  
string
- FirstName**  
string
- LastName  
string
- EmailAddress  
string
- Phone  
string
- CompanyName  
string

## Step 2. Implement the transform logic

### Note

Custom visual transforms only support Python scripts. Scala is not supported.

To add the code that implements the function defined by the .json config file, it is recommended to place the Python file in the same location as the .json file, with the same name but with the “.py” extension. AWS Glue Studio automatically pairs the .json and .py files so that you don’t need to specify the path of the Python file in the config file.

In the Python file, add the declared function, with the named parameters configured and register it to be used in `DynamicFrame`. The following is an example of a Python file:

```
from awsglue import DynamicFrame

# self refers to the DynamicFrame to transform,
# the parameter names must match the ones defined in the config
# if it's optional, need to provide a default value
def myTransform(self, email, phone, age=None, gender="",
                country="", promotion=False):
    resulting_dynf = # do some transformation on self
    return resulting_dynf

DynamicFrame.myTransform = myTransform
```

It is recommended to use an AWS Glue notebook for the quickest way to develop and test the python code. See [Getting started with notebooks in AWS Glue Studio](#).

To illustrate how to implement the transform logic, the custom visual transform in the example below is a transform to filter incoming data to keep only the data related to a specific US state. The .json file contains the parameter for functionName as custom\_filter\_state and two arguments ("state" and "colName" with type "str").

The example config .json file is:

```
{
  "name": "custom_filter_state",
  "displayName": "Filter State",
  "description": "A simple example to filter the data to keep only the state indicated.",
  "functionName": "custom_filter_state",
  "parameters": [
    {
      "name": "colName",
      "displayName": "Column name",
      "type": "str",
      "description": "Name of the column in the data that holds the state postal code"
    },
    {
      "name": "state",
      "displayName": "State postal code",
      "type": "str",
      "description": "The postal code of the state whole rows to keep"
    }
  ]
}
```

### To implement the companion script in Python

1. Start a AWS Glue notebook and run the initial cell provided for the session to be started. Running the initial cell creates the basic components required.
2. Create a function that performs the filtering as describe in the example and register it on DynamicFrame. Copy the code below and paste into a cell in the AWS Glue notebook.

```
from awsglue import DynamicFrame

def custom_filter_state(self, colName, state):
    return self.filter(lambda row: row[colName] == state)

DynamicFrame.custom_filter_state = custom_filter_state
```

3. Create or load sample data to test the code in the same cell or a new cell. If you add the sample data in a new cell, don't forget to run the cell. For example:

```
# A few of rows of sample data to test
data_sample = [
    {"state": "CA", "count": 4},
    {"state": "NY", "count": 2},
    {"state": "WA", "count": 3}
]
df1 = glueContext.sparkSession.sparkContext.parallelize(data_sample).toDF()
dynf1 = DynamicFrame.fromDF(df1, glueContext, None)
```

4. Test to validate the “custom\_filter\_state” with different arguments:

```
[14]: dynf1.custom_filter_state("state", "NY").show()
      {"count": 2, "state": "NY"}
```

5. After running several tests, save the code with the .py extension and name the .py file with a name that mirrors the .json file name. The .py and .json files should be in the same transform folder.

Copy the following code and paste it to a file and rename it with a .py file extension.

```
from awsglue import DynamicFrame

def custom_filter_state(self, colName, state):
    return self.filter(lambda row: row[colName] == state)

DynamicFrame.custom_filter_state = custom_filter_state
```

6. In AWS Glue Studio, open a visual job and add the transform to the job by selecting it from the list of available **Transforms**.

To reuse this transform in a Python script code, add the Amazon S3 path to the .py file in the job under "Referenced files path" and in the script, import the name of the python file (without the extension) by adding it to the top of the file. For example: `import <name of the file (without the extension)>`

### Step 3. Validate and troubleshoot custom visual transforms in AWS Glue Studio

AWS Glue Studio validates the JSON config file before custom visual transforms are loaded into AWS Glue Studio. Validation includes:

- Presence of required fields
- JSON format validation
- Incorrect or invalid parameters
- Presence of both the .py and .json files in the same Amazon S3 path
- Matching filenames for the .py and .json

If validation succeeds, the transform is listed in the list of available **Actions** in the visual editor. If a custom icon has been provided, it should be visible beside the **Action**.

If validation fails, AWS Glue Studio does not load the custom visual transform.

### Step 4. Update custom visual transforms as needed

Once created and used, the transform script can be updated as long as the transform follows the corresponding json definition:

- The name used when assigning to DynamicFrame must match the json `functionName`.
- The function arguments must be defined in the json file as described in [Step 1. Create a JSON config file](#).
- The Amazon S3 path of the Python file cannot change, since the jobs depend directly on it.

**Note**

If any updates need to be made, ensure the script and the .json file are consistently updated and any visual jobs are correctly saved again with the new transform. If visual jobs are not saved after the updates were made, the updates will not be applied and validated. If the Python script file is renamed or not placed next to the .json file, then you need to specify the full path in the .json file.

**Custom icon**

If you determine the default icon for your **Action** does not visually distinguish it as part of your workflows, you can provide a custom icon, as described in [the section called "Getting started with custom visual transforms"](#). You can update the icon by updating the corresponding SVG hosted in Amazon S3.

For best results, design your image to be viewed at 32x32px following guidelines from the Cloudscape Design System. For more information about Cloudscape guidelines, see [The Cloudscape documentation](#)

**Step 5. Use custom visual transforms in AWS Glue Studio**

To use a custom visual transform in AWS Glue Studio, you upload the config and source files, then select the transform from the **Action** menu. Any parameters that need values or input are available to you in the **Transform** tab.

1. Upload the two files (Python source file and JSON config file) to the Amazon S3 assets folder where the job scripts are stored. By default, AWS Glue pulls all JSON files from the **/transforms** folder within the same Amazon S3 bucket.
2. From the **Action** menu, choose the custom visual transform. It is named with the transform `displayName` or name that you specified in the .json config file.
3. Enter values for any parameters that were configured in the config file.

The screenshot displays the AWS Glue console interface. On the left, a visual workflow diagram shows a data source node labeled 'Data source - S3 bucket Amazon S3' with a green checkmark, connected by a blue arrow to a transform node labeled 'Transform - Dynamic Trans... My Transform' with a red warning triangle. On the right, the 'Transform' tab is selected, showing a configuration form. The form includes the following fields:

- Email Address:** A text input field with the description 'Enter your work email address below'.
- Phone Number:** A text input field with the description 'Enter your mobile phone number below'.
- Your age:** A text input field.
- Your gender:** A dropdown menu.
- Your origin country? - optional:** A dropdown menu with the text 'What country were you born in?' and a 'Choose options' button.
- Do you want to receive promotional newsletter from us? - optional:** A checkbox.

## Usage examples

The following is an example of all possible parameters in a .json config file.

```
{
  "name": "MyTransform",
  "displayName": "My Transform",
  "description": "This transform description will be displayed in UI",
  "functionName": "myTransform",
  "parameters": [
    {
      "name": "email",
      "displayName": "Email Address",
      "type": "str",
      "description": "Enter your work email address below",
      "validationType": "RegularExpression",
      "validationRule": "^\\w+([\\.-]?\\w+)*@\\w+([\\.-]?\\w+)*(\\.\\w{2,3})+$",
      "validationMessage": "Please enter a valid email address"
    },
    {
      "name": "phone",
      "displayName": "Phone Number",
      "type": "str",
      "description": "Enter your mobile phone number below",
      "validationRule": "^\\((?\\d{3})\\)?[- ]?(\\d{3})[- ]?(\\d{4})$",
      "validationMessage": "Please enter a valid US number"
    }
  ]
}
```

```

},
{
  "name": "age",
  "displayName": "Your age",
  "type": "int",
  "isOptional": true
},
{
  "name": "gender",
  "displayName": "Your gender",
  "type": "str",
  "listOptions": [
    {"label": "Male", "value": "male"},
    {"label": "Female", "value": "female"},
    {"label": "Other", "value": "other"}
  ],
  "isOptional": true
},
{
  "name": "country",
  "displayName": "Your origin country ?",
  "type": "list",
  "listOptions": "Afghanistan,Albania,Algeria,American

    "displayName": "Do you want to receive promotional newsletter from us?",
    "type": "bool",
    "isOptional": true
  }
]
}

```

## Examples of custom visual scripts

The following examples perform equivalent transformations. However, the second example (SparkSQL) is the cleanest and most efficient, followed by the Pandas UDF and finally the low level mapping in the first example. The following example is a complete example of a simple transformation to add up two columns:

```

from awsglue import DynamicFrame

# You can have other auxiliary variables, functions or classes on this file, it won't
# affect the runtime
def record_sum(rec, col1, col2, resultCol):
    rec[resultCol] = rec[col1] + rec[col2]
    return rec

# The number and name of arguments must match the definition on json config file
# (expect self which is the current DynamicFrame to transform

```

```
# If an argument is optional, you need to define a default value here
# (resultCol in this example is an optional argument)
def custom_add_columns(self, col1, col2, resultCol="result"):
    # The mapping will alter the columns order, which could be important
    fields = [field.name for field in self.schema()]
    if resultCol not in fields:
        # If it's a new column put it at the end
        fields.append(resultCol)
    return self.map(lambda record: record_sum(record, col1, col2,
resultCol)).select_fields(paths=fields)

# The name we assign on DynamicFrame must match the configured "functionName"
DynamicFrame.custom_add_columns = custom_add_columns
```

The following example is an equivalent transform leveraging the SparkSQL API.

```
from awsglue import DynamicFrame

# The number and name of arguments must match the definition on json config file
# (expect self which is the current DynamicFrame to transform
# If an argument is optional, you need to define a default value here
# (resultCol in this example is an optional argument)
def custom_add_columns(self, col1, col2, resultCol="result"):
    df = self.toDF()
    return DynamicFrame.fromDF(
        df.withColumn(resultCol, df[col1] + df[col2]) # This is the conversion logic
        , self.glue_ctx, self.name)

# The name we assign on DynamicFrame must match the configured "functionName"
DynamicFrame.custom_add_columns = custom_add_columns
```

The following example uses the same transformations but using a pandas UDF, which is more efficient than using a plain UDF. For more information about writing pandas UDFs see: [Apache Spark SQL documentation](#).

```
from awsglue import DynamicFrame
import pandas as pd
from pyspark.sql.functions import pandas_udf
```

```
# The number and name of arguments must match the definition on json config file
# (expect self which is the current DynamicFrame to transform
# If an argument is optional, you need to define a default value here
# (resultCol in this example is an optional argument)
def custom_add_columns(self, col1, col2, resultCol="result"):
    @pandas_udf("integer") # We need to declare the type of the result column
    def add_columns(value1: pd.Series, value2: pd.Series) # pd.Series:
        return value1 + value2

    df = self.toDF()
    return DynamicFrame.fromDF(
        df.withColumn(resultCol, add_columns(col1, col2)) # This is the conversion
        logic
        , self.glue_ctx, self.name)

# The name we assign on DynamicFrame must match the configured "functionName"
DynamicFrame.custom_add_columns = custom_add_columns
```

## Video

The following video provides an introduction to visual custom transforms and demonstrates how to use them.

## Using Data Lake frameworks with AWS Glue Studio

### Overview

Open source data lake frameworks simplify incremental data processing for files stored in data lakes built on Amazon S3. AWS Glue 3.0 and later supports the following open-source data lake storage frameworks:

- Apache Hudi
- Linux Foundation Delta Lake
- Apache Iceberg

As of AWS Glue 4.0, AWS Glue provides native support for these frameworks so that you can read and write data that you store in Amazon S3 in a transactionally consistent manner. There's no need to install a separate connector or complete extra configuration steps in order to use these frameworks in AWS Glue jobs.

Data Lake frameworks can be used as a source or a target within AWS Glue Studio through Spark Script Editor jobs. For more information on using Apache Hudi, Apache Iceberg and Delta Lake see: [Using data lake frameworks with AWS Glue ETL jobs](#).

## Creating open table formats from an AWS Glue Streaming source

AWS Glue streaming ETL jobs continuously consume data from streaming sources, clean and transform the data in-flight, and make it available for analysis in seconds.

AWS offers a broad selection of services to support your needs. A database replication service such as AWS Database Migration Service can replicate the data from your source systems to Amazon S3, which commonly hosts the storage layer of the data lake. Although it's straightforward to apply updates on a relational database management system (RDBMS) that backs an online source application, it's difficult to apply this CDC process on your data lakes. The open-source data management frameworks simplify incremental data processing and data pipeline development, and are a good option to solve this problem.

For more information, see:

- [Create an Apache Hudi-based near-real-time transactional data lake using AWS Glue Streaming](#)
- [Build a real-time GDPR-aligned Apache Iceberg data lake](#)

## Using Hudi framework in AWS Glue Studio

When creating or editing a job, AWS Glue Studio automatically adds the corresponding Hudi libraries for you depending on the version of AWS Glue you are using. For more information, see [Using the Hudi framework in AWS Glue](#).

### Using Apache Hudi framework in Data Catalog data sources

**To add a Hudi data source format to a job:**

1. From the Source menu, choose AWS Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. AWS Glue Studio displays the format type as Apache Hudi and the Amazon S3 URL.

## Using Hudi framework in Amazon S3 data sources

1. From the Source menu, choose Amazon S3.
2. If you choose Data Catalog table as the Amazon S3 source type, choose a database and table.
3. AWS Glue Studio displays the format as Apache Hudi and the Amazon S3 URL.
4. If you choose Amazon S3 location as the **Amazon S3 source type**, choose the Amazon S3 URL by clicking **Browse Amazon S3**.
5. In **Data format**, select Apache Hudi.

### Note

If AWS Glue Studio is unable to infer the schema from the Amazon S3 folder or file you selected, choose **Additional options** to select a new folder or file.

In **Additional options** choose from the following options under **Schema inference**:

- Let AWS Glue Studio automatically choose a sample file — AWS Glue Studio will choose a sample file in the Amazon S3 location so that the schema can be inferred. In the **Auto-sampled file** field, you can view the file that was automatically selected.
- Choose a sample file from Amazon S3 — choose the Amazon S3 file to use by clicking **Browse Amazon S3**.

6. Click **Infer schema**. You can then view the output schema by clicking on the **Output schema** tab.
7. Choose **Additional options** to enter a key-value pair.

#### Additional options [Info](#)

Enter additional key-value pairs for your data source connection.

Key

Value

**Add new option**

## Using Apache Hudi framework in data targets

### Using Apache Hudi framework in Data Catalog data targets

1. From the **Target** menu, choose AWS Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. AWS Glue Studio displays the format type as Apache Hudi and the Amazon S3 URL.

### Using Apache Hudi framework in Amazon S3 data targets

Enter values or select from the available options to configure Apache Hudi format. For more information on Apache Hudi, see [Apache Hudi documentation](#).

**Data Catalog update options** Info

Choose how you want to update the Data Catalog table's schema and partitions. These options will only apply if the Data Catalog table is an S3 backed source.

**Do not update the Data Catalog**

**Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions**

**Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions**

**Partition keys - optional**  
Add partition keys.

- **Hudi Table Name** — this is the name of your hudi table.
- **Hudi Storage Type** — choose from two options:
  - **Copy on write** — recommended for optimizing read performance. This is the default Hudi storage type. Each update creates a new version of files during a write.
  - **Merge on read** — recommended for minimizing write latency. Updates are logged to row-based delta files and are compacted as needed to create new versions of the columnar files.
- **Hudi Write Operation** - choose from the following options:
  - **Upsert** — this is the default operation where the input records are first tagged as inserts or updates by looking up the index. Recommended where you are updating existing data.
  - **Insert** — this inserts records but doesn't check for existing records and may result in duplicates.
  - **Bulk Insert** — this inserts records and is recommended for large amounts of data.
- **Hudi Record Key Fields** — use the search bar to search for and choose primary record keys. Records in Hudi are identified by a primary key which is a pair of record key and partition path where the record belongs to.
- **Hudi Precombine Field** — this is the field used in preCombining before actual write. When two records have the same key value, AWS Glue Studio will pick the one with the largest value for the precombine field. Set a field with incremental value (e.g. updated\_at) belongs to.
- **Compression Type** — choose from one of the compression type options: Uncompressed, GZIP, LZO, or Snappy.
- **Amazon S3 Target Location** — choose the Amazon S3 target location by clicking **Browse S3**.
- **Data Catalog update options** — choose from the following options:
  - Do not update the Data Catalog: (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes or new partitions are added.
  - Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions: If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table if the schema changes or new partitions are added.

You must also select a database from the Data Catalog and enter a table name.

- Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions: If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table only to add new partitions.

You must also select a database from the Data Catalog and enter a table name.

- **Partition keys:** Choose which columns to use as partitioning keys in the output. To add more partition keys, choose Add a partition key.
- **Additional options** — enter a key-value pair as needed.

## Generating code through AWS Glue Studio

When the job is saved, the following job parameters are added to the job if a Hudi source or target are detected:

- `--datalake-formats` – a distinct list of data lake formats detected in the visual job (either directly by choosing a “Format” or indirectly by selecting a catalog table that is backed by a data lake).
- `--conf` – generated based on the value of `--datalake-formats`. For example, if the value for `--datalake-formats` is 'hudi', AWS Glue generates a value of `spark.serializer=org.apache.spark.serializer.KryoSerializer --conf spark.sql.hive.convertMetastoreParquet=false` for this parameter.

## Overriding AWS Glue-provided libraries

To use a version of Hudi that AWS Glue doesn't support, you can specify your own Hudi library JAR files. To use your own JAR file:

- use the `--extra-jars` job parameter. For example, '`--extra-jars`': `'s3pathtojarfile.jar'`. For more information, see [AWS Glue job parameters](#).
- do not include `hudi` as a value for the `--datalake-formats` job parameter. Entering a blank string as a value ensures that no data lake libraries are provided for you by AWS Glue automatically. For more information, see [Using the Hudi framework in AWS Glue](#).

## Using Delta Lake framework in AWS Glue Studio

### Using Delta Lake framework in data sources

### Using Delta Lake framework in Amazon S3 data sources

1. From the Source menu, choose Amazon S3.

2. If you choose Data Catalog table as the Amazon S3 source type, choose a database and table.
3. AWS Glue Studio displays the format as Delta Lake and the Amazon S3 URL.
4. Choose **Additional options** to enter a key-value pair. For example, a key-value pair could be: **key:** timestampAsOf and **value:** 2023-02-24 14:16:18.

#### Additional options [Info](#)

Enter additional key-value pairs for your data source connection.

Key	Value	
<input type="text"/>	<input type="text"/>	
<input type="button" value="Add new option"/>		

5. If you choose Amazon S3 location as the **Amazon S3 source type**, choose the Amazon S3 URL by clicking **Browse Amazon S3**.
6. In **Data format**, choose Delta Lake.

#### Note

If AWS Glue Studio is unable to infer the schema from the Amazon S3 folder or file you selected, choose **Additional options** to select a new folder or file.

In **Additional options** choose from the following options under **Schema inference**:

- Let AWS Glue Studio automatically choose a sample file — AWS Glue Studio will choose a sample file in the Amazon S3 location so that the schema can be inferred. In the **Auto-sampled file** field, you can view the file that was automatically selected.
- Choose a sample file from Amazon S3 — choose the Amazon S3 file to use by clicking **Browse Amazon S3**.

7. Click **Infer schema**. You can then view the output schema by clicking on the **Output schema** tab.

## Using Delta Lake framework in Data Catalog data sources

1. From the **Source** menu, choose AWS Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.

3. AWS Glue Studio displays the format type as Delta Lake and the Amazon S3 URL.

#### Note

If your Delta Lake source is not registered as the AWS Glue Data Catalog table yet, you have two options:

1. Create a AWS Glue crawler for the Delta Lake data store. For more information, see [How to specify configuration options for a Delta Lake data store](#).
2. Use an Amazon S3 data source to select your Delta Lake data source. See [Using Delta Lake framework in Amazon S3 data sources](#).

## Using Delta Lake formats in data targets

### Using Delta Lake formats in Data Catalog data targets

1. From the **Target** menu, choose AWS Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. AWS Glue Studio displays the format type as Delta Lake and the Amazon S3 URL.

### Using Delta Lake formats in Amazon S3 data sources

Enter values or select from the available options to configure Delta Lake format.

- **Compression Type** — choose from one of the compression type options: Uncompressed or Snappy.
- **Amazon S3 Target Location** — choose the Amazon S3 target location by clicking **Browse S3**.
- **Data Catalog update options** — updating the Data Catalog is not supported for this format in the Glue Studio visual editor.
  - Do not update the Data Catalog: (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes or new partitions are added.
  - To update the Data Catalog after the AWS Glue job execution, run or schedule a AWS Glue crawler. For more information, see [How to specify configuration options for a Delta Lake data store](#).
- **Partition keys** — Choose which columns to use as partitioning keys in the output. To add more partition keys, choose **Add a partition key**.

- Optionally, choose **Additional options** to enter a key-value pair. For example, a key-value pair could be: **key:** timestampAsOf and **value:** 2023-02-24 14:16:18.

## Using Apache Iceberg framework in AWS Glue Studio

### Using Apache Iceberg framework in data targets

#### Using Apache Iceberg framework in Data Catalog data targets

1. From the **Target** menu, choose AWS Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. AWS Glue Studio displays the format type as Apache Iceberg and the Amazon S3 URL.

#### Using Apache Iceberg framework in Amazon S3 data targets

Enter values or select from the available options to configure Apache Iceberg format.

- **Format** – choose **Apache Iceberg** from the drop-down menu.
- **Amazon S3 Target Location** – choose the Amazon S3 target location by clicking **Browse S3**.
- **Data Catalog update options** – **Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions** must be selected to proceed. Writing a new Iceberg table using AWS Glue requires the Data Catalog to be configured as the catalog for the Iceberg table. To update an existing Iceberg table that has been registered in the Data Catalog, choose Data Catalog as the target.
  - **Database** – Choose the database from the Data Catalog.
  - **Table Name** – Enter the value for your table name. Apache Iceberg table names must be in all lower case. Use underscores if needed since spaces are not allowed. For example "data\_lake\_format\_tables".

Node properties	Data target properties - S3	Output schema	Data preview
-----------------	-----------------------------	---------------	--------------

**Format**

Apache Iceberg

**Compression Type**

GZIP

**S3 Target Location**

Choose an S3 location in the format `s3://bucket/prefix/object/` with a trailing slash (/).

s3://data-lake-format-data/output/ View Browse S3

**Data Catalog update options**

Choose how you want to update the Data Catalog table's schema and partitions. These options will only apply if the Data Catalog table is an S3 backed source.

- Do not update the Data Catalog
- Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions
- Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions

**Database**

Choose the database from the AWS Glue Data Catalog.

data\_lake\_format\_tables Refresh

► **Use runtime parameters**

**Table name**

Enter a table name for the AWS Glue Data Catalog.

my\_new\_table

## Using Apache Iceberg framework in Amazon S3 data sources

## Using Apache Iceberg framework in Data Catalog data sources

1. From the **Source** menu, choose AWS Glue Studio Data Catalog.
2. In the **Data source properties** tab, choose a database and table.
3. AWS Glue Studio displays the format type as Apache Iceberg and the Amazon S3 URL.

Node properties	Data source properties - S3	Output schema	Data preview
<p><b>S3 source type</b></p> <p><input type="radio"/> S3 location Choose a file or folder in an S3 bucket.</p> <p><input checked="" type="radio"/> Data Catalog table</p>

<p><b>Table</b></p> <p>source_iceberg <span>▼</span> <span>↻</span></p> <p>▶ Use runtime parameters</p>			
<p><b>Format</b> Apache Iceberg</p>			
<p><b>S3 URL</b> <a href="s3://data-lake-format-data/iceberg/">s3://data-lake-format-data/iceberg/</a> <span>↗</span></p>			
<p><b>Partition predicate - optional</b> Enter a boolean expression supported by Spark SQL, using only partition columns.</p> <p><input type="text"/></p> <p>Partition predicate syntax for Spark SQL is <code>year == year(date_sub(current_date, 7)) AND month == month(date_sub(current_date, 7)) AND day == day(date_sub(current_date, 7))</code>.</p>			

## Using Apache Iceberg framework in Amazon S3 data sources

Apache Iceberg is not available as a data option for Amazon S3 source nodes in AWS Glue Studio.

## Configuring data target nodes

The data target is where the job writes the transformed data.

### Overview of data target options

Your data target (also called a *data sink*) can be:

- **S3** – The job writes the data in a file in the Amazon S3 location you choose and in the format you specify.

If you configure partition columns for the data target, then the job writes the dataset to Amazon S3 into directories based on the partition key.

- **AWS Glue Data Catalog** – The job uses the information associated with the table in the Data Catalog to write the output data to a target location.

You can create the table manually or with the crawler. You can also use AWS CloudFormation templates to create tables in the Data Catalog.

- A connector – A connector is a piece of code that facilitates communication between your data store and AWS Glue. The job uses the connector and associated connection to write the output data to a target location. You can either subscribe to a connector offered in AWS Marketplace, or you can create your own custom connector. For more information, see [Adding connectors to AWS Glue Studio](#)

You can choose to update the Data Catalog when your job writes to an Amazon S3 data target. Instead of requiring a crawler to update the Data Catalog when the schema or partitions change, this option makes it easy to keep your tables up to date. This option simplifies the process of making your data available for analytics by optionally adding new tables to the Data Catalog, updating table partitions, and updating the schema of your tables directly from the job.

## Editing the data target node

The data target is where the job writes the transformed data.

### To add or configure a data target node in your job diagram

1. (Optional) If you need to add a target node, choose **Target** in the toolbar at the top of the visual editor, and then choose either **S3** or **Glue Data Catalog**.
  - If you choose **S3** for the target, then the job writes the dataset to one or more files in the Amazon S3 location you specify.
  - If you choose **AWS Glue Data Catalog** for the target, then the job writes to a location described by the table selected from the Data Catalog.
2. Choose a data target node in the job diagram. When you choose a node, the node details panel appears on the right-side of the page.
3. Choose the **Node properties** tab, and then enter the following information:

- **Name:** Enter a name to associate with the node in the job diagram.
- **Node type:** A value should already be selected, but you can change it as needed.
- **Node parents:** The parent node is the node in the job diagram that provides the output data you want to write to the target location. For a pre-populated job diagram, the target node should already have the parent node selected. If there is no parent node displayed, then choose a parent node from the list.

A target node has a single parent node.

4. Configure the **Data target properties** information. For more information, see the following sections:
  - [Using Amazon S3 for the data target](#)
  - [Using Data Catalog tables for the data target](#)
  - [Using a connector for the data target](#)
5. (Optional) After configuring the data target node properties, you can view the output schema for your data by choosing the **Output schema** tab in the node details panel. The first time you choose this tab for any node in your job, you are prompted to provide an IAM role to access the data. If you have not specified an IAM role on the **Job details** tab, you are prompted to enter an IAM role here.

## Using Amazon S3 for the data target

For all data sources except Amazon S3 and connectors, a table must exist in the AWS Glue Data Catalog for the source type that you choose. AWS Glue Studio does not create the Data Catalog table.

### To configure a data target node that writes to Amazon S3

1. Go to the visual editor for a new or saved job.
2. Choose a data source node in the job diagram.
3. Choose the **Data source properties** tab, and then enter the following information:
  - **Format:** Choose a format from the list. The available format types for the data results are:
    - **JSON:** JavaScript Object Notation.
    - **CSV:** Comma-separated values.

- **Avro:** Apache Avro JSON binary.
- **Parquet:** Apache Parquet columnar storage.
- **Glue Parquet:** A custom Parquet writer type that is optimized for DynamicFrames as the data format. Instead of requiring a precomputed schema for the data, it computes and modifies the schema dynamically.
- **ORC:** Apache Optimized Row Columnar (ORC) format.

To learn more about these format options, see [Format Options for ETL Inputs and Outputs in AWS Glue](#) in the *AWS Glue Developer Guide*.

- **Compression Type:** You can choose to optionally compress the data using either the gzip or bzip2 format. The default is no compression, or **None**.
- **S3 Target Location:** The Amazon S3 bucket and location for the data output. You can choose the **Browse S3** button to see the Amazon S3 buckets that you have access to and choose one as the target destination.
- **Data catalog update options**
  - **Do not update the Data Catalog:** (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes or new partitions are added.
  - **Create a table in the Data Catalog and on subsequent runs, update the schema and add new partitions:** If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table if the schema changes or new partitions are added.

You must also select a database from the Data Catalog and enter a table name.

- **Create a table in the Data Catalog and on subsequent runs, keep existing schema and add new partitions:** If you choose this option, the job creates the table in the Data Catalog on the first run of the job. On subsequent job runs, the job updates the Data Catalog table only to add new partitions.

You must also select a database from the Data Catalog and enter a table name.

- **Partition keys:** Choose which columns to use as partitioning keys in the output. To add more partition keys, choose **Add a partition key**.

## Using Data Catalog tables for the data target

For all data sources except Amazon S3 and connectors, a table must exist in the AWS Glue Data Catalog for the target type that you choose. AWS Glue Studio does not create the Data Catalog table.

### To configure the data properties for a target that uses a Data Catalog table

1. Go to the visual editor for a new or saved job.
2. Choose a data target node in the job diagram.
3. Choose the **Data target properties** tab, and then enter the following information:
  - **Database:** Choose the database that contains the table you want to use as the target from the list. This database must already exist in the Data Catalog.
  - **Table:** Choose the table that defines the schema of your output data from the list. This table must already exist in the Data Catalog.

A table in the Data Catalog consists of the names of columns, data type definitions, partition information, and other metadata about the target dataset. Your job writes to a location described by this table in the Data Catalog.

For more information about creating tables in the Data Catalog, see [Defining Tables in the Data Catalog](#) in the *AWS Glue Developer Guide*.

- **Data catalog update options**
  - **Do not change table definition:** (Default) Choose this option if you don't want the job to update the Data Catalog, even if the schema changes, or new partitions are added.
  - **Update schema and add new partitions:** If you choose this option, the job updates the Data Catalog table if the schema changes or new partitions are added.
  - **Keep existing schema and add new partitions:** If you choose this option, the job updates the Data Catalog table only to add new partitions.
  - **Partition keys:** Choose which columns to use as partitioning keys in the output. To add more partition keys, choose **Add a partition key**.

## Using a connector for the data target

If you select a connector for the **Node type**, follow the instructions at [Authoring jobs with custom connectors](#) to finish configuring the data target properties.

## Editing or uploading a job script

Use the AWS Glue Studio visual editor to edit the job script or upload your own script.

You can use the visual editor to edit job nodes only if the jobs were created with AWS Glue Studio. If the job was created using the AWS Glue console, through API commands, or with the command line interface (CLI), you can use the script editor in AWS Glue Studio to edit the job script, parameters, and schedule. You can also edit the script for a job created in AWS Glue Studio by converting the job to script-only mode.

### To edit the job script or upload your own script

1. If creating a new job, on the **Jobs** page, choose the **Spark script editor** option to create a Spark job or choose the **Python Shell script editor** to create a Python shell job. You can either write a new script, or upload an existing script. If you choose **Spark script editor**, you can write or upload either a Scala or Python script. If you choose **Python Shell script editor**, you can only write or upload a Python script.

After choosing the option to create a new job, in the **Options** section that appears, you can choose to either start with a starter script (**Create a new script with boilerplate code**), or you can upload a local file to use as the job script.

If you chose **Spark script editor**, you can upload either Python or Scala script files. Scala scripts must have the file extension `.scala`. Python scripts must be recognized as files of type Python. If you chose **Python Shell script editor**, you can upload only Python script files.

When you are finished making your choices, choose **Create** to create the job and open the visual editor.

2. Go to the visual job editor for the new or saved job, and then choose the **Script** tab.
3. If you didn't create a new job using one of the script editor options, and you have never edited the script for an existing job, the **Script** tab displays the heading **Script (Locked)**. This means the script editor is in read-only mode. Choose **Edit script** to unlock the script for editing.

To make the script editable, AWS Glue Studio converts your job from a visual job to a script-only job. If you unlock the script for editing, you can't use the visual editor anymore for this job after you save it.

In the confirmation window, choose **Confirm** to continue or **Cancel** to keep the job available for visual editing.

If you choose **Confirm**, the **Visual** tab no longer appears in the editor. You can use AWS Glue Studio to modify the script using the script editor, modify the job details or schedule, or view job runs.

 **Note**

Until you save the job, the conversion to a script-only job is not permanent. If you refresh the console web page, or close the job before saving it and reopen it in the visual editor, you will still be able to edit the individual nodes in the visual editor.

4. Edit the script as needed.

When you are done editing the script, choose **Save** to save the job and permanently convert the job from visual to script-only.

5. (Optional) You can download the script from the AWS Glue Studio console by choosing the **Download** button on the **Script** tab. When you choose this button, a new browser window opens, displaying the script from its location in Amazon S3. The **Script filename** and **Script path** parameters in the **Job details** tab of the job determine the name and location of the script file in Amazon S3.

## Join test job2

Visual | Script | **Job details** | Runs | Schedules

### ▼ Advanced properties

Script filename

Join test job.py

Script path

S3 location of the script. Path must be in the form `s3://bucket/prefix/path/`. It must end with a slash (/) and not include any files.

🔍 s3://aws-glue-assets-111122223333-t ✕

View ↗

Browse S3

- Job metrics [Info](#)  
Enable the creation of CloudWatch metrics when this job runs.
- Continuous logging [Info](#)  
Enable logs in CloudWatch.
- Spark UI [Info](#)  
Enable using Spark UI for monitoring this job.

When you save the job, AWS Glue save the job script at the location specified by these fields. If you modify the script file at this location within Amazon S3, AWS Glue Studio will load the modified script the next time you edit the job.

## Creating and editing Scala scripts in AWS Glue Studio

When you choose the script editor for creating a job, by default, the job programming language is set to Python 3. If you choose to write a new script instead of uploading a script, AWS Glue Studio starts a new script with boilerplate text written in Python. If you want to write a Scala script instead, you must first configure the script editor to use Scala.

### **Note**

If you choose Scala as the programming language for the job and use the visual editor to design your job, the generated job script is written in Scala, and no further actions are needed.

## To write a new Scala script in AWS Glue Studio

1. Create a new job by choosing the **Spark script editor** option.
2. Under **Options**, choose **Create a new script with boilerplate code**.
3. Choose the **Job details** tab and set **Language** to Scala (instead of Python 3).

### Note

The **Type** property for the job is automatically set to Spark when you choose the **Spark script editor** option to create a job.

4. Choose the **Script** tab.
5. Remove the Python boilerplate text. You can replace it with the following Scala boilerplate text.

```
import com.amazonaws.services.glue.{DynamicRecord, GlueContext}
import org.apache.spark.SparkContext
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job

object MyScript {
  def main(args: Array[String]): Unit = {
    val sc: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(sc)

  }
}
```

6. Write your Scala job script in the editor. Add additional import statements as needed.

## Creating and editing Python shell jobs in AWS Glue Studio

When you choose the Python shell script editor for creating a job, you can upload an existing Python script, or write a new one. If you choose to write a new script, boilerplate code is added to the new Python job script.

### To create a new Python shell job

Refer to the instructions at [Starting jobs in AWS Glue Studio](#).

The job properties that are supported for Python shell jobs are not the same as those supported for Spark jobs. The following list describes the changes to the available job parameters for Python shell jobs on the **Job details** tab.

- The **Type** property for the job is automatically set to `Python Shell` and can't be changed.
- Instead of **Language**, there is a **Python version** property for the job. Currently, Python shell jobs created in AWS Glue Studio use Python 3.6.
- The **Glue version** property is not available, because it does not apply to Python shell jobs.
- Instead of **Worker type** and **Number of workers**, a **Data processing units** property is shown instead. This job property determines how many data processing units (DPUs) are consumed by the Python shell when running the job.
- The **Job bookmark** property is not available, because it is not supported for Python shell jobs.
- Under **Advanced properties**, the following properties are not available for Python shell jobs.
  - **Job metrics**
  - **Continuous logging**
  - **Spark UI** and **Spark UI logs path**
  - **Dependent jars path**, under the heading **Libraries**

## Changing the parent nodes for a node in the job diagram

You can change a node's parents to move nodes within the job diagram or to change a data source for a node.

### To change the parent node

1. Choose the node in the job diagram that you want to modify.
2. In the node details panel, on the **Node properties** tab, under the heading **Node parents** remove the current parent for the node.
3. Choose a new parent node from the list.
4. Modify the other properties of the node as needed to match the newly selected parent node.

If you modified a node by mistake, you can use the **Undo** button on the toolbar to reverse the action.

## Deleting nodes from the job diagram

When working with Visual ETL jobs, you can remove nodes from the canvas without having to re-add or restructure any nodes that are connected to the removed node.

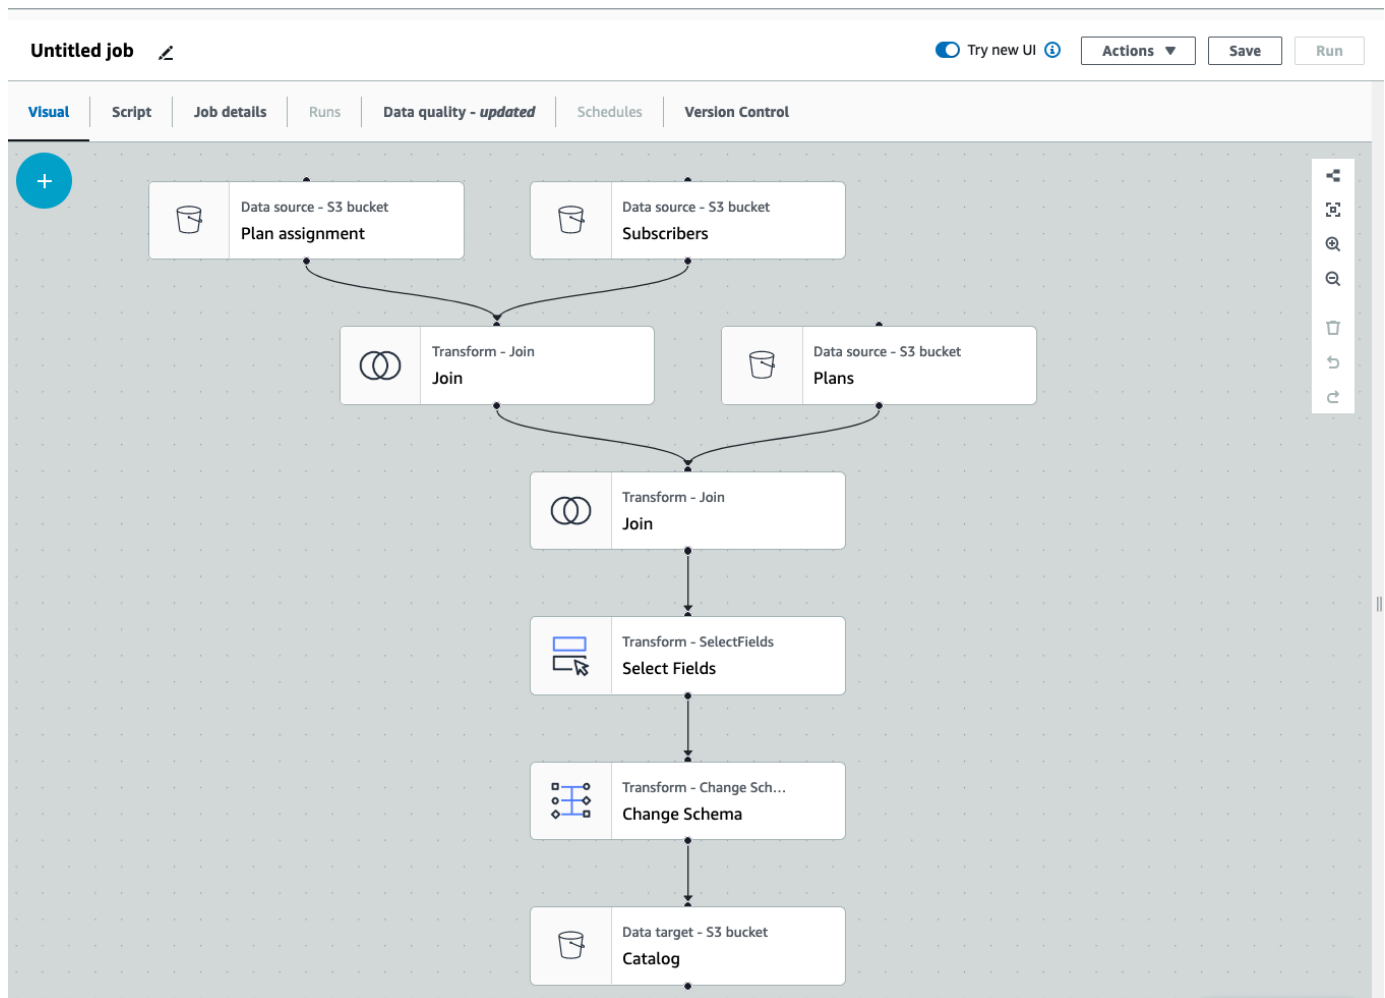

In the example below, you can follow along by choosing **ETL jobs > Visual ETL**, then in **Example jobs**, choosing **Visual ETL job to join multiple sources**. Choose **Create example job** to create a job and follow along with the steps below.

The screenshot shows the AWS Glue console interface. On the left is a navigation menu with 'Visual ETL' highlighted. The main content area shows the 'Create job' section with three options: 'Visual ETL', 'Notebook', and 'Script editor'. Below this is the 'Example jobs' section, where the 'Visual ETL job to join multiple sources' option is selected and highlighted with a red box. At the bottom, the 'Your jobs (1)' table shows a single job named 'job\_101521'.

Job name	Type	Last modified	AWS Glue version
job_101521	Glue ETL	1/31/2022, 11:44:06 AM	2.0

### To remove a node from the canvas

1. From the AWS Glue console, choose **Visual ETL** from the navigation menu and choose an existing job. The job canvas displays the example job as depicted below.

- Choose the node you want to remove. The canvas will zoom in to the node. In the toolbar on the right side of the canvas, choose the **Trash** icon. This will remove the node and any node connected to the node will move to take its place in the workflow. In this example, the first **Join** node was deleted from the canvas.

If you delete a node in the workflow, AWS Glue will re-arrange the nodes so that they are organized in a way that does not result in an invalid workflow. You may still need to correct a node's configuration.

In the example, the **Join** node beneath the **Subscribers** node was removed. As a result, the **Plans** source node has been moved to the top level and is still connected to the child **Join** node. The **Join** node now requires additional configuration since **Join** requires two parent source nodes with selected tables. The **Transform** tab to the right of the canvas displays the missing requirement under **Join conditions**.

The screenshot displays the AWS Glue Studio interface for an 'Untitled job'. The workflow consists of several nodes: three data source nodes ('Plan assignment', 'Subscribers', 'Plans'), a 'Join' node, a 'Select Fields' node, and a 'Change Schema' node. The 'Join' node is highlighted with a red box. A yellow warning box at the bottom left states 'Node is misconfigured' for the 'Join' node. The right-hand 'Transform' panel shows the configuration for the 'Join' node, including its name, node parents, join type (Inner join), and join conditions. A red box highlights a warning in the 'Join conditions' section: 'Insufficient source nodes. The Join transform requires two parent source nodes with selected tables.'

3. Delete the second **Join** node and **Select Fields** node. When the nodes have been deleted, the workflow will look like the example below.

4. To modify the node connections, click on the node's handle and drag the connection to a new node. This will allow you to delete nodes and rearrange the nodes in a logical flow. In the example, a new connection is being made by clicking the handle on the Plans node and dragging the connection to the Join node as depicted by the red arrow.

5. If you need to undo any action, choose the **Undo** icon directly beneath the **Trash** icon in the toolbar on the right side of the canvas.

## Adding source and target parameters to the AWS Glue Data Catalog node

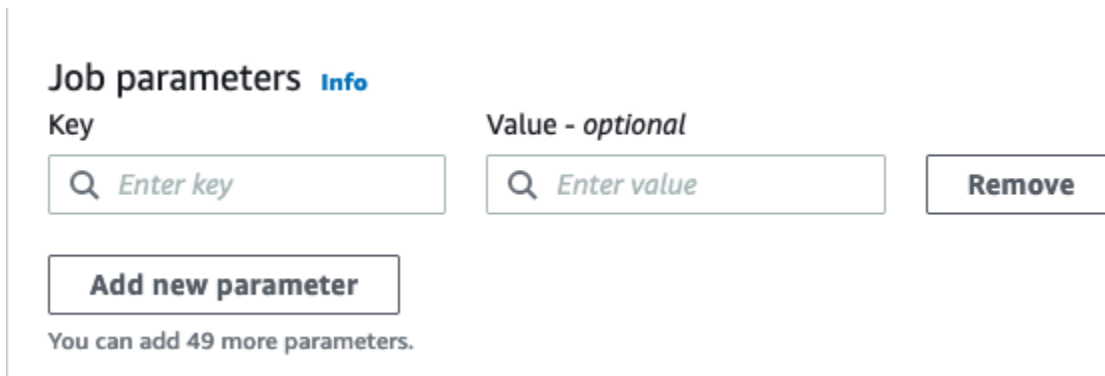

AWS Glue Studio allows you to parameterize visual jobs. Since catalog table names in production and development environment may be different, you can define and select runtime parameters for databases and tables that will run when your job runs.

Job parameterization allows you to parameterize sources and targets, and save those parameters to the job when using the AWS Glue Data Catalog node. When you specify sources and targets as parameters, you are enabling the reusability of jobs, particularly when using the same job in multiple environments. This is useful when promoting code across deployment environments by saving time and effort in managing your sources and targets. In addition, the custom parameters you specify will override any default arguments for specific runs of AWS Glue jobs.

## To add source and target parameters

Whether you are using the AWS Glue Data Catalog node as a source or a target, you can define runtime parameters in the **Advanced properties** section on the **Job details** tab.

1. Choose the AWS Glue Data Catalog node as either the source node or the target node.
2. Choose the **Job details** tab.
3. Choose **Advanced properties**.
4. In the Job parameters section, enter a key value. For example, `--db.source` would be the parameter for a database source. You can enter any name for the key, as long as the key name is followed by the 'dash dash'.

The screenshot shows the 'Job parameters' section of the AWS Glue console. It features a table with two columns: 'Key' and 'Value - optional'. Below the table is an 'Add new parameter' button. A note below the button states 'You can add 49 more parameters.' The table is currently empty.

Key	Value - optional	
<input type="text" value="Enter key"/>	<input type="text" value="Enter value"/>	<input type="button" value="Remove"/>

You can add 49 more parameters.

5. Enter the value. For example, `databaseName` would be the value for database being parameterized.
6. Choose **Add new parameter** if you want to add more parameters. Max 50 parameters is allowed. Once the key value pair has been defined, you can use the parameter in the AWS Glue Data Catalog node.

## To select a runtime parameter

### Note

The process to select runtime parameters for databases and tables is the same whether the the AWS Glue Data Catalog node is the source or the target.

1. Choose the AWS Glue Data Catalog node as either the source node or the target node.
2. In the **Data source properties - Data Catalog** tab, under **Database**, choose **Use runtime parameters**.

▼ **Use runtime parameters**

Select runtime parameter

Runtime parameters can be configured in the **Advanced properties** section on the **Job details** tab

ApplyClear

3. Choose a parameter from the drop-down menu. For example, when you select a parameter you defined for a source database, the database will automatically populate in the database drop-down menu when you choose **Apply**.
4. In the Table section, choose a parameter you already defined as a source table. When you choose **Apply**, the table is automatically populated as the table to use.
5. When you save and run the job, AWS Glue Studio will reference the selected parameters during the job run.

## Using Git version control systems in AWS Glue

### Note

Notebooks are not currently supported for version control in AWS Glue Studio. However, version control for AWS Glue job scripts and visual ETL jobs are supported.

If you have remote repositories and want to manage your AWS Glue jobs using your repositories, you can use AWS Glue Studio or the AWS CLI to sync changes to your repositories and your jobs in AWS Glue. When you sync changes this way, you're pushing the job from AWS Glue Studio to your repository, or pulling from the repository to AWS Glue Studio.

With Git integration in AWS Glue Studio, you can:

- Integrate with Git version control systems, such as AWS CodeCommit, GitHub, GitLab, and Bitbucket
- Edit AWS Glue jobs in AWS Glue Studio whether you use visual jobs or script jobs and sync them to a repository

- Parameterize sources and targets in jobs
- Pull jobs from a repository and edit them in AWS Glue Studio
- Test jobs by pulling from branches and/or pushing to branches utilizing multi-branch workflows in AWS Glue Studio
- Download files from a repository and upload jobs into AWS Glue Studio for cross-account job creation
- Use your automation tool of choice (for example, Jenkins, AWS CodeDeploy, etc.)

This video demonstrates how you can integrate AWS Glue with Git and build a continuous and collaborative code pipeline.

## IAM permissions

Ensure the job has one of the following IAM permissions. For more information on how to set up IAM permissions, see [Set up IAM permissions for AWS Glue Studio](#).

- `AWSGlueServiceRole`
- `AWSGlueConsoleFullAccess`

At minimum, the following actions are needed for Git integration:

- `glue:UpdateJobFromSourceControl` — to be able to update AWS Glue with a job present in a version control system
- `glue:UpdateSourceControlFromJob` — to be able to update the version control system with a job stored in AWS Glue
- `s3:GetObject` — to be able to retrieve the script for the job while pushing to version control system
- `s3:PutObject` — to be able to update the script when pulling a job from a source control system

## Prerequisites

In order to push jobs to a source control repository, you will need:

- a repository that has already been created by your administrator
- a branch in the repository

- a personal access token (for Bitbucket, this is the Repository Access Token)
- the username of the repository owner
- set permissions in the repository to allow AWS Glue Studio to read and write to the repository
  - **GitLab** – set token scopes to `api`, `read_repository`, and `write_repository`
  - **Bitbucket** – set permissions to:
    - **Workspace membership** – read, write
    - **Projects** – write, admin read
    - **Repositories** – read, write, admin, delete

### Note

When using AWS CodeCommit, personal access token and repository owner are not needed. See [Getting started with Git and AWS CodeCommit](#).

## Using jobs from your source control repository in AWS Glue Studio

In order to pull a job from your source control repository that is not in AWS Glue Studio, and to use that job in AWS Glue Studio, the prerequisites will depend on the type of job.

### For visual jobs:

- you need a folder and a JSON file of the job definition that matches the job name

For example, see the job definition below. The branch in your repository should contain a path `my-visual-job/my-visual-job.json` where both the folder and the JSON file match the job name

```
{
  "name" : "my-visual-job",
  "description" : "",
  "role" : "arn:aws:iam::aws_account_id:role/Rolename",
  "command" : {
    "name" : "glueetl",
    "scriptLocation" : "s3://foldername/scripts/my-visual-job.py",
    "pythonVersion" : "3"
  },
}
```

```

"codegenConfigurationNodes" : "{\\"node-nodeID\\":{\\"S3CsvSource\\":
{\\"AdditionalOptions\\":{\\"EnableSamplePath\\":false,\\"SamplePath\\":\\"s3://notebook-
test-input/netflix_titles.csv\\"},\\"Escaper\\":\\"\\",\\"Exclusions\\":[],\\"Name\\":\\"Amazon
S3\\",\\"OptimizePerformance\\":false,\\"OutputSchemas\\":[{\\"Columns\\":[{\\"Name\\":
\\"show_id\\",\\"Type\\":\\"string\\"},{\\"Name\\":\\"type\\",\\"Type\\":\\"string\\"},{\\"Name\\":
\\"title\\",\\"Type\\":\\"choice\\"},{\\"Name\\":\\"director\\",\\"Type\\":\\"string\\"},{\\"Name\\":
\\"cast\\",\\"Type\\":\\"string\\"},{\\"Name\\":\\"country\\",\\"Type\\":\\"string\\"},{\\"Name\\":
\\"date_added\\",\\"Type\\":\\"string\\"},{\\"Name\\":\\"release_year\\",\\"Type\\":\\"bigint\\"},
{\\"Name\\":\\"rating\\",\\"Type\\":\\"string\\"},{\\"Name\\":\\"duration\\",\\"Type\\":\\"string
\\"},{\\"Name\\":\\"listed_in\\",\\"Type\\":\\"string\\"},{\\"Name\\":\\"description\\",\\"Type
\\":\\"string\\"}]]}],\\"Paths\\":[\\"s3://dalamgir-notebook-test-input/netflix_titles.csv
\\"],\\"QuoteChar\\":\\"quote\\",\\"Recurse\\":true,\\"Separator\\":\\"comma\\",\\"WithHeader
\\":true}}}"
}

```

### For script jobs:

- you need a folder, a JSON file of the job definition, and the script
- the folder and JSON file should match the job name. The script name needs to match the `scriptLocation` in the job definition along with the file extension

For example, in the job definition below, the branch in your repository should contain a path `my-script-job/my-script-job.json` and `my-script-job/my-script-job.py`. The script name should match the name in the `scriptLocation` including the extension of the script

```

{
  "name" : "my-script-job",
  "description" : "",
  "role" : "arn:aws:iam::aws_account_id:role/Rolename",
  "command" : {
    "name" : "glueetl",
    "scriptLocation" : "s3://foldername/scripts/my-script-job.py",
    "pythonVersion" : "3"
  }
}

```

## Limitations

- AWS Glue currently does not support pushing/pulling from [GitLab-Groups](#).

## Connecting version control repositories with AWS Glue

You can enter your version control repository details and manage them in the **Version Control** tab in the AWS Glue Studio job editor. To integrate with your Git repository, you must connect to your repository every time you log in to AWS Glue Studio.

To connect a Git version control system:

1. In AWS Glue Studio, start a new job and choose the **Version Control** tab.

**Untitled job** 

---

Visual | Script | Job details | Runs | Schedules | **Version Control**

 Your job has not been committed to version control. If you wish to do so, choose the **Push to repository** option from the **Actions** dropdown.

**Version control configuration** Reset

Configure the version control system you want to associate with your job.

Version control system  
Choose a version control system.

None 

2. In **Version control system**, choose the Git Service from the available options by clicking on the drop-down menu.

- AWS CodeCommit
- GitHub
- GitLab
- Bitbucket

3. Depending on the Git version control system you choose, you will have different fields to complete.

#### For AWS CodeCommit:

Complete the repository configuration by selecting the repository and branch for your job:

- **Repository** — if you have set up repositories in AWS CodeCommit, select the repository from the drop-down menu. Your repositories will automatically populate in the list
- **Branch** — select the branch from the drop-down menu
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created. The folder name defaults to the job name

#### For GitHub:

Complete the GitHub configuration by completing the fields:

- **Personal access token** — this is the token provided by the GitHub repository. For more information on personal access tokens, see [GitHub Docs](#)
- **Repository owner** — this is the owner of the GitHub repository.

Complete the repository configuration by selecting the repository and branch from GitHub.

- **Repository** — if you have set up repositories in GitHub, select the repository from the drop-down menu. Your repositories will automatically populate in the list
- **Branch** — select the branch from the drop-down menu
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created. The folder name defaults to the job name

#### For GitLab:

##### Note

AWS Glue currently does not support pushing/pulling from [GitLab-Groups](#).

- **Personal access token** — this is the token provided by the GitLab repository. For more information on personal access tokens, see [GitLab Personal access tokens](#)
- **Repository owner** — this is the owner of the GitLab repository.

Complete the repository configuration by selecting the repository and branch from GitLab.

- **Repository** — if you have set up repositories in GitLab, select the repository from the drop-down menu. Your repositories will automatically populate in the list
- **Branch** — select the branch from the drop-down menu
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created. The folder name defaults to the job name

#### For Bitbucket:

- **App password** — Bitbucket uses App passwords and not Repository Access Tokens. For more information on App passwords, see [App passwords](#).
- **Repository owner** — this is the owner of the Bitbucket repository. In Bitbucket, the owner is the creator of the repository.

Complete the repository configuration by selecting the workspace, repository, branch, and folder from Bitbucket.

- **Workspace** – if you have workspaces set up in Bitbucket, select the workspace from the drop-down menu. Your workspaces are automatically populated
- **Repository** — if you have set up repositories in Bitbucket, select the repository from the drop-down menu. Your repositories are automatically populated
- **Branch** — select the branch from the drop-down menu. Your branches are automatically populated
- **Folder** — *optional* - enter the name of the folder in which to save your job. If left empty, a folder is automatically created with the job name.

4. Choose **Save** at the top of the AWS Glue Studio job

## Pushing AWS Glue jobs to the source repository

Once you've entered the details of your version control system, you can edit jobs in AWS Glue Studio and push the jobs to your source repository. If you're unfamiliar with Git concepts such as pushing and pulling, see this tutorial on [Getting started with Git and AWS CodeCommit](#).

In order to push your job to a repository, you need to enter the details of your version control system and save your job.

1. In the AWS Glue Studio job, choose **Actions**. This will open additional menu options.

2. Choose **Push to repository**.

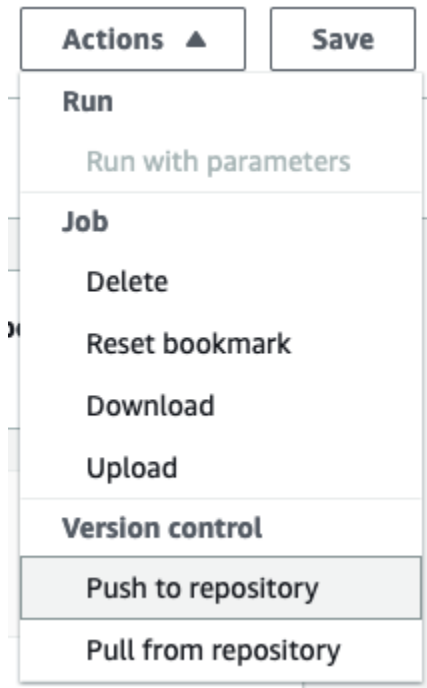

This action will save the job. When you push to repository, AWS Glue Studio pushes the last saved change. If the job in the repository was modified by you or another user and is out of sync with the job in AWS Glue Studio, the job in the repository is overwritten with the job saved in AWS Glue Studio when you push the job from AWS Glue Studio.

3. Choose **Confirm** to complete the action. This creates a new commit in the repository. If you are using AWS CodeCommit, a confirmation message will display a link to the latest commit on AWS CodeCommit.

## Pulling AWS Glue jobs from the source repository

Once you've entered details of your Git repository into the **Version control** tab, you can also pull jobs from your repository and edit them in AWS Glue Studio.

1. In the AWS Glue Studio job, choose **Actions**. This will open additional menu options.

2. Choose **Pull from repository**.
3. Choose **Confirm**. This takes the latest commit from the repository and updates your job in AWS Glue Studio.
4. Edit your job in AWS Glue Studio. If you make changes, you can sync your job to your repository by choosing **Push to repository** from the **Actions** drop-down menu.

## Authoring code with AWS Glue Studio notebooks

Data engineers can author AWS Glue jobs faster and more easily than before using the interactive notebook interface in AWS Glue Studio or interactive sessions in AWS Glue.

### Topics

- [Overview of using notebooks](#)
- [Creating an ETL job using notebooks in AWS Glue Studio](#)
- [Notebook editor components](#)

- [Saving your notebook and job script](#)
- [Managing notebook sessions](#)
- [Using CodeWhisperer with AWS Glue Studio notebooks](#)

## Overview of using notebooks

AWS Glue Studio allows you to interactively author jobs in a notebook interface based on Jupyter Notebooks. Through notebooks in AWS Glue Studio, you can edit job scripts and view the output without having to run a full job, and you can edit data integration code and view the output without having to run a full job, and you can add markdown and save notebooks as .ipynb files and job scripts. You can start a notebook without installing software locally or managing servers. When you are satisfied with your code, AWS Glue Studio can convert your notebook to a Glue job with the click of a button.

Some benefits of using notebooks include:

- No cluster to provision or manage
- No idle clusters to pay for
- No up-front configuration required
- No installation of Jupyter notebooks required
- The same runtime/platform as AWS Glue ETL

When you start a notebook through AWS Glue Studio, all the configuration steps are done for you so that you can explore your data and start developing your job script after only a few seconds. AWS Glue Studio configures a Jupyter notebook with the AWS Glue Jupyter kernel. You don't have to configure VPCs, network connections, or development endpoints to use this notebook.

To create jobs using the notebook interface:

- configure the necessary IAM permissions.
- start a notebook session to create a job
- write code in the cells in the notebook
- run and test the code to view the output
- save the job

After your notebook is saved, your notebook is a full AWS Glue job. You can manage all aspects of the job, such as scheduling jobs runs, setting job parameters, and viewing the job run history right along side your notebook.

## Creating an ETL job using notebooks in AWS Glue Studio

### To start using notebooks in the AWS Glue Studio console

1. Attach AWS Identity and Access Management policies to the AWS Glue Studio user and create an IAM role for your ETL job and notebook.
2. Configure additional IAM security for notebooks, as described in [Granting permissions for the IAM role](#).
3. Open the AWS Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.

#### Note

Check that your browser does not block third-party cookies. Any browser that blocks third party cookies either by default or as a user-enabled setting will prevent notebooks from launching. For more information on managing cookies, see:

- [Chrome](#)
- [Firefox](#)
- [Safari](#)

4. Choose the **Jobs** link in the left-side navigation menu.
5. Choose **Jupyter notebook** and then choose **Create** to start a new notebook session.
6. On the **Create job in Jupyter notebook** page, provide the job name, and choose the IAM role to use. Choose **Create job**.

After a short time period, the notebook editor appears.

7. After you add the code you must execute the cell to initiate a session. There are multiple ways to execute the cell:
  - Press the play button.
  - Use a keyboard shortcut:
    - On MacOS, **Command + Enter** to run the cell.

- On Windows, **Shift + Enter** to run the cell.

For information about writing code using a Jupyter notebook interface, see [The Jupyter Notebook User Documentation](#) .

8. To test your script, run the entire script, or individual cells. Any command output will be displayed in the area beneath the cell.
9. After you have finished developing your notebook, you can save the job and then run it. You can find the script in the **Script** tab. Any magics you added to the notebook will be stripped away and won't be saved as part of the script of the generated AWS Glue job. AWS Glue Studio will auto-add a `job.commit()` to the end of your generated script from the notebook contents.

For more information about running jobs, see [Start a job run](#).

## Notebook editor components

The notebook editor interface has the following main sections.

- Notebook interface (main panel) and toolbar
- Job editing tabs

### The notebook editor

The AWS Glue Studio notebook editor is based on the Jupyter Notebook Application. The AWS Glue Studio notebook interface is similar to that provided by Jupyter Notebooks, which is described in the section [Notebook user interface](#) . The notebook used by interactive sessions is a Jupyter Notebook.

Although the AWS Glue Studio notebook is similar to Jupyter Notebooks, it differs in a few key ways:

- currently, the AWS Glue Studio notebook cannot install extensions
- you cannot use multiple tabs; there is a 1:1 relationship between a job and a notebook
- the AWS Glue Studio notebook does not have the same top file menu that exists in Jupyter Notebooks

- currently, the AWS Glue Studio notebook only runs with the AWS Glue kernel. Note that you cannot update the kernel on your own.

## AWS Glue Studio job editing tabs

The tabs that you use to interact with the ETL job are at the top of the notebook page. They are similar to tabs that appear in the visual job editor of AWS Glue Studio, and they perform the same actions.

- **Notebook** – Use this tab to view the job script using the notebook interface.
- **Job details** – Configure the environment and properties for the job runs.
- **Runs** – View information about previous runs of this job.
- **Schedules** – Configure a schedule for running your job at specific times.

## Saving your notebook and job script

You can save your notebook and the job script you are creating at any time. Simply choose the **Save** button in the upper right corner, the same as if you were using the visual or script editor.

When you choose **Save**, the notebook file is saved in the default locations:

- By default, the job script is saved to the Amazon S3 location indicated in the **Job Details** tab, under **Advanced properties**, in the Job details property **Script path**. Job scripts are saved in a subfolder named **Scripts**.
- By default, the notebook file (`.ipynb`) is saved to the Amazon S3 location indicated in the **Job Details** tab, under **Advanced properties**, in the Job details **Script path**. Notebook files are saved in a subfolder named **Notebooks**.

### Note

When you save the job, the job script contains only the code cells from the notebook. The Markdown cells and magics aren't included in the job script. However, the `.ipynb` file will contain any markdown and magics.

After you save the job, you can then run the job using the script that you created in the notebook.

## Managing notebook sessions

Notebooks in AWS Glue Studio are based on the interactive sessions feature of AWS Glue. There is a cost for using interactive sessions. To help manage your costs, you can monitor the sessions created for your account, and configure the default settings for all sessions.

### Change the default timeout for all notebook sessions

By default, the provisioned AWS Glue Studio notebook times out after 12 hours if the notebook was launched and no cells have been executed. There is no cost associated to it and the timeout is not configurable.

Once you execute a cell this will start an interactive session. This session has a default timeout of 48 hours. This timeout can be configured by passing an `%idle_timeout` magic before executing a cell.

### To modify the default session timeout for notebooks in AWS Glue Studio

1. In the notebook, enter the `%idle_timeout` magic in a cell and specify the timeout value in minutes.
2. For example: `%idle_timeout 15` will change the default timeout to 15 minutes. If the session is not used in 15 minutes, the session is automatically stopped.

## Installing additional Python modules

If you would like to install additional modules to your session using pip you can do so by using `%additional_python_modules` to add them to your session:

```
%additional_python_modules awswrangler, s3://mybucket/mymodule.whl
```

All arguments to `additional_python_modules` are passed to `pip3 install -m <>`

For a list of available Python modules, see [Using Python libraries with AWS Glue](#).

## Changing AWS Glue Configuration

You can use magics to control AWS Glue job configuration values. If you want to change a job configuration value you have to use the proper magic in the notebook. See [Magics supported by AWS Glue interactive sessions for Jupyter](#).

### Note

Overriding properties for a running session is no longer available. In order to change the session's configurations, you can stop the session, set the new configurations and then start a new session.

AWS Glue supports various worker types. You can set the worker type with `%worker_type`. For example: `%worker_type G.2X`. The default is `G.1X`.

You can also specify the Number of workers with `%number_of_workers`. For example, to specify 40 workers: `%number_of_workers 40`.

For more information see [Defining Job Properties](#)

## Stop a notebook session

To stop a notebook session, use the magic `%stop_session`.

If you navigate away from the notebook in the AWS console, you will receive a warning message where you can choose to stop the session.

## Using CodeWhisperer with AWS Glue Studio notebooks

AWS Glue Studio allows you to interactively author jobs in a notebook interface based on Jupyter Notebooks. Using CodeWhisperer improves the authoring experience within AWS Glue Studio notebooks.

The Amazon CodeWhisperer extension supports writing code by generating code recommendations and suggesting improvements related to code issues.

## What is Amazon CodeWhisperer?

Amazon CodeWhisperer is a service powered by machine learning that helps improve developer productivity. CodeWhisperer achieves this by generating code recommendations based on

developers' comments in natural language and their code in the IDE. During preview, Amazon CodeWhisperer is available for the Java, JavaScript, Python, C# and TypeScript programming languages. The service integrates with JupyterLab, Amazon SageMaker Studio, Amazon SageMaker notebook instances, and other integrated development environments (IDEs).

For more information, see the [Setting up CodeWhisperer with AWS Glue Studio](#).

## AWS Glue job run statuses on the console

You can view the status of an AWS Glue extract, transform, and load (ETL) job while it is running or after it has stopped. You can view the status using the AWS Glue console. For more information about job run statuses, see [the section called "Job run statuses"](#).

### Accessing the job monitoring dashboard

You access the job monitoring dashboard by choosing the **Monitoring** link in the AWS Glue navigation pane.

### Overview of the job monitoring dashboard

The job monitoring dashboard provides an overall summary of the job runs, with totals for the jobs with a status of **Running**, **Canceled**, **Success**, or **Failed**. Additional tiles provide the overall job run success rate, the estimated DPU usage for jobs, a breakdown of the job status counts by job type, worker type, and by day.

The graphs in the tiles are interactive. You can choose any block in a graph to run a filter that displays only those jobs in the **Job runs** table at the bottom of the page.

You can change the date range for the information displayed on this page by using the **Date range** selector. When you change the date range, the information tiles adjust to show the values for the specified number of days before the current date. You can also use a specific date range if you choose **Custom** from the date range selector.

### Job runs view

#### Note

Job run history is accessible for 90 days for your workflow and job run.

The **Job runs** resource list shows the jobs for the specified date range and filters.

You can filter the jobs on additional criteria, such as status, worker type, job type, and the job name. In the filter box at the top of the table, you can enter the text to use as a filter. The table results are updated with rows that contain matching text as you enter the text.

You can view a subset of the jobs by choosing elements from the graphs on the job monitoring dashboard. For example, if you choose the number of running jobs in the **Job runs summary** tile, then the **Job runs** list displays only the jobs that currently have a status of Running. If you choose one of the bars in the **Worker type breakdown** bar chart, then only job runs with the matching worker type and status are shown in the **Job runs** list.

The **Job runs** resource list displays the details for the job runs. You can sort the rows in the table by choosing a column heading. The table contains the following information:

Property	Description
Job name	The name of the job.
Type	The type of job environment: <ul style="list-style-type: none"> <li>• <b>Glue ETL:</b> Runs in an Apache Spark environment managed by AWS Glue.</li> <li>• <b>Glue Streaming:</b> Runs in an Apache Spark environment and performs ETL on data streams.</li> <li>• <b>Python shell:</b> Runs Python scripts as a shell.</li> </ul>
Start time	The date and time at which this job run was started.
End time	The date and time that this job run completed.
Run status	The current state of the job run. Values can be: <ul style="list-style-type: none"> <li>• STARTING</li> <li>• RUNNING</li> <li>• STOPPING</li> <li>• STOPPED</li> </ul>

Property	Description
	<ul style="list-style-type: none"><li data-bbox="829 212 1036 243">• SUCCEEDED</li><li data-bbox="829 268 980 300">• FAILED</li><li data-bbox="829 325 997 357">• TIMEOUT</li></ul>
Run time	The amount of time that the job run consumed resources.
Capacity	The number of AWS Glue data processing units (DPUs) that were allocated for this job run. For more information about capacity planning, see <a href="#">Monitoring for DPU Capacity Planning</a> in the <i>AWS Glue Developer Guide</i> .

Property	Description
Worker type	<p>The type of predefined worker that was allocated when the job ran. Values can be G.1X, G.2X, G.4X or G.8X.</p> <ul style="list-style-type: none"><li>• <b>G.1X</b> – When you choose this type, you also provide a value for <b>Number of workers</b>. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free). We recommend this worker type for memory-intensive jobs. This is the default <b>Worker type</b> for AWS Glue Version 2.0 or later jobs.</li><li>• <b>G.2X</b> – When you choose this type, you also provide a value for <b>Number of workers</b>. Each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free). We recommend this worker type for memory-intensive jobs and jobs that run machine learning transforms.</li><li>• <b>G.4X</b> – When you choose this type, you also provide a value for <b>Number of workers</b>. Each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe</li></ul>

Property	Description
	<p>(Frankfurt), Europe (Ireland), and Europe (Stockholm).</p> <ul style="list-style-type: none"> <li>• <b>G.8X</b> – When you choose this type, you also provide a value for <b>Number of workers</b>. Each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.</li> </ul>
DPU hours	The estimated number of DPUs used for the job run. A DPU is a relative measure of processing power. DPUs are used to determine the cost of running your job. For more information, see the <a href="#">AWS Glue pricing</a> page.

You can choose any job run in the list and view additional information. Choose a job run, and then do one of the following:

- Choose the **Actions** menu and the **View job** option to view the job in the visual editor.
- Choose the **Actions** menu and the **Stop run** option to stop the current run of the job.
- Choose the **View CloudWatch logs** button to view the job run logs for that job.
- Choose **View details** to view the job run details page.

## Viewing the job run logs

You can view the job logs in a variety of ways:

- On the **Monitoring** page, in the **Job runs** table, choose a job run, and then choose **View CloudWatch logs**.
- In the visual job editor, on the **Runs** tab for a job, choose the hyperlinks to view the logs:
  - **Logs** – Links to the Apache Spark job logs written when continuous logging is enabled for a job run. When you choose this link, it takes you to the Amazon CloudWatch logs in the `/aws-glue/jobs/logs-v2` log group. By default, the logs exclude non-useful Apache Hadoop YARN heartbeat and Apache Spark driver or executor log messages. For more information about continuous logging, see [Continuous Logging for AWS Glue Jobs](#) in the *AWS Glue Developer Guide*.
  - **Error logs** – Links to the logs written to `stderr` for this job run. When you choose this link, it takes you to the Amazon CloudWatch logs in the `/aws-glue/jobs/error` log group. You can use these logs to view details about any errors that were encountered during the job run.
  - **Output logs** – Links to the logs written to `stdout` for this job run. When you choose this link, it takes you to the Amazon CloudWatch logs in the `/aws-glue/jobs/output` log group. You can use these logs to see all the details about the tables that were created in the AWS Glue Data Catalog and any errors that were encountered.

## Viewing the details of a job run

You can choose a job in the **Job runs** list on the **Monitoring** page, and then choose **View run details** to see detailed information for that run of the job.

The information displayed on the job run detail page includes:

Property	Description
Job name	The name of the job.
Run Status	The current state of the job run. Values can be: <ul style="list-style-type: none"> <li>• STARTING</li> <li>• RUNNING</li> <li>• STOPPING</li> <li>• STOPPED</li> <li>• SUCCEEDED</li> <li>• FAILED</li> </ul>

Property	Description
	<ul style="list-style-type: none"><li>TIMEOUT</li></ul>
Glue version	The AWS Glue version used by the job run.
Recent attempt	The number of automatic retry attempts for this job run.
Start time	The date and time at which this job run was started.
End time	The date and time that this job run completed.
Start-up time	The amount of time spent preparing to run the job.
Execution time	The amount of time spent running the job script.
Trigger name	The name of the trigger associated with the job.
Last modified on	The date when the job was last modified.
Security configuration	The security configuration for the job, which includes Amazon S3 encryption, CloudWatch encryption, and job bookmarks encryption settings.
Timeout	The job run timeout threshold value.
Allocated capacity	The number of AWS Glue data processing units (DPUs) that were allocated for this job run. For more information about capacity planning, see <a href="#">Monitoring for DPU Capacity Planning</a> in the <i>AWS Glue Developer Guide</i> .
Max capacity	The maximum capacity available to the job run.

Property	Description
Number of workers	The number of workers used for the job run.
Worker type	<p>The type of predefined workers allocated for the job run. Values can be G.1X or G.2X.</p> <ul style="list-style-type: none"> <li>• <b>G.1X</b> – When you choose this type, you also provide a value for <b>Number of workers</b>. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory, 64 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs. This is the default <b>Worker type</b> for AWS Glue Version 2.0 or later jobs.</li> <li>• <b>G.2X</b> – When you choose this type, you also provide a value for <b>Number of workers</b>. Each worker maps to 2 DPUs (8 vCPUs, 32 GB of memory, 128 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs and jobs that run machine learning transforms.</li> </ul>
Logs	A link to the job logs for continuous logging ( <code>/aws-glue/jobs/logs-v2</code> ).
Output Logs	A link to the job output log files ( <code>/aws-glue/jobs/output</code> ).
Error logs	A link to the job error log files ( <code>/aws-glue/jobs/error</code> ).

You can also view the following additional items, which are available when you view information for recent job runs. For more information, see [the section called “View information for recent job runs”](#).

- **Input arguments**

- **Continuous logs**
- **Metrics** – You can see visualizations of basic metrics. For more information on included metrics, see [the section called “Viewing Amazon CloudWatch metrics for a Spark job run”](#).
- **Spark UI** – You can visualize Spark logs for your job in the Spark UI. For more information about using the Spark Web UI, see [the section called “Monitoring with the Spark UI”](#). Enable this feature by following the procedure in [the section called “Enabling the Spark UI for jobs”](#).

## Viewing Amazon CloudWatch metrics for a Spark job run

On the details page for a job run, below the **Run details** section, you can view the job metrics. AWS Glue Studio sends job metrics to Amazon CloudWatch for every job run.

AWS Glue reports metrics to Amazon CloudWatch every 30 seconds. The AWS Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute. However, the Apache Spark metrics that AWS Glue passes on to Amazon CloudWatch are generally absolute values that represent the current state at the time they are reported.

### Note

You must configure your account to access Amazon CloudWatch, .

The metrics provide information about your job run, such as:

- **ETL Data Movement** – The number of bytes read from or written to Amazon S3.
- **Memory Profile: Heap used** – The number of memory bytes used by the Java virtual machine (JVM) heap.
- **Memory Profile: heap usage** – The fraction of memory (scale: 0–1), shown as a percentage, used by the JVM heap.
- **CPU Load** – The fraction of CPU system load used (scale: 0–1), shown as a percentage.

## Viewing Amazon CloudWatch metrics for a Ray job run

On the details page for a job run, below the **Run details** section, you can view the job metrics. AWS Glue Studio sends job metrics to Amazon CloudWatch for every job run.

AWS Glue reports metrics to Amazon CloudWatch every 30 seconds. The AWS Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute. However, the Apache Spark metrics that AWS Glue passes on to Amazon CloudWatch are generally absolute values that represent the current state at the time they are reported.

**Note**

You must configure your account to access Amazon CloudWatch, as described in .

In Ray jobs, you can view the following aggregated metric graphs. With these, you can build a profile of your cluster and tasks, and can access detailed information about each node. The time-series data that back these graphs is available in CloudWatch for further analysis.

**Task Profile: Task State**

Shows the number of Ray tasks in the system. Each task lifecycle is given its own time series.

**Task Profile: Task Name**

Shows the number of Ray tasks in the system. Only pending and active tasks are shown. Each type of task (by name) is given its own time series.

**Cluster Profile: CPUs in use**

Shows the number of CPU cores that are used. Each node is given its own time series. Nodes are identified by IP addresses, which are ephemeral and only used for identification.

**Cluster Profile: Object store memory use**

Shows memory use by the Ray object cache. Each memory location (physical memory, cached on disk, and spilled in Amazon S3) is given its own time series. The object store manages data storage across all nodes in the cluster. For more information, see [Objects](#) in the Ray documentation.

**Cluster Profile: Node count**

Shows the number of nodes provisioned for the cluster.

**Node Detail: CPU use**

Shows CPU utilization on each node as a percentage. Each series shows an aggregated percentage of CPU usage across all cores on the node.

### **Node Detail: Memory use**

Shows memory use on each node in GB. Each series shows memory aggregated between all processes on the node, including Ray tasks and the Plasma store process. This will not reflect objects stored to disk or spilled to Amazon S3.

### **Node Detail: Disk use**

Shows disk use on each node in GB.

### **Node Detail: Disk I/O speed**

Shows disk I/O on each node in KB/s.

### **Node Detail: Network I/O throughput**

Shows network I/O on each node in KB/s.

### **Node Detail: CPU use by Ray component**

Shows CPU use in fractions of a core. Each ray component on each node is given its own time series.

### **Node Detail: Memory use by Ray component**

Shows memory use in GiB. Each ray component on each node is given its own time series.

## **Detect and process sensitive data**

The Detect PII transform identifies Personal Identifiable Information (PII) in your data source. You choose the PII entity to identify, how you want the data to be scanned, and what to do with the PII entity that have been identified by the Detect PII transform.

The Detect PII transform provides the ability to detect, mask, or remove entities that you define, or are pre-defined by AWS. This enables you to increase compliance and reduce liability. For example, you may want to ensure that no personally identifiable information exists in your data that can be read and want to mask social security numbers with a fixed string (such as xxx-xx-xxxx), phone numbers, or addresses.

To work with sensitive data outside of AWS Glue Studio, see [Using Sensitive Data Detection outside AWS Glue Studio](#)

### **Topics**

- [Choosing how you want the data to be scanned](#)

- [Choosing the PII entities to detect](#)
- [Specifying the level of detection sensitivity](#)
- [Choosing what to do with identified PII data](#)
- [Adding fine-grained action overrides](#)

## Choosing how you want the data to be scanned

When you scan your dataset for sensitive data like personally identifiable information (PII), you can choose to detect PII in each row or detect the columns that contain PII data.

<input type="radio"/> <b>Detect PII in each cell</b> Scan the entire data set, and act on each occurrence individually.	<input checked="" type="radio"/> <b>Detect fields containing PII</b> To reduce costs and improve performance, sample only a portion of the data and act on fields across all records.
--	--

### Sample portion

The percentage of rows to sample out of the entire data set.

 %

Between 1 and 100.

### Detection threshold

To consider a field as containing PII, set the minimum percentage of detected rows out of the sampled rows.

 %

Between 1 and 100.

When you choose **Detect PII in each cell**, you're choosing to scan all rows in the data source. This is a comprehensive scan to ensure that PII entities are identified.

When you choose **Detect fields containing PII**, you're choosing to scan a sample of rows for PII entities. This is a way to keep costs and resources low while also identifying the fields where PII entities are found.

When you choose to detect fields that contain PII, you can reduce costs and improve performance by sampling a portion of rows. Choosing this option will allow you to specify additional options:

- **Sample portion:** This allows you to specify the percentage of rows to sample. For example, if you enter '50', you're specifying that you want 50 percent of scanned rows for the PII entity.

- **Detection threshold:** This allows you to specify the percentage of rows that contain the PII entity in order for the entire column to be identified as having the PII entity. For example, if you enter '10', you're specifying that the number of the PII entity, US Phone, in the rows that are scanned must be 10 percent or greater in order for the field to be identified as having the PII entity, US Phone. If the percentage of rows that contain the PII entity is less than 10 percent, that field will not be labeled as having the PII entity, US Phone, in it.

## Choosing the PII entities to detect

If you chose **Detect PII in each cell**, you can choose from one of three options:

- All available PII patterns - this includes AWS entities.
- Select categories - when you select categories, PII patterns will automatically include patterns in the categories that you select.
- Select specific patterns - Only the patterns that you select will be detected.

For a full list of managed sensitive data types, see [Managed data types](#).

### Choose from all available PII patterns

If you choose **All available PII patterns**, select entities pre-defined by AWS. You can select one, more than one, or all entities.

## Select entities to detect

Available entities (19)

Select all

Clear all

Manage

All categories ▼

&lt; 1 &gt;

<input type="checkbox"/>	Entity name ▼	Category ▲
<input type="checkbox"/>	Person's name	Universal, HIPAA
<input type="checkbox"/>	Email (General)	Universal
<input type="checkbox"/>	Credit Card	Universal
<input type="checkbox"/>	IP Address	Networking
<input type="checkbox"/>	MAC Address	Networking
<input type="checkbox"/>	US Phone	United States, HIPAA
<input type="checkbox"/>	US Passport	United States
<input type="checkbox"/>	Social Security Number (SSN)	United States, HIPAA
<input type="checkbox"/>	US Individual Taxpayer Identification Number (ITIN)	United States, HIPAA
<input type="checkbox"/>	US/Canada bank account	United States, HIPAA
<input type="checkbox"/>	US driving license	HIPAA
<input type="checkbox"/>	Healthcare Common Procedure Coding System (HCPCS) code	HIPAA
<input type="checkbox"/>	National Drug Code (NDC)	HIPAA
<input type="checkbox"/>	National Provider Identifier (NPI)	HIPAA
<input type="checkbox"/>	Drug Enforcement Agency (DEA) Registration Number	HIPAA
<input type="checkbox"/>	Health Insurance Claim Number (HICN)	HIPAA
<input type="checkbox"/>	Medicare Beneficiary Identifier	HIPAA

## Select categories

If you chose **Select categories** as the PII patterns to detect, you can select from the options in the drop-down menu. Note that some entities can belong to more than one category. For example, *Person's name* is an entity that belongs to the *Universal* and *HIPAA* categories.

- Universal (examples: Email, Credit Card)
- HIPAA (examples: US Driving License, Healthcare Common Procedure Coding System (HCPCS) code)
- Networking (examples: IP Address, MAC Address)
- Argentina
- Australia
- Austria
- Belgium
- Bosnia
- Bulgaria
- Canada
- Chile
- Colombia
- Croatia
- Cyprus
- Czechia
- Denmark
- Estonia
- Finland
- France
- Germany
- Greece
- Hungary
- Ireland
- Korea
- Japan

- Mexico
- Netherlands
- New Zealand
- Norway
- Portugal
- Romania
- Singapore
- Slovakia
- Slovenia
- Spain
- Sweden
- Switzerland
- Turkey
- Ukraine
- United States
- United Kingdom
- Venezuela

## Select specific patterns

If you choose **Select specific patterns** as the PII patterns to detect, you can search or browse from a list of patterns you've already created, or create a new detection entity pattern.

The steps below describe how to create a new custom pattern for detecting sensitive data. You will create the custom pattern by entering a name for the custom pattern, add a regular expression, and optionally, define context words.

1. To create a new pattern, click the **Create new** button.

### Select patterns

The screenshot shows a user interface for selecting patterns. It features a search bar with a magnifying glass icon and the placeholder text "search patterns by name, or browse to select". To the right of the search bar are two buttons: "Browse" and "Create new" with an external link icon.

2. In the Create detection entity page, enter the entity name and a regular expression. The regular expression (Regex) is what AWS Glue will use to match entities.
3. Click **Validate**. If the validation is successful, you will see a confirmation message stating that the string is a valid regular expression. If the validation is not successful, you will see a message stating that the string does not conform to proper formatting and accepted character literals, operators or constructs.
4. You can choose to add Context words in addition to the regular expression. Context words may increase the likelihood of a match. These can be useful in cases where field names are not descriptive of the entity. For example, social security numbers may be named 'SSN' or 'SS'. Adding these context words can help match the entity.
5. Click **Create** to create the detection entity. Any created entities are visible in the AWS Glue Studio console. Click on **Detection entities** in the left-hand navigation menu.

You can edit, delete, or create detection entities from the **Detection entities** page. You can also search for a pattern using the search field.

## Specifying the level of detection sensitivity

You can set the level of sensitivity when using detecting sensitive data.

- **High** – (Default) Detects more entities for use cases that require a higher level of sensitivity. All AWS Glue jobs created after November 2023 are automatically opted-in to this setting.
- **Low** – Detects fewer entities and reduces false positives.

### Select global detection sensitivity

Choose the level of detection sensitivity to apply to your data set.

- High (default)**  
Detects more entities for use cases that require a higher level of sensitivity.
- Low**  
Detects fewer entities and reduces false positives.

## Choosing what to do with identified PII data

If you chose to detect PII in the entire data source, you can select a global action to apply:

- **Enrich data with detection results:** If you chose Detect PII in each cell, you can store the detected entities into a new column.
- **Redact detected text:** You can replace the detected PII value with a string that you specify in the optional Replacing text input field. If no string is specified, the detected PII entity is replaced with '\*\*\*\*\*'.
- **Partially redact detected text:** You can replace part of the detected PII value with a string you choose. There are two possible options: to either leave the ends unmasked or to mask by providing an explicit regex pattern. This feature is not available in AWS Glue 2.0.
- **Apply cryptographic hash:** You can pass the detected PII value to a SHA-256 cryptographic hash function and replace the value with the function's output.

#### Select global action (required)

Choose an action to take on detected entities.

- DETECT. Enrich data with detection results.**  
Create a new column that will contain any entity type detected in that row.
- REDACT. Redact detected text.**  
Replace detected entity with a string you choose.
- PARTIAL\_REDACT. Partially redact detected text.**  
Replace part of a detected entity with a string you choose.
- SHA256\_HASH. Apply cryptographic hash.**  
Apply a SHA-256 cryptographic hash function to the input string.

## Differences between AWS Glue versions 2.0 and 3.0+

AWS Glue 2.0 jobs will return a new DataFrame with the detected PII information for each column in a supplementary column. Any redaction or hash work is visible within the AWS Glue script in the visual tab.

AWS Glue 3.0 and 4.0 jobs will return a new DataFrame with this same supplementary column. A new key for "actionUsed" is present and can be one of DETECT, REDACT, PARTIAL\_REDACT, or SHA256\_HASH. If a masking action is selected, the DataFrame will return data with sensitive data masked.

## Adding fine-grained action overrides

Additional detection and action settings can be added to the fine-grained actions overrides table. This allows you to:

- **Include or exclude certain columns from detection** – An inferred schema on the data source will populate the table with available columns.
- **Specify specific settings that are more fine-grained than using global actions** – For example, you can specify different redaction text settings for different entity types.
- **Specify a different action than the global action** – If a different action wants to be applied on a different sensitive data type, that can be done here. Note that two different edit-in-place actions (redaction and hashing) cannot be used on the same column, but detect can always be used.

**Fine grained actions (overrides) (0)**

Select entities to add a fine grained action different from the global action above.

< 1 >

	Entity type ▲	Action ▼	Action options	Columns
No overrides				

## Managing ETL jobs with AWS Glue Studio

You can use the simple graphical interface in AWS Glue Studio to manage your ETL jobs. Using the navigation menu, choose **Jobs** to view the **Jobs** page. On this page, you can see all the jobs that you have created either with AWS Glue Studio or the AWS Glue console. You can view, manage, and run your jobs on this page.

**You can also perform the following tasks on this page:**

- [Start a job run](#)
- [Schedule job runs](#)
- [Manage job schedules](#)
- [Stop job runs](#)
- [View your jobs](#)
- [View information for recent job runs](#)

- [View the job script](#)
- [Modify the job properties](#)
- [Save the job](#)
- [Clone a job](#)
- [Delete jobs](#)

## Start a job run

In AWS Glue Studio, you can run your jobs on demand. A job can run multiple times, and each time you run the job, AWS Glue collects information about the job activities and performance. This information is referred to as a *job run* and is identified by a job run ID.

You can initiate a job run in the following ways in AWS Glue Studio:

- On the **Jobs** page, choose the job you want to start, and then choose the **Run job** button.
- If you're viewing a job in the visual editor and the job has been saved, you can choose the **Run** button to start a job run.

For more information about job runs, see [Working with Jobs on the AWS Glue Console](#) in the *AWS Glue Developer Guide*.

## Schedule job runs

In AWS Glue Studio, you can create a schedule to have your jobs run at specific times. You can specify constraints, such as the number of times that the jobs run, which days of the week they run, and at what time. These constraints are based on `cron` and have the same limitations as `cron`. For example, if you choose to run your job on day 31 of each month, keep in mind that some months don't have 31 days. For more information about `cron`, see [Cron Expressions](#) in the *AWS Glue Developer Guide*.

### To run jobs according to a schedule

1. Create a job schedule using one of the following methods:
  - On the **Jobs** page, choose the job you want to create a schedule for, choose **Actions**, and then choose **Schedule job**.

- If you're viewing a job in the visual editor and the job has been saved, choose the **Schedules** tab. Then choose **Create Schedule**.
2. On the **Schedule job run** page, enter the following information:
    - **Name:** Enter a name for your job schedule.
    - **Frequency:** Enter the frequency for the job schedule. You can choose the following:
      - **Hourly:** The job will run every hour, starting at a specific minute. You can specify the **Minute** of the hour that the job should run. By default, when you choose hourly, the job runs at the beginning of the hour (minute 0).
      - **Daily:** The job will run every day, starting at a time. You can specify the **Minute** of the hour that the job should run and the **Start hour** for the job. Hours are specified using a 23-hour clock, where you use the numbers 13 to 23 for the afternoon hours. The default values for minute and hour are 0, which means that if you select **Daily**, the job by default will run at midnight.
      - **Weekly:** The job will run every week on one or more days. In addition to the same settings described previous for Daily, you can choose the days of the week on which the job will run. You can choose one or more days.
      - **Monthly:** The job will run every month on a specific day. In addition to the same settings described previous for Daily, you can choose the day of the month on which the job will run. Specify the day as a numeric value from 1 to 31. If you select a day that does not exist in a month, for example the 30<sup>th</sup> day of February, then the job does not run that month.
      - **Custom:** Enter an expression for your job schedule using the cron syntax. Cron expressions allow you to create more complicated schedules, such as the last day of the month (instead of a specific day of the month) or every third month on the 7<sup>th</sup> and 21<sup>st</sup> days of the month.

See [Cron Expressions](#) in the *AWS Glue Developer Guide*

    - **Description:** You can optionally enter a description for your job schedule. If you plan to use the same schedule for multiple jobs, having a description makes it easier to determine what the job schedule does.
  3. Choose **Create schedule** to save the job schedule.
  4. After you create the schedule, a success message appears at the top of the console page. You can choose **Job details** in this banner to view the job details. This opens the visual job editor page, with the **Schedules** tab selected.

## Manage job schedules

After you have created schedules for a job, you can open the job in the visual editor and choose the **Schedules** tab to manage the schedules.

On the **Schedules** tab of the visual editor, you can perform the following tasks:

- Create a new schedule.

Choose **Create schedule**, then enter the information for your schedule as described in [the section called "Schedule job runs"](#).

- Edit an existing schedule.

Choose the schedule you want to edit, then choose **Action** followed by **Edit schedule**. When you choose to edit an existing schedule, the **Frequency** shows as **Custom**, and the schedule is displayed as a cron expression. You can either modify the cron expression, or specify a new schedule using the **Frequency** button. When you finish with your changes, choose **Update schedule**.

- Pause an active schedule.

Choose an active schedule, and then choose **Action** followed by **Pause schedule**. The schedule is instantly deactivated. Choose the refresh (reload) button to see the updated job schedule status.

- Resume a paused schedule.

Choose a deactivated schedule, and then choose **Action** followed by **Resume schedule**. The schedule is instantly activated. Choose the refresh (reload) button to see the updated job schedule status.

- Delete a schedule.

Choose the schedule you want to remove, and then choose **Action** followed by **Delete schedule**. The schedule is instantly deleted. Choose the refresh (reload) button to see the updated job schedule list. The schedule will show a status of **Deleting** until it has been completely removed.

## Stop job runs

You can stop a job before it has completed its job run. You might choose this option if you know that the job isn't configured correctly, or if the job is taking too long to complete.

On the **Monitoring** page, in the **Job runs** list, choose the job that you want to stop, choose **Actions**, and then choose **Stop run**.

## View your jobs

You can view all your jobs on the **Jobs** page. You can access this page by choosing **Jobs** in the navigation pane.

On the **Jobs** page, you can see all the jobs that were created in your account. The **Your jobs** list shows the job name, its type, the status of the last run of that job, and the dates on which the job was created and last modified. You can choose the name of a job to see detailed information for that job.

You can also use the Monitoring dashboard to view all your jobs. You can access the dashboard by choosing **Monitoring** in the navigation pane.

## Customize the job display

You can customize how the jobs are displayed in the **Your jobs** section of the **Jobs** page. Also, you can enter text in the search text field to display only jobs with a name that contains that text.

If you choose the settings icon

in the **Your jobs** section, you can customize how AWS Glue Studio displays the information in the table. You can choose to wrap the lines of text in the display, change the number of jobs displayed on the page, and specify which columns to display.

## View information for recent job runs

A job can run multiple times as new data is added at the source location. Each time a job runs, the job run is assigned a unique ID, and information about that job run is collected. You can view this information by using the following methods:

- Choose the **Runs** tab of the visual editor to view the job run information for the currently displayed job.

On the **Runs** tab (the **Recent job runs** page), there is a card for each job run. The information displayed on the **Runs** tab includes:

- Job run ID

- Number of attempts to run this job
  - Status of the job run
  - Start and end time for the job run
  - The runtime for the job run
  - A link to the job log files
  - A link to the job error log files
  - The error returned for failed jobs
- You can select a job run to view additional information about the job, including the following:
    - **Input arguments**
    - **Continuous logs**
    - **Metrics** – You can see visualizations of basic metrics. For more information on included metrics, see [the section called “Viewing Amazon CloudWatch metrics for a Spark job run”](#).
    - **Spark UI** – You can visualize Spark logs for your job in the Spark UI. For more information about using the Spark Web UI, see [the section called “Monitoring with the Spark UI”](#). Enable this feature by following the procedure in [the section called “Enabling the Spark UI for jobs”](#).

You can select **View details** to view similar information on the job run details page. Alternatively, you can navigate to the job run details page through the **Monitoring** page. In the navigation pane, choose **Monitoring**. Scroll down to the **Job runs** list. Choose the job and then choose **View run details**. The contents are described in [Viewing the details of a job run](#).

For more information about the job logs, see [Viewing the job run logs](#).

## View the job script

After you provide information for all the nodes in the job, AWS Glue Studio generates a script that is used by the job to read the data from the source, transform the data, and write the data in the target location. If you save the job, you can view this script at any time.

### To view the generated script for your job

1. Choose **Jobs** in the navigation pane.
2. On the **Jobs** page, in the **Your Jobs** list, choose the name of the job you want to review. Alternatively, you can select a job in the list, choose the **Actions** menu, and then choose **Edit job**.

3. On the visual editor page, choose the **Script** tab at the top to view the job script.

If you want to edit the job script, see [AWS Glue programming guide](#).

## Modify the job properties

The nodes in the job diagram define the actions performed by the job, but there are several properties that you can configure for the job as well. These properties determine the environment that the job runs in, the resources it uses, the threshold settings, the security settings, and more.

### To customize the job run environment

1. Choose **Jobs** in the navigation pane.
2. On the **Jobs** page, in the **Your Jobs** list, choose the name of the job you want to review.
3. On the visual editor page, choose the **Job details** tab at the top of the job editing pane.
4. Modify the job properties, as needed.

For more information about the job properties, see [Defining Job Properties](#) in the *AWS Glue Developer Guide*.

5. Expand the **Advanced properties** section if you need to specify these additional job properties:
  - **Script filename** – The name of the file that stores the job script in Amazon S3.
  - **Script path** – The Amazon S3 location where the job script is stored.
  - **Job metrics** – (Not available for Python shell jobs) Turns on the creation of Amazon CloudWatch metrics when this job runs.
  - **Continuous logging** – (Not available for Python shell jobs) Turns on continuous logging to CloudWatch, so the logs are available for viewing before the job completes.
  - **Spark UI and Spark UI logs path** – (Not available for Python shell jobs) Turns on the use of Spark UI for monitoring this job and specifies the location for the Spark UI logs.
  - **Maximum concurrency** – Sets the maximum number of concurrent runs that are allowed for this job.
  - **Temporary path** – The location of a working directory in Amazon S3 where temporary intermediate results are written when AWS Glue runs the job script.
  - **Delay notification threshold (minutes)** – Specify a delay threshold for the job. If the job runs for a longer time than that specified by the threshold, then AWS Glue sends a delay notification for the job to CloudWatch.

- **Security configuration and Server-side encryption** – Use these fields to choose the encryption options for the job.
  - **Use Glue Data Catalog as the Hive metastore** – Choose this option if you want to use the AWS Glue Data Catalog as an alternative to Apache Hive Metastore.
  - **Additional network connection** – For a data source in a VPC, you can specify a connection of type `Network` to ensure your job accesses your data through the VPC.
  - **Python library path, Dependent jars path** (Not available for Python shell jobs), or **Referenced files path** – Use these fields to specify the location of additional files used by the job when it runs the script.
  - **Job Parameters** – You can add a set of key-value pairs that are passed as named parameters to the job script. In Python calls to AWS Glue APIs, it's best to pass parameters explicitly by name. For more information about using parameters in a job script, see [Passing and Accessing Python Parameters in AWS Glue](#) in the *AWS Glue Developer Guide*.
  - **Tags** – You can add tags to the job to help you organize and identify them.
6. After you have modified the job properties, save the job.

## Store Spark shuffle files on Amazon S3

Some ETL jobs require reading and combining information from multiple partitions, for example, when using a join transform. This operation is referred to as *shuffling*. During a shuffle, data is written to disk and transferred across the network. With AWS Glue version 3.0, you can configure Amazon S3 as a storage location for these files. AWS Glue provides a shuffle manager which writes and reads shuffle files to and from Amazon S3. Writing and reading shuffle files from Amazon S3 is slower (by 5%-20%) compared to local disk (or Amazon EBS which is heavily optimized for Amazon EC2). However, Amazon S3 provides unlimited storage capacity, so you don't have to worry about "No space left on device" errors when running your job.

### To configure your job to use Amazon S3 for shuffle files

1. On the **Jobs** page, in the **Your Jobs** list, choose the name of the job you want to modify.
2. On the visual editor page, choose the **Job details** tab at the top of the job editing pane.

Scroll down to the **Job parameters** section.

3. Specify the following key-value pairs.
  - `--write-shuffle-files-to-s3 — true`

This is the main parameter that configures the shuffle manager in AWS Glue to use Amazon S3 buckets for writing and reading shuffle data. By default, this parameter has a value of `false`.

- (Optional) `--write-shuffle-spills-to-s3` — `true`

This parameter allows you to offload spill files to Amazon S3 buckets, which provides additional resiliency to your Spark job in AWS Glue. This is only required for large workloads that spill a lot of data to disk. By default, this parameter has a value of `false`.

- (Optional) `--conf spark.shuffle.glue.s3ShuffleBucket` — `S3://<shuffle-bucket>`

This parameter specifies the Amazon S3 bucket to use when writing the shuffle files. If you do not set this parameter, the location is the `shuffle-data` folder in the location specified for **Temporary path** (`--TempDir`).

#### Note

Make sure the location of the shuffle bucket is in the same AWS Region in which the job runs.

Also, the shuffle service does not clean the files after the job finishes running, so you should configure the Amazon S3 storage life cycle policies on the shuffle bucket location. For more information, see [Managing your storage lifecycle](#) in the *Amazon S3 User Guide*.

## Save the job

A red **Job has not been saved** callout is displayed to the left of the **Save** button until you save the job.

Job has not been saved

 Save

### To save your job

1. Provide all the required information in the **Visual** and **Job details** tabs.
2. Choose the **Save** button.

After you save the job, the 'not saved' callout changes to display the time and date that the job was last saved.

If you exit AWS Glue Studio before saving your job, the next time you sign in to AWS Glue Studio, a notification appears. The notification indicates that there is an unsaved job, and asks if you want to restore it. If you choose to restore the job, you can continue to edit it.

## Troubleshooting errors when saving a job

If you choose the **Save** button, but your job is missing some required information, then a red callout appears on the tab where the information is missing. The number in the callout indicates how many missing fields were detected.

- If a node in the visual editor isn't configured correctly, the **Visual** tab shows a red callout, and the node with the error displays a warning symbol .
  1. Choose the node. In the node details panel, a red callout appears on the tab where the missing or incorrect information is located.
  2. Choose the tab in the node details panel that shows a red callout, and then locate the problem fields, which are highlighted. An error message below the fields provides additional information about the problem.

The screenshot displays the AWS Glue console interface for an "Untitled job". At the top right, there is a red notification "Job has not been saved" and buttons for "Save" and "Run". The navigation tabs include "Visual 2", "Script", "Job details 1", "Runs", and "Schedules". The "Job details" tab is active, showing a toolbar with "Source", "Transform", "Target", "Undo", "Redo", and "Remove" options. The main workspace is a grid where a "Data source - S3 bucket" node is placed, with a red warning icon next to it. On the right, the "Data source properties - S3 2" panel is open, showing the "Output schema" section. Under "S3 source type", "Data Catalog table" is selected. The "Database" dropdown is set to "Choose a database" and is highlighted in red with the error message "Database is required." Below it, the "Table" dropdown is also set to "Choose a table" and is highlighted in red with the error message "Table is required." The "Partition predicate" field is optional and currently empty.

- If there is a problem with the job properties, the **Job details** tab shows a red callout. Choose that tab and locate the problem fields, which are highlighted. The error messages below the fields provide additional information about the problem.

## Untitled job

Visual **2** | Script | **Job details 1** | Runs | Schedules

### Basic properties [Info](#)

#### Name

#### Description - optional

Descriptions can be up to 2048 characters long.

#### IAM Role

Role assumed by the job with permission to access your data stores. Ensure that this role has permission to your Amazon S3 sources, targets, temporary directory, scripts, and any libraries used by the job.

 IAM Role is required.

#### Type

The type of ETL job. This is set automatically based on the types of data sources you have selected.

## Clone a job

You can use the **Clone job** action to copy an existing job into a new job.

### To create a new job by copying an existing job

1. On the **Jobs** page, in the **Your jobs** list, choose the job that you want to duplicate.
2. From the **Actions** menu, choose **Clone job**.
3. Enter a name for the new job. You can then save or edit the job.

## Delete jobs

You can remove jobs that are no longer needed. You can delete one or more jobs in a single operation.

## To remove jobs from AWS Glue Studio

1. On the **Jobs** page, in the **Your jobs** list, choose the jobs that you want to delete.
2. From the **Actions** menu, choose **Delete job**.
3. Verify that you want to delete the job by entering **delete**.

You can also delete a saved job when you're viewing the **Job details** tab for that job in the visual editor.

# Working with jobs in AWS Glue

The following sections provide information on ETL and Ray jobs in AWS Glue.

## Topics

- [AWS Glue versions](#)

## AWS Glue versions

You can configure the AWS Glue version parameter when you add or update a job. The AWS Glue version determines the versions of Apache Spark and Python that AWS Glue supports. The Python version indicates the version that's supported for jobs of type Spark. The following table lists the available AWS Glue versions, the corresponding Spark and Python versions, and other changes in functionality.

## AWS Glue versions

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
AWS Glue 4.0	<b>Spark environment versions</b> <ul style="list-style-type: none"> <li>• Spark 3.3.0</li> <li>• Python 3.10</li> </ul>	Java 8	AWS Glue 4.0 is the latest version of AWS Glue. There are several optimizations and upgrades built into this AWS Glue release, such as:

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			<ul style="list-style-type: none"> <li>• Many Spark functionality upgrades from Spark 3.1 to Spark 3.3:</li> <li>• Several functionality improvements when paired with Pandas. For more information, see <a href="#">What's New in Spark 3.3</a>.</li> <li>• Additional optimizations developed on Amazon EMR.</li> <li>• Upgrade to EMR File System (EMRFS) 2.53.</li> <li>• Log4j 2 migration from Log4j 1.x</li> <li>• Several Python module updates from AWS Glue 3.0, such as an upgraded version of Boto.</li> <li>• Upgrade of several connectors, including the default Amazon Redshift connector</li> </ul>

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			<p>. See <a href="#">Appendix C: Connector upgrades</a>.</p> <ul style="list-style-type: none"> <li>• Upgrade of several JDBC drivers. See <a href="#">Appendix B: JDBC driver upgrades</a>.</li> <li>• Updated with a new Amazon Redshift connector and JDBC driver.</li> <li>• Native support for open-data lake frameworks with Apache Hudi, Delta Lake, and Apache Iceberg.</li> <li>• Native support for the Amazon S3-based Cloud Shuffle Storage Plugin (an Apache Spark plugin) to use Amazon S3 for shuffling and elastic storage capacity.</li> </ul> <p><b>Limitations</b></p>

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
			<p>The following are limitations with AWS Glue 4.0:</p> <ul style="list-style-type: none"><li>• AWS Glue machine learning and personally identifiable information (PII) transforms are not yet available in AWS Glue 4.0.</li></ul> <p>For more information about migrating to AWS Glue version 4.0, see <a href="#">Migrating AWS Glue for Spark jobs to AWS Glue version 4.0</a>.</p>

AWS Glue version	Supported runtime environment versions	Supported Java version	Changes in functionality
	<p><b>Ray environment versions</b></p> <ul style="list-style-type: none"> <li>Ray 2.4.0</li> </ul> <p>Python 3.9</p>	N/A	<p>Build and run distributed Python applications with AWS Glue for Ray.</p> <ul style="list-style-type: none"> <li>Supports Ray-2.4.0 data distribution (<code>ray[data]</code>) with Python 3.9. ## Running Spark ETL jobs with reduced startup times

AWS Glue versions 2.0 and later provide an upgraded infrastructure for running Apache Spark ETL (extract, transform, and load) jobs in AWS Glue with reduced startup times. With the reduced wait times, data engineers can be more productive and increase their interactivity with AWS Glue. The reduced variance in job start times can help you meet or exceed your SLAs of making data available for analytics.

To use this feature with your AWS Glue ETL jobs, choose **2.0** or a later version for the Glue version when creating your jobs.

## Topics

- [New features supported](#)
- [Logging behavior](#)
- [Features not supported](#)

## New features supported

This section describes new features supported with AWS Glue versions 2.0 and later.

### Support for specifying additional Python modules at the job level

AWS Glue versions 2.0 and later also let you provide additional Python modules or different versions at the job level. You can use the `--additional-python-modules` option with a list of comma-separated Python modules to add a new module or change the version of an existing module.

For example to update or to add a new `scikit-learn` module use the following key/value: `--additional-python-modules", "scikit-learn==0.21.3"`.

Also, within the `--additional-python-modules` option you can specify an Amazon S3 path to a Python wheel module. For example:

```
--additional-python-modules s3://aws-glue-native-spark/tests/j4.2/ephem-3.7.7.1-cp37-cp37m-linux_x86_64.whl,s3://aws-glue-native-spark/tests/j4.2/fbprophet-0.6-py3-none-any.whl,scikit-learn==0.21.3
```

AWS Glue uses the Python Package Installer (`pip3`) to install the additional modules. You can pass additional options specified by the `python-modules-installer-option` to `pip3` for installing the modules. Any incompatibility or limitations from `pip3` will apply.

### Python modules already provided in AWS Glue version 2.0

AWS Glue version 2.0 supports the following python modules out of the box:

- `setuptools`—45.2.0
- `subprocess32`—3.5.4

- ptvsd—4.3.2
- pydevd—1.9.0
- PyMySQL—0.9.3
- docutils—0.15.2
- jmespath—0.9.4
- six—1.14.0
- python\_dateutil—2.8.1
- urllib3—1.25.8
- botocore—1.15.4
- s3transfer—0.3.3
- boto3—1.12.4
- certifi—2019.11.28
- chardet—3.0.4
- idna—2.9
- requests—2.23.0
- pyparsing—2.4.6
- enum34—1.1.9
- pytz—2019.3
- numpy—1.18.1
- cyclcr—0.10.0
- kiwisolver—1.1.0
- scipy—1.4.1
- pandas—1.0.1
- pyarrow—0.16.0
- matplotlib—3.1.3
- pyhocon—0.3.54
- mpmath—1.1.0
- sympy—1.5.1
- patsy—0.5.1
- statsmodels—0.11.1

- fsspec—0.6.2
- s3fs—0.4.0
- Cython—0.29.15
- joblib—0.14.1
- pmdarima—1.5.3
- scikit-learn—0.22.1
- tbats—1.0.9

## Logging behavior

AWS Glue versions 2.0 and later support different default logging behavior. The differences include:

- Logging occurs in realtime.
- There are separate streams for drivers and executors.
- For each driver and executor there are two streams, the output stream and the error stream.

### Driver and executor streams

Driver streams are identified by the job run ID. Executor streams are identified by the job *<run id>\_<executor task id>*. For example:

- "logStreamName":  
"jr\_8255308b426fff1b4e09e00e0bd5612b1b4ec848d7884cebe61ed33a31789...\_g-f65f617bd31d54bd94482af755b6cdf464542..."

### Output and errors streams

The output stream has the standard output (stdout) from your code. The error stream has logging messages from the your code/library.

- Log streams:
  - Driver log streams have *<jr>*, where *<jr>* is the job run ID.
  - Executor log streams have *<jr>\_<g>*, where *<g>* is the task ID for the executor. You can look up the executor task ID in the driver error log.

The default log groups for AWS Glue version 2.0 are as follows:

- `/aws-glue/jobs/logs/output` for output
- `/aws-glue/jobs/logs/error` for errors

When a security configuration is provided, the log group names change to:

- `/aws-glue/jobs/<security configuration>-role/<Role Name>/output`
- `/aws-glue/jobs/<security configuration>-role/<Role Name>/error`

On the console the **Logs** link points to the output log group and the **Error** link points to the error log group. When continuous logging is enabled, the **Logs** link points to the continuous log group, and the **Output** link points to the output log group.

## Logging rules

### Note

The default log groupname for continuous logging is `/aws-glue/jobs/logs-v2`.

In AWS Glue versions 2.0 and later, continuous logging has the same behavior as in AWS Glue version 1.0:

- Default log group: `/aws-glue/jobs/logs-v2`
- Driver log stream: `<jr>-driver`
- Executor log stream: `<jr>-<executor ID>`

The log group name can be changed by setting `--continuous-log-logGroupName`

The log streams name can be prefixed by setting `--continuous-log-logStreamPrefix`

## Features not supported

The following AWS Glue features are not supported:

- Development endpoints
- AWS Glue versions 2.0 and later do not run on Apache YARN, so YARN settings do not apply

- AWS Glue versions 2.0 and later do not have a Hadoop Distributed File System (HDFS)
- AWS Glue versions 2.0 and later do not use dynamic allocation, hence the `ExecutorAllocationManager` metrics are not available
- For AWS Glue version 2.0 or later jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue versions 2.0 and later do not support `s3n` out of the box. We recommend using `s3` or `s3a`. If jobs need to use `s3n` for any reason, you can pass the following additional argument:

```
--conf spark.hadoop.fs.s3n.impl=com.amazon.ws.emr.hadoop.fs.EmrFileSystem
```

## Migrating AWS Glue for Spark jobs to AWS Glue version 3.0

This topic describes the changes between AWS Glue versions 0.9, 1.0, 2.0 and 3.0 to allow you to migrate your Spark applications and ETL jobs to AWS Glue 3.0.

To use this feature with your AWS Glue ETL jobs, choose **3.0** for the Glue version when creating your jobs.

### Topics

- [New features supported](#)
- [Actions to migrate to AWS Glue 3.0](#)
- [Migration check list](#)
- [Migrating from AWS Glue 0.9 to AWS Glue 3.0](#)
- [Migrating from AWS Glue 1.0 to AWS Glue 3.0](#)
- [Migrating from AWS Glue 2.0 to AWS Glue 3.0](#)
- [Appendix A: notable dependency upgrades](#)
- [Appendix B: JDBC driver upgrades](#)

### New features supported

This section describes new features and advantages of AWS Glue version 3.0.

- It is based on Apache Spark 3.1.1, which has optimizations from open-source Spark and developed by the AWS Glue and EMR services such as adaptive query execution, vectorized readers, and optimized shuffles and partition coalescing.

- Upgraded JDBC drivers for all Glue native sources including MySQL, Microsoft SQL Server, Oracle, PostgreSQL, MongoDB, and upgraded Spark libraries and dependencies brought in by Spark 3.1.1.
- Optimized Amazon S3 access with upgraded EMRFS and enabled Amazon S3 optimized output committers by default.
- Optimized Data Catalog access with partition indexes, push down predicates, partition listing, and upgraded Hive metastore client.
- Integration with Lake Formation for governed catalog tables with cell-level filtering and data lake transactions.
- Improved Spark UI experience with Spark 3.1.1 with new Spark executor memory metrics and Spark structured streaming metrics.
- Reduced startup latency improving overall job completion times and interactivity, similar to AWS Glue 2.0.
- Spark jobs are billed in 1-second increments with a 10x lower minimum billing duration—from a 10-minute minimum to a 1-minute minimum, similar to AWS Glue 2.0.

## Actions to migrate to AWS Glue 3.0

For existing jobs, change the Glue version from the previous version to Glue 3.0 in the job configuration.

- In the console, choose Spark 3.1, Python 3 (Glue Version 3.0) or Spark 3.1, Scala 2 (Glue Version 3.0) in Glue version.
- In AWS Glue Studio, choose Glue 3.0 - Supports spark 3.1, Scala 2, Python 3 in Glue version.
- In the API, choose **3.0** in the GlueVersion parameter in the [UpdateJob](#) API.

For new jobs, choose Glue 3.0 when you create a job.

- In the console, choose Spark 3.1, Python 3 (Glue Version 3.0) or Spark 3.1, Scala 2 (Glue Version 3.0) in Glue version.
- In AWS Glue Studio, choose Glue 3.0 - Supports spark 3.1, Scala 2, Python 3 in Glue version.
- In the API, choose **3.0** in the GlueVersion parameter in the [CreateJob](#) API.

To view Spark event logs of AWS Glue 3.0, [launch an upgraded Spark history server for Glue 3.0 using CloudFormation or Docker](#).

## Migration check list

Review this checklist for migration.

- Does your job depend on HDFS? If yes, try replacing HDFS with S3.
  - Search the file system path starting with `hdfs://` or `/` as DFS path in the job script code.
  - Check if your default file system is not configured with HDFS. If it is configured explicitly, you need to remove the `fs.defaultFS` configuration.
  - Check if your job contains any `dfs.*` parameters. If it contains any, you need to verify it is okay to disable the parameters.
- Does your job depend on YARN? If yes, verify the impacts by checking if your job contains the following parameters. If it contains any, you need to verify it is okay to disable the parameters.

- `spark.yarn.*`

For example:

```
spark.yarn.executor.memoryOverhead
spark.yarn.driver.memoryOverhead
spark.yarn.scheduler.reporterThread.maxFailures
```

- `yarn.*`

For example:

```
yarn.scheduler.maximum-allocation-mb
yarn.nodemanager.resource.memory-mb
```

- Does your job depend on Spark 2.2.1 or Spark 2.4.3? If yes, verify the impacts by checking if your job uses features changed in Spark 3.1.1.
  - <https://spark.apache.org/docs/latest/sql-migration-guide.html#upgrading-from-spark-sql-22-to-23>

For example the `percentile_approx` function, or the `SparkSession` with `SparkSession.builder.getOrCreate()` when there is an existing `SparkContext`.

- <https://spark.apache.org/docs/latest/sql-migration-guide.html#upgrading-from-spark-sql-23-to-24>

For example the `array_contains` function, or the `CURRENT_DATE`, `CURRENT_TIMESTAMP` function with `spark.sql.caseSensitive=true`.

- Do your job's extra jars conflict in Glue 3.0?
  - From AWS Glue 0.9/1.0: Extra jars supplied in existing AWS Glue 0.9/1.0 jobs may bring in classpath conflicts due to upgraded or new dependencies available in Glue 3.0. You can avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter or by shading your dependencies.
  - From AWS Glue 2.0: You can still avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter or by shading your dependencies.
- Do your jobs depend on Scala 2.11?
  - AWS Glue 3.0 uses Scala 2.12 so you need to rebuild your libraries with Scala 2.12 if your libraries depend on Scala 2.11.
- Do your job's external Python libraries depend on Python 2.7/3.6?
  - Use the `--additional-python-modules` parameters instead of setting the egg/wheel/zip file in the Python library path.
  - Update the dependent libraries from Python 2.7/3.6 to Python 3.7 as Spark 3.1.1 removed Python 2.7 support.

## Migrating from AWS Glue 0.9 to AWS Glue 3.0

Note the following changes when migrating:

- AWS Glue 0.9 uses open-source Spark 2.2.1 and AWS Glue 3.0 uses EMR-optimized Spark 3.1.1.
  - Several Spark changes alone may require revision of your scripts to ensure removed features are not being referenced.
  - For example, Spark 3.1.1 does not enable Scala-untyped UDFs but Spark 2.2 does allow them.
- All jobs in AWS Glue 3.0 will be executed with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration since startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed since AWS Glue 2.0.
- Several dependency updates, highlighted in [Appendix A: notable dependency upgrades](#).
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backwards compatible with Scala 2.11.

- Python 3.7 is also the default version used for Python scripts, as AWS Glue 0.9 was only utilizing Python 2.
  - Python 2.7 is not supported with Spark 3.1.1.
  - A new mechanism of installing additional Python modules is available.
- AWS Glue 3.0 does not run on Apache YARN, so YARN settings do not apply.
- AWS Glue 3.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra jars supplied in existing AWS Glue 0.9 jobs may bring in conflicting dependencies since there were upgrades in several dependencies in 3.0 from 0.9. You can avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter.
- AWS Glue 3.0 does not yet support dynamic allocation, hence the `ExecutorAllocationManager` metrics are not available.
- In AWS Glue version 3.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue 3.0 does not yet support machine learning transforms.
- AWS Glue 3.0 does not yet support development endpoints.

Refer to the Spark migration documentation:

- see [Upgrading from Spark SQL 2.2 to 2.3](#)
- see [Upgrading from Spark SQL 2.3 to 2.4](#)
- see [Upgrading from Spark SQL 2.4 to 3.0](#)
- see [Upgrading from Spark SQL 3.0 to 3.1](#)
- see [Changes in Datetime behavior to be expected since Spark 3.0.](#)

## Migrating from AWS Glue 1.0 to AWS Glue 3.0

Note the following changes when migrating:

- AWS Glue 1.0 uses open-source Spark 2.4 and AWS Glue 3.0 uses EMR-optimized Spark 3.1.1.
  - Several Spark changes alone may require revision of your scripts to ensure removed features are not being referenced.
  - For example, Spark 3.1.1 does not enable Scala-untyped UDFs but Spark 2.4 does allow them.

- All jobs in AWS Glue 3.0 will be executed with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration since startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed since AWS Glue 2.0.
- Several dependency updates, highlighted in
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backwards compatible with Scala 2.11.
- Python 3.7 is also the default version used for Python scripts, as AWS Glue 0.9 was only utilizing Python 2.
  - Python 2.7 is not supported with Spark 3.1.1.
  - A new mechanism of installing additional Python modules is available.
- AWS Glue 3.0 does not run on Apache YARN, so YARN settings do not apply.
- AWS Glue 3.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra jars supplied in existing AWS Glue 1.0 jobs may bring in conflicting dependencies since there were upgrades in several dependencies in 3.0 from 1.0. You can avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter.
- AWS Glue 3.0 does not yet support dynamic allocation, hence the `ExecutorAllocationManager` metrics are not available.
- In AWS Glue version 3.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue 3.0 does not yet support machine learning transforms.
- AWS Glue 3.0 does not yet support development endpoints.

Refer to the Spark migration documentation:

- see [Upgrading from Spark SQL 2.4 to 3.0](#)
- see [Changes in Datetime behavior to be expected since Spark 3.0.](#)

## Migrating from AWS Glue 2.0 to AWS Glue 3.0

Note the following changes when migrating:

- All existing job parameters and major features that exist in AWS Glue 2.0 will exist in AWS Glue 3.0.

- The EMRFS S3-optimized committer for writing Parquet data into Amazon S3 is enabled by default in AWS Glue 3.0. However, you can still disable it by setting `--enable-s3-parquet-optimized-committer` to `false`.
- AWS Glue 2.0 uses open-source Spark 2.4 and AWS Glue 3.0 uses EMR-optimized Spark 3.1.1.
  - Several Spark changes alone may require revision of your scripts to ensure removed features are not being referenced.
  - For example, Spark 3.1.1 does not enable Scala-untyped UDFs but Spark 2.4 does allow them.
- AWS Glue 3.0 also features an update to EMRFS, updated JDBC drivers, and inclusions of additional optimizations onto Spark itself provided by AWS Glue.
- All jobs in AWS Glue 3.0 will be executed with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration since startup latency will go from 10 minutes maximum to 1 minute maximum.
- Python 2.7 is not supported with Spark 3.1.1.
- Several dependency updates, highlighted in [Appendix A: notable dependency upgrades](#).
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backwards compatible with Scala 2.11.
- Any extra jars supplied in existing AWS Glue 2.0 jobs may bring in conflicting dependencies since there were upgrades in several dependencies in 3.0 from 2.0. You can avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter.
- AWS Glue 3.0 has different Spark task parallelism for driver/executor configuration compared to AWS Glue 2.0 and improves the performance and better utilizes the available resources. Both `spark.driver.cores` and `spark.executor.cores` are configured to number of cores on AWS Glue 3.0 (4 on the standard and G.1X worker, and 8 on the G.2X worker). These configurations do not change the worker type or hardware for the AWS Glue job. You can use these configurations to calculate the number of partitions or splits to match the Spark task parallelism in your Spark application.

In general, jobs will see either similar or improved performance compared to AWS Glue 2.0. If jobs run slower, you can increase the task parallelism by passing the following job argument:

- key: `--executor-cores` value: *<desired number of tasks that can run in parallel>*
- The value should not exceed 2x the number of vCPUs on the worker type, which is 8 on G.1X, 16 on G.2X, 32 on G.4X and 64 on G.8X. You should exercise caution while updating this

configuration as it could impact job performance because the increased parallelism causes memory and disk pressure, as well as it could throttle the source and target systems.

- AWS Glue 3.0 uses Spark 3.1, which changes the behavior to loading/saving of timestamps from/to parquet files. For more details, see [Upgrading from Spark SQL 3.0 to 3.1](#).

We recommend to set the following parameters when reading/writing parquet data that contains timestamp columns. Setting those parameters can resolve the calendar incompatibility issue that occurs during the Spark 2 to Spark 3 upgrade, for both the AWS Glue Dynamic Frame and Spark Data Frame. Use the CORRECTED option to read the datetime value as it is; and the LEGACY option to rebase the datetime values with regard to the calendar difference during reading.

```
- Key: --conf
- Value: spark.sql.legacy.parquet.int96RebaseModeInRead=[CORRECTED|LEGACY] --conf spark.sql.legacy.parquet.int96RebaseModeInWrite=[CORRECTED|LEGACY] --conf spark.sql.legacy.parquet.datetimeRebaseModeInRead=[CORRECTED|LEGACY]
```

Refer to the Spark migration documentation:

- see [Upgrading from Spark SQL 2.4 to 3.0](#)
- see [Changes in Datetime behavior to be expected since Spark 3.0](#).

## Appendix A: notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in AWS Glue 0.9	Version in AWS Glue 1.0	Version in AWS Glue 2.0	Version in AWS Glue 3.0
Spark	2.2.1	2.4.3	2.4.3	3.1.1-amzn-0
Hadoop	2.7.3-amzn-6	2.8.5-amzn-1	2.8.5-amzn-5	3.2.1-amzn-3
Scala	2.11	2.11	2.11	2.12
Jackson	2.7.x	2.7.x	2.7.x	2.10.x
Hive	1.2	1.2	1.2	2.3.7-amzn-4

Dependency	Version in AWS Glue 0.9	Version in AWS Glue 1.0	Version in AWS Glue 2.0	Version in AWS Glue 3.0
EMRFS	2.20.0	2.30.0	2.38.0	2.46.0
Json4s	3.2.x	3.5.x	3.5.x	3.6.6
Arrow	N/A	0.10.0	0.10.0	2.0.0
AWS Glue Catalog client	N/A	N/A	1.10.0	3.0.0

## Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in past AWS Glue versions	JDBC driver version in AWS Glue 3.0
MySQL	5.1	8.0.23
Microsoft SQL Server	6.1.0	7.0.0
Oracle Databases	11.2	21.1
PostgreSQL	42.1.0	42.2.18
MongoDB	2.0.0	4.0.0

## Migrating AWS Glue for Spark jobs to AWS Glue version 4.0

This topic describes the changes between AWS Glue versions 0.9, 1.0, 2.0, and 3.0 to allow you to migrate your Spark applications and ETL jobs to AWS Glue 4.0. It also describes the features in AWS Glue 4.0 and the advantages of using it.

To use this feature with your AWS Glue ETL jobs, choose **4.0** for the Glue version when creating your jobs.

### Topics

- [New features supported](#)
- [Actions to migrate to AWS Glue 4.0](#)
- [Migration checklist](#)
- [Migrating from AWS Glue 3.0 to AWS Glue 4.0](#)
- [Migrating from AWS Glue 2.0 to AWS Glue 4.0](#)
- [Migrating from AWS Glue 1.0 to AWS Glue 4.0](#)
- [Migrating from AWS Glue 0.9 to AWS Glue 4.0](#)
- [Connector and JDBC driver migration for AWS Glue 4.0](#)
- [Appendix A: Notable dependency upgrades](#)
- [Appendix B: JDBC driver upgrades](#)
- [Appendix C: Connector upgrades](#)

## New features supported

This section describes new features and advantages of AWS Glue version 4.0.

- It is based on Apache Spark 3.3.0, but includes optimizations in AWS Glue, and Amazon EMR, such as adaptive query runs, vectorized readers, and optimized shuffles and partition coalescing.
- Upgraded JDBC drivers for all AWS Glue native sources including MySQL, Microsoft SQL Server, Oracle, PostgreSQL, MongoDB, and upgraded Spark libraries and dependencies brought in by Spark 3.3.0.
- Updated with a new Amazon Redshift connector and JDBC driver.
- Optimized Amazon S3 access with upgraded EMR File System (EMRFS) and enabled Amazon S3-optimized output committers, by default.
- Optimized Data Catalog access with partition indexes, pushdown predicates, partition listing, and an upgraded Hive metastore client.
- Integration with Lake Formation for governed catalog tables with cell-level filtering and data lake transactions.
- Reduced startup latency to improve overall job completion times and interactivity.
- Spark jobs are billed in 1-second increments with a 10x lower minimum billing duration—from a 10-minute minimum to a 1-minute minimum.
- Native support for open-data lake frameworks with Apache Hudi, Delta Lake, and Apache Iceberg.

- Native support for the Amazon S3-based Cloud Shuffle Storage Plugin (an Apache Spark plugin) to use Amazon S3 for shuffling and elastic storage capacity.

## Major enhancements from Spark 3.1.1 to Spark 3.3.0

Note the following enhancements:

- Row-level runtime filtering ([SPARK-32268](#)).
- ANSI enhancements ([SPARK-38860](#)).
- Error message improvements ([SPARK-38781](#)).
- Support complex types for Parquet vectorized reader ([SPARK-34863](#)).
- Hidden file metadata support for Spark SQL ([SPARK-37273](#)).
- Provide a profiler for Python/Pandas UDFs ([SPARK-37443](#)).
- Introduce Trigger.AvailableNow for running streaming queries like Trigger.Once in multiple batches ([SPARK-36533](#)).
- More comprehensive Datasource V2 pushdown capabilities ([SPARK-38788](#)).
- Migrating from log4j 1 to log4j 2 ([SPARK-37814](#)).

## Other notable changes

Note the following changes:

- Breaking changes
  - Drop references to Python 3.6 support in docs and Python/docs ([SPARK-36977](#)).
  - Remove named tuple hack by replacing built-in pickle to cloudpickle ([SPARK-32079](#)).
  - Bump minimum pandas version to 1.0.5 ([SPARK-37465](#)).

## Actions to migrate to AWS Glue 4.0

For existing jobs, change the Glue version from the previous version to Glue 4.0 in the job configuration.

- In AWS Glue Studio, choose Glue 4.0 - Supports Spark 3.3, Scala 2, Python 3 in Glue version.
- In the API, choose 4.0 in the GlueVersion parameter in the [UpdateJob](#) API operation.

For new jobs, choose Glue 4.0 when you create a job.

- In the console, choose Spark 3.3, Python 3 (Glue Version 4.0) or Spark 3.3, Scala 2 (Glue Version 3.0) in Glue version.
- In AWS Glue Studio, choose Glue 4.0 - Supports Spark 3.3, Scala 2, Python 3 in Glue version.
- In the API, choose 4.0 in the GlueVersion parameter in the [CreateJob](#) API operation.

To view Spark event logs of AWS Glue 4.0 coming from AWS Glue 2.0 or earlier, [launch an upgraded Spark history server for AWS Glue 4.0 using AWS CloudFormation or Docker](#).

## Migration checklist

Review this checklist for migration:

### Note

For checklist items related to AWS Glue 3.0, see [Migration check list](#).

- Do your job's external Python libraries depend on Python 2.7/3.6?
  - Update the dependent libraries from Python 2.7/3.6 to Python 3.10 as Spark 3.3.0 completely removed Python 2.7 and 3.6 support.

## Migrating from AWS Glue 3.0 to AWS Glue 4.0

Note the following changes when migrating:

- All existing job parameters and major features that exist in AWS Glue 3.0 will exist in AWS Glue 4.0.
- AWS Glue 3.0 uses Amazon EMR-optimized Spark 3.1.1, and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.

Several Spark changes alone might require revision of your scripts to ensure that removed features are not being referenced.

- AWS Glue 4.0 also features an update to EMRFS and Hadoop. For the specific version, see [Appendix A: Notable dependency upgrades](#).

- The AWS SDK provided in ETL jobs is now upgraded from 1.11 to 1.12.
- All Python jobs will be using Python version 3.10. Previously, Python 3.7 was used in AWS Glue 3.0.

As a result, some pymodules brought out-of-the-box by AWS Glue are upgraded.

- Log4j has been upgraded to Log4j2.
  - For information on the Log4j2 migration path, see the [Log4j documentation](#).
  - You must rename any custom log4j.properties file as a log4j2.properties file instead, with the appropriate log4j2 properties.
- For migrating certain connectors, see [Connector and JDBC driver migration for AWS Glue 4.0](#).
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See the instructions for AWS Glue job migration.

You can safely upgrade an AWS Glue 2.0/3.0 job to an AWS Glue 4.0 job because AWS Glue 2.0/3.0 already contains the AWS Encryption SDK bridge version.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)

## Migrating from AWS Glue 2.0 to AWS Glue 4.0

Note the following changes when migrating:

### Note

For migration steps related to AWS Glue 3.0, see [Migrating from AWS Glue 3.0 to AWS Glue 4.0](#).

- All existing job parameters and major features that exist in AWS Glue 2.0 will exist in AWS Glue 4.0.

- The EMRFS S3-optimized committer for writing Parquet data into Amazon S3 is enabled by default since AWS Glue 3.0. However, you can still disable it by setting `--enable-s3-parquet-optimized-committer` to `false`.
- AWS Glue 2.0 uses open-source Spark 2.4 and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
  - Several Spark changes alone may require revision of your scripts to ensure that removed features are not being referenced.
  - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.4 does allow them.
- The AWS SDK provided in ETL jobs is now upgraded from 1.11 to 1.12.
- AWS Glue 4.0 also features an update to EMRFS, updated JDBC drivers, and inclusions of additional optimizations onto Spark itself provided by AWS Glue.
- Scala is updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is the default version used for Python scripts, as AWS Glue 2.0 was only using Python 3.7 and 2.7.
  - Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an `IllegalArgumentException`.
  - A new mechanism of installing additional Python modules is available since AWS Glue 2.0.
- Several dependency updates, highlighted in [Appendix A: Notable dependency upgrades](#).
- Any extra JAR files supplied in existing AWS Glue 2.0 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 4.0 from 2.0. You can avoid classpath conflicts in AWS Glue 4.0 with the `--user-jars-first` AWS Glue job parameter.
- AWS Glue 4.0 uses Spark 3.3. Starting with Spark 3.1, there was a change in the behavior of loading/saving of timestamps from/to parquet files. For more details, see [Upgrading from Spark SQL 3.0 to 3.1](#).

We recommend to set the following parameters when reading/writing parquet data that contains timestamp columns. Setting those parameters can resolve the calendar incompatibility issue that occurs during the Spark 2 to Spark 3 upgrade, for both the AWS Glue Dynamic Frame and Spark Data Frame. Use the `CORRECTED` option to read the datetime value as it is; and the `LEGACY` option to rebase the datetime values with regard to the calendar difference during reading.

- Key: `--conf`

```
- Value: spark.sql.legacy.parquet.int96RebaseModeInRead=[CORRECTED|LEGACY] --  
conf spark.sql.legacy.parquet.int96RebaseModeInWrite=[CORRECTED|LEGACY] --conf  
spark.sql.legacy.parquet.datetimeRebaseModeInRead=[CORRECTED|LEGACY]
```

- For migrating certain connectors, see [Connector and JDBC driver migration for AWS Glue 4.0](#).
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See these instructions for AWS Glue job migration:
  - You can safely upgrade an AWS Glue 2.0 job to an AWS Glue 4.0 job because AWS Glue 2.0 already contains the AWS Encryption SDK bridge version.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 2.4 to 3.0](#)
- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)
- [Changes in Datetime behavior to be expected since Spark 3.0](#).

## Migrating from AWS Glue 1.0 to AWS Glue 4.0

Note the following changes when migrating:

- AWS Glue 1.0 uses open-source Spark 2.4 and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
  - Several Spark changes alone may require revision of your scripts to ensure that removed features are not being referenced.
  - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.4 does allow them.
- All jobs in AWS Glue 4.0 will be run with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration since startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed significantly in AWS Glue 4.0, Spark 3.3.0 has a minimum requirement of Log4j2.
- Several dependency updates, highlighted in the appendix.
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.

- Python 3.10 is also the default version used for Python scripts, as AWS Glue 0.9 was only using Python 2.

Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an `IllegalArgumentException`.

- A new mechanism of installing additional Python modules through pip is available since AWS Glue 2.0. For more information, see [Installing additional Python modules with pip in AWS Glue 2.0+](#).
- AWS Glue 4.0 does not run on Apache YARN, so YARN settings do not apply.
- AWS Glue 4.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra JAR files supplied in existing AWS Glue 1.0 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 4.0 from 1.0. We enable AWS Glue 4.0 with the `--user-jars-first` AWS Glue job parameter by default, to avoid this problem.
- AWS Glue 4.0 supports auto scaling. Therefore, the `ExecutorAllocationManager` metric will be available when auto scaling is enabled.
- In AWS Glue version 4.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue 4.0 does not yet support machine learning transforms.
- For migrating certain connectors, see [Connector and JDBC driver migration for AWS Glue 4.0](#).
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See these instructions for AWS Glue job migration.
  - You cannot migrate an AWS Glue 0.9/1.0 job to an AWS Glue 4.0 job directly. This is because when upgrading directly to version 2.x or later and enabling all new features immediately, the AWS Encryption SDK won't be able to decrypt the ciphertext encrypted under earlier versions of the AWS Encryption SDK.
  - To safely upgrade, we first recommend that you migrate to an AWS Glue 2.0/3.0 job that contains the AWS Encryption SDK bridge version. Run the job once to utilize the AWS Encryption SDK bridge version.
  - Upon completion, you can safely migrate the AWS Glue 2.0/3.0 job to AWS Glue 4.0.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 2.4 to 3.0](#)
- [Upgrading from Spark SQL 3.0 to 3.1](#)
- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)
- [Changes in Datetime behavior to be expected since Spark 3.0.](#)

## Migrating from AWS Glue 0.9 to AWS Glue 4.0

Note the following changes when migrating:

- AWS Glue 0.9 uses open-source Spark 2.2.1 and AWS Glue 4.0 uses Amazon EMR-optimized Spark 3.3.0.
  - Several Spark changes alone might require revision of your scripts to ensure that removed features are not being referenced.
  - For example, Spark 3.3.0 does not enable Scala-untyped UDFs, but Spark 2.2 does allow them.
- All jobs in AWS Glue 4.0 will be run with significantly improved startup times. Spark jobs will be billed in 1-second increments with a 10x lower minimum billing duration because startup latency will go from 10 minutes maximum to 1 minute maximum.
- Logging behavior has changed significantly since AWS Glue 4.0, Spark 3.3.0 has a minimum requirement of Log4j2 as mentioned here (<https://spark.apache.org/docs/latest/core-migration-guide.html#upgrading-from-core-32-to-33>).
- Several dependency updates, highlighted in the appendix.
- Scala is also updated to 2.12 from 2.11, and Scala 2.12 is not backward compatible with Scala 2.11.
- Python 3.10 is also the default version used for Python scripts, as AWS Glue 0.9 was only using Python 2.
  - Python 2.7 is not supported with Spark 3.3.0. Any job requesting Python 2 in the job configuration will fail with an `IllegalArgumentException`.
  - A new mechanism of installing additional Python modules through pip is available.
- AWS Glue 4.0 does not run on Apache YARN, so YARN settings do not apply.
- AWS Glue 4.0 does not have a Hadoop Distributed File System (HDFS).
- Any extra JAR files supplied in existing AWS Glue 0.9 jobs might bring in conflicting dependencies because there were upgrades in several dependencies in 3.0 from 0.9. You

can avoid classpath conflicts in AWS Glue 3.0 with the `--user-jars-first` AWS Glue job parameter.

- AWS Glue 4.0 supports auto scaling. Therefore, the `ExecutorAllocationManager` metric will be available when auto scaling is enabled.
- In AWS Glue version 4.0 jobs, you specify the number of workers and worker type, but do not specify a `maxCapacity`.
- AWS Glue 4.0 does not yet support machine learning transforms.
- For migrating certain connectors, see [Connector and JDBC driver migration for AWS Glue 4.0](#).
- The AWS Encryption SDK is upgraded from 1.x to 2.x. AWS Glue jobs using AWS Glue security configurations and jobs dependent on the AWS Encryption SDK dependency provided in runtime are affected. See these instructions for AWS Glue job migration.
  - You cannot migrate an AWS Glue 0.9/1.0 job to an AWS Glue 4.0 job directly. This is because when upgrading directly to version 2.x or later and enabling all new features immediately, the AWS Encryption SDK won't be able to decrypt the ciphertext encrypted under earlier versions of the AWS Encryption SDK.
  - To safely upgrade, we first recommend that you migrate to an AWS Glue 2.0/3.0 job that contains the AWS Encryption SDK bridge version. Run the job once to utilize the AWS Encryption SDK bridge version.
  - Upon completion, you can safely migrate the AWS Glue 2.0/3.0 job to AWS Glue 4.0.

Refer to the Spark migration documentation:

- [Upgrading from Spark SQL 2.2 to 2.3](#)
- [Upgrading from Spark SQL 2.3 to 2.4](#)
- [Upgrading from Spark SQL 2.4 to 3.0](#)
- [Upgrading from Spark SQL 3.0 to 3.1](#)
- [Upgrading from Spark SQL 3.1 to 3.2](#)
- [Upgrading from Spark SQL 3.2 to 3.3](#)
- [Changes in Datetime behavior to be expected since Spark 3.0](#).

## Connector and JDBC driver migration for AWS Glue 4.0

For the versions of JDBC and data lake connectors that were upgraded, see:

- [Appendix B: JDBC driver upgrades](#)
- [Appendix C: Connector upgrades](#)

## Hudi

- Spark SQL support improvements:
  - Through the `Call Procedure` command, there is added support for upgrade, downgrade, bootstrap, clean, and repair. `Create/Drop/Show/Refresh Index` syntax is possible in Spark SQL.
  - A performance gap has been closed between usage through a Spark DataSource as opposed to Spark SQL. Datasource writes in the past used to be faster than SQL.
  - All built-in key generators implement more performant Spark-specific API operations.
  - Replaced UDF transformation in the bulk `insert` operation with RDD transformations to cut down on costs of using SerDe.
  - Spark SQL with Hudi requires a `primaryKey` to be specified by `tblproperties` or options in the SQL statement. For update and delete operations, the `preCombineField` is required as well.
- Any Hudi table created before version 0.10.0 without a `primaryKey` needs to be recreated with a `primaryKey` field since version 0.10.0.

## PostgreSQL

- Several vulnerabilities (CVEs) were addressed.
- Java 8 is natively supported.
- If the job is using Arrays of Arrays, with the exception of byte arrays, this scenario can be treated as multidimensional arrays.

## MongoDB

- The current MongoDB connector supports Spark version 3.1 or later and MongoDB version 4.0 or later.
- Due to the connector upgrade, a few property names changed. For example, the URI property name changed to `connection.uri`. For more information on the current options, see the [MongoDB Spark Connector blog](#).

- Using MongoDB 4.0 hosted by Amazon DocumentDB has some functional differences. For more information, see these topics:
  - [Functional Differences: Amazon DocumentDB and MongoDB](#)
  - [Supported MongoDB APIs, Operations, and Data Types](#).
- The "partitioner" option is restricted to `ShardedPartitioner`, `PaginateIntoPartitionsPartitioner`, and `SinglePartitionPartitioner`. It cannot use default `SamplePartitioner` and `PaginateBySizePartitioner` for Amazon DocumentDB because the stage operator does not support the MongoDB API. For more information, see [Supported MongoDB APIs, Operations, and Data Types](#).

## Delta Lake

- Delta Lake now supports [time travel in SQL](#) to query older data easily. With this update, time travel is now available both in Spark SQL and through the DataFrame API. Support has been added for the current version of `TIMESTAMP` in SQL.
- Spark 3.3 introduces [Trigger.AvailableNow](#) for running streaming queries as an equivalent to `Trigger.Once` for batch queries. This support is also available when using Delta tables as a streaming source.
- Support for `SHOW COLUMNS` to return the list of columns in a table.
- Support for [DESCRIBE DETAIL](#) in the Scala and Python DeltaTable API. It retrieves detailed information about a Delta table using either the DeltaTable API or Spark SQL.
- Support for returning operation metrics from SQL [Delete](#), [Merge](#), and [Update](#) commands. Previously these SQL commands returned an empty DataFrame, now they return a DataFrame with useful metrics about the operation performed.
- Optimize performance improvements:
  - Set the configuration option `spark.databricks.delta.optimize.repartition.enabled=true` to use `repartition(1)` instead of `coalesce(1)` in the `Optimize` command for better performance when compacting many small files.
  - [Improved performance](#) by using a queue-based approach to parallelize compaction jobs.
- Other notable changes:
  - [Support for using variables](#) in the `VACUUM` and `OPTIMIZE` SQL commands.
  - Improvements for `CONVERT TO DELTA` with catalog tables including:
    - [Autofill the partition schema](#) from the catalog when it's not provided.

- [Use partition information](#) from the catalog to find the data files to commit instead of doing a full directory scan. Instead of committing all data files in the table directory, only data files under the directories of active partitions will be committed.
- [Support for Change Data Feed \(CDF\) batch reads](#) on column mapping enabled tables when DROP COLUMN and RENAME COLUMN have not been used. For more information, see the [Delta Lake documentation](#).
- [Improve Update command performance](#) by enabling schema pruning in the first pass.

## Apache Iceberg

- Added several [performance improvements](#) for scan planning and Spark queries.
- Added a common REST catalog client that uses change-based commits to resolve commit conflicts on the service side.
- AS OF syntax for SQL time travel queries is supported.
- Added merge-on-read support for MERGE and UPDATE queries.
- Added support to rewrite partitions using Z-order.
- Added a spec and implementation for Puffin, a format for large stats and index blobs, like [Theta sketches](#) or bloom filters.
- Added new interfaces for consuming data incrementally (both append and changelog scans).
- Added support for bulk operations and ranged reads to FileIO interfaces.
- Added more metadata tables to show delete files in the metadata tree.
- The drop table behavior changed. In Iceberg 0.13.1, running DROP TABLE removes the table from the catalog and deletes the table contents as well. In Iceberg 1.0.0, DROP TABLE only removes the table from the catalog. To delete the table contents use DROP TABLE PURGE.
- Parquet vectorized reads are enabled by default in Iceberg 1.0.0. If you want to disable vectorized reads, set `read.parquet.vectorization.enabled` to false.

## Oracle

Changes are minor.

## MySQL

Changes are minor.

## Amazon Redshift

AWS Glue 4.0 features a new Amazon Redshift connector with a new JDBC driver. For information about the enhancements and how to migrate from previous AWS Glue versions, see [the section called “Redshift connections”](#).

## Appendix A: Notable dependency upgrades

The following are dependency upgrades:

Dependency	Version in AWS Glue 4.0	Version in AWS Glue 3.0	Version in AWS Glue 2.0	Version in AWS Glue 1.0
Spark	3.3.0-amzn-1	3.1.1-amzn-0	2.4.3	2.4.3
Hadoop	3.3.3-amzn-0	3.2.1-amzn-3	2.8.5-amzn-5	2.8.5-amzn-1
Scala	2.12	2.12	2.11	2.11
Jackson	2.13.3	2.10.x	2.7.x	2.7.x
Hive	2.3.9-amzn-2	2.3.7-amzn-4	1.2	1.2
EMRFS	2.54.0	2.46.0	2.38.0	2.30.0
Json4s	3.7.0-M11	3.6.6	3.5.x	3.5.x
Arrow	7.0.0	2.0.0	0.10.0	0.10.0
AWS Glue Data Catalog client	3.7.0	3.0.0	1.10.0	N/A
Python	3.10	3.7	2.7 & 3.6	2.7 & 3.6
Boto	1.26	1.18	1.12	N/A

## Appendix B: JDBC driver upgrades

The following are JDBC driver upgrades:

Driver	JDBC driver version in past AWS Glue versions	JDBC driver version in AWS Glue 3.0	JDBC driver version in AWS Glue 4.0
MySQL	5.1	8.0.23	8.0.23
Microsoft SQL Server	6.1.0	7.0.0	9.4.0
Oracle Databases	11.2	21.1	21.7
PostgreSQL	42.1.0	42.2.18	42.3.6
MongoDB	2.0.0	4.0.0	4.7.2
Amazon Redshift	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017	redshift-jdbc42-2.1.0.16

## Appendix C: Connector upgrades

The following are connector upgrades:

Driver	Connector version in AWS Glue 3.0	Connector version in AWS Glue 4.0
MongoDB	3.0.0	10.0.4
Hudi	0.10.1	0.12.1
Delta Lake	1.0.0	2.1.0
Iceberg	0.13.1	1.0.0
DynamoDB	1.11	1.12

## Migrating AWS Glue for Ray from preview to the Ray2.4 runtime environment

### Warning

When you save your AWS Glue for Ray (preview) job in AWS Glue Studio, it will be automatically upgraded to the Ray2.4 runtime. If you experience compatibility issues with your script, please contact support.

You should migrate AWS Glue jobs that were created during the AWS Glue for Ray (preview) to AWS Glue for Ray. This will involve a few concurrent changes to your job configuration.

- In the Runtime field, provide the Ray2.4 runtime value. This will upgrade the underlying Ray version from 2.0.0 to 2.4.0.
- Certain Python libraries included by default in the preview are no longer provided. If your job takes advantage of the AWS SDK for pandas (aws wrangler), dask, modin, or pymars, you will need to include these as additional libraries. For more information on including additional Python libraries, see [the section called “Additional Python modules for Ray jobs”](#).
- If you're using the `--additional-python-modules` parameter, the parameters used to support this workflow have been broken out into `--pip-install` and `--s3-py-modules`. For more information about these parameters, see [the section called “Additional Python modules for Ray jobs”](#).
- If you're using the `--auto-scaling-ray-min-workers` parameter, it has been renamed `--min-workers`.

## AWS Glue version support policy

AWS Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development. An *AWS Glue job* contains the business logic that performs the data integration work in AWS Glue. There are three types of jobs in AWS Glue: *Spark (batch and streaming)*, *Ray* and *Python shell*. When you define your job, you specify the AWS Glue version, which configures versions in the underlying Spark, Ray or Python runtime environment. For example: an AWS Glue version 2.0 Spark job supports Spark 2.4.3 and Python 3.7.

## Support policy

Occasionally AWS Glue discontinues support for old AWS Glue versions. However, jobs running on deprecated versions are no longer eligible for technical support. AWS Glue will no longer apply security patches or other updates to deprecated versions. AWS Glue will also not honor SLAs when jobs are run on deprecated versions.

When end of support occurs for AWS Glue version 2.0 or later, you will not be able to create jobs, but only edit or run jobs.

The following AWS Glue versions have reached or are scheduled for end of support. End of support starts at midnight (Pacific time zone) on the specified date.

Type	Glue version	End of support
Spark	Spark 2.2, Scala 2 (Glue version 0.9)	6/1/2022
Spark	Spark 2.2, Python 2 (Glue version 0.9)	6/1/2022
Spark	Spark 2.4, Python 2 (Glue version 1.0)	6/1/2022
Spark	Spark 2.4, Python 3 (Glue version 1.0)	9/30/2022
Spark	Spark 2.4, Scala 2 (Glue version 1.0)	9/30/2022
Spark	Glue version 2.0	1/31/2024
Type	Python version	End of support
Python shell	Python 2 (Glue Version 1.0)	6/1/2022
Type	Notebook version	End of support
Development endpoint	Zeppelin notebook	9/30/2022

AWS strongly recommends that you migrate your jobs to supported versions.

For information on migrating your Spark jobs to the latest AWS Glue version, see [Migrating AWS Glue jobs to AWS Glue version 4.0](#).

For migrating your Python shell jobs to the latest AWS Glue version:

- In the console, choose Python 3 (Glue Version 4.0).
- In the [CreateJob/UpdateJob](#) API, set the `GlueVersion` parameter to 2.0, and the `PythonVersion` to 3 under the `Command` parameter. The `GlueVersion` configuration does not affect the behavior of Python shell jobs, so there is no advantage to incrementing `GlueVersion`.
- You need to make your job script compatible with Python 3.

#### Note

All AWS Regions that were launched prior to the launch of the Jakarta, Indonesia (ap-southeast-3) Region in August 2022 have an allow list of customers who are allowed to run AWS Glue version 0.9/1.0 job runs. In these older Regions, you can create a job with a null value and it will default to version 0.9/1.0 depending on Region. For any later launched AWS Regions, you must explicitly set the AWS Glue version in the API. AWS Glue no longer accepts a null parameter. If you pass 0.9 or 1.0 in the parameter you encounter the error "Glue Version 0.9 (or) 1.0 is not supported."

## Working with Spark jobs in AWS Glue

Provides information on AWS Glue for Spark ETL jobs.

### Topics

- [AWS Glue job parameters](#)
- [AWS Glue Spark and PySpark jobs](#)
- [Streaming ETL jobs in AWS Glue](#)
- [Record matching with AWS Lake Formation FindMatches](#)
- [Migrate Apache Spark programs to AWS Glue](#)

## AWS Glue job parameters

When creating a AWS Glue job, you set some standard fields, such as `Role` and `WorkerType`. You can provide additional configuration information through the `Argument` fields (**Job Parameters** in the console). In these fields, you can provide AWS Glue jobs with the arguments (parameters) listed in this topic. For more information about the AWS Glue Job API, see [the section called “Jobs”](#).

### Setting job parameters

You can configure a job through the console on the **Job details** tab, under the **Job Parameters** heading. You can also configure a job through the AWS CLI by setting `DefaultArguments` or `NonOverridableArguments` on a job, or setting `Arguments` on a job run. Arguments set on the job will be passed in every time the job is run, while arguments set on the job run will only be passed in for that individual run.

For example, the following is the syntax for running a job using `--arguments` to set a job parameter.

```
$ aws glue start-job-run --job-name "CSV to CSV" --arguments='--scriptLocation="s3://my_glue/libraries/test_lib.py"'
```

### Accessing job parameters

When writing AWS Glue scripts, you may want to access job parameter values to alter the behavior of your own code. We provide helper methods to do so in our libraries. These methods resolve job run parameter values that override job parameter values. When resolving parameters set in multiple places, job `NonOverridableArguments` will override job run `Arguments`, which will override job `DefaultArguments`.

#### In Python:

In Python jobs, we provide a function named `getResolvedParameters`. For more information, see [the section called “getResolvedOptions”](#). Job parameters are available in the `sys.argv` variable.

#### In Scala:

In Scala jobs, we provide an object named `GlueArgParser`. For more information, see [the section called “GlueArgParser”](#). Job parameters are available in the `sysArgs` variable.

## Job parameter reference

**AWS Glue recognizes the following argument names that you can use to set up the script environment for your jobs and job runs:**

### **--additional-python-modules**

A comma delimited list representing a set of Python packages to be installed. You can install packages from PyPI or provide a custom distribution. A PyPI package entry will be in the format *package*==*version*, with the PyPI name and version of your target package. A custom distribution entry is the S3 path to the distribution.

Entries use Python version matching to match package and version. This means you will need to use two equals signs, such as ==. There are other version matching operators, for more information see [PEP 440](#).

To pass module installation options to pip3, use the [--python-modules-installer-option](#) parameter.

### **--auto-scale-within-microbatch**

The default value is false. This parameter can only be used for AWS Glue streaming jobs, which process the streaming data in a series of micro batches, and auto scaling must be enabled. When setting this value to false, it computes the exponential moving average of batch duration for completed micro-batches and compares this value with the window size to determine whether to scale up or scale down the number of executors. Scaling only happens when a micro batch is completed. When setting this value to true, during a micro-batch, it scales up when the number of Spark tasks remains the same for 30 seconds, or the current batch processing is greater than the window size. The number of executors will drop if an executor has been idle for more than 60 seconds, or the exponential moving average of batch duration is low.

### **--class**

The Scala class that serves as the entry point for your Scala script. This applies only if your `--job-language` is set to `scala`.

### **--continuous-log-conversionPattern**

Specifies a custom conversion log pattern for a job enabled for continuous logging. The conversion pattern applies only to driver logs and executor logs. It does not affect the AWS Glue progress bar.

## **--continuous-log-logGroup**

Specifies a custom Amazon CloudWatch log group name for a job enabled for continuous logging.

## **--continuous-log-logStreamPrefix**

Specifies a custom CloudWatch log stream prefix for a job enabled for continuous logging.

## **--customer-driver-env-vars and --customer-executor-env-vars**

These parameters set environment variables on the operating system respectively for each worker (driver or executor). You can use these parameters when building platforms and custom frameworks on top of AWS Glue, to let your users write jobs on top of it. Enabling these two flags will allow you to set different environment variables on the driver and executor respectively without having to inject the same logic in the job script itself.

### **Example usage**

The following is an example of using these parameters:

```
"--customer-driver-env-vars", "CUSTOMER_KEY1=VAL1,CUSTOMER_KEY2=\"val2,val2 val2\"",  
"--customer-executor-env-vars", "CUSTOMER_KEY3=VAL3,KEY4=VAL4"
```

Setting these in the job run argument is equivalent to running the following commands:

In the driver:

- export CUSTOMER\_KEY1=VAL1
- export CUSTOMER\_KEY2="val2,val2 val2"

In the executor:

- export CUSTOMER\_KEY3=VAL3

Then, in the job script itself, you can retrieve the environment variables using `os.environ.get("CUSTOMER_KEY1")` or `System.getenv("CUSTOMER_KEY1")`.

### **Enforced syntax**

Observe the following standards when defining environment variables:

- Each key must have the `CUSTOMER_` prefix.

For example: for `"CUSTOMER_KEY3=VAL3,KEY4=VAL4"`, `KEY4=VAL4` will be ignored and not set.

- Each key and value pair must be delineated with a single comma.

For example: "CUSTOMER\_KEY3=VAL3,CUSTOMER\_KEY4=VAL4"

- If the "value" has spaces or commas, then it must be defined within quotations.

For example: CUSTOMER\_KEY2=\"val2, val2 val2\"

This syntax closely models the standards of setting bash environment variables.

## **--datalake-formats**

Supported in AWS Glue 3.0 and later versions.

Specifies the data lake framework to use. AWS Glue adds the required JAR files for the frameworks that you specify into the classpath. For more information, see [Using data lake frameworks with AWS Glue ETL jobs](#).

You can specify one or more of the following values, separated by a comma:

- hudi
- delta
- iceberg

For example, pass the following argument to specify all three frameworks.

```
'--datalake-formats': 'hudi,delta,iceberg'
```

## **--disable-proxy-v2**

Disable the service proxy to allow AWS service calls to Amazon S3, CloudWatch, and AWS Glue originating from your script through your VPC. For more information, see [Configuring AWS calls to go through your VPC](#). To disable the service proxy, set the value of this parameter to `true`.

## **--enable-auto-scaling**

Turns on auto scaling and per-worker billing when you set the value to `true`.

## **--enable-continuous-cloudwatch-log**

Enables real-time continuous logging for AWS Glue jobs. You can view real-time Apache Spark job logs in CloudWatch.

**--enable-continuous-log-filter**

Specifies a standard filter (`true`) or no filter (`false`) when you create or edit a job enabled for continuous logging. Choosing the standard filter prunes out non-useful Apache Spark driver/executor and Apache Hadoop YARN heartbeat log messages. Choosing no filter gives you all the log messages.

**--enable-glue-datacatalog**

Enables you to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To enable this feature, set the value to `true`.

**--enable-job-insights**

Enables additional error analysis monitoring with AWS Glue job run insights. For details, see [the section called "Monitoring with AWS Glue job run insights"](#). By default, the value is set to `true` and job run insights are enabled.

This option is available for AWS Glue version 2.0 and 3.0.

**--enable-metrics**

Enables the collection of metrics for job profiling for this job run. These metrics are available on the AWS Glue console and the Amazon CloudWatch console. The value of this parameter is not relevant. To enable this feature, you can provide this parameter with any value, but `true` is recommended for clarity. To disable this feature, remove this parameter from your job configuration.

**--enable-observability-metrics**

Enables a set of Observability metrics to generate insights into what is happening inside each job run on Job Runs Monitoring page under AWS Glue console and the Amazon CloudWatch console. To enable this feature, set the value of this parameter to `true`. To disable this feature, set it to `false` or remove this parameter from your job configuration.

**--enable-rename-algorithm-v2**

Sets the EMRFS rename algorithm version to version 2. When a Spark job uses dynamic partition overwrite mode, there is a possibility that a duplicate partition is created. For instance, you can end up with a duplicate partition such as `s3://bucket/table/location/p1=1/p1=1`. Here, P1 is the partition that is being overwritten. Rename algorithm version 2 fixes this issue.

This option is only available on AWS Glue version 1.0.

**--enable-s3-parquet-optimized-commmitter**

Enables the EMRFS S3-optimized commmitter for writing Parquet data into Amazon S3. You can supply the parameter/value pair via the AWS Glue console when creating or updating an AWS Glue job. Setting the value to **true** enables the commmitter. By default, the flag is turned on in AWS Glue 3.0 and off in AWS Glue 2.0.

For more information, see [Using the EMRFS S3-optimized Commmitter](#).

**--enable-spark-ui**

When set to **true**, turns on the feature to use the Spark UI to monitor and debug AWS Glue ETL jobs.

**--executor-cores**

Number of spark tasks that can run in parallel. This option is supported on AWS Glue 3.0+. The value should not exceed 2x the number of vCPUs on the worker type, which is 8 on G.1X, 16 on G.2X, 32 on G.4X and 64 on G.8X. You should exercise caution while updating this configuration as it could impact job performance because increased task parallelism causes memory, disk pressure as well as it could throttle the source and target systems (for example: it would cause more concurrent connections on Amazon RDS).

**--extra-files**

The Amazon S3 paths to additional files, such as configuration files that AWS Glue copies to the working directory of your script before running it. Multiple values must be complete paths separated by a comma (,). Only individual files are supported, not a directory path. This option is not supported for Python Shell job types.

**--extra-jars**

The Amazon S3 paths to additional Java .jar files that AWS Glue adds to the Java classpath before executing your script. Multiple values must be complete paths separated by a comma (,).

**--extra-py-files**

The Amazon S3 paths to additional Python modules that AWS Glue adds to the Python path before running your script. Multiple values must be complete paths separated by a comma (,). Only individual files are supported, not a directory path.

**--job-bookmark-option**

Controls the behavior of a job bookmark. The following option values can be set.

<b>--job-bookmark-option value</b>	<b>Description</b>
job-bookmark-enable	Keep track of previously processed data. When a job runs, process new data since the last checkpoint.
job-bookmark-disable	Always process the entire dataset. You are responsible for managing the output from previous job runs.
job-bookmark-pause	<p>Process incremental data since the last successful run or the data in the range identified by the following suboptions, without updating the state of the last bookmark. You are responsible for managing the output from previous job runs. The two suboptions are as follows:</p> <ul style="list-style-type: none"> <li>• <b>job-bookmark-from</b> &lt;from-value&gt; is the run ID that represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input is ignored.</li> <li>• <b>job-bookmark-to</b> &lt;to-value&gt; is the run ID that represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input excluding the input identified by the &lt;from-value&gt; is processed by the job. Any input later than this input is also excluded for processing.</li> </ul> <p>The job bookmark state is not updated when this option set is specified.</p> <p>The suboptions are optional. However, when used, both suboptions must be provided.</p>

For example, to enable a job bookmark, pass the following argument.

```
'--job-bookmark-option': 'job-bookmark-enable'
```

## --job-language

The script programming language. This value must be either `scala` or `python`. If this parameter is not present, the default is `python`.

## --python-modules-installer-option

A plaintext string that defines options to be passed to `pip3` when installing modules with [--additional-python-modules](#). Provide options as you would in the command line, separated by spaces and prefixed by dashes. For more information about usage, see [the section called "Installing additional Python modules with pip in AWS Glue 2.0+"](#).

### Note

This option is not supported for AWS Glue jobs when you use Python 3.9.

## --scriptLocation

The Amazon Simple Storage Service (Amazon S3) location where your ETL script is located (in the form `s3://path/to/my/script.py`). This parameter overrides a script location set in the `JobCommand` object.

## --spark-event-logs-path

Specifies an Amazon S3 path. When using the Spark UI monitoring feature, AWS Glue flushes the Spark event logs to this Amazon S3 path every 30 seconds to a bucket that can be used as a temporary directory for storing Spark UI events.

## --TempDir

Specifies an Amazon S3 path to a bucket that can be used as a temporary directory for the job.

For example, to set a temporary directory, pass the following argument.

```
'--TempDir': 's3-path-to-directory'
```

### Note

AWS Glue creates a temporary bucket for jobs if a bucket doesn't already exist in a Region. This bucket might permit public access. You can either modify the bucket in

Amazon S3 to set the public access block, or delete the bucket later after all jobs in that Region have completed.

### **--use-postgres-driver**

When setting this value to `true`, it prioritizes the Postgres JDBC driver in the class path to avoid a conflict with the Amazon Redshift JDBC driver. This option is only available in AWS Glue version 2.0.

### **--user-jars-first**

When setting this value to `true`, it prioritizes the customer's extra JAR files in the classpath. This option is only available in AWS Glue version 2.0 or later.

### **--conf**

Controls Spark config parameters. It is for advanced use cases.

### **--encryption-type**

Legacy parameter. The corresponding behavior should be configured using security configurations. For more information about security configurations, see [the section called "Encrypting data written by AWS Glue"](#).

AWS Glue uses the following arguments internally and you should never use them:

- `--debug` — Internal to AWS Glue. Do not set.
- `--mode` — Internal to AWS Glue. Do not set.
- `--JOB_NAME` — Internal to AWS Glue. Do not set.
- `--endpoint` — Internal to AWS Glue. Do not set.

AWS Glue supports bootstrapping an environment with Python's `site` module using `sitecustomize` to perform site-specific customizations. Bootstrapping your own initialization functions is recommended for advanced use cases only and is supported on a best-effort basis on AWS Glue 4.0.

The environment variable prefix, `GLUE_CUSTOMER`, is reserved for customer use.

## AWS Glue Spark and PySpark jobs

The following sections provide information on AWS Glue Spark and PySpark jobs.

## Adding Spark and PySpark jobs in AWS Glue

The following sections provide information on adding Spark and PySpark jobs in AWS Glue.

### Topics

- [Configuring job properties for Spark jobs in AWS Glue](#)
- [Editing Spark scripts in the AWS Glue console](#)
- [Jobs \(legacy\)](#)

## Configuring job properties for Spark jobs in AWS Glue

An AWS Glue job encapsulates a script that connects to your source data, processes it, and then writes it out to your data target. Typically, a job runs extract, transform, and load (ETL) scripts. Jobs can also run general-purpose Python scripts (Python shell jobs.) AWS Glue *triggers* can start jobs based on a schedule or event, or on demand. You can monitor job runs to understand runtime metrics such as completion status, duration, and start time.

You can use scripts that AWS Glue generates or you can provide your own. With a source schema and target location or schema, the AWS Glue code generator can automatically create an Apache Spark API (PySpark) script. You can use this script as a starting point and edit it to meet your goals.

AWS Glue can write output files in several data formats, including JSON, CSV, ORC (Optimized Row Columnar), Apache Parquet, and Apache Avro. For some data formats, common compression formats can be written.

There are three types of jobs in AWS Glue: *Spark*, *Streaming ETL*, and *Python shell*.

- A Spark job is run in an Apache Spark environment managed by AWS Glue. It processes data in batches.
- A streaming ETL job is similar to a Spark job, except that it performs ETL on data streams. It uses the Apache Spark Structured Streaming framework. Some Spark job features are not available to streaming ETL jobs.
- A Python shell job runs Python scripts as a shell and supports a Python version that depends on the AWS Glue version you are using. You can use these jobs to schedule and run tasks that don't require an Apache Spark environment.

## Defining job properties for Spark jobs

When you define your job on the AWS Glue console, you provide values for properties to control the AWS Glue runtime environment.

The following list describes the properties of a Spark job. For the properties of a Python shell job, see [Defining job properties for Python shell jobs](#). For properties of a streaming ETL job, see [the section called “Defining job properties for a streaming ETL job”](#).

The properties are listed in the order in which they appear on the **Add job** wizard on AWS Glue console.

### Name

Provide a UTF-8 string with a maximum length of 255 characters.

### Description

Provide an optional description of up to 2048 characters.

### IAM Role

Specify the IAM role that is used for authorization to resources used to run the job and access data stores. For more information about permissions for running jobs in AWS Glue, see [Identity and access management for AWS Glue](#).

### Type

The type of ETL job. This is set automatically based on the type of data sources you select.

- **Spark** runs an Apache Spark ETL script with the job command `glueetl`.
- **Spark Streaming** runs a Apache Spark streaming ETL script with the job command `gluestreaming`. For more information, see [the section called “Streaming ETL jobs”](#).

- **Python shell** run a Python script with the job command `pythonshell`. For more information, see [Configuring job properties for Python shell jobs in AWS Glue](#).

## AWS Glue version

AWS Glue version determines the versions of Apache Spark and Python that are available to the job, as specified in the following table.

AWS Glue version	Supported Spark and Python versions
4.0	<ul style="list-style-type: none"> <li>• Spark 3.3.0</li> <li>• Python 3.10</li> </ul>
3.0	<ul style="list-style-type: none"> <li>• Spark 3.1.1</li> <li>• Python 3.7</li> </ul>
2.0	<ul style="list-style-type: none"> <li>• Spark 2.4.3</li> <li>• Python 3.7</li> </ul>
1.0	<ul style="list-style-type: none"> <li>• Spark 2.4.3</li> <li>• Python 2.7</li> <li>• Python 3.6</li> </ul>
0.9	<ul style="list-style-type: none"> <li>• Spark 2.2.1</li> <li>• Python 2.7</li> </ul>

## Worker type

The following worker types are available:

The resources available on AWS Glue workers are measured in DPUs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory.

- **G.1X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free). We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- **G.2X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB

free). We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.

- **G.4X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).
- **G.8X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free). We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- **G.025X** – When you choose this type, you also provide a value for **Number of workers**. Each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free). We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 streaming jobs.

You are charged an hourly rate based on the number of DPUs used to run your ETL jobs. For more information, see the [AWS Glue pricing page](#).

For AWS Glue version 1.0 or earlier jobs, when you configure a job using the console and specify a **Worker type** of **Standard**, the **Maximum capacity** is set and the **Number of workers** becomes the value of **Maximum capacity** - 1. If you use the AWS Command Line Interface (AWS CLI) or AWS SDK, you can specify the **Max capacity** parameter, or you can specify both **Worker type** and the **Number of workers**.

For AWS Glue version 2.0 or later jobs, you cannot specify a **Maximum capacity**. Instead, you should specify a **Worker type** and the **Number of workers**.

## Language

The code in the ETL script defines your job's logic. The script can be coded in Python or Scala. You can choose whether the script that the job runs is generated by AWS Glue or provided by you. You provide the script name and location in Amazon Simple Storage Service (Amazon S3).

Confirm that there isn't a file with the same name as the script directory in the path. To learn more about writing scripts, see [AWS Glue programming guide](#).

### Requested number of workers

For most worker types, you must specify the number of workers that are allocated when the job runs.

### Job bookmark

Specify how AWS Glue processes state information when the job runs. You can have it remember previously processed data, update state information, or ignore state information. For more information, see [the section called "Tracking processed data using job bookmarks"](#).

### Flex execution

When you configure a job using AWS Studio or the API you may specify a standard or flexible job execution class. Your jobs may have varying degrees of priority and time sensitivity. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for non-urgent jobs such as pre-production jobs, testing, and one-time data loads. Flexible job runs are supported for jobs using AWS Glue version 3.0 or later and G.1X or G.2X worker types.

Flex job runs are billed based on the number of workers running at any point in time. Number of workers may be added or removed for a running flexible job run. Instead of billing as a simple calculation of `Max Capacity * Execution Time`, each worker will contribute for the time it ran during the job run. The bill is the sum of `(Number of DPUs per worker * time each worker ran)`.

For more information, see the help panel in AWS Studio, or [Jobs](#) and [Job runs](#).

### Number of retries

Specify the number of times, from 0 to 10, that AWS Glue should automatically restart the job if it fails. Jobs that reach the timeout limit are not restarted.

### Job timeout

Sets the maximum execution time in minutes. The default is 2880 minutes (48 hours) for batch jobs. When the job execution time exceeds this limit, the job run state changes to TIMEOUT.

Streaming jobs must have timeout values less than 7 days or 10080 minutes. When the value is left blank, the job will be restarted after 7 days based if you have not setup a maintenance

window. If you have setup a maintenance window, it will be restarted during the maintenance window after 7 days.

### **Best practices for job timeouts**

Jobs are billed based on execution time. To avoid unexpected charges, configure timeout values appropriate for the expected execution time of your job.

## **Advanced Properties**

### **Script filename**

A unique script name for your job. Cannot be named **Untitled job**.

### **Script path**

The Amazon S3 location of the script. The path must be in the form `s3://bucket/prefix/path/`. It must end with a slash (/) and not include any files.

### **Job metrics**

Turn on or turn off the creation of Amazon CloudWatch metrics when this job runs. To see profiling data, you must enable this option. For more information about how to turn on and visualize metrics, see [Job monitoring and debugging](#).

### **Job observability metrics**

Turn on the creation of additional observability CloudWatch metrics when this job runs. For more information, see [the section called "Monitoring with AWS Glue Observability metrics"](#).

### **Continuous logging**

Turn on continuous logging to Amazon CloudWatch. If this option is not enabled, logs are available only after the job completes. For more information, see [the section called "Continuous logging for AWS Glue jobs"](#).

### **Spark UI**

Turn on the use of Spark UI for monitoring this job. For more information, see [Enabling the Apache Spark web UI for AWS Glue jobs](#).

### **Spark UI logs path**

The path to write logs when Spark UI is enabled.

## Spark UI logging and monitoring configuration

Choose one of the following options:

- *Standard*: write logs using the AWS Glue job run ID as the filename. Turn on Spark UI monitoring in the AWS Glue console.
- *Legacy*: write logs using 'spark-application-{timestamp}' as the filename. Do not turn on Spark UI monitoring.
- *Standard and legacy*: write logs to both the standard and legacy locations. Turn on Spark UI monitoring in the AWS Glue console.

## Maximum concurrency

Sets the maximum number of concurrent runs that are allowed for this job. The default is 1. An error is returned when this threshold is reached. The maximum value you can specify is controlled by a service limit. For example, if a previous run of a job is still running when a new instance is started, you might want to return an error to prevent two instances of the same job from running concurrently.

## Temporary path

Provide the location of a working directory in Amazon S3 where temporary intermediate results are written when AWS Glue runs the script. Confirm that there isn't a file with the same name as the temporary directory in the path. This directory is used when AWS Glue reads and writes to Amazon Redshift and by certain AWS Glue transforms.

### Note

AWS Glue creates a temporary bucket for jobs if a bucket doesn't already exist in a region. This bucket might permit public access. You can either modify the bucket in Amazon S3 to set the public access block, or delete the bucket later after all jobs in that region have completed.

## Delay notification threshold (minutes)

Sets the threshold (in minutes) before a delay notification is sent. You can set this threshold to send notifications when a RUNNING, STARTING, or STOPPING job run takes more than an expected number of minutes.

## Security configuration

Choose a security configuration from the list. A security configuration specifies how the data at the Amazon S3 target is encrypted: no encryption, server-side encryption with AWS KMS-managed keys (SSE-KMS), or Amazon S3-managed encryption keys (SSE-S3).

## Server-side encryption

If you select this option, when the ETL job writes to Amazon S3, the data is encrypted at rest using SSE-S3 encryption. Both your Amazon S3 data target and any data that is written to an Amazon S3 temporary directory is encrypted. This option is passed as a job parameter. For more information, see [Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys \(SSE-S3\)](#) in the *Amazon Simple Storage Service User Guide*.

### Important

This option is ignored if a security configuration is specified.

## Use Glue data catalog as the Hive metastore

Select to use the AWS Glue Data Catalog as the Hive metastore. The IAM role used for the job must have the `glue:CreateDatabase` permission. A database called “default” is created in the Data Catalog if it does not exist.

## Connections

Choose a VPC configuration to access Amazon S3 data sources located in your virtual private cloud (VPC). You can create and manage Network connection in AWS Glue. For more information, see [Connecting to data](#).

## Libraries

### Python library path, Dependent JARs path, and Referenced files path

Specify these options if your script requires them. You can define the comma-separated Amazon S3 paths for these options when you define the job. You can override these paths when you run the job. For more information, see [Providing your own custom scripts](#).

### Job parameters

A set of key-value pairs that are passed as named parameters to the script. These are default values that are used when the script is run, but you can override them in triggers or when

you run the job. You must prefix the key name with `--`; for example: `--myKey`. You pass job parameters as a map when using the AWS Command Line Interface.

For examples, see Python parameters in [Passing and accessing Python parameters in AWS Glue](#).

## Tags

Tag your job with a **Tag key** and an optional **Tag value**. After tag keys are created, they are read-only. Use tags on some resources to help you organize and identify them. For more information, see [AWS tags in AWS Glue](#).

## Restrictions for jobs that access Lake Formation managed tables

Keep in mind the following notes and restrictions when creating jobs that read from or write to tables managed by AWS Lake Formation:

- The following features are not supported in jobs that access tables with cell-level filters:
  - [Job bookmarks](#) and [bounded execution](#)
  - [Push-down predicates](#)
  - [Server-side catalog partition predicates](#)
  - [enableUpdateCatalog](#)

## Editing Spark scripts in the AWS Glue console

A script contains the code that extracts data from sources, transforms it, and loads it into targets. AWS Glue runs a script when it starts a job.

AWS Glue ETL scripts can be coded in Python or Scala. Python scripts use a language that is an extension of the PySpark Python dialect for extract, transform, and load (ETL) jobs. The script contains *extended constructs* to deal with ETL transformations. When you automatically generate the source code logic for your job, a script is created. You can edit this script, or you can provide your own script to process your ETL work.

For information about defining and editing scripts in AWS Glue, see [AWS Glue programming guide](#).

## Additional libraries or files

If your script requires additional libraries or files, you can specify them as follows:

## Python library path

Comma-separated Amazon Simple Storage Service (Amazon S3) paths to Python libraries that are required by the script.

### Note

Only pure Python libraries can be used. Libraries that rely on C extensions, such as the pandas Python Data Analysis Library, are not yet supported.

## Dependent jars path

Comma-separated Amazon S3 paths to JAR files that are required by the script.

### Note

Currently, only pure Java or Scala (2.11) libraries can be used.

## Referenced files path

Comma-separated Amazon S3 paths to additional files (for example, configuration files) that are required by the script.

## Jobs (legacy)

A script contains the code that performs extract, transform, and load (ETL) work. You can provide your own script, or AWS Glue can generate a script with guidance from you. For information about creating your own scripts, see [Providing your own custom scripts](#).

You can edit a script in the AWS Glue console. When you edit a script, you can add sources, targets, and transforms.

## To edit a script

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>. Then choose the **Jobs** tab.
2. Choose a job in the list, and then choose **Action, Edit script** to open the script editor.

You can also access the script editor from the job details page. Choose the **Script** tab, and then choose **Edit script**.

## Script editor

The AWS Glue script editor lets you insert, modify, and delete sources, targets, and transforms in your script. The script editor displays both the script and a diagram to help you visualize the flow of data.

To create a diagram for the script, choose **Generate diagram**. AWS Glue uses annotation lines in the script beginning with **##** to render the diagram. To correctly represent your script in the diagram, you must keep the parameters in the annotations and the parameters in the Apache Spark code in sync.

The script editor lets you add code templates wherever your cursor is positioned in the script. At the top of the editor, choose from the following options:

- To add a source table to the script, choose **Source**.
- To add a target table to the script, choose **Target**.
- To add a target location to the script, choose **Target location**.
- To add a transform to the script, choose **Transform**. For information about the functions that are called in your script, see [Program AWS Glue ETL scripts in PySpark](#).
- To add a Spigot transform to the script, choose **Spigot**.

In the inserted code, modify the parameters in both the annotations and Apache Spark code. For example, if you add a **Spigot** transform, verify that the path is replaced in both the `@args` annotation line and the output code line.

The **Logs** tab shows the logs that are associated with your job as it runs. The most recent 1,000 lines are displayed.

The **Schema** tab shows the schema of the selected sources and targets, when available in the Data Catalog.

## Tracking processed data using job bookmarks

AWS Glue tracks data that has already been processed during a previous run of an ETL job by persisting state information from the job run. This persisted state information is called a *job bookmark*. Job bookmarks help AWS Glue maintain state information and prevent the reprocessing of old data. With job bookmarks, you can process new data when rerunning on a scheduled interval. A job bookmark is composed of the states for various elements of jobs, such as sources, transformations, and targets. For example, your ETL job might read new partitions in an Amazon S3 file. AWS Glue tracks which partitions the job has processed successfully to prevent duplicate processing and duplicate data in the job's target data store.

Job bookmarks are implemented for JDBC data sources, the Relationalize transform, and some Amazon Simple Storage Service (Amazon S3) sources. The following table lists the Amazon S3 source formats that AWS Glue supports for job bookmarks.

AWS Glue version	Amazon S3 source formats
Version 0.9	JSON, CSV, Apache Avro, XML
Version 1.0 and later	JSON, CSV, Apache Avro, XML, Parquet, ORC

For information about AWS Glue versions, see [Defining job properties for Spark jobs](#).

The job bookmarks feature has additional functionalities when accessed through AWS Glue scripts. When browsing your generated script, you may see transformation contexts, which are related to this feature. For more information, see [the section called “Using job bookmarks”](#).

### Topics

- [Using job bookmarks in AWS Glue](#)
- [Operational details of the job bookmarks feature](#)

### Using job bookmarks in AWS Glue

The job bookmark option is passed as a parameter when the job is started. The following table describes the options for setting job bookmarks on the AWS Glue console.

Job bookmark	Description
Enable	Causes the job to update the state after a run to keep track of previously processed data. If your job has a source with job bookmark support, it will keep track of processed data, and when a job runs, it processes new data since the last checkpoint.
Disable	Job bookmarks are not used, and the job always processes the entire dataset. You are responsible for managing the output from previous job runs. This is the default.
Pause	<p>Process incremental data since the last successful run or the data in the range identified by the following sub-options, without updating the state of last bookmark. You are responsible for managing the output from previous job runs. The two sub-options are:</p> <ul style="list-style-type: none"> <li>• <b>job-bookmark-from</b> &lt;from-value&gt; is the run ID which represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input is ignored.</li> <li>• <b>job-bookmark-to</b> &lt;to-value&gt; is the run ID which represents all the input that was processed until the last successful run before and including the specified run ID. The corresponding input excluding the input identified by the &lt;from-value&gt; is processed by the job. Any input later than this input is also excluded for processing.</li> </ul> <p>The job bookmark state is not updated when this option set is specified .</p> <p>The sub-options are optional, however when used both the sub-options needs to be provided.</p>

For details about the parameters passed to a job on the command line, and specifically for job bookmarks, see [AWS Glue job parameters](#).

For Amazon S3 input sources, AWS Glue job bookmarks check the last modified time of the objects to verify which objects need to be reprocessed. If your input source data has been modified since your last job run, the files are reprocessed when you run the job again.

For JDBC sources, the following rules apply:

- For each table, AWS Glue uses one or more columns as bookmark keys to determine new and processed data. The bookmark keys combine to form a single compound key.
- AWS Glue by default uses the primary key as the bookmark key, provided that it is sequentially increasing or decreasing (with no gaps).
- You can specify the columns to use as bookmark keys in your AWS Glue script. For more information about using Job bookmarks in AWS Glue scripts, see [the section called “Using job bookmarks”](#).
- AWS Glue doesn't support using columns with case-sensitive names as job bookmark keys.

You can rewind your job bookmarks for your AWS Glue Spark ETL jobs to any previous job run. You can support data backfilling scenarios better by rewinding your job bookmarks to any previous job run, resulting in the subsequent job run reprocessing data only from the bookmarked job run.

If you intend to reprocess all the data using the same job, reset the job bookmark. To reset the job bookmark state, use the AWS Glue console, the [ResetJobBookmark action \(Python: reset\\_job\\_bookmark\)](#) API operation, or the AWS CLI. For example, enter the following command using the AWS CLI:

```
aws glue reset-job-bookmark --job-name my-job-name
```

When you rewind or reset a bookmark, AWS Glue does not clean the target files because there could be multiple targets and targets are not tracked with job bookmarks. Only source files are tracked with job bookmarks. You can create different output targets when rewinding and reprocessing the source files to avoid duplicate data in your output.

AWS Glue keeps track of job bookmarks by job. If you delete a job, the job bookmark is deleted.

In some cases, you might have enabled AWS Glue job bookmarks but your ETL job is reprocessing data that was already processed in an earlier run. For information about resolving common causes of this error, see [Troubleshooting errors in AWS Glue for Spark](#).

## Operational details of the job bookmarks feature

This section describes more of the operational details of using job bookmarks.

Job bookmarks store the states for a job. Each instance of the state is keyed by a job name and a version number. When a script invokes `job.init`, it retrieves its state and always gets the latest version. Within a state, there are multiple state elements, which are specific to each source, transformation, and sink instance in the script. These state elements are identified by a transformation context that is attached to the corresponding element (source, transformation, or sink) in the script. The state elements are saved atomically when `job.commit` is invoked from the user script. The script gets the job name and the control option for the job bookmarks from the arguments.

The state elements in the job bookmark are source, transformation, or sink-specific data. For example, suppose that you want to read incremental data from an Amazon S3 location that is being constantly written to by an upstream job or process. In this case, the script must determine what has been processed so far. The job bookmark implementation for the Amazon S3 source saves information so that when the job runs again, it can filter only the new objects using the saved information and recompute the state for the next run of the job. A timestamp is used to filter the new files.

In addition to the state elements, job bookmarks have a *run number*, an *attempt number*, and a *version number*. The run number tracks the run of the job, and the attempt number records the attempts for a job run. The job run number is a monotonically increasing number that is incremented for every successful run. The attempt number tracks the attempts for each run, and is only incremented when there is a run after a failed attempt. The version number increases monotonically and tracks the updates to a job bookmark.

In the AWS Glue service database, the bookmark states for all the transformations are stored together as key-value pairs:

```
{
  "job_name" : ...,
  "run_id": ...,
  "run_number": ..,
  "attempt_number": ...
  "states": {
    "transformation_ctx1" : {
      bookmark_state1
    },
    "transformation_ctx2" : {
      bookmark_state2
    }
  }
}
```

```
}
```

## Best practices

The following are best practices for using job bookmarks.

- *Do not change the data source property with the bookmark enabled.* For example, there is a `datasource0` pointing to an Amazon S3 input path A, and the job has been reading from a source which has been running for several rounds with the bookmark enabled. If you change the input path of `datasource0` to Amazon S3 path B without changing the `transformation_ctx`, the AWS Glue job will use the old bookmark state stored. That will result in missing or skipping files in the input path B as AWS Glue would assume that those files had been processed in previous runs.
- *Use a catalog table with bookmarks for better partition management.* Bookmarks works both for data sources from the Data Catalog or from options. However, it's difficult to remove/add new partitions with the from options approach. Using a catalog table with crawlers can provide better automation to track the newly added [partitions](#) and give you the flexibility to select particular partitions with a [pushdown predicate](#).
- *Use the [AWS Glue Amazon S3 file lister](#) for large datasets.* A bookmark will list all files under each input partition and do the filtering, so if there are too many files under a single partition the bookmark can run into driver OOM. Use the AWS Glue Amazon S3 file lister to avoid listing all files in memory at once.

## AWS Glue Spark shuffle plugin with Amazon S3

Shuffling is an important step in a Spark job whenever data is rearranged between partitions. This is required because wide transformations such as `join`, `groupByKey`, `reduceByKey`, and `repartition` require information from other partitions to complete processing. Spark gathers the required data from each partition and combines it into a new partition. During a shuffle, data is written to disk and transferred across the network. As a result, the shuffle operation is bound to local disk capacity. Spark throws a `No space left on device` or `MetadataFetchFailedException` error when there is not enough disk space left on the executor and there is no recovery.

### Note

AWS Glue Spark shuffle plugin with Amazon S3 is only supported for AWS Glue ETL jobs.

## **Solution**

With AWS Glue, you can now use Amazon S3 to store Spark shuffle data. Amazon S3 is an object storage service that offers industry-leading scalability, data availability, security, and performance. This solution disaggregates compute and storage for your Spark jobs, and gives complete elasticity and low-cost shuffle storage, allowing you to run your most shuffle-intensive workloads reliably.

We are introducing a new Cloud Shuffle Storage Plugin for Apache Spark to use Amazon S3. You can turn on Amazon S3 shuffling to run your AWS Glue jobs reliably without failures if they are known to be bound by the local disk capacity for large shuffle operations. In some cases, shuffling

to Amazon S3 is marginally slower than local disk (or EBS) if you have a large number of small partitions or shuffle files written out to Amazon S3.

## Prerequisites for using Cloud Shuffle Storage Plugin

In order to use the Cloud Shuffle Storage Plugin with AWS Glue ETL jobs, you need the following:

- An Amazon S3 bucket located in the same region as your job run, for storing the intermediate shuffle and spilled data. The Amazon S3 prefix of shuffle storage can be specified with `--conf spark.shuffle.glue.s3ShuffleBucket=s3://shuffle-bucket/prefix/`, as in the following example:

```
--conf spark.shuffle.glue.s3ShuffleBucket=s3://glue-shuffle-123456789-us-east-1/glue-shuffle-data/
```

- Set the Amazon S3 storage lifecycle policies on the *prefix* (such as `glue-shuffle-data`) as the shuffle manager does not clean the files after the job is done. The intermediate shuffle and spilled data should be deleted after a job is finished. Users can set a short lifecycle policies on the prefix. Instructions for setting up an Amazon S3 lifecycle policy are available at [Setting lifecycle configuration on a bucket](#) in the Amazon Simple Storage Service User Guide.

## Using AWS Glue Spark shuffle manager from the AWS console

To set up the AWS Glue Spark shuffle manager using the AWS Glue console or AWS Glue Studio when configuring a job: choose the `--write-shuffle-files-to-s3` job parameter to turn on Amazon S3 shuffling for the job.

### Job parameters

Key	Value - optional	
<input type="text" value="--write-shuffle-files-"/>	<input type="text"/>	<input type="button" value="Remove"/>

You can add 49 more parameters.

## Using AWS Glue Spark shuffle plugin

The following job parameters turn on and tune the AWS Glue shuffle manager. These parameters are flags, so any values provided are not considered.

- `--write-shuffle-files-to-s3` — The main flag, which enables the AWS Glue Spark shuffle manager to use Amazon S3 buckets for writing and reading shuffle data. When the flag is not specified, the shuffle manager is not used.
- `--write-shuffle-spills-to-s3` — (Supported only on AWS Glue version 2.0). An optional flag that allows you to offload spill files to Amazon S3 buckets, which provides additional resiliency to your Spark job. This is only required for large workloads that spill a lot of data to disk. When the flag is not specified, no intermediate spill files are written.
- `--conf spark.shuffle.glue.s3ShuffleBucket=s3://<shuffle-bucket>` — Another optional flag that specifies the Amazon S3 bucket where you write the shuffle files. By default, `--TempDir/shuffle-data`. AWS Glue 3.0+ supports writing shuffle files to multiple buckets by specifying buckets with comma delimiter, as in `--conf spark.shuffle.glue.s3ShuffleBucket=s3://shuffle-bucket-1/prefix,s3://shuffle-bucket-2/prefix/`. Using multiple buckets improves performance.

You need to provide security configuration settings to enable encryption at-rest for the shuffle data. For more information about security configurations, see [the section called “Setting up encryption”](#). AWS Glue supports all other shuffle related configurations provided by Spark.

## Software binaries for the Cloud Shuffle Storage plugin

You can also download the software binaries of the Cloud Shuffle Storage Plugin for Apache Spark under the Apache 2.0 license and run it on any Spark environment. The new plugin comes with out-of-the box support for Amazon S3, and can also be easily configured to use other forms of cloud storage such as [Google Cloud Storage and Microsoft Azure Blob Storage](#). For more information, see [Cloud Shuffle Storage Plugin for Apache Spark](#).

## Notes and limitations

The following are notes or limitations for the AWS Glue shuffle manager:

- AWS Glue shuffle manager doesn't automatically delete the (temporary) shuffle data files stored in your Amazon S3 bucket after a job is completed. To ensure data protection, follow the instructions in [Prerequisites for using Cloud Shuffle Storage Plugin](#) before enabling the Cloud Shuffle Storage Plugin.
- You can use this feature if your data is skewed.

## Cloud Shuffle Storage Plugin for Apache Spark

The Cloud Shuffle Storage Plugin is an Apache Spark plugin compatible with the [ShuffleDataIO API](#) which allows storing shuffle data on cloud storage systems (such as Amazon S3). It helps you to supplement or replace local disk storage capacity for large shuffle operations, commonly triggered by transformations such as `join`, `reduceByKey`, `groupByKey` and `repartition` in your Spark applications, thereby reducing common failures or price/performance dislocation of your serverless data analytics jobs and pipelines.

### AWS Glue

AWS Glue versions 3.0 and 4.0 comes with the plugin pre-installed and ready to enable shuffling to Amazon S3 without any extra steps. For more information, see [AWS Glue Spark shuffle plugin with Amazon S3](#) to enable the feature for your Spark applications.

### Other Spark environments

The plugin requires the following Spark configurations to be set on other Spark environments:

- `--conf spark.shuffle.sort.io.plugin.class=com.amazonaws.spark.shuffle.io.cloud.Chopped`  
This informs Spark to use this plugin for Shuffle IO.
- `--conf spark.shuffle.storage.path=s3://bucket-name/shuffle-file-dir`: The path where your shuffle files will be stored.

#### Note

The plugin overwrites one Spark core class. As a result, the plugin jar needs to be loaded before Spark jars. You can do this using `userClassPathFirst` in on-prem YARN environments if the plugin is used outside AWS Glue.

### Bundling the plugin with your Spark applications

You can bundle the plugin with your Spark applications and Spark distributions (versions 3.1 and above) by adding the plugin dependency in your Maven `pom.xml` while developing your Spark applications locally. For more information on the plugin and Spark versions, see [Plugin versions](#).

```
<repositories>
```

```

...
<repository>
  <id>aws-glue-etl-artifacts</id>
  <url>https://aws-glue-etl-artifacts.s3.amazonaws.com/release/ </url>
</repository>
</repositories>
...
<dependency>
  <groupId>com.amazonaws</groupId>
  <artifactId>chopper-plugin</artifactId>
  <version>3.1-amzn-LATEST</version>
</dependency>

```

You can alternatively download the binaries from AWS Glue Maven artifacts directly and include them in your Spark application as follows.

```

#!/bin/bash
sudo wget -v https://aws-glue-etl-artifacts.s3.amazonaws.com/release/com/amazonaws/
chopper-plugin/3.1-amzn-LATEST/chopper-plugin-3.1-amzn-LATEST.jar -P /usr/lib/spark/
jars/

```

### Example spark-submit

```

spark-submit --deploy-mode cluster \
--conf spark.shuffle.storage.s3.path=s3://<ShuffleBucket>/<shuffle-dir> \
--conf spark.driver.extraClassPath=<Path to plugin jar> \
--conf spark.executor.extraClassPath=<Path to plugin jar> \
--class <your test class name> s3://<ShuffleBucket>/<Your application jar> \

```

### Optional configurations

These are optional configuration values that control Amazon S3 shuffle behavior.

- `spark.shuffle.storage.s3.enableServerSideEncryption`: Enable/disable S3 SSE for shuffle and spill files. Default value is `true`.
- `spark.shuffle.storage.s3.serverSideEncryption.algorithm`: The SSE algorithm to be used. Default value is `AES256`.
- `spark.shuffle.storage.s3.serverSideEncryption.kms.key`: The KMS key ARN when SSE `aws:kms` is enabled.

Along with these configurations, you may need to set configurations such as `spark.hadoop.fs.s3.enableServerSideEncryption` and **other environment-specific configurations** to ensure appropriate encryption is applied for your use case.

## Plugin versions

This plugin is supported for the Spark versions associated with each AWS Glue version. The following table shows the AWS Glue version, Spark version and associated plugin version with Amazon S3 location for the plugin's software binary.

AWS Glue version	Spark version	Plugin version	Amazon S3 location
3.0	3.1	3.1-amzn-LATEST	s3://aws-glue-etl-artifacts/release/com/amazonaws/chopper-plugin/3.1-amzn-0/chopper-plugin-3.1-amzn-LATEST.jar
4.0	3.3	3.3-amzn-LATEST	s3://aws-glue-etl-artifacts/release/com/amazonaws/chopper-plugin/3.3-amzn-0/chopper-plugin-3.3-amzn-LATEST.jar

## License

The software binary for this plugin is licensed under the Apache-2.0 License.

## Monitoring AWS Glue Spark jobs

### Topics

- [Spark Metrics available in AWS Glue Studio](#)
- [Monitoring jobs using the Apache Spark web UI](#)

- [Monitoring with AWS Glue job run insights](#)
- [Monitoring with Amazon CloudWatch](#)
- [Job monitoring and debugging](#)

## Spark Metrics available in AWS Glue Studio

The **Metrics** tab shows metrics collected when a job runs and profiling is turned on. The following graphs are shown in Spark jobs:

- ETL Data Movement
- Memory Profile: Driver and Executors

Choose **View additional metrics** to show the following graphs:

- ETL Data Movement
- Memory Profile: Driver and Executors
- Data Shuffle Across Executors
- CPU Load: Driver and Executors
- Job Execution: Active Executors, Completed Stages & Maximum Needed Executors

Data for these graphs is pushed to CloudWatch metrics if the job is configured to collect metrics. For more information about how to turn on metrics and interpret the graphs, see [Job monitoring and debugging](#).

### Example ETL data movement graph

The ETL Data Movement graph shows the following metrics:

- The number of bytes read from Amazon S3 by all executors  
—[glue.ALL.s3.filesystem.read\\_bytes](#)
- The number of bytes written to Amazon S3 by all executors  
—[glue.ALL.s3.filesystem.write\\_bytes](#)

Jobs &gt; e2e-straggler

## Detailed job metrics

ETL Data Movement

## Example Memory profile graph

The Memory Profile graph shows the following metrics:

- The fraction of memory used by the JVM heap for this driver (scale: 0–1) by the driver, an executor identified by *executorId*, or all executors—
  - [glue.driver.jvm.heap.usage](#)
  - [glue.executorId.jvm.heap.usage](#)
  - [glue.ALL.jvm.heap.usage](#)

## Example Data shuffle across executors graph

The Data Shuffle Across Executors graph shows the following metrics:

- The number of bytes read by all executors to shuffle data between them  
—[glue.driver.aggregate.shuffleLocalBytesRead](#)
- The number of bytes written by all executors to shuffle data between them  
—[glue.driver.aggregate.shuffleBytesWritten](#)

### Example CPU load graph

The CPU Load graph shows the following metrics:

- The fraction of CPU system load used (scale: 0–1) by the driver, an executor identified by *executorId*, or all executors—
  - [glue.driver.system.cpuSystemLoad](#)
  - [glue.executorId.system.cpuSystemLoad](#)
  - [glue.ALL.system.cpuSystemLoad](#)

### Example Job execution graph

The Job Execution graph shows the following metrics:

- The number of actively running executors  
—[glue.driver.ExecutorAllocationManager.executors.numberAllExecutors](#)
- The number of completed stages—[glue.aggregate.numCompletedStages](#)
- The number of maximum needed executors  
—[glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors](#)

## Monitoring jobs using the Apache Spark web UI

You can use the Apache Spark web UI to monitor and debug AWS Glue ETL jobs running on the AWS Glue job system, and also Spark applications running on AWS Glue development endpoints. The Spark UI enables you to check the following for each job:

- The event timeline of each Spark stage
- A directed acyclic graph (DAG) of the job
- Physical and logical plans for SparkSQL queries
- The underlying Spark environmental variables for each job

For more information about using the Spark Web UI, see [Web UI](#) in the Spark documentation. For guidance on how to interpret Spark UI results to improve the performance of your job, see [Best practices for performance tuning AWS Glue for Apache Spark jobs](#) in AWS Prescriptive Guidance.

For newer jobs, you can see the Spark UI in the AWS Glue console. This is available when an AWS Glue job runs on AWS Glue 3.0 or later versions with logs generated in the Standard (rather than legacy) format, which is the default for newer jobs. For more information on finding the Spark UI in the console, see [the section called “View information for recent job runs”](#). For other versions of AWS Glue, provision your own history server. For more information, see [the section called “Launching the Spark history server”](#).

You can enable the Spark UI by using the AWS Glue console or the AWS Command Line Interface (AWS CLI). When you enable the Spark UI, AWS Glue ETL jobs and Spark applications on AWS Glue development endpoints can back up Spark event logs to a location that you specify in Amazon Simple Storage Service (Amazon S3). You can use the backed up event logs in Amazon S3 with the Spark UI, both in real time as the job is operating and after the job is complete. While the logs remain in Amazon S3, the Spark UI in the AWS Glue console can view them.

## Permissions

In order to use the Spark UI in the AWS Glue console, you can use `UseGlueStudio` or add all the individual service APIs. All APIs are needed to use the Spark UI completely, however users can access SparkUI features by adding its service APIs in their IAM permission for fine-grained access.

`RequestLogParsing` is the most critical as it performs the parsing of logs. The remaining APIs are for reading the respective parsed data. For example, `GetStages` provides access to the data about all stages of a Spark job.

The list of Spark UI service APIs mapped to `UseGlueStudio` are below in the sample policy. The policy below provides access to use only Spark UI features. To add more permissions like Amazon S3 and IAM see [Creating Custom IAM Policies for AWS Glue Studio](#).

The list of Spark UI service APIs mapped to `UseGlueStudio` is below in the sample policy. When using a Spark UI service API, use the following namespace: `glue:<ServiceAPI>`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGlueStudioSparkUI",
      "Effect": "Allow",
      "Action": [
        "glue:RequestLogParsing",
        "glue:GetLogParsingStatus",
        "glue:GetEnvironment",
        "glue:GetJobs",
        "glue:GetJob",
        "glue:GetStage",
        "glue:GetStages",
        "glue:GetStageFiles",
        "glue:BatchGetStageFiles",
        "glue:GetStageAttempt",
        "glue:GetStageAttemptTaskList",

```

```

        "glue:GetStageAttemptTaskSummary",
        "glue:GetExecutors",
        "glue:GetExecutorsThreads",
        "glue:GetStorage",
        "glue:GetStorageUnit",
        "glue:GetQueries",
        "glue:GetQuery"
    ],
    "Resource": [
        "*"
    ]
}
]
}

```

## Limitations

- Spark UI in the AWS Glue console is not available for job runs that occurred before 20 Nov 2023 because they are in the legacy log format.
- Spark UI in the AWS Glue console does not support rolling logs, such as those generated by default in streaming jobs.

You can turn off rolling logs for a streaming job by passing an additional configuration. Note that very large log files may be costly to maintain.

To turn off rolling logs, provide the following configuration:

```

'--spark-ui-event-logs-path': 'true',
'--conf': 'spark.eventLog.rolling.enabled=false'

```

## Example: Apache Spark web UI

This example shows you how to use the Spark UI to understand your job performance. Screen shots show the Spark web UI as provided by a self-managed Spark history server. Spark UI in the AWS Glue console provides similar views. For more information about using the Spark Web UI, see [Web UI](#) in the Spark documentation.

The following is an example of a Spark application that reads from two data sources, performs a join transform, and writes it out to Amazon S3 in Parquet format.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from pyspark.sql.functions import count, when, expr, col, sum, isnull
from pyspark.sql.functions import countDistinct
from awsglue.dynamicframe import DynamicFrame

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'])

df_persons = spark.read.json("s3://awsglue-datasets/examples/us-legislators/all/
persons.json")
df_memberships = spark.read.json("s3://awsglue-datasets/examples/us-legislators/all/
memberships.json")

df_joined = df_persons.join(df_memberships, df_persons.id == df_memberships.person_id,
'fullouter')
df_joined.write.parquet("s3://aws-glue-demo-sparkui/output/")

job.commit()
```

The following DAG visualization shows the different stages in this Spark job.

## Topics

- [Enabling the Apache Spark web UI for AWS Glue jobs](#)
- [Launching the Spark history server](#)

## Enabling the Apache Spark web UI for AWS Glue jobs

You can use the Apache Spark web UI to monitor and debug AWS Glue ETL jobs running on the AWS Glue job system. You can configure the Spark UI using the AWS Glue console or the AWS Command Line Interface (AWS CLI).

Every 30 seconds, AWS Glue backs up the Spark event logs to the Amazon S3 path that you specify.

## Topics

- [Configuring the Spark UI \(console\)](#)
- [Configuring the Spark UI \(AWS CLI\)](#)
- [Configuring the Spark UI for sessions using Notebooks](#)

## Configuring the Spark UI (console)

Follow these steps to configure the Spark UI by using the AWS Management Console. When creating an AWS Glue job, Spark UI is enabled by default.

### To turn on the Spark UI when you create or edit a job

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Jobs**.
3. Choose **Add job**, or select an existing one.
4. In **Job details**, open the **Advanced properties**.
5. Under the **Spark UI** tab, choose **Write Spark UI logs to Amazon S3**.
6. Specify an Amazon S3 path for storing the Spark event logs for the job. Note that if you use a security configuration in the job, the encryption also applies to the Spark UI log file. For more information, see [Encrypting data written by AWS Glue](#).
7. Under **Spark UI logging and monitoring configuration**:
  - Select **Standard** if you are generating logs to view in the AWS Glue console.

- Select **Legacy** if you are generating logs to view on a Spark history server.
- You can also choose to generate both.

## Configuring the Spark UI (AWS CLI)

To generate logs for viewing with Spark UI, in the AWS Glue console, use the AWS CLI to pass the following job parameters to AWS Glue jobs. For more information, see [the section called “Job parameters”](#).

```
'--enable-spark-ui': 'true',  
'--spark-event-logs-path': 's3://s3-event-log-path'
```

To distribute logs to their legacy locations, set the `--enable-spark-ui-legacy-path` parameter to `"true"`. If you do not want to generate logs in both formats, remove the `--enable-spark-ui` parameter.

## Configuring the Spark UI for sessions using Notebooks

### Warning

AWS Glue interactive sessions do not currently support Spark UI in the console. Configure a Spark history server.

If you use AWS Glue notebooks, set up SparkUI config before starting the session. To do this, use the `%%configure` cell magic:

```
%%configure { "--enable-spark-ui": "true", "--spark-event-logs-path": "s3://path" }
```

## Launching the Spark history server

You can use a Spark history server to visualize Spark logs on your own infrastructure. You can see the same visualizations in the AWS Glue console for AWS Glue job runs on AWS Glue 4.0 or later versions with logs generated in the Standard (rather than legacy) format. For more information, see [the section called “Monitoring with the Spark UI”](#).

You can launch the Spark history server using a AWS CloudFormation template that hosts the server on an EC2 instance, or launch locally using Docker.

## Topics

- [Launching the Spark history server and viewing the Spark UI using AWS CloudFormation](#)
- [Launching the Spark history server and viewing the Spark UI using Docker](#)

## Launching the Spark history server and viewing the Spark UI using AWS CloudFormation

You can use an AWS CloudFormation template to start the Apache Spark history server and view the Spark web UI. These templates are samples that you should modify to meet your requirements.

### To start the Spark history server and view the Spark UI using AWS CloudFormation

1. Choose one of the **Launch Stack** buttons in the following table. This launches the stack on the AWS CloudFormation console.

Region	Launch
US East (Ohio)	
US East (N. Virginia)	
US West (N. California)	
US West (Oregon)	
Africa (Cape Town)	
Asia Pacific (Hong Kong)	
Asia Pacific (Mumbai)	
Asia Pacific (Osaka)	
Asia Pacific (Seoul)	

Region	Launch
Asia Pacific (Singapore)	
Asia Pacific (Sydney)	
Asia Pacific (Tokyo)	
Canada (Central)	
Europe (Frankfurt)	
Europe (Ireland)	
Europe (London)	
Europe (Milan)	
Europe (Paris)	
Europe (Stockholm)	
Middle East (Bahrain)	
South America (São Paulo)	

2. On the **Specify template** page, choose **Next**.
3. On the **Specify stack details** page, enter the **Stack name**. Enter additional information under **Parameters**.
  - a. **Spark UI configuration**

Provide the following information:

- **IP address range** — The IP address range that can be used to view the Spark UI. If you want to restrict access from a specific IP address range, you should use a custom value.
  - **History server port** — The port for the Spark UI. You can use the default value.
  - **Event log directory** — Choose the location where Spark event logs are stored from the AWS Glue job or development endpoints. You must use `s3a://` for the event logs path scheme.
  - **Spark package location** — You can use the default value.
  - **Keystore path** — SSL/TLS keystore path for HTTPS. If you want to use a custom keystore file, you can specify the S3 path `s3://path_to_your_keystore_file` here. If you leave this parameter empty, a self-signed certificate based keystore is generated and used.
  - **Keystore password** — Enter a SSL/TLS keystore password for HTTPS.
- b. **EC2 instance configuration**

Provide the following information:

- **Instance type** — The type of Amazon EC2 instance that hosts the Spark history server. Because this template launches Amazon EC2 instance in your account, Amazon EC2 cost will be charged in your account separately.
  - **Latest AMI ID** — The AMI ID of Amazon Linux 2 for the Spark history server instance. You can use the default value.
  - **VPC ID** — The virtual private cloud (VPC) ID for the Spark history server instance. You can use any of the VPCs available in your account. Using a default VPC with a [default Network ACL](#) is not recommended. For more information, see [Default VPC and Default Subnets](#) and [Creating a VPC](#) in the *Amazon VPC User Guide*.
  - **Subnet ID** — The ID for the Spark history server instance. You can use any of the subnets in your VPC. You must be able to reach the network from your client to the subnet. If you want to access via the internet, you must use a public subnet that has the internet gateway in the route table.
- c. Choose **Next**.
4. On the **Configure stack options** page, to use the current user credentials for determining how CloudFormation can create, modify, or delete resources in the stack, choose **Next**. You can also specify a role in the **Permissions** section to use instead of the current user permissions, and then choose **Next**.

5. On the **Review** page, review the template.

Select **I acknowledge that AWS CloudFormation might create IAM resources**, and then choose **Create stack**.

6. Wait for the stack to be created.
7. Open the **Outputs** tab.
  - a. Copy the URL of **SparkUiPublicUrl** if you are using a public subnet.
  - b. Copy the URL of **SparkUiPrivateUrl** if you are using a private subnet.
8. Open a web browser, and paste in the URL. This lets you access the server using HTTPS on the specified port. Your browser may not recognize the server's certificate, in which case you have to override its protection and proceed anyway.

## Launching the Spark history server and viewing the Spark UI using Docker

If you prefer local access (not to have an EC2 instance for the Apache Spark history server), you can also use Docker to start the Apache Spark history server and view the Spark UI locally. This Dockerfile is a sample that you should modify to meet your requirements.

### Prerequisites

For information about how to install Docker on your laptop see the [Docker Engine community](#).

### To start the Spark history server and view the Spark UI locally using Docker

1. Download files from GitHub.

Download the Dockerfile and `pom.xml` from [AWS Glue code samples](#).

2. Determine if you want to use your user credentials or federated user credentials to access AWS.
  - To use the current user credentials for accessing AWS, get the values to use for `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` in the `docker run` command. For more information, see [Managing access keys for IAM users](#) in the *IAM User Guide*.
  - To use SAML 2.0 federated users for accessing AWS, get the values for `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `AWS_SESSION_TOKEN`. For more information, see [Requesting temporary security credentials](#)
3. Determine the location of your event log directory, to use in the `docker run` command.

4. Build the Docker image using the files in the local directory, using the name `glue/sparkui`, and the tag `latest`.

```
$ docker build -t glue/sparkui:latest .
```

5. Create and start the docker container.

In the following commands, use the values obtained previously in steps 2 and 3.

- a. To create the docker container using your user credentials, use a command similar to the following

```
docker run -itd -e SPARK_HISTORY_OPTS="$SPARK_HISTORY_OPTS -  
Dspark.history.fs.logDirectory=s3a://path_to_eventlog -  
-Dspark.hadoop.fs.s3a.access.key=AWS_ACCESS_KEY_ID -  
Dspark.hadoop.fs.s3a.secret.key=AWS_SECRET_ACCESS_KEY" -  
-p 18080:18080 glue/sparkui:latest "/opt/spark/bin/spark-class  
org.apache.spark.deploy.history.HistoryServer"
```

- b. To create the docker container using temporary credentials, use `org.apache.hadoop.fs.s3a.TemporaryAWSCredentialsProvider` as the provider, and provide the credential values obtained in step 2. For more information, see [Using Session Credentials with TemporaryAWSCredentialsProvider](#) in the *Hadoop: Integration with Amazon Web Services* documentation.

```
docker run -itd -e SPARK_HISTORY_OPTS="$SPARK_HISTORY_OPTS -  
Dspark.history.fs.logDirectory=s3a://path_to_eventlog -  
-Dspark.hadoop.fs.s3a.access.key=AWS_ACCESS_KEY_ID -  
Dspark.hadoop.fs.s3a.secret.key=AWS_SECRET_ACCESS_KEY -  
-Dspark.hadoop.fs.s3a.session.token=AWS_SESSION_TOKEN -  
-  
Dspark.hadoop.fs.s3a.aws.credentials.provider=org.apache.hadoop.fs.s3a.TemporaryAWSCred  
-p 18080:18080 glue/sparkui:latest "/opt/spark/bin/spark-class  
org.apache.spark.deploy.history.HistoryServer"
```

**Note**

These configuration parameters come from the [Hadoop-AWS Module](#). You may need to add specific configuration based on your use case. For example: users in isolated regions will need to configure the `spark.hadoop.fs.s3a.endpoint`.

6. Open `http://localhost:18080` in your browser to view the Spark UI locally.

## Monitoring with AWS Glue job run insights

AWS Glue job run insights is a feature in AWS Glue that simplifies job debugging and optimization for your AWS Glue jobs. AWS Glue provides [Spark UI](#), and [CloudWatch logs and metrics](#) for monitoring your AWS Glue jobs. With this feature, you get this information about your AWS Glue job's execution:

- Line number of your AWS Glue job script that had a failure.
- Spark action that executed last in the Spark query plan just before the failure of your job.
- Spark exception events related to the failure presented in a time-ordered log stream.
- Root cause analysis and recommended action (such as tuning your script) to fix the issue.
- Common Spark events (log messages relating to a Spark action) with a recommended action that addresses the root cause.

All these insights are available to you using two new log streams in the CloudWatch logs for your AWS Glue jobs.

## Requirements

The AWS Glue job run insights feature is available for AWS Glue versions 2.0, 3.0, and 4.0. You can follow the [migration guide](#) for your existing jobs to upgrade them from older AWS Glue versions.

## Enabling job run insights for an AWS Glue ETL job

You can enable job run insights through AWS Glue Studio or the CLI.

## AWS Glue Studio

When creating a job via AWS Glue Studio, you can enable or disable job run insights under the **Job Details** tab. Check that the **Generate job insights** box is selected.

### Requested number of workers

The number of workers you want AWS Glue to allocate to this job.

The maximums are 299 for G.1X and 149 for G.2X, and the minimum is 2.

### Generate job insights

AWS Glue will analyze your job runs and provide insights on how to optimize your jobs and the reasons for job failures.

## Command line

If creating a job via the CLI, you can start a job run with a single new [job parameter](#): `--enable-job-insights = true`.

By default, the job run insights log streams are created under the same default log group used by [AWS Glue continuous logging](#), that is, `/aws-glue/jobs/logs-v2/`. You may set up custom log group name, log filters and log group configurations using the same set of arguments for continuous logging. For more information, see [Enabling Continuous Logging for AWS Glue Jobs](#).

## Accessing the job run insights log streams in CloudWatch

With the job run insights feature enabled, there may be two log streams created when a job run fails. When a job finishes successfully, neither of the streams are generated.

1. *Exception analysis log stream*: `<job-run-id>-job-insights-rca-driver`. This stream provides the following:
  - Line number of your AWS Glue job script that caused the failure.
  - Spark action that executed last in the Spark query plan (DAG).
  - Concise time-ordered events from the Spark driver and executors that are related to the exception. You can find details such as complete error messages, the failed Spark task and its executors ID that help you to focus on the specific executor's log stream for a deeper investigation if needed.
2. *Rule-based insights stream*:
  - Root cause analysis and recommendations on how to fix the errors (such as using a specific job parameter to optimize the performance).

- Relevant Spark events serving as the basis for root cause analysis and a recommended action.

### Note

The first stream will exist only if any exception Spark events are available for a failed job run, and the second stream will exist only if any insights are available for the failed job run. For example, if your job finishes successfully, neither of the streams will be generated; if your job fails but there isn't a service-defined rule that can match with your failure scenario, then only the first stream will be generated.

If the job is created from AWS Glue Studio, the links to the above streams are also available under the job run details tab (Job run insights) as "Concise and consolidated error logs" and "Error analysis and guidance".

## Job run - jr\_ [REDACTED]

### Run details [Info](#)

 An error occurred while calling o134.pyWriteDynamicFrame. No such file or directory 's3://[REDACTED]'

## Example for AWS Glue job run insights

In this section we present an example of how the job run insights feature can help you resolve an issue in your failed job. In this example, a user forgot to import the required module (tensorflow) in an AWS Glue job to analyze and build a machine learning model on their data.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from pyspark.sql.types import *
from pyspark.sql.functions import udf,col

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

data_set_1 = [1, 2, 3, 4]
data_set_2 = [5, 6, 7, 8]

scoresDf = spark.createDataFrame(data_set_1, IntegerType())

def data_multiplier_func(factor, data_vector):
    import tensorflow as tf
    with tf.compat.v1.Session() as sess:
        x1 = tf.constant(factor)
        x2 = tf.constant(data_vector)
        result = tf.multiply(x1, x2)
        return sess.run(result).tolist()

data_multiplier_udf = udf(lambda x:data_multiplier_func(x, data_set_2),
    ArrayType(IntegerType(),False))
factoredDf = scoresDf.withColumn("final_value", data_multiplier_udf(col("value")))
print(factoredDf.collect())
```

Without the job run insights feature, as the job fails, you only see this message thrown by Spark:

An error occurred while calling `o111.collectToPython`. Traceback (most recent call last):

The message is ambiguous and limits your debugging experience. In this case, this feature provides with you additional insights in two CloudWatch log streams:

### 1. The `job-insights-rca-driver` log stream:

- **Exception events:** This log stream provides you the Spark exception events related to the failure collected from the Spark driver and different distributed workers. These events help you understand the time-ordered propagation of the exception as faulty code executes across Spark tasks, executors, and stages distributed across the AWS Glue workers.
- **Line numbers:** This log stream identifies line 21, which made the call to import the missing Python module that caused the failure; it also identifies line 24, the call to Spark Action `collect()`, as the last executed line in your script.

Timestamp	Message
	No older events at this moment. <a href="#">Retry</a>
2022-01-31T06:07:04.750-08:00	22/01/31 14:07:04 ERROR GlueExceptionAnalysisListener: [Glue Exception Analysis] Event: GlueExceptionAnalysisTaskFailed Failure Reason: Traceb...

### 2. The `job-insights-rule-driver` log stream:

- **Root cause and recommendation:** In addition to the line number and last executed line number for the fault in your script, this log stream shows the root cause analysis and recommendation for you to follow the AWS Glue doc and set up the necessary job parameters in order to use an additional Python module in your AWS Glue job.
- **Basis event:** This log stream also shows the Spark exception event that was evaluated with the service-defined rule to infer the root cause and provide a recommendation.

## Monitoring with Amazon CloudWatch

You can monitor AWS Glue using Amazon CloudWatch, which collects and processes raw data from AWS Glue into readable, near-real-time metrics. These statistics are recorded for a period of two weeks so that you can access historical information for a better perspective on how your web application or service is performing. By default, AWS Glue metrics data is sent to CloudWatch automatically. For more information, see [What Is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*, and [AWS Glue metrics](#).

## Continuous logging

AWS Glue also supports real-time continuous logging for AWS Glue jobs. When continuous logging is enabled for a job, you can view the real-time logs on the AWS Glue console or the CloudWatch console dashboard. For more information, see [Continuous logging for AWS Glue jobs](#).

## Observability metrics

When **Job observability metrics** is enabled, additional Amazon CloudWatch metrics are generated when the job is run. Use AWS Glue Observability metrics to generate insights into what is happening inside your AWS Glue to improve triaging and analysis of issues.

## Topics

- [Monitoring AWS Glue using Amazon CloudWatch metrics](#)
- [Setting up Amazon CloudWatch alarms on AWS Glue job profiles](#)

## Monitoring AWS Glue using Amazon CloudWatch metrics

You can profile and monitor AWS Glue operations using AWS Glue job profiler. It collects and processes raw data from AWS Glue jobs into readable, near real-time metrics stored in Amazon CloudWatch. These statistics are retained and aggregated in CloudWatch so that you can access historical information for a better perspective on how your application is performing.

### Note

You may incur additional charges when you enable job metrics and CloudWatch custom metrics are created. For more information, see [Amazon CloudWatch pricing](#).

## AWS Glue metrics overview

When you interact with AWS Glue, it sends metrics to CloudWatch. You can view these metrics using the AWS Glue console (the preferred method), the CloudWatch console dashboard, or the AWS Command Line Interface (AWS CLI).

### To view metrics using the AWS Glue console dashboard

You can view summary or detailed graphs of metrics for a job, or detailed graphs for a job run.

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Job run monitoring**.
3. In **Job runs** choose **Actions** to stop a job that is currently running, view a job, or rewind job bookmark.
4. Select a job, then choose **View run details** to view additional information about the job run.

### To view metrics using the CloudWatch console dashboard

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

2. In the navigation pane, choose **Metrics**.
3. Choose the **Glue** namespace.

### To view metrics using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace Glue
```

AWS Glue reports metrics to CloudWatch every 30 seconds, and the CloudWatch metrics dashboards are configured to display them every minute. The AWS Glue metrics represent delta values from the previously reported values. Where appropriate, metrics dashboards aggregate (sum) the 30-second values to obtain a value for the entire last minute.

### AWS Glue metrics behavior for Spark jobs

AWS Glue metrics are enabled at initialization of a `GlueContext` in a script and are generally updated only at the end of an Apache Spark task. They represent the aggregate values across all completed Spark tasks so far.

However, the Spark metrics that AWS Glue passes on to CloudWatch are generally absolute values representing the current state at the time they are reported. AWS Glue reports them to CloudWatch every 30 seconds, and the metrics dashboards generally show the average across the data points received in the last 1 minute.

AWS Glue metrics names are all preceded by one of the following types of prefix:

- `glue.driver.` – Metrics whose names begin with this prefix either represent AWS Glue metrics that are aggregated from all executors at the Spark driver, or Spark metrics corresponding to the Spark driver.
- `glue.executorId.` – The *executorId* is the number of a specific Spark executor. It corresponds with the executors listed in the logs.
- `glue.ALL.` – Metrics whose names begin with this prefix aggregate values from all Spark executors.

## AWS Glue metrics

AWS Glue profiles and sends the following metrics to CloudWatch every 30 seconds, and the AWS Glue Metrics Dashboard report them once a minute:

Metric	Description
<code>glue.driver.aggregate.bytesRead</code>	<p>The number of bytes read from all data sources by all completed Spark tasks running in all executors.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Bytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> <li>• Bytes read.</li> <li>• Job progress.</li> <li>• JDBC data sources.</li> <li>• Job Bookmark Issues.</li> <li>• Variance across Job Runs.</li> </ul> <p>This metric can be used the same way as the <code>glue.ALL.s3.filesystem.read_bytes</code> metric, with the difference that this metric is updated at the end of a Spark task and captures non-S3 data sources as well.</p>
<code>glue.driver.aggregate.elapsedTime</code>	<p>The ETL elapsed time in milliseconds (does not include the job bootstrap times).</p>

Metric	Description
	<p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Milliseconds</p> <p>Can be used to determine how long it takes a job run to run on average.</p> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Set alarms for stragglers.</li><li>• Measure variance across job runs.</li></ul>

Metric	Description
<code>glue.driver.aggregate.numCompletedStages</code>	<p>The number of completed stages in the job.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Job progress.</li><li>• Per-stage timeline of job execution,when correlated with other metrics.</li></ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Identify demanding stages in the execution of a job.</li><li>• Set alarms for correlated spikes (demanding stages) across job runs.</li></ul>

Metric	Description
<code>glue.driver.aggregate.numCompletedTasks</code>	<p>The number of completed tasks in the job.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Job progress.</li><li>• Parallelism within a stage.</li></ul>

Metric	Description
<code>glue.driver.aggregate.numFailedTasks</code>	<p>The number of failed tasks.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Data abnormalities that cause job tasks to fail.</li><li>• Cluster abnormalities that cause job tasks to fail.</li><li>• Script abnormalities that cause job tasks to fail.</li></ul> <p>The data can be used to set alarms for increased failures that might suggest abnormalities in data, cluster or scripts.</p>

Metric	Description
<code>glue.driver.aggregate.numKilledTasks</code>	<p>The number of tasks killed.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Abnormalities in Data Skew that result in exceptions (OOMs) that kill tasks.</li><li>• Script abnormalities that result in exceptions (OOMs) that kill tasks.</li></ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Set alarms for increased failures indicating data abnormalities.</li><li>• Set alarms for increased failures indicating cluster abnormalities.</li><li>• Set alarms for increased failures indicating script abnormalities.</li></ul>

Metric	Description
<code>glue.driver.aggregate.recordsRead</code>	<p>The number of records read from all data sources by all completed Spark tasks running in all executors.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Records read.</li><li>• Job progress.</li><li>• JDBC data sources.</li><li>• Job Bookmark Issues.</li><li>• Skew in Job Runs over days.</li></ul> <p>This metric can be used in a similar way to the <code>glue.ALL.s3.filesystem.read_bytes</code> metric, with the difference that this metric is updated at the end of a Spark task.</p>

Metric	Description
<code>glue.driver.aggregate.shuffleBytesWritten</code>	<p>The number of bytes written by all executors to shuffle data between them since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes written for this purpose during the previous minute).</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Bytes</p> <p>Can be used to monitor: Data shuffle in jobs (large joins, groupBy, repartition, coalesce).</p> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Repartition or decompress large input files before further processing.</li><li>• Repartition data more uniformly to avoid hot keys.</li><li>• Pre-filter data before joins or groupBy operations.</li></ul>

Metric	Description
<code>glue.driver.aggregate.shuffleLocalBytesRead</code>	<p>The number of bytes read by all executors to shuffle data between them since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes read for this purpose during the previous minute).</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard, a SUM statistic is used for aggregation.</p> <p>Unit: Bytes</p> <p>Can be used to monitor: Data shuffle in jobs (large joins, groupBy, repartition, coalesce).</p> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Repartition or decompress large input files before further processing.</li><li>• Repartition data more uniformly using hot keys.</li><li>• Pre-filter data before joins or groupBy operations.</li></ul>

Metric	Description
<code>glue.driver.BlockManager.disk.diskSpaceUsed_MB</code>	<p>The number of megabytes of disk space used across all executors.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Megabytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Disk space used for blocks that represent cached RDD partitions.</li><li>• Disk space used for blocks that represent intermediate shuffle outputs.</li><li>• Disk space used for blocks that represent broadcasts.</li></ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Identify job failures due to increased disk usage.</li><li>• Identify large partitions resulting in spilling or shuffling.</li><li>• Increase provisioned DPU capacity to correct these issues.</li></ul>

Metric	Description
<code>glue.driver.ExecutorAllocationManager.executors.numberAllExecutors</code>	<p>The number of actively running job executors.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Job activity.</li><li>• Straggling executors (with a few executors running only)</li><li>• Current executor-level parallelism.</li></ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Repartition or decompress large input files beforehand if cluster is under-utilized.</li><li>• Identify stage or job execution delays due to straggler scenarios.</li><li>• Compare with <code>numberMaxNeededExecutors</code> to understand backlog for provisioning more DPUs.</li></ul>

Metric	Description
<code>glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors</code>	<p>The number of maximum (actively running and pending) job executors needed to satisfy the current load.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Maximum. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Job activity.</li><li>• Current executor-level parallelism and backlog of pending tasks not yet scheduled because of unavailable executors due to DPU capacity or killed/failed executors.</li></ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• Identify pending/backlog of scheduling queue.</li><li>• Identify stage or job execution delays due to straggler scenarios.</li><li>• Compare with <code>numberAllExecutors</code> to understand backlog for provisioning more DPUs.</li><li>• Increase provisioned DPU capacity to correct the pending executor backlog.</li></ul>

Metric	Description
<code>glue.driver.jvm.heap.usage</code>	The fraction of memory used by the JVM heap for this driver (scale: 0-1) for driver, executor identified by <code>executorId</code> , or ALL executors.
<code>glue.executorId.jvm.heap.usage</code>	Valid dimensions: <code>JobName</code> (the name of the AWS Glue Job), <code>JobRunId</code> (the JobRun ID. or ALL), and <code>Type</code> (gauge).
<code>glue.ALL.jvm.heap.usage</code>	<p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Percentage</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> <li>• Driver out-of-memory conditions (OOM) using <code>glue.driver.jvm.heap.usage</code> .</li> <li>• Executor out-of-memory conditions (OOM) using <code>glue.ALL.jvm.heap.usage</code> .</li> </ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"> <li>• Identify memory-consuming executor ids and stages.</li> <li>• Identify straggling executor ids and stages.</li> <li>• Identify a driver out-of-memory condition (OOM).</li> <li>• Identify an executor out-of-memory condition (OOM) and obtain the corresponding executor ID so as to be able to get a stack trace from the executor log.</li> <li>• Identify files or partitions that may have data skew resulting in stragglers or out-of-memory conditions (OOMs).</li> </ul>

Metric	Description
<p><code>glue.driver.jvm.heap.used</code></p> <p><code>glue.executorId.jvm.heap.used</code></p> <p><code>glue.ALL.jvm.heap.used</code></p>	<p>The number of memory bytes used by the JVM heap for the driver, the executor identified by <i>executorId</i>, or ALL executors.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This is a Spark metric, reported as an absolute value.</p> <p>Unit: Bytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"> <li>• Driver out-of-memory conditions (OOM).</li> <li>• Executor out-of-memory conditions (OOM).</li> </ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"> <li>• Identify memory-consuming executor ids and stages.</li> <li>• Identify stragglers executor ids and stages.</li> <li>• Identify a driver out-of-memory condition (OOM).</li> <li>• Identify an executor out-of-memory condition (OOM) and obtain the corresponding executor ID so as to be able to get a stack trace from the executor log.</li> <li>• Identify files or partitions that may have data skew resulting in stragglers or out-of-memory conditions (OOMs).</li> </ul>

Metric	Description
<code>glue.driver.s3.filesystem.read_bytes</code>	<p>The number of bytes read from Amazon S3 by the driver, an executor identified by <i>executorId</i>, or ALL executors since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes read during the previous minute).</p>
<code>glue.executorId.s3.filesystem.read_bytes</code>	<p>Valid dimensions: JobName, JobRunId, and Type (gauge).</p>
<code>glue.ALL.s3.filesystem.read_bytes</code>	<p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard a SUM statistic is used for aggregation. The area under the curve on the AWS Glue Metrics Dashboard can be used to visually compare bytes read by two different job runs.</p> <p>Unit: Bytes.</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• ETL data movement.</li><li>• Job progress.</li><li>• Job bookmark issues (data processed, reprocessed, and skipped).</li><li>• Comparison of reads to ingestion rate from external data sources.</li><li>• Variance across job runs.</li></ul> <p>Resulting data can be used for:</p> <ul style="list-style-type: none"><li>• DPU capacity planning.</li><li>• Setting alarms for large spikes or dips in data read for job runs and job stages.</li></ul>

Metric	Description
<code>glue.driver.s3.filesystem.write_bytes</code>	<p>The number of bytes written to Amazon S3 by the driver, an executor identified by <i>executorId</i>, or ALL executors since the previous report (aggregated by the AWS Glue Metrics Dashboard as the number of bytes written during the previous minute).</p>
<code>glue.executorId.s3.filesystem.write_bytes</code>	<p>Valid dimensions: JobName, JobRunId, and Type (gauge).</p>
<code>glue.ALL.s3.filesystem.write_bytes</code>	<p>Valid Statistics: SUM. This metric is a delta value from the last reported value, so on the AWS Glue Metrics Dashboard a SUM statistic is used for aggregation. The area under the curve on the AWS Glue Metrics Dashboard can be used to visually compare bytes written by two different job runs.</p> <p>Unit: Bytes</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• ETL data movement.</li><li>• Job progress.</li><li>• Job bookmark issues (data processed, reprocessed, and skipped).</li><li>• Comparison of reads to ingestion rate from external data sources.</li><li>• Variance across job runs.</li></ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"><li>• DPU capacity planning.</li><li>• Setting alarms for large spikes or dips in data read for job runs and job stages.</li></ul>

Metric	Description
<code>glue.driver.streaming.numRecords</code>	<p>The number of records that are received in a micro-batch. This metric is only available for AWS Glue streaming jobs with AWS Glue version 2.0 and above.</p> <p>Valid dimensions: JobName (the name of the AWS Glue job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: Sum, Maximum, Minimum, Average, Percentile</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Records read.</li><li>• Job progress.</li></ul>
<code>glue.driver.streaming.batchProcessingTimeInMs</code>	<p>The time it takes to process the batches in milliseconds. This metric is only available for AWS Glue streaming jobs with AWS Glue version 2.0 and above.</p> <p>Valid dimensions: JobName (the name of the AWS Glue job), JobRunId (the JobRun ID. or ALL), and Type (count).</p> <p>Valid Statistics: Sum, Maximum, Minimum, Average, Percentile</p> <p>Unit: Count</p> <p>Can be used to monitor:</p> <ul style="list-style-type: none"><li>• Job progress.</li><li>• Script performance.</li></ul>

Metric	Description
<code>glue.driver.system.cpuSystemLoad</code>	<p>The fraction of CPU system load used (scale: 0-1) by the driver, an executor identified by <i>executorId</i>, or ALL executors.</p>
<code>glue.executorId.system.cpuSystemLoad</code>	<p>Valid dimensions: JobName (the name of the AWS Glue job), JobRunId (the JobRun ID. or ALL), and Type (gauge).</p> <p>Valid Statistics: Average. This metric is reported as an absolute value.</p> <p>Unit: Percentage</p>
<code>glue.ALL.system.cpuSystemLoad</code>	<p>Can be used to monitor:</p> <ul style="list-style-type: none"> <li>• Driver CPU load.</li> <li>• Executor CPU load.</li> <li>• Detecting CPU-bound or IO-bound executors or stages in a Job.</li> </ul> <p>Some ways to use the data:</p> <ul style="list-style-type: none"> <li>• DPU capacity Planning along with IO Metrics (Bytes Read/Shuffle Bytes, Task Parallelism) and the number of maximum needed executors metric.</li> <li>• Identify the CPU/IO-bound ratio. This allows for repartitioning and increasing provisioned capacity for long-running jobs with splittable datasets having lower CPU utilization.</li> </ul>

## Dimensions for AWS Glue Metrics

AWS Glue metrics use the AWS Glue namespace and provide metrics for the following dimensions:

Dimension	Description
JobName	This dimension filters for metrics of all job runs of a specific AWS Glue job.
JobRunId	This dimension filters for metrics of a specific AWS Glue job run by a JobRun ID, or ALL.
Type	This dimension filters for metrics by either count (an aggregate number) or gauge (a value at a point in time).

For more information, see the [Amazon CloudWatch User Guide](#).

## Setting up Amazon CloudWatch alarms on AWS Glue job profiles

AWS Glue metrics are also available in Amazon CloudWatch. You can set up alarms on any AWS Glue metric for scheduled jobs.

A few common scenarios for setting up alarms are as follows:

- Jobs running out of memory (OOM): Set an alarm when the memory usage exceeds the normal average for either the driver or an executor for an AWS Glue job.
- Stragglers: Set an alarm when the number of executors falls below a certain threshold for a large duration of time in an AWS Glue job.
- Data backlog or reprocessing: Compare the metrics from individual jobs in a workflow using a CloudWatch math expression. You can then trigger an alarm on the resulting expression value (such as the ratio of bytes written by a job and bytes read by a following job).

For detailed instructions on setting alarms, see [Create or Edit a CloudWatch Alarm](#) in the [Amazon CloudWatch Events User Guide](#).

For monitoring and debugging scenarios using CloudWatch, see [Job monitoring and debugging](#).

## Continuous logging for AWS Glue jobs

AWS Glue provides real-time, continuous logging for AWS Glue jobs. You can view real-time Apache Spark job logs in Amazon CloudWatch, including driver logs, executor logs, and an Apache Spark job progress bar. Viewing real-time logs provides you with a better perspective on the running job.

When you start an AWS Glue job, it sends the real-time logging information to CloudWatch (every 5 seconds and before each executor termination) after the Spark application starts running. You can view the logs on the AWS Glue console or the CloudWatch console dashboard.

The continuous logging feature includes the following capabilities:

- Continuous logging
- A custom script logger to log application-specific messages
- A console progress bar to track the running status of the current AWS Glue job

For information about how continuous logging is supported in AWS Glue version 2.0, see [Running Spark ETL Jobs with Reduced Startup Times](#).

You can restrict access to CloudWatch log groups or streams for IAM roles to read the logs. For more details on restricting access, see [Using identity-based policies \(IAM policies\) for CloudWatch Logs](#) in the CloudWatch documentation.

### Note

You may incur additional charges when you enable continuous logging and additional CloudWatch log events are created. For more information, see [Amazon CloudWatch pricing](#).

## Topics

- [Enabling continuous logging for AWS Glue jobs](#)
- [Viewing continuous logging for AWS Glue jobs](#)

## Enabling continuous logging for AWS Glue jobs

You can enable continuous logging using the AWS Glue console or through the AWS Command Line Interface (AWS CLI).

You can enable continuous logging when you create a new job, edit an existing job, or enable it through the AWS CLI.

You can also specify custom configuration options such as the Amazon CloudWatch log group name, CloudWatch log stream prefix before the AWS Glue job run ID driver/executor ID, and log conversion pattern for log messages. These configurations help you to set aggregate logs in custom CloudWatch log groups with different expiration policies, and analyze them further with custom log stream prefixes and conversions patterns.

## Topics

- [Using the AWS Management Console](#)
- [Logging application-specific messages using the custom script logger](#)
- [Enabling the progress bar to show job progress](#)
- [Security configuration with continuous logging](#)

## Using the AWS Management Console

Follow these steps to use the console to enable continuous logging when creating or editing an AWS Glue job.

### To create a new AWS Glue job with continuous logging

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **ETL jobs**.
3. Choose **Visual ETL**.
4. In the **Job details** tab, expand the **Advanced properties** section.
5. Under **Continuous logging** select **Enable logs in CloudWatch**.

### To enable continuous logging for an existing AWS Glue job

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Jobs**.
3. Choose an existing job from the **Jobs** list.
4. Choose **Action, Edit job**.
5. In the **Job details** tab, expand the **Advanced properties** section.

## 6. Under **Continuous logging** select **Enable logs in CloudWatch**.

### Using the AWS CLI

To enable continuous logging, you pass in job parameters to an AWS Glue job. Pass the following special job parameters similar to other AWS Glue job parameters. For more information, see [AWS Glue job parameters](#).

```
'--enable-continuous-cloudwatch-log': 'true'
```

You can specify a custom Amazon CloudWatch log group name. If not specified, the default log group name is `/aws-glue/jobs/logs-v2/`.

```
'--continuous-log-logGroup': 'custom_log_group_name'
```

You can specify a custom Amazon CloudWatch log stream prefix. If not specified, the default log stream prefix is the job run ID.

```
'--continuous-log-logStreamPrefix': 'custom_log_stream_prefix'
```

You can specify a custom continuous logging conversion pattern. If not specified, the default conversion pattern is `%d{yy/MM/dd HH:mm:ss} %p %c{1}: %m%n`. Note that the conversion pattern only applies to driver logs and executor logs. It does not affect the AWS Glue progress bar.

```
'--continuous-log-conversionPattern': 'custom_log_conversion_pattern'
```

### Logging application-specific messages using the custom script logger

You can use the AWS Glue logger to log any application-specific messages in the script that are sent in real time to the driver log stream.

The following example shows a Python script.

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)
logger = glueContext.get_logger()
logger.info("info message")
```

```
logger.warn("warn message")
logger.error("error message")
```

The following example shows a Scala script.

```
import com.amazonaws.services.glue.log.GlueLogger

object GlueApp {
  def main(sysArgs: Array[String]) {
    val logger = new GlueLogger
    logger.info("info message")
    logger.warn("warn message")
    logger.error("error message")
  }
}
```

### Enabling the progress bar to show job progress

AWS Glue provides a real-time progress bar under the `JOB_RUN_ID-progress-bar` log stream to check AWS Glue job run status. Currently it supports only jobs that initialize `glueContext`. If you run a pure Spark job without initializing `glueContext`, the AWS Glue progress bar does not appear.

The progress bar shows the following progress update every 5 seconds.

```
Stage Number (Stage Name): > (numCompletedTasks + numActiveTasks) /
totalNumOfTasksInThisStage]
```

### Security configuration with continuous logging

If a security configuration is enabled for CloudWatch logs, AWS Glue will create a log group named as follows for continuous logs:

```
<Log-Group-Name>-<Security-Configuration-Name>
```

The default and custom log groups will be as follows:

- The default continuous log group will be `/aws-glue/jobs/logs-v2-<Security-Configuration-Name>`
- The custom continuous log group will be `<custom-log-group-name>-<Security-Configuration-Name>`

You need to add the `logs:AssociateKmsKey` to your IAM role permissions, if you enable a security configuration with CloudWatch Logs. If that permission is not included, continuous logging will be disabled. Also, to configure the encryption for the CloudWatch Logs, follow the instructions at [Encrypt Log Data in CloudWatch Logs Using AWS Key Management Service](#) in the *Amazon CloudWatch Logs User Guide*.

For more information on creating security configurations, see [Working with security configurations on the AWS Glue console](#).

## Viewing continuous logging for AWS Glue jobs

You can view real-time logs using the AWS Glue console or the Amazon CloudWatch console.

### To view real-time logs using the AWS Glue console dashboard

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Jobs**.
3. Add or start an existing job. Choose **Action, Run job**.

When you start running a job, you navigate to a page that contains information about the running job:

- The **Logs** tab shows the older aggregated application logs.
  - The **Continuous logging** tab shows a real-time progress bar when the job is running with `glueContext` initialized.
  - The **Continuous logging** tab also contains the **Driver logs**, which capture real-time Apache Spark driver logs, and application logs from the script logged using the AWS Glue application logger when the job is running.
4. For older jobs, you can also view the real-time logs under the **Job History** view by choosing **Logs**. This action takes you to the CloudWatch console that shows all Spark driver, executor, and progress bar log streams for that job run.

### To view real-time logs using the CloudWatch console dashboard

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Log**.
3. Choose the `/aws-glue/jobs/logs-v2/` log group.

4. In the **Filter** box, paste the job run ID.

You can view the driver logs, executor logs, and progress bar (if using the **Standard filter**).

## Monitoring with AWS Glue Observability metrics

### Note

AWS Glue Observability metrics is available on AWS Glue 4.0 and later versions.

Use AWS Glue Observability metrics to generate insights into what is happening inside your AWS Glue for Apache Spark jobs to improve triaging and analysis of issues. Observability metrics are visualized through Amazon CloudWatch dashboards and can be used to help perform root cause analysis for errors and for diagnosing performance bottlenecks. You can reduce the time spent debugging issues at scale so you can focus on resolving issues faster and more effectively.

AWS Glue Observability provides Amazon CloudWatch metrics categorized in following four groups:

- **Reliability (i.e., Errors Classes)** – easily identify the most common failure reasons at given time range that you may want to address.
- **Performance (i.e., Skewness)** – identify a performance bottleneck and apply tuning techniques. For example, when you experience degraded performance due to job skewness, you may want to enable Spark Adaptive Query Execution and fine-tune the skew join threshold.
- **Throughput (i.e., per source/sink throughput)** – monitor trends of data reads and writes. You can also configure Amazon CloudWatch alarms for anomalies.
- **Resource Utilization (i.e., workers, memory and disk utilization)** – efficiently find the jobs with low capacity utilization. You may want to enable AWS Glue auto-scaling for those jobs.

## Getting started with AWS Glue Observability metrics

### Note

The new metrics are enabled by default in the AWS Glue Studio console.

## To configure observability metrics in AWS Glue Studio:

1. Log in to the AWS Glue console and choose **ETL jobs** from the console menu.
2. Choose a job by clicking on the job name in the **Your jobs** section.
3. Choose the **Job details** tab.
4. Scroll to the bottom and choose **Advanced properties**, then **Job observability metrics**.

The screenshot shows the AWS Glue Studio interface for job 'obs-test'. The 'Job details' tab is selected. Under the 'Advanced properties' section, the 'Job observability metrics' option is highlighted with a red box. The checkbox for 'Enable the creation of additional observability CloudWatch metrics when this job runs.' is checked. Other options like 'Job metrics', 'Continuous logging', 'Spark UI', and 'Serverless Spark UI' are also visible and checked.

## To enable AWS Glue Observability metrics using AWS CLI:

- Add to the `--default-arguments` map the following key-value in the input JSON file:

```
--enable-observability-metrics, true
```

## Using AWS Glue observability

Because the AWS Glue observability metrics is provided through Amazon CloudWatch, you can use the Amazon CloudWatch console, AWS CLI, SDK or API to query the observability metrics datapoints. See [Using Glue Observability for monitoring resource utilization to reduce cost](#) for an example use case when to use AWS Glue observability metrics.

## Using AWS Glue observability in the Amazon CloudWatch console

### To query and visualize metrics in the Amazon CloudWatch console:

1. Open the Amazon CloudWatch console and choose **All metrics**.
2. Under custom namespaces, choose **AWS Glue**.
3. Choose **Job Observability Metrics, Observability Metrics Per Source, or Observability Metrics Per Sink**.
4. Search for the specific metric name, job name, job run ID, and select them.
5. Under the **Graphed metrics** tab, configure your preferred statistic, period, and other options.

### To query an Observability metric using AWS CLI:

1. Create a metric definition JSON file and replace your `-Glue-job-name` and your `-Glue-job-run-id` with yours.

```
$ cat multiplequeries.json
[
```

```

{
  "Id": "avgWorkerUtil_0",
  "MetricStat": {
    "Metric": {
      "Namespace": "Glue",
      "MetricName": "glue.driver.workerUtilization",
      "Dimensions": [
        {
          "Name": "JobName",
          "Value": "<your-Glue-job-name-A>"
        },
        {
          "Name": "JobRunId",
          "Value": "<your-Glue-job-run-id-A>"
        },
        {
          "Name": "Type",
          "Value": "gauge"
        },
        {
          "Name": "ObservabilityGroup",
          "Value": "resource_utilization"
        }
      ]
    },
    "Period": 1800,
    "Stat": "Minimum",
    "Unit": "None"
  }
},
{
  "Id": "avgWorkerUtil_1",
  "MetricStat": {
    "Metric": {
      "Namespace": "Glue",
      "MetricName": "glue.driver.workerUtilization",
      "Dimensions": [
        {
          "Name": "JobName",
          "Value": "<your-Glue-job-name-B>"
        },
        {
          "Name": "JobRunId",
          "Value": "<your-Glue-job-run-id-B>"
        }
      ]
    }
  }
}

```

```

        },
        {
            "Name": "Type",
            "Value": "gauge"
        },
        {
            "Name": "ObservabilityGroup",
            "Value": "resource_utilization"
        }
    ]
},
"Period": 1800,
"Stat": "Minimum",
"Unit": "None"
}
}
]

```

## 2. Run the get-metric-data command:

```

$ aws cloudwatch get-metric-data --metric-data-queries file://multiplequeries.json \
\
  --start-time '2023-10-28T18: 20' \
  --end-time '2023-10-28T19: 10' \
  --region us-east-1
{
  "MetricDataResults": [
    {
      "Id": "avgWorkerUtil_0",
      "Label": "<your-label-for-A>",
      "Timestamps": [
        "2023-10-28T18:20:00+00:00"
      ],
      "Values": [
        0.067187500000000001
      ],
      "StatusCode": "Complete"
    },
    {
      "Id": "avgWorkerUtil_1",
      "Label": "<your-label-for-B>",
      "Timestamps": [

```

```

        "2023-10-28T18:50:00+00:00"
    ],
    "Values": [
        0.5959183673469387
    ],
    "StatusCode": "Complete"
}
],
"Messages": []
}

```

## Observability metrics

AWS Glue Observability profiles and sends the following metrics to Amazon CloudWatch every 30 seconds, and some of these metrics can be visible in the AWS Glue Studio Job Runs Monitoring Page.

Metric	Description	Category
glue.driver.skewness.stage	<p>Metric Category: job_performance</p> <p>The spark stages execution Skewness: this metric captures execution skewness, which might be caused by input data skewness or by a transformation (e.g., skewed join). The values of this metric falls into the range of [0, infinity[, where 0 means the ratio of the maximum to median tasks' execution time, among all tasks in the stage is less than a certain stage skewness factor. The default stage skewness factor is `5`</p>	job_performance

Metric	Description	Category
	<p>and it be overwritten via spark conf: spark.metrics.conf.driver.source.glue.jobPerformance.skewnessFactor</p> <p>A stage skewness value of 1 means the ratio is twice the stage skewness factor.</p> <p>The value of stage skewnewss is updated every 30 seconds to reflect the current skewness. The value at the end of the stage reflects the final stage skewnwss.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (job_performance)</p> <p>Valid Statistics: Average, Maximum, Minimum, Percentile</p> <p>Unit: Count</p>	

Metric	Description	Category
glue.driver.skewness.job	<p>Metric Category: job_performance</p> <p>Job skewness is the weighted average of the job stages skewness. Weighted average gives more weight to stages that takes longer to execute. This is to avoid the corner case when a very skewed stage is actually running for very short time relative to other stages (and thus its skewness is not significant for the overall job performance and does not worth the effort to try to address its skewness)</p> <p>.</p> <p>This metric is updated upon completion of each stage, and thus the last value reflects the actual overall job skewness.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (job_performance)</p> <p>Valid Statistics: Average, Maximum, Minimum, Percentile</p> <p>Unit: Count</p>	job_performance

Metric	Description	Category
glue.succeed.ALL	<p>Metric Category: error</p> <p>Total number of successful job runs, to complete the picture of failures categories</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error)</p> <p>Valid Statistics: SUM</p> <p>Unit: Count</p>	error
glue.error.ALL	<p>Metric Category: error</p> <p>Total number of job run errors, to complete the picture of failures categories</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error)</p> <p>Valid Statistics: SUM</p> <p>Unit: Count</p>	error

Metric	Description	Category
glue.error.[error category]	<p>Metric Category: error</p> <p>This is actually a set of metrics, that are updated only when a job run fails. The error categorization helps with triaging and debugging. When a job run fails, the error causing the failure is categorized and the corresponding error category metric is set to 1. This helps to perform over time failures analysis, as well as over all jobs error analysis to identify most common failure categories to start addressing them. AWS Glue has 28 error categories, including OUT_OF_MEMORY (driver and executor), PERMISSION, SYNTAX and THROTTLING error categories. Error categories also include COMPILATION, LAUNCH and TIMEOUT error categories.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (count), and ObservabilityGroup (error)</p> <p>Valid Statistics: SUM</p>	error

Metric	Description	Category
	Unit: Count	
glue.driver.workerUtilization	<p>Metric Category: resource_utilization</p> <p>The percentage of the allocated workers which are actually used. If not good, auto scaling can help.</p> <p>Valid dimensions: JobName (the name of the AWS Glue Job), JobRunId (the JobRun ID. or ALL), Type (gauge), and ObservabilityGroup (resource_utilization)</p> <p>Valid Statistics: Average, Maximum, Minimum, Percentile</p> <p>Unit: Percentage</p>	resource_utilization

Metric	Description	Category
glue.driver.memory.heap.[available   used]	<p data-bbox="591 226 1029 310">Metric Category: resource_utilization</p> <p data-bbox="591 352 1029 772">The driver's available / used heap memory during the job run. ## Error categories

Error categories	Description
COMPILATION_ERROR	Errors arise during the compilation of Scala code.
CONNECTION_ERROR	Errors arise during connecting to a service/remote host/database service, etc.
DISK_NO_SPACE_ERROR	Errors arise when there is no space left in disk on driver/executor.

Error categories	Description
OUT_OF_MEMORY_ERROR	Errors arise when there is no space left in memory on driver/executor.
IMPORT_ERROR	Errors arise when import dependencies.
INVALID_ARGUMENT_ERROR	Errors arise when the input arguments are invalid/illegal.
PERMISSION_ERROR	Errors arise when lacking the permission to service, data, etc.
RESOURCE_NOT_FOUND_ERROR	Errors arise when data, location, etc does not exist.
QUERY_ERROR	Errors arise from Spark SQL query execution.
SYNTAX_ERROR	Errors arise when there is syntax error in the script.
THROTTLING_ERROR	Errors arise when hitting service concurrency limitation or exceeding service quota limitaion .
DATA_LAKE_FRAMEWORK_ERROR	Errors arise from AWS Glue native-supported data lake framework like Hudi, Iceberg, etc.
UNSUPPORTED_OPERATION_ERROR	Errors arise when making unsupported operation.
RESOURCES_ALREADY_EXISTS_ERROR	Errors arise when a resource to be created or added already exists.
GLUE_INTERNAL_SERVICE_ERROR	Errors arise when there is a AWS Glue internal service issue.
GLUE_OPERATION_TIMEOUT_ERROR	Errors arise when a AWS Glue operation is timeout.

Error categories	Description
GLUE_VALIDATION_ERROR	Errors arise when a required value could not be validated for AWS Glue job.
GLUE_JOB_BOOKMARK_VERSION_MISMATCH_ERROR	Errors arise when same job exon the same source bucket and write to the same/different destination concurrently (concurrency >1)
LAUNCH_ERROR	Errors arise during the AWS Glue job launch phase.
DYNAMODB_ERROR	Generic errors arise from Amazon DynamoDB service.
GLUE_ERROR	Generic Errors arise from AWS Glue service.
LAKEFORMATION_ERROR	Generic Errors arise from AWS Lake Formation service.
REDSHIFT_ERROR	Generic Errors arise from Amazon Redshift service.
S3_ERROR	Generic Errors arise from Amazon S3 service.
SYSTEM_EXIT_ERROR	Generic system exit error.
TIMEOUT_ERROR	Generic errors arise when job failed by operation time out.
UNCLASSIFIED_SPARK_ERROR	Generic errors arise from Spark.
UNCLASSIFIED_ERROR	Default error category.

## Limitations

### Note

`glueContext` must be initialized to publish the metrics.

In the Source Dimension, the value is either Amazon S3 path or table name, depending on the source type. In addition, if the source is JDBC and the query option is used, the query string is set in the source dimension. If the value is longer than 500 characters, it is trimmed within 500 characters. The following are limitations in the value:

- Non-ASCII characters will be removed.
- If the source name doesn't contain any ASCII character, it is converted to <non-ASCII input>.

### Limitations and considerations for throughput metrics

- DataFrame and DataFrame-based DynamicFrame (e.g. JDBC, reading from parquet on Amazon S3) are supported, however, RDD-based DynamicFrame (e.g. reading csv, json on Amazon S3, etc.) is not supported. Technically, all reads and writes visible on Spark UI are supported.
- The `recordsRead` metric will be emitted if the data source is catalog table and the format is JSON, CSV, text, or Iceberg.
- `glue.driver.throughput.recordsWritten`, `glue.driver.throughput.bytesWritten`, and `glue.driver.throughput.filesWritten` metrics are not available in JDBC and Iceberg tables.
- Metrics may be delayed. If the job finishes in about one minute, there may be no throughput metrics in Amazon CloudWatch Metrics.

### Job monitoring and debugging

You can collect metrics about AWS Glue jobs and visualize them on the AWS Glue and Amazon CloudWatch consoles to identify and fix issues. Profiling your AWS Glue jobs requires the following steps:

1. Enable metrics:
  - a. Enable the **Job metrics** option in the job definition. You can enable profiling in the AWS Glue console or as a parameter to the job. For more information see [Defining job properties for Spark jobs](#) or [AWS Glue job parameters](#).
  - b. Enable the **AWS Glue Observability metrics** option in the job definition. You can enable Observability in the AWS Glue console or as a parameter to the job. For more information see [Monitoring with AWS Glue Observability metrics](#).

2. Confirm that the job script initializes a GlueContext. For example, the following script snippet initializes a GlueContext and shows where profiled code is placed in the script. This general format is used in the debugging scenarios that follow.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

...
...
code-to-profile
...
...

job.commit()
```

3. Run the job.
4. Visualize the metrics:
  - a. Visualize job metrics on the AWS Glue console and identify abnormal metrics for the driver or an executor.
  - b. Check observability metrics in the Job run monitoring page, job run details page, or on Amazon CloudWatch. For more information, see [Monitoring with AWS Glue Observability metrics](#).
5. Narrow down the root cause using the identified metric.
6. Optionally, confirm the root cause using the log stream of the identified driver or job executor.

## Use cases for AWS Glue observability metrics

- [Debugging OOM exceptions and job abnormalities](#)
- [Debugging demanding stages and straggler tasks](#)
- [Monitoring the progress of multiple jobs](#)
- [Monitoring for DPU capacity planning](#)
- [Using AWS Glue Observability for monitoring resource utilization to reduce cost](#)

## Debugging OOM exceptions and job abnormalities

You can debug out-of-memory (OOM) exceptions and job abnormalities in AWS Glue. The following sections describe scenarios for debugging out-of-memory exceptions of the Apache Spark driver or a Spark executor.

- [Debugging a driver OOM exception](#)
- [Debugging an executor OOM exception](#)

### Debugging a driver OOM exception

In this scenario, a Spark job is reading a large number of small files from Amazon Simple Storage Service (Amazon S3). It converts the files to Apache Parquet format and then writes them out to Amazon S3. The Spark driver is running out of memory. The input Amazon S3 data has more than 1 million files in different Amazon S3 partitions.

The profiled code is as follows:

```
data = spark.read.format("json").option("inferSchema", False).load("s3://input_path")
data.write.format("parquet").save(output_path)
```

### Visualize the profiled metrics on the AWS Glue console

The following graph shows the memory usage as a percentage for the driver and executors. This usage is plotted as one data point that is averaged over the values reported in the last minute. You can see in the memory profile of the job that the [driver memory](#) crosses the safe threshold of 50 percent usage quickly. On the other hand, the [average memory usage](#) across all executors is still less than 4 percent. This clearly shows abnormality with driver execution in this Spark job.

The job run soon fails, and the following error appears in the **History** tab on the AWS Glue console: Command Failed with Exit Code 1. This error string means that the job failed due to a systemic error—which in this case is the driver running out of memory.

e2e-metrics    python    s3://aws-glue-scripts-6569...    7 June 2018 7:37 PM UTC-7    Disable

[History](#)   [Details](#)   [Script](#)   [Metrics](#)

Run ID	Retry attempt	Run status	Error	Logs	Error logs	Execution time	Timeout	Delay	Triggered by	Start time
jr_651bfc34...	-	Failed	! ...	Logs	Error logs	2 mins	2880 mins			7 June 2018
jr_5731b225...	-	Failed	Command failed with exit code 1							7 June 2018

On the console, choose the **Error logs** link on the **History** tab to confirm the finding about driver OOM from the CloudWatch Logs. Search for "**Error**" in the job's error logs to confirm that it was indeed an OOM exception that failed the job:

```
# java.lang.OutOfMemoryError: Java heap space
# -XX:OnOutOfMemoryError="kill -9 %p"
# Executing /bin/sh -c "kill -9 12039"...
```

On the **History** tab for the job, choose **Logs**. You can find the following trace of driver execution in the CloudWatch Logs at the beginning of the job. The Spark driver tries to list all the files in all the directories, constructs an `InMemoryFileIndex`, and launches one task per file. This in turn results in the Spark driver having to maintain a large amount of state in memory to track all the tasks. It caches the complete list of a large number of files for the in-memory index, resulting in a driver OOM.

### Fix the processing of multiple files using grouping

You can fix the processing of the multiple files by using the *grouping* feature in AWS Glue. Grouping is automatically enabled when you use dynamic frames and when the input dataset has a large number of files (more than 50,000). Grouping allows you to coalesce multiple files together into a group, and it allows a task to process the entire group instead of a single file. As a result, the Spark driver stores significantly less state in memory to track fewer tasks. For more information about manually enabling grouping for your dataset, see [Reading input files in larger groups](#).

To check the memory profile of the AWS Glue job, profile the following code with grouping enabled:

```
df = glueContext.create_dynamic_frame_from_options("s3", {'paths': ["s3://input_path"],
  "recurse":True, 'groupFiles': 'inPartition'}, format="json")
datasink = glueContext.write_dynamic_frame.from_options(frame = df, connection_type
  = "s3", connection_options = {"path": output_path}, format = "parquet",
  transformation_ctx = "datasink")
```

You can monitor the memory profile and the ETL data movement in the AWS Glue job profile.

The driver runs below the threshold of 50 percent memory usage over the entire duration of the AWS Glue job. The executors stream the data from Amazon S3, process it, and write it out to Amazon S3. As a result, they consume less than 5 percent memory at any point in time.

The data movement profile below shows the total number of Amazon S3 bytes that are [read](#) and [written](#) in the last minute by all executors as the job progresses. Both follow a similar pattern as the data is streamed across all the executors. The job finishes processing all one million files in less than three hours.

### Debugging an executor OOM exception

In this scenario, you can learn how to debug OOM exceptions that could occur in Apache Spark executors. The following code uses the Spark MySQL reader to read a large table of about 34

million rows into a Spark dataframe. It then writes it out to Amazon S3 in Parquet format. You can provide the connection properties and use the default Spark configurations to read the table.

```
val connectionProperties = new Properties()
connectionProperties.put("user", user)
connectionProperties.put("password", password)
connectionProperties.put("Driver", "com.mysql.jdbc.Driver")
val sparkSession = glueContext.sparkSession
val dfSpark = sparkSession.read.jdbc(url, tableName, connectionProperties)
dfSpark.write.format("parquet").save(output_path)
```

## Visualize the profiled metrics on the AWS Glue console

If the slope of the memory usage graph is positive and crosses 50 percent, then if the job fails before the next metric is emitted, then memory exhaustion is a good candidate for the cause. The following graph shows that within a minute of execution, the [average memory usage](#) across all executors spikes up quickly above 50 percent. The usage reaches up to 92 percent and the container running the executor is stopped by Apache Hadoop YARN.

As the following graph shows, there is always a [single executor](#) running until the job fails. This is because a new executor is launched to replace the stopped executor. The JDBC data source reads are not parallelized by default because it would require partitioning the table on a column and opening multiple connections. As a result, only one executor reads in the complete table sequentially.

As the following graph shows, Spark tries to launch a new task four times before failing the job. You can see the [memory profile](#) of three executors. Each executor quickly uses up all of its memory. The fourth executor runs out of memory, and the job fails. As a result, its metric is not reported immediately.

You can confirm from the error string on the AWS Glue console that the job failed due to OOM exceptions, as shown in the following image.

Run ID	Retry attempt	Run status	Error	Logs	Error logs	Execution time	Timeout	Delay	Triggered by	Start time	End time
j_f3d637910a2160209d4c11e71001...	-	Failed				4 mins	2880 mins			13 June 2018 8:02 AM UT...	13 June 2018 8:08 AM UT...

**Job output logs:** To further confirm your finding of an executor OOM exception, look at the CloudWatch Logs. When you search for **Error**, you find the four executors being stopped in roughly the same time windows as shown on the metrics dashboard. All are terminated by YARN as they exceed their memory limits.

## Executor 1

```
18/06/13 16:54:29 WARN YarnAllocator: Container killed by YARN for exceeding

caused by one of the running tasks) Reason: Container killed by YARN for
exceeding memory limits. 5.5 GB of 5.5 GB physical memory used. Consider boosting
spark.yarn.executor.memoryOverhead.
```

## Fix the fetch size setting using AWS Glue dynamic frames

The executor ran out of memory while reading the JDBC table because the default configuration for the Spark JDBC fetch size is zero. This means that the JDBC driver on the Spark executor tries to fetch the 34 million rows from the database together and cache them, even though Spark streams through the rows one at a time. With Spark, you can avoid this scenario by setting the fetch size parameter to a non-zero default value.

You can also fix this issue by using AWS Glue dynamic frames instead. By default, dynamic frames use a fetch size of 1,000 rows that is a typically sufficient value. As a result, the executor does not take more than 7 percent of its total memory. The AWS Glue job finishes in less than two minutes with only a single executor. While using AWS Glue dynamic frames is the recommended approach, it is also possible to set the fetch size using the Apache Spark `fetchsize` property. See the [Spark SQL, DataFrames and Datasets Guide](#).

```
val (url, database, tableName) = {
  ("jdbc_url", "db_name", "table_name")
}
val source = glueContext.getSource(format, sourceJson)
val df = source.getDynamicFrame
glueContext.write_dynamic_frame.from_options(frame = df, connection_type = "s3",
  connection_options = {"path": output_path}, format = "parquet", transformation_ctx =
  "datasink")
```

**Normal profiled metrics:** The [executor memory](#) with AWS Glue dynamic frames never exceeds the safe threshold, as shown in the following image. It streams in the rows from the database and caches only 1,000 rows in the JDBC driver at any point in time. An out of memory exception does not occur.

## Debugging demanding stages and straggler tasks

You can use AWS Glue job profiling to identify demanding stages and straggler tasks in your extract, transform, and load (ETL) jobs. A straggler task takes much longer than the rest of the tasks in a stage of an AWS Glue job. As a result, the stage takes longer to complete, which also delays the total execution time of the job.

## Coalescing small input files into larger output files

A straggler task can occur when there is a non-uniform distribution of work across the different tasks, or a data skew results in one task processing more data.

You can profile the following code—a common pattern in Apache Spark—to coalesce a large number of small files into larger output files. For this example, the input dataset is 32 GB of JSON Gzip compressed files. The output dataset has roughly 190 GB of uncompressed JSON files.

The profiled code is as follows:

```
datasource0 = spark.read.format("json").load("s3://input_path")
df = datasource0.coalesce(1)
df.write.format("json").save(output_path)
```

## Visualize the profiled metrics on the AWS Glue console

You can profile your job to examine four different sets of metrics:

- ETL data movement
- Data shuffle across executors
- Job execution
- Memory profile

**ETL data movement:** In the **ETL Data Movement** profile, the bytes are [read](#) fairly quickly by all the executors in the first stage that completes within the first six minutes. However, the total job execution time is around one hour, mostly consisting of the data [writes](#).

**Data shuffle across executors:** The number of bytes [read](#) and [written](#) during shuffling also shows a spike before Stage 2 ends, as indicated by the **Job Execution** and **Data Shuffle** metrics. After the data shuffles from all executors, the reads and writes proceed from executor number 3 only.

**Job execution:** As shown in the graph below, all other executors are idle and are eventually relinquished by the time 10:09. At that point, the total number of executors decreases to only one. This clearly shows that executor number 3 consists of the straggler task that is taking the longest execution time and is contributing to most of the job execution time.

**Memory profile:** After the first two stages, only [executor number 3](#) is actively consuming memory to process the data. The remaining executors are simply idle or have been relinquished shortly after the completion of the first two stages.

## Fix straggling executors using grouping

You can avoid straggling executors by using the *grouping* feature in AWS Glue. Use grouping to distribute the data uniformly across all the executors and coalesce files into larger files using all the available executors on the cluster. For more information, see [Reading input files in larger groups](#).

To check the ETL data movements in the AWS Glue job, profile the following code with grouping enabled:

```
df = glueContext.create_dynamic_frame_from_options("s3", {'paths': ["s3://input_path"],
"recurse":True, 'groupFiles': 'inPartition'}, format="json")
datasink = glueContext.write_dynamic_frame.from_options(frame = df, connection_type =
"s3", connection_options = {"path": output_path}, format = "json", transformation_ctx
= "datasink4")
```

**ETL data movement:** The data writes are now streamed in parallel with the data reads throughout the job execution time. As a result, the job finishes within eight minutes—much faster than previously.

**Data shuffle across executors:** As the input files are coalesced during the reads using the grouping feature, there is no costly data shuffle after the data reads.

**Job execution:** The job execution metrics show that the total number of active executors running and processing data remains fairly constant. There is no single straggler in the job. All executors are active and are not relinquished until the completion of the job. Because there is no intermediate shuffle of data across the executors, there is only a single stage in the job.

**Memory profile:** The metrics show the [active memory consumption](#) across all executors—reconfirming that there is activity across all executors. As data is streamed in and written out in parallel, the total memory footprint of all executors is roughly uniform and well below the safe threshold for all executors.

## Monitoring the progress of multiple jobs

You can profile multiple AWS Glue jobs together and monitor the flow of data between them. This is a common workflow pattern, and requires monitoring for individual job progress, data processing backlog, data reprocessing, and job bookmarks.

### Topics

- [Profiled code](#)
- [Visualize the profiled metrics on the AWS Glue console](#)
- [Fix the processing of files](#)

### Profiled code

In this workflow, you have two jobs: an Input job and an Output job. The Input job is scheduled to run every 30 minutes using a periodic trigger. The Output job is scheduled to run after each successful run of the Input job. These scheduled jobs are controlled using job triggers.

Triggers A trigger starts a job when it fires.

Trigger name	Trigger type	Trigger status	Trigger parameters	Jobs to trigger
<input type="checkbox"/> e2e-bookmark-input	Schedule	ACTIVATED	Every 15 minutes	e2ebookmark-input
<input type="checkbox"/> e2e-bookmark-output	Job events	ACTIVATED	Job events: e2ebookmark-input	e2e-bookmark

**Input job:** This job reads in data from an Amazon Simple Storage Service (Amazon S3) location, transforms it using `ApplyMapping`, and writes it to a staging Amazon S3 location. The following code is profiled code for the Input job:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": ["s3://input_path"],
  "useS3ListImplementation":True,"recurse":True}, format="json")
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
  connection_type = "s3", connection_options = {"path": staging_path, "compression":
  "gzip"}, format = "json")
```

**Output job:** This job reads the output of the Input job from the staging location in Amazon S3, transforms it again, and writes it to a destination:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": [staging_path],
  "useS3ListImplementation":True,"recurse":True}, format="json")
```

```

appliedmapping1 = ApplyMapping.apply(frame = datasource0, mappings = [map_spec])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = appliedmapping1,
  connection_type = "s3", connection_options = {"path": output_path}, format = "json")

```

## Visualize the profiled metrics on the AWS Glue console

The following dashboard superimposes the Amazon S3 bytes written metric from the Input job onto the Amazon S3 bytes read metric on the same timeline for the Output job. The timeline shows different job runs of the Input and Output jobs. The Input job (shown in red) starts every 30 minutes. The Output Job (shown in brown) starts at the completion of the Input Job, with a Max Concurrency of 1.

In this example, [job bookmarks](#) are not enabled. No transformation contexts are used to enable job bookmarks in the script code.

**Job History:** The Input and Output jobs have multiple runs, as shown on the **History** tab, starting from 12:00 PM.

The Input job on the AWS Glue console looks like this:

Run ID	Retry attempt	Run status	Error	Logs	Error logs	Execution time	Timeout	Delay	Triggered by	Start time	End time
j_r_0ce47b1a581051f6c9ae96e...	-	Succeeded		<a href="#">Logs</a>		8 mins	2880 mins		e2e-bookmark-input	11 June 2018 2:30 PM UT...	11 June 2018 2:40 PM UT...

**First job runs:** As shown in the Data Bytes Read and Written graph below, the first job runs of the Input and Output jobs between 12:00 and 12:30 show roughly the same area under the curves. Those areas represent the Amazon S3 bytes written by the Input job and the Amazon S3 bytes read by the Output job. This data is also confirmed by the ratio of Amazon S3 bytes written (summed over 30 minutes – the job trigger frequency for the Input job). The data point for the ratio for the Input job run that started at 12:00PM is also 1.

The following graph shows the data flow ratio across all the job runs:

**Second job runs:** In the second job run, there is a clear difference in the number of bytes read by the Output job compared to the number of bytes written by the Input job. (Compare the area under the curve across the two job runs for the Output job, or compare the areas in the second run of the Input and Output jobs.) The ratio of the bytes read and written shows that the Output Job read about 2.5x the data written by the Input job in the second span of 30 minutes from 12:30 to 13:00. This is because the Output Job reprocessed the output of the first job run of the Input job because job bookmarks were not enabled. A ratio above 1 shows that there is an additional backlog of data that was processed by the Output job.

**Third job runs:** The Input job is fairly consistent in terms of the number of bytes written (see the area under the red curves). However, the third job run of the Input job ran longer than expected (see the long tail of the red curve). As a result, the third job run of the Output job started late. The third job run processed only a fraction of the data accumulated in the staging location in the remaining 30 minutes between 13:00 and 13:30. The ratio of the bytes flow shows that it only processed 0.83 of data written by the third job run of the Input job (see the ratio at 13:00).

**Overlap of Input and Output jobs:** The fourth job run of the Input job started at 13:30 as per the schedule, before the third job run of the Output job finished. There is a partial overlap between these two job runs. However, the third job run of the Output job captures only the files that it listed in the staging location of Amazon S3 when it began around 13:17. This consists of all data output from the first job runs of the Input job. The actual ratio at 13:30 is around 2.75. The third job run of the Output job processed about 2.75x of data written by the fourth job run of the Input job from 13:30 to 14:00.

As these images show, the Output job is reprocessing data from the staging location from all prior job runs of the Input job. As a result, the fourth job run for the Output job is the longest and overlaps with the entire fifth job run of the Input job.

### Fix the processing of files

You should ensure that the Output job processes only the files that haven't been processed by previous job runs of the Output job. To do this, enable job bookmarks and set the transformation context in the Output job, as follows:

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": [staging_path],
  "useS3ListImplementation":True,"recurse":True}, format="json", transformation_ctx =
  "bookmark_ctx")
```

With job bookmarks enabled, the Output job doesn't reprocess the data in the staging location from all the previous job runs of the Input job. In the following image showing the data read and written, the area under the brown curve is fairly consistent and similar with the red curves.

The ratios of byte flow also remain roughly close to 1 because there is no additional data processed.

A job run for the Output job starts and captures the files in the staging location before the next Input job run starts putting more data into the staging location. As long as it continues to do this, it processes only the files captured from the previous Input job run, and the ratio stays close to 1.

Suppose that the Input job takes longer than expected, and as a result, the Output job captures files in the staging location from two Input job runs. The ratio is then higher than 1 for that Output job run. However, the following job runs of the Output job don't process any files that are already processed by the previous job runs of the Output job.

### Monitoring for DPU capacity planning

You can use job metrics in AWS Glue to estimate the number of data processing units (DPUs) that can be used to scale out an AWS Glue job.

#### **Note**

This page is only applicable to AWS Glue versions 0.9 and 1.0. Later versions of AWS Glue contain cost-saving features that introduce additional considerations when capacity planning.

### Topics

- [Profiled code](#)
- [Visualize the profiled metrics on the AWS Glue console](#)
- [Determine the optimal DPU capacity](#)

## Profiled code

The following script reads an Amazon Simple Storage Service (Amazon S3) partition containing 428 gzipped JSON files. The script applies a mapping to change the field names, and converts and writes them to Amazon S3 in Apache Parquet format. You provision 10 DPUs as per the default and run this job.

```
datasource0 = glueContext.create_dynamic_frame.from_options(connection_type="s3",
  connection_options = {"paths": [input_path],
  "useS3ListImplementation":True,"recurse":True}, format="json")
applymapping1 = ApplyMapping.apply(frame = datasource0, mappings = [(map_spec)])
datasink2 = glueContext.write_dynamic_frame.from_options(frame = applymapping1,
  connection_type = "s3", connection_options = {"path": output_path}, format =
  "parquet")
```

## Visualize the profiled metrics on the AWS Glue console

**Job run 1:** In this job run we show how to find if there are under-provisioned DPUs in the cluster. The job execution functionality in AWS Glue shows the total [number of actively running executors](#), the [number of completed stages](#), and the [number of maximum needed executors](#).

The number of maximum needed executors is computed by adding the total number of running tasks and pending tasks, and dividing by the tasks per executor. This result is a measure of the total number of executors required to satisfy the current load.

In contrast, the number of actively running executors measures how many executors are running active Apache Spark tasks. As the job progresses, the maximum needed executors can change and typically goes down towards the end of the job as the pending task queue diminishes.

The horizontal red line in the following graph shows the number of maximum allocated executors, which depends on the number of DPUs that you allocate for the job. In this case, you allocate 10 DPUs for the job run. One DPU is reserved for management. Nine DPUs run two executors each and one executor is reserved for the Spark driver. The Spark driver runs inside the primary application. So, the number of maximum allocated executors is  $2 \times 9 - 1 = 17$  executors.

Jobs &gt; e2e-dpus

Detailed job metrics

As the graph shows, the number of maximum needed executors starts at 107 at the beginning of the job, whereas the number of active executors remains 17. This is the same as the number of maximum allocated executors with 10 DPUs. The ratio between the maximum needed executors and maximum allocated executors (adding 1 to both for the Spark driver) gives you the under-provisioning factor:  $108/18 = 6x$ . You can provision 6 (under provisioning ratio) \* 9 (current DPU capacity - 1) + 1 DPUs = 55 DPUs to scale out the job to run it with maximum parallelism and finish faster.

The AWS Glue console displays the detailed job metrics as a static line representing the original number of maximum allocated executors. The console computes the maximum allocated executors from the job definition for the metrics. By contrast, for detailed job run metrics, the console computes the maximum allocated executors from the job run configuration, specifically the DPUs allocated for the job run. To view metrics for an individual job run, select the job run and choose **View run metrics**.

Jobs &gt; e2e-dpus

Detailed job metrics

Looking at the Amazon S3 bytes [read](#) and [written](#), notice that the job spends all six minutes streaming in data from Amazon S3 and writing it out in parallel. All the cores on the allocated DPUs are reading and writing to Amazon S3. The maximum number of needed executors being 107 also matches the number of files in the input Amazon S3 path—428. Each executor can launch four Spark tasks to process four input files (JSON gzipped).

### Determine the optimal DPU capacity

Based on the results of the previous job run, you can increase the total number of allocated DPUs to 55, and see how the job performs. The job finishes in less than three minutes—half the time it required previously. The job scale-out is not linear in this case because it is a short running job. Jobs with long-lived tasks or a large number of tasks (a large number of max needed executors) benefit from a close-to-linear DPU scale-out performance speedup.

Jobs &gt; e2e-dpua

Detailed job metrics

As the above image shows, the total number of active executors reaches the maximum allocated —107 executors. Similarly, the maximum needed executors is never above the maximum allocated executors. The maximum needed executors number is computed from the actively running and pending task counts, so it might be smaller than the number of active executors. This is because there can be executors that are partially or completely idle for a short period of time and are not yet decommissioned.

Jobs &gt; e2e-dpus

Detailed job metrics

This job run uses 6x more executors to read and write from Amazon S3 in parallel. As a result, this job run uses more Amazon S3 bandwidth for both reads and writes, and finishes faster.

## Identify overprovisioned DPUs

Next, you can determine whether scaling out the job with 100 DPUs ( $99 * 2 = 198$  executors) helps to scale out any further. As the following graph shows, the job still takes three minutes to finish. Similarly, the job does not scale out beyond 107 executors (55 DPUs configuration), and the remaining 91 executors are overprovisioned and not used at all. This shows that increasing the number of DPUs might not always improve performance, as evident from the maximum needed executors.

Jobs > e2e-dpus

Detailed job metrics

### Compare time differences

The three job runs shown in the following table summarize the job execution times for 10 DPUs, 55 DPUs, and 100 DPUs. You can find the DPU capacity to improve the job execution time using the estimates you established by monitoring the first job run.

Job ID	Number of DPUs	Execution time
jr_c894524c8ef5048a4d9...	10	6 min.
jr_1a466cf2575e7ffe6856...	55	3 min.
jr_34fa1ed4c6aa9ff0a814...	100	3 min.

## Streaming ETL jobs in AWS Glue

You can create streaming extract, transform, and load (ETL) jobs that run continuously, consume data from streaming sources like Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK). The jobs cleanse and transform the data, and then load the results into Amazon S3 data lakes or JDBC data stores.

Additionally, you can produce data for Amazon Kinesis Data Streams streams. This feature is only available when writing AWS Glue scripts. For more information, see [the section called “Kinesis connections”](#).

By default, AWS Glue processes and writes out data in 100-second windows. This allows data to be processed efficiently and permits aggregations to be performed on data arriving later than expected. You can modify this window size to increase timeliness or aggregation accuracy. AWS Glue streaming jobs use checkpoints rather than job bookmarks to track the data that has been read.

**Note**

AWS Glue bills hourly for streaming ETL jobs while they are running.

This video discusses streaming ETL cost challenges, and cost-saving features in AWS Glue.

Creating a streaming ETL job involves the following steps:

1. For an Apache Kafka streaming source, create an AWS Glue connection to the Kafka source or the Amazon MSK cluster.
2. Manually create a Data Catalog table for the streaming source.
3. Create an ETL job for the streaming data source. Define streaming-specific job properties, and supply your own script or optionally modify the generated script.

For more information, see [Streaming ETL in AWS Glue](#).

When creating a streaming ETL job for Amazon Kinesis Data Streams, you don't have to create an AWS Glue connection. However, if there is a connection attached to the AWS Glue streaming ETL job that has Kinesis Data Streams as a source, then a virtual private cloud (VPC) endpoint to Kinesis is required. For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*. When specifying a Amazon Kinesis Data Streams stream in another account, you must setup the roles and policies to allow cross-account access. For more information, see [Example: Read From a Kinesis Stream in a Different Account](#).

AWS Glue streaming ETL jobs can auto-detect compressed data, transparently decompress the streaming data, perform the usual transformations on the input source, and load to the output store.

AWS Glue supports auto-decompression for the following compression types given the input format:

Compression type	Avro file	Avro datum	JSON	CSV	Grok
BZIP2	Yes	Yes	Yes	Yes	Yes
GZIP	No	Yes	Yes	Yes	Yes
SNAPPY	Yes (raw Snappy)	Yes (framed Snappy)	Yes (framed Snappy)	Yes (framed Snappy)	Yes (framed Snappy)
XZ	Yes	Yes	Yes	Yes	Yes
ZSTD	Yes	No	No	No	No
DEFLATE	Yes	Yes	Yes	Yes	Yes

## Topics

- [Creating an AWS Glue connection for an Apache Kafka data stream](#)
- [Creating a Data Catalog table for a streaming source](#)

## Creating an AWS Glue connection for an Apache Kafka data stream

To read from an Apache Kafka stream, you must create an AWS Glue connection.

### To create an AWS Glue connection for a Kafka source (Console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **Data catalog**, choose **Connections**.
3. Choose **Add connection**, and on the **Set up your connection's properties** page, enter a connection name.

**Note**

For more information about specifying connection properties, see [AWS Glue connection properties](#).

4. For **Connection type**, choose **Kafka**.
5. For **Kafka bootstrap servers URLs**, enter the host and port number for the bootstrap brokers for your Amazon MSK cluster or Apache Kafka cluster. Use only Transport Layer Security (TLS) endpoints for establishing the initial connection to the Kafka cluster. Plaintext endpoints are not supported.

The following is an example list of hostname and port number pairs for an Amazon MSK cluster.

```
myserver1.kafka.us-east-1.amazonaws.com:9094,myserver2.kafka.us-  
east-1.amazonaws.com:9094,  
myserver3.kafka.us-east-1.amazonaws.com:9094
```

For more information about getting the bootstrap broker information, see [Getting the Bootstrap Brokers for an Amazon MSK Cluster](#) in the *Amazon Managed Streaming for Apache Kafka Developer Guide*.

6. If you want a secure connection to the Kafka data source, select **Require SSL connection**, and for **Kafka private CA certificate location**, enter a valid Amazon S3 path to a custom SSL certificate.

For an SSL connection to self-managed Kafka, the custom certificate is mandatory. It's optional for Amazon MSK.

For more information about specifying a custom certificate for Kafka, see [the section called "SSL connection properties"](#).

7. Use AWS Glue Studio or the AWS CLI to specify a Kafka client authentication method. To access AWS Glue Studio select **AWS Glue** from the **ETL** menu in the left navigation pane.

For more information about Kafka client authentication methods, see [AWS Glue Kafka connection properties for client authentication](#).

8. Optionally enter a description, and then choose **Next**.

9. For an Amazon MSK cluster, specify its virtual private cloud (VPC), subnet, and security group. The VPC information is optional for self-managed Kafka.
10. Choose **Next** to review all connection properties, and then choose **Finish**.

For more information about AWS Glue connections, see [Connecting to data](#).

## **AWS Glue Kafka connection properties for client authentication**

### **SASL/GSSAPI (Kerberos) authentication**

Choosing this authentication method will allow you to specify Kerberos properties.

#### **Kerberos Keytab**

Choose the location of the keytab file. A keytab stores long-term keys for one or more principals. For more information, see [MIT Kerberos Documentation: Keytab](#).

#### **Kerberos krb5.conf file**

Choose the krb5.conf file. This contains the default realm (a logical network, similar to a domain, that defines a group of systems under the same KDC) and the location of the KDC server. For more information, see [MIT Kerberos Documentation: krb5.conf](#).

#### **Kerberos principal and Kerberos service name**

Enter the Kerberos principal and service name. For more information, see [MIT Kerberos Documentation: Kerberos principal](#).

### **SASL/SCRAM-SHA-512 authentication**

Choosing this authentication method will allow you to specify authentication credentials.

#### **AWS Secrets Manager**

Search for your token in the Search box by typing the name or ARN.

#### **Provider username and password directly**

Search for your token in the Search box by typing the name or ARN.

### **SSL client authentication**

Choosing this authentication method allows you to select the location of the Kafka client keystore by browsing Amazon S3. Optionally, you can enter the Kafka client keystore password and Kafka client key password.

## IAM authentication

This authentication method does not require any additional specifications and is only applicable when the Streaming source is MSK Kafka.

## SASL/PLAIN authentication

Choosing this authentication method allows you to specify authentication credentials.

## Creating a Data Catalog table for a streaming source

A Data Catalog table that specifies source data stream properties, including the data schema can be manually created for a streaming source. This table is used as the data source for the streaming ETL job.

If you don't know the schema of the data in the source data stream, you can create the table without a schema. Then when you create the streaming ETL job, you can turn on the AWS Glue schema detection function. AWS Glue determines the schema from the streaming data.

Use the [AWS Glue console](#), the AWS Command Line Interface (AWS CLI), or the AWS Glue API to create the table. For information about creating a table manually with the AWS Glue console, see [the section called "Creating tables"](#).

### Note

You can't use the AWS Lake Formation console to create the table; you must use the AWS Glue console.

Also consider the following information for streaming sources in Avro format or for log data that you can apply Grok patterns to.

- [the section called "Notes and restrictions for Avro streaming sources"](#)
- [the section called "Applying grok patterns to streaming sources"](#)

## Topics

- [Kinesis data source](#)
- [Kafka data source](#)
- [AWS Glue Schema Registry table source](#)

## Kinesis data source

When creating the table, set the following streaming ETL properties (console).

### Type of Source

#### Kinesis

**For a Kinesis source in the same account:**

#### Region

The AWS Region where the Amazon Kinesis Data Streams service resides. The Region and Kinesis stream name are together translated to a Stream ARN.

Example: `https://kinesis.us-east-1.amazonaws.com`

#### Kinesis stream name

Stream name as described in [Creating a Stream](#) in the *Amazon Kinesis Data Streams Developer Guide*.

**For a Kinesis source in another account, refer to [this example](#) to set up the roles and policies to allow cross-account access. Configure these settings:**

#### Stream ARN

The ARN of the Kinesis data stream that the consumer is registered with. For more information, see [Amazon Resource Names \(ARNs\) and AWS Service Namespaces](#) in the *AWS General Reference*.

#### Assumed Role ARN

The Amazon Resource Name (ARN) of the role to assume.

#### Session name (optional)

An identifier for the assumed role session.

Use the role session name to uniquely identify a session when the same role is assumed by different principals or for different reasons. In cross-account scenarios, the role session name is visible to, and can be logged by the account that owns the role. The role session name is also used in the ARN of the assumed role principal. This means that subsequent cross-account API requests that use the temporary security credentials will expose the role session name to the external account in their AWS CloudTrail logs.

## To set streaming ETL properties for Amazon Kinesis Data Streams (AWS Glue API or AWS CLI)

- To set up streaming ETL properties for a Kinesis source in the same account, specify the `streamName` and `endpointUrl` parameters in the `StorageDescriptor` structure of the `CreateTable` API operation or the `create_table` CLI command.

```
"StorageDescriptor": {
  "Parameters": {
    "typeOfData": "kinesis",
    "streamName": "sample-stream",
    "endpointUrl": "https://kinesis.us-east-1.amazonaws.com"
  }
  ...
}
```

Or, specify the `streamARN`.

### Example

```
"StorageDescriptor": {
  "Parameters": {
    "typeOfData": "kinesis",
    "streamARN": "arn:aws:kinesis:us-east-1:123456789:stream/sample-stream"
  }
  ...
}
```

- To set up streaming ETL properties for a Kinesis source in another account, specify the `streamARN`, `awsSTSRoleARN` and `awsSTSSessionName` (optional) parameters in the `StorageDescriptor` structure in the `CreateTable` API operation or the `create_table` CLI command.

```
"StorageDescriptor": {
  "Parameters": {
    "typeOfData": "kinesis",
    "streamARN": "arn:aws:kinesis:us-east-1:123456789:stream/sample-stream",
    "awsSTSRoleARN": "arn:aws:iam::123456789:role/sample-assume-role-arn",
    "awsSTSSessionName": "optional-session"
  }
  ...
}
```

```
}
```

## Kafka data source

When creating the table, set the following streaming ETL properties (console).

### Type of Source

#### Kafka

#### For a Kafka source:

##### Topic name

Topic name as specified in Kafka.

##### Connection

An AWS Glue connection that references a Kafka source, as described in [the section called "Creating a connection for a Kafka data stream"](#).

## AWS Glue Schema Registry table source

To use AWS Glue Schema Registry for streaming jobs, follow the instructions at [Use case: AWS Glue Data Catalog](#) to create or update a Schema Registry table.

Currently, AWS Glue Streaming supports only Glue Schema Registry Avro format with schema inference set to `false`.

## Notes and restrictions for Avro streaming sources

The following notes and restrictions apply for streaming sources in the Avro format:

- When schema detection is turned on, the Avro schema must be included in the payload. When turned off, the payload should contain only data.
- Some Avro data types are not supported in dynamic frames. You can't specify these data types when defining the schema with the **Define a schema** page in the create table wizard in the AWS Glue console. During schema detection, unsupported types in the Avro schema are converted to supported types as follows:
  - `EnumType => StringType`

- FixedType => BinaryType
- UnionType => StructType
- If you define the table schema using the **Define a schema** page in the console, the implied root element type for the schema is record. If you want a root element type other than record, for example array or map, you can't specify the schema using the **Define a schema** page. Instead you must skip that page and specify the schema either as a table property or within the ETL script.
- To specify the schema in the table properties, complete the create table wizard, edit the table details, and add a new key-value pair under **Table properties**. Use the key `avroSchema`, and enter a schema JSON object for the value, as shown in the following screenshot.

The screenshot shows the 'Edit table details' page in the AWS Glue console. It features a form with several sections:

- Key** and **Value** input fields for adding new properties.
- Description** text area.
- Table properties** section containing a table of existing properties:

Key	Value	
classification	avro	✕
avroSchema	{"type":"array","items":"strin	✕

- To specify the schema in the ETL script, modify the `datasource0` assignment statement and add the `avroSchema` key to the `additional_options` argument, as shown in the following Python and Scala examples.

## Python

```
SCHEMA_STRING = '{"type":"array","items":"string"}'  
datasource0 = glueContext.create_data_frame.from_catalog(database =  
    "database", table_name = "table_name", transformation_ctx = "datasource0",  
    additional_options = {"startingPosition": "TRIM_HORIZON", "inferSchema":  
    "false", "avroSchema": SCHEMA_STRING})
```

## Scala

```
val SCHEMA_STRING = """"{"type":"array","items":"string"}"""  
val datasource0 = glueContext.getCatalogSource(database = "database", tableName  
    = "table_name", redshiftTmpDir = "", transformationContext = "datasource0",  
    additionalOptions = JsonOptions(s""""{"startingPosition": "TRIM_HORIZON",  
    "inferSchema": "false", "avroSchema": "$SCHEMA_STRING"}""")).getDataFrame()
```

## Applying grok patterns to streaming sources

You can create a streaming ETL job for a log data source and use Grok patterns to convert the logs to structured data. The ETL job then processes the data as a structured data source. You specify the Grok patterns to apply when you create the Data Catalog table for the streaming source.

For information about Grok patterns and custom pattern string values, see [Writing grok custom classifiers](#).

### To add grok patterns to the Data Catalog table (console)

- Use the create table wizard, and create the table with the parameters specified in [the section called "Creating a Data Catalog table for a streaming source"](#). Specify the data format as Grok, fill in the **Grok pattern** field, and optionally add custom patterns under **Custom patterns (optional)**.

### Choose a data format

**Classification**

CSV  
 JSON  
 ORC  
 Parquet  
 Avro  
 Grok

Choose the format of the data in your table.

**Grok pattern**

%{PATTERN-NAME:field-name:optional-data-type}

Built-in and custom named patterns used to parse your data into a structured schema. For more information, see the [list of built-in patterns](#).

**Custom patterns**

1

Optional custom building blocks for the grok pattern.

Press **Enter** after each custom pattern.

## To add grok patterns to the Data Catalog table (AWS Glue API or AWS CLI)

- Add the GrokPattern parameter and optionally the CustomPatterns parameter to the CreateTable API operation or the create\_table CLI command.

```

"Parameters": {
...
  "grokPattern": "string",
  "grokCustomPatterns": "string",
...
},

```

Express grokCustomPatterns as a string and use "\n" as the separator between patterns.

The following is an example of specifying these parameters.

## Example

```
"parameters": {  
  ...  
  "grokPattern": "%{USERNAME:username} %{DIGIT:digit:int}",  
  "grokCustomPatterns": "digit \\d",  
  ...  
}
```

## Defining job properties for a streaming ETL job

When you define a streaming ETL job in the AWS Glue console, provide the following streams-specific properties. For descriptions of additional job properties, see [Defining job properties for Spark jobs](#).

### IAM role

Specify the AWS Identity and Access Management (IAM) role that is used for authorization to resources that are used to run the job, access streaming sources, and access target data stores.

For access to Amazon Kinesis Data Streams, attach the `AmazonKinesisFullAccess` AWS managed policy to the role, or attach a similar IAM policy that permits more fine-grained access. For sample policies, see [Controlling Access to Amazon Kinesis Data Streams Resources Using IAM](#).

For more information about permissions for running jobs in AWS Glue, see [Identity and access management for AWS Glue](#).

### Type

Choose **Spark streaming**.

### AWS Glue version

The AWS Glue version determines the versions of Apache Spark, and Python or Scala, that are available to the job. Choose a selection that specifies the version of Python or Scala available to the job. AWS Glue Version 2.0 with Python 3 support is the default for streaming ETL jobs.

### Maintenance window

Specifies a window where a streaming job can be restarted. See [the section called "Maintenance windows"](#).

## Job timeout

Optionally enter a duration in minutes. The default value is blank.

- Streaming jobs must have a timeout value less than 7 days or 10080 minutes.
- When the value is left blank, the job will be restarted after 7 days, if you have not set up a maintenance window. If you have set up a maintenance window, the job will be restarted during the maintenance window after 7 days.

## Data source

Specify the table that you created in [the section called “Creating a Data Catalog table for a streaming source”](#).

## Data target

Do one of the following:

- Choose **Create tables in your data target** and specify the following data target properties.

### Data store

Choose Amazon S3 or JDBC.

### Format

Choose any format. All are supported for streaming.

- Choose **Use tables in the data catalog and update your data target**, and choose a table for a JDBC data store.

## Output schema definition

Do one of the following:

- Choose **Automatically detect schema of each record** to turn on schema detection. AWS Glue determines the schema from the streaming data.
- Choose **Specify output schema for all records** to use the Apply Mapping transform to define the output schema.

## Script

Optionally supply your own script or modify the generated script to perform operations that the Apache Spark Structured Streaming engine supports. For information on the available operations, see [Operations on streaming DataFrames/Datasets](#).

## Streaming ETL notes and restrictions

Keep in mind the following notes and restrictions:

- Auto-decompression for AWS Glue streaming ETL jobs is only available for the supported compression types. Also note the following:
  - Framed Snappy refers to the official [framing format](#) for Snappy.
  - Deflate is supported in Glue version 3.0, not Glue version 2.0.
- When using schema detection, you cannot perform joins of streaming data.
- AWS Glue streaming ETL jobs do not support the Union data type for AWS Glue Schema Registry with Avro format.
- Your ETL script can use AWS Glue's built-in transforms and the transforms native to Apache Spark Structured Streaming. For more information, see [Operations on streaming DataFrames/Datasets](#) on the Apache Spark website or [AWS Glue PySpark transforms reference](#).
- AWS Glue streaming ETL jobs use checkpoints to keep track of the data that has been read. Therefore, a stopped and restarted job picks up where it left off in the stream. If you want to reprocess data, you can delete the checkpoint folder referenced in the script.
- Job bookmarks aren't supported.
- To use enhanced fan-out feature of Kinesis Data Streams in your job, consult [the section called "Using enhanced fan-out in Kinesis streaming jobs"](#).
- If you use a Data Catalog table created from AWS Glue Schema Registry, when a new schema version becomes available, to reflect the new schema, you need to do the following:
  1. Stop the jobs associated with the table.
  2. Update the schema for the Data Catalog table.
  3. Restart the jobs associated with the table.

## Record matching with AWS Lake Formation FindMatches

### Note

Record matching is currently unavailable in the following Regions in the AWS Glue console: Middle East (UAE), Europe (Spain) (eu-south-2), and Europe (Zurich) (eu-central-2).

AWS Lake Formation provides machine learning capabilities to create custom transforms to cleanse your data. There is currently one available transform named FindMatches. The FindMatches transform enables you to identify duplicate or matching records in your dataset, even when the records do not have a common unique identifier and no fields match exactly. This will not require writing any code or knowing how machine learning works. FindMatches can be useful in many different problems, such as:

- **Matching customers:** Linking customer records across different customer databases, even when many customer fields do not match exactly across the databases (e.g. different name spelling, address differences, missing or inaccurate data, etc).
- **Matching products:** Matching products in your catalog against other product sources, such as product catalog against a competitor's catalog, where entries are structured differently.
- **Improving fraud detection:** Identifying duplicate customer accounts, determining when a newly created account is (or might be) a match for a previously known fraudulent user.
- **Other matching problems:** Match addresses, movies, parts lists, etc etc. In general, if a human being could look at your database rows and determine that they were a match, there is a really good chance that the FindMatches transform can help you.

You can create these transforms when you create a job. The transform that you create is based on a source data store schema and example data from the source data set that you label (we call this process "teaching" a transform). The records that you label must be present in the source dataset. In this process we generate a file which you label and then upload back which the transform would learn from. After you teach your transform, you can call it from your Spark-based AWS Glue job (PySpark or Scala Spark) and use it in other scripts with a compatible source data store.

After the transform is created, it is stored in AWS Glue. On the AWS Glue console, you can manage the transforms that you create. In the navigation pane under **Data Integration and ETL, Data classification tools > Record Matching**, you can edit and continue to teach your machine learning transform. For more information about managing transforms on the console, see [Working with machine learning transforms on the AWS Glue console](#).

#### Note

AWS Glue version 2.0 FindMatches jobs use the Amazon S3 bucket `aws-glue-temp-<accountID>-<region>` to store temporary files while the transform is processing data.

You can delete this data after the run has completed, either manually or by setting an Amazon S3 Lifecycle rule.

## Types of machine learning transforms

You can create machine learning transforms to cleanse your data. You can call these transforms from your ETL script. Your data passes from transform to transform in a data structure called a *DynamicFrame*, which is an extension to an Apache Spark SQL `DataFrame`. The `DynamicFrame` contains your data, and you reference its schema to process your data.

The following types of machine learning transforms are available:

### *Find matches*

Finds duplicate records in the source data. You teach this machine learning transform by labeling example datasets to indicate which rows match. The machine learning transform learns which rows should be matches the more you teach it with example labeled data. Depending on how you configure the transform, the output is one of the following:

- A copy of the input table plus a `match_id` column filled in with values that indicate matching sets of records. The `match_id` column is an arbitrary identifier. Any records which have the same `match_id` have been identified as matching to each other. Records with different `match_id`'s do not match.
- A copy of the input table with duplicate rows removed. If multiple duplicates are found, then the record with the lowest primary key is kept.

### *Find incremental matches*

The Find matches transform can also be configured to find matches across the existing and incremental frames and return as output a column containing a unique ID per match group.

For more information, see: [Finding incremental matches](#)

## Using the FindMatches transform

You can use the `FindMatches` transform to find duplicate records in the source data. A labeling file is generated or provided to help teach the transform.

**Note**

Currently, FindMatches transforms that use a custom encryption key aren't supported in the following Regions:

- Asia Pacific (Osaka) - ap-northeast-3

To get started with the FindMatches transform, you can follow the steps below. For a more advanced and detailed example, see the **AWS Big Data Blog**: [Harmonize data using AWS Glue and AWS Lake Formation FindMatches ML to build a customer 360 view](#).

**Getting started using the Find Matches transform**

Follow these steps to get started with the FindMatches transform:

1. Create a table in the AWS Glue Data Catalog for the source data that is to be cleaned. For information about how to create a crawler, see [Working with Crawlers on the AWS Glue Console](#).

If your source data is a text-based file such as a comma-separated values (CSV) file, consider the following:

- Keep your input record CSV file and labeling file in separate folders. Otherwise, the AWS Glue crawler might consider them as multiple parts of the same table and create tables in the Data Catalog incorrectly.
  - Unless your CSV file includes ASCII characters only, ensure that UTF-8 without BOM (byte order mark) encoding is used for the CSV files. Microsoft Excel often adds a BOM in the beginning of UTF-8 CSV files. To remove it, open the CSV file in a text editor, and resave the file as **UTF-8 without BOM**.
2. On the AWS Glue console, create a job, and choose the **Find matches** transform type.

**Important**

The data source table that you choose for the job can't have more than 100 columns.

3. Tell AWS Glue to generate a labeling file by choosing **Generate labeling file**. AWS Glue takes the first pass at grouping similar records for each `labeling_set_id` so that you can review those groupings. You label matches in the `label` column.

- If you already have a labeling file, that is, an example of records that indicate matching rows, upload the file to Amazon Simple Storage Service (Amazon S3). For information about the format of the labeling file, see [Labeling file format](#). Proceed to step 4.
4. Download the labeling file and label the file as described in the [Labeling](#) section.
  5. Upload the corrected labelled file. AWS Glue runs tasks to teach the transform how to find matches.

On the **Machine learning transforms** list page, choose the **History** tab. This page indicates when AWS Glue performs the following tasks:

- **Import labels**
  - **Export labels**
  - **Generate labels**
  - **Estimate quality**
6. To create a better transform, you can iteratively download, label, and upload the labelled file. In the initial runs, a lot more records might be mismatched. But AWS Glue learns as you continue to teach it by verifying the labeling file.
  7. Evaluate and tune your transform by evaluating performance and results of finding matches. For more information, see [Tuning machine learning transforms in AWS Glue](#).

## Labeling

When `FindMatches` generates a labeling file, records are selected from your source table. Based on previous training, `FindMatches` identifies the most valuable records to learn from.

The act of *labeling* is editing a labeling file (we suggest using a spreadsheet such as Microsoft Excel) and adding identifiers, or labels, into the `label` column that identifies matching and nonmatching records. It is important to have a clear and consistent definition of a match in your source data. `FindMatches` learns from which records you designate as matches (or not) and uses your decisions to learn how to find duplicate records.

When a labeling file is generated by `FindMatches`, approximately 100 records are generated. These 100 records are typically divided into 10 *labeling sets*, where each labeling set is identified by a unique `labeling_set_id` generated by `FindMatches`. Each labeling set should be viewed as a separate labeling task independent of the other labeling sets. Your task is to identify matching and non-matching records within each labeling set.

## Tips for editing labeling files in a spreadsheet

When editing the labeling file in a spreadsheet application, consider the following:

- The file might not open with column fields fully expanded. You might need to expand the `labeling_set_id` and `label` columns to see content in those cells.
- If the primary key column is a number, such as a long data type, the spreadsheet might interpret it as a number and change the value. This key value must be treated as text. To correct this problem, format all the cells in the primary key column as **Text data**.

## Labeling file format

The labeling file that is generated by AWS Glue to teach your `FindMatches` transform uses the following format. If you generate your own file for AWS Glue, it must follow this format as well:

- It is a comma-separated values (CSV) file.
- It must be encoded in UTF-8. If you edit the file using Microsoft Windows, it might be encoded with `cp1252`.
- It must be in an Amazon S3 location to pass it to AWS Glue.
- Use a moderate number of rows for each labeling task. 10–20 rows per task are recommended, although 2–30 rows per task are acceptable. Tasks larger than 50 rows are not recommended and may cause poor results or system failure.
- If you have already-labeled data consisting of pairs of records labeled as a "match" or a "no-match", this is fine. These labeled pairs can be represented as labeling sets of size 2. In this case label both records with, for instance, a letter "A" if they match, but label one as "A" and one as "B" if they do not match.

### Note

Because it has additional columns, the labeling file has a different schema from a file that contains your source data. Place the labeling file in a different folder from any transform input CSV file so that the AWS Glue crawler does not consider it when it creates tables in the Data Catalog. Otherwise, the tables created by the AWS Glue crawler might not correctly represent your data.

- The first two columns (`labeling_set_id`, `label`) are required by AWS Glue. The remaining columns must match the schema of the data that is to be processed.

- For each `labeling_set_id`, you identify all matching records by using the same label. A label is a unique string placed in the `label` column. We recommend using labels that contain simple characters, such as A, B, C, and so on. Labels are case sensitive and are entered in the `label` column.
- Rows that contain the same `labeling_set_id` and the same label are understood to be labeled as a match.
- Rows that contain the same `labeling_set_id` and a different label are understood to be labeled as *not* a match
- Rows that contain a different `labeling_set_id` are understood to be conveying no information for or against matching.

The following is an example of labeling the data:

<code>labeling_set_id</code>	<code>label</code>	<code>first_name</code>	<code>last_name</code>	<code>Birthday</code>
ABC123	A	John	Doe	04/01/1980
ABC123	B	Jane	Smith	04/03/1980
ABC123	A	Johnny	Doe	04/01/1980
ABC123	A	Jon	Doe	04/01/1980
DEF345	A	Richard	Jones	12/11/1992
DEF345	A	Rich	Jones	11/12/1992
DEF345	B	Sarah	Jones	12/11/1992
DEF345	C	Richie	Jones Jr.	05/06/2017
DEF345	B	Sarah	Jones-Walker	12/11/1992
GHI678	A	Robert	Miller	1/3/1999
GHI678	A	Bob	Miller	1/3/1999
XYZABC	A	William	Robinson	2/5/2001

labeling_set_id	label	first_name	last_name	Birthday
XYZABC	B	Andrew	Robinson	2/5/1971

- In the above example we identify John/Johnny/Jon Doe as being a match and we teach the system that these records do not match Jane Smith. Separately, we teach the system that Richard and Rich Jones are the same person, but that these records are not a match to Sarah Jones/Jones-Walker and Richie Jones Jr.
- As you can see, the scope of the labels is limited to the `labeling_set_id`. So labels do not cross `labeling_set_id` boundaries. For example, a label "A" in `labeling_set_id` 1 does not have any relation to label "A" in `labeling_set_id` 2.
- If a record does not have any matches within a labeling set, then assign it a unique label. For instance, Jane Smith does not match any record in labeling set ABC123, so it is the only record in that labeling set with the label of B.
- The labeling set "GHI678" shows that a labeling set can consist of just two records which are given the same label to show that they match. Similarly, "XYZABC" shows two records given different labels to show that they do not match.
- Note that sometimes a labeling set may contain no matches (that is, you give every record in the labeling set a different label) or a labeling set might all be "the same" (you gave them all the same label). This is okay as long as your labeling sets collectively contain examples of records that are and are not "the same" by your criteria.

### Important

Confirm that the IAM role that you pass to AWS Glue has access to the Amazon S3 bucket that contains the labeling file. By convention, AWS Glue policies grant permission to Amazon S3 buckets or folders whose names are prefixed with **aws-glue-**. If your labeling files are in a different location, add permission to that location in the IAM role.

## Tuning machine learning transforms in AWS Glue

You can tune your machine learning transforms in AWS Glue to improve the results of your data-cleansing jobs to meet your objectives. To improve your transform, you can teach it by generating a labeling set, adding labels, and then repeating these steps several times until you get your desired results. You can also tune by changing some machine learning parameters.

For more information about machine learning transforms, see [Record matching with AWS Lake Formation FindMatches](#).

## Topics

- [Machine learning measurements](#)
- [Deciding between precision and recall](#)
- [Deciding Between accuracy and cost](#)
- [Estimating the quality of matches using match confidence scores](#)
- [Teaching the Find Matches transform](#)

## Machine learning measurements

To understand the measurements that are used to tune your machine learning transform, you should be familiar with the following terminology:

### True positive (TP)

A match in the data that the transform correctly found, sometimes called a *hit*.

### True negative (TN)

A nonmatch in the data that the transform correctly rejected.

### False positive (FP)

A nonmatch in the data that the transform incorrectly classified as a match, sometimes called a *false alarm*.

### False negative (FN)

A match in the data that the transform didn't find, sometimes called a *miss*.

For more information about the terminology that is used in machine learning, see [Confusion matrix](#) in Wikipedia.

To tune your machine learning transforms, you can change the value of the following measurements in the **Advanced properties** of the transform.

- **Precision** measures how well the transform finds true positives among the total number of records that it identifies as positive (true positives and false positives). For more information, see [Precision and recall](#) in Wikipedia.

- **Recall** measures how well the transform finds true positives from the total records in the source data. For more information, see [Precision and recall](#) in Wikipedia.
- **Accuracy** measures how well the transform finds true positives and true negatives. Increasing accuracy requires more machine resources and cost. But it also results in increased recall. For more information, see [Accuracy and precision](#) in Wikipedia.
- **Cost** measures how many compute resources (and thus money) are consumed to run the transform.

## Deciding between precision and recall

Each FindMatches transform contains a precision-recall parameter. You use this parameter to specify one of the following:

- If you are more concerned about the transform falsely reporting that two records match when they actually don't match, then you should emphasize *precision*.
- If you are more concerned about the transform failing to detect records that really do match, then you should emphasize *recall*.

You can make this trade-off on the AWS Glue console or by using the AWS Glue machine learning API operations.

## When to favor precision

Favor precision if you are more concerned about the risk that FindMatches results in a pair of records matching when they don't actually match. To favor precision, choose a *higher* precision-recall trade-off value. With a higher value, the FindMatches transform requires more evidence to decide that a pair of records should be matched. The transform is tuned to bias toward saying that records do not match.

For example, suppose that you're using FindMatches to detect duplicate items in a video catalog, and you provide a higher precision-recall value to the transform. If your transform incorrectly detects that *Star Wars: A New Hope* is the same as *Star Wars: The Empire Strikes Back*, a customer who wants *A New Hope* might be shown *The Empire Strikes Back*. This would be a poor customer experience.

However, if the transform fails to detect that *Star Wars: A New Hope* and *Star Wars: Episode IV —A New Hope* are the same item, the customer might be confused at first but might eventually recognize them as the same. It would be a mistake, but not as bad as the previous scenario.

## When to favor recall

Favor recall if you are more concerned about the risk that the `FindMatches` transform results might fail to detect a pair of records that actually do match. To favor recall, choose a *lower* precision-recall trade-off value. With a lower value, the `FindMatches` transform requires less evidence to decide that a pair of records should be matched. The transform is tuned to bias toward saying that records do match.

For example, this might be a priority for a security organization. Suppose that you are matching customers against a list of known defrauders, and it is important to determine whether a customer is a defrauder. You are using `FindMatches` to match the defrauder list against the customer list. Every time `FindMatches` detects a match between the two lists, a human auditor is assigned to verify that the person is, in fact, a defrauder. Your organization might prefer to choose recall over precision. In other words, you would rather have the auditors manually review and reject some cases when the customer is not a defrauder than fail to identify that a customer is, in fact, on the defrauder list.

## How to favor both precision and recall

The best way to improve both precision and recall is to label more data. As you label more data, the overall accuracy of the `FindMatches` transform improves, thus improving both precision and recall. Nevertheless, even with the most accurate transform, there is always a gray area where you need to experiment with favoring precision or recall, or choose a value in the middle.

## Deciding Between accuracy and cost

Each `FindMatches` transform contains an accuracy-cost parameter. You can use this parameter to specify one of the following:

- If you are more concerned with the transform accurately reporting that two records match, then you should emphasize *accuracy*.
- If you are more concerned about the cost or speed of running the transform, then you should emphasize *lower cost*.

You can make this trade-off on the AWS Glue console or by using the AWS Glue machine learning API operations.

## When to favor accuracy

Favor accuracy if you are more concerned about the risk that the `find_matches` results won't contain matches. To favor accuracy, choose a *higher* accuracy-cost trade-off value. With a higher value, the `FindMatches` transform requires more time to do a more thorough search for correctly matching records. Note that this parameter doesn't make it less likely to falsely call a nonmatching record pair a match. The transform is tuned to bias towards spending more time finding matches.

### When to favor cost

Favor cost if you are more concerned about the cost of running the `find_matches` transform and less about how many matches are found. To favor cost, choose a *lower* accuracy-cost trade-off value. With a lower value, the `FindMatches` transform requires fewer resources to run. The transform is tuned to bias towards finding fewer matches. If the results are acceptable when favoring lower cost, use this setting.

### How to favor both accuracy and lower cost

It takes more machine time to examine more pairs of records to determine whether they might be matches. If you want to reduce cost without reducing quality, here are some steps you can take:

- Eliminate records in your data source that you aren't concerned about matching.
- Eliminate columns from your data source that you are sure aren't useful for making a match/no-match decision. A good way of deciding this is to eliminate columns that you don't think affect your own decision about whether a set of records is "the same."

### Estimating the quality of matches using match confidence scores

Match confidence scores provide an estimate of the quality of matches found by `FindMatches` to distinguish between matched records in which the machine learning model is highly confident, uncertain, or unlikely. A match confidence score will be between 0 and 1, where a higher score means higher similarity. Examining match confidence scores lets you distinguish between clusters of matches in which the system is highly confident (which you may decide to merge), clusters about which the system is uncertain (which you may decide to have reviewed by a human), and clusters that the system deems to be unlikely (which you may decide to reject).

You may want to adjust your training data in situations where you see a high match confidence score, but determine there are not matches, or where you see a low score but determine there are, in fact, matches.

Confidence scores are particularly useful when there are large sized industrial datasets, where it is infeasible to review every FindMatches decision.

Match confidence scores are available in AWS Glue version 2.0 or later.

## Generating match confidence scores

You can generate match confidence scores by setting the Boolean value of `computeMatchConfidenceScores` to `True` when calling the `FindMatches` or `FindIncrementalMatches` API.

AWS Glue adds a new column `match_confidence_score` to the output.

## Match scoring examples

For example, consider the following matched records:

### Score $\geq$ 0.9

Summary of matched records:

primary_id	match_id	match_confidence_score
3281355037663	85899345947	0.9823658302132061
1546188247619	85899345947	0.9823658302132061

### Details:

raw_id	phone source	website	poi_id	display_position	primary_name locale_name	street1 street2 street3
city state country postal_code street_in_one_line	primary_id	match_id match_confidence_score				
ae3q8SD01CbIqHFPPL1j1g +43262681160  yelp http://www.commerzbank.at yelp::ae3q8SD01CbIqHFPPL1j1g geo:47.711590000,16.344020000 Commerzbank Mattersburg  en_US Hauptstr. 59  null  null Forchtenstein  1  AT  7212	Hauptstr. 59 1546188247619 85899345947  0.9823658302132061					
uWhQk6v2j5Lz4N8lXm-q0 +43268747266  yelp http://www.commerzbank.at yelp::uWhQk6v2j5Lz4N8lXm-q0 geo:47.787420000,16.455440000 Commerzbank Mattersburg  en_US  Hauptstr. 9  null  null  Hirm  1  AT  7024	Hauptstr. 9 3281355037663 85899345947  0.9823658302132061					

From this example, we can see that two records are very similar and share `display_position`, `primary_name`, and `street` name.

### Score $\geq$ 0.8 and score $<$ 0.9

Summary of matched records:

primary_id	match_id	match_confidence_score
------------	----------	------------------------

309237680432	85899345928	0.8309852373674638

- PySpark: [FindIncrementalMatches class](#)
- Scala: [FindMatches class](#)
- Scala: [FindIncrementalMatches class](#)

## Teaching the Find Matches transform

Each FindMatches transform must be taught what should be considered a match and what should not be considered a match. You teach your transform by adding labels to a file and uploading your choices to AWS Glue.

You can orchestrate this labeling on the AWS Glue console or by using the AWS Glue machine learning API operations.

### How many times should I add labels? How many labels do I need?

The answers to these questions are mostly up to you. You must evaluate whether FindMatches is delivering the level of accuracy that you need and whether you think the extra labeling effort is worth it for you. The best way to decide this is to look at the “Precision,” “Recall,” and “Area under the precision recall curve” metrics that you can generate when you choose **Estimate quality** on the AWS Glue console. After you label more sets of tasks, rerun these metrics and verify whether they have improved. If, after labeling a few sets of tasks, you don't see improvement on the metric that you are focusing on, the transform quality might have reached a plateau.

### Why are both true positive and true negative labels needed?

The FindMatches transform needs both positive and negative examples to learn what you think is a match. If you are labeling FindMatches-generated training data (for example, using the **I do not have labels** option), FindMatches tries to generate a set of “label set ids” for you. Within each task, you give the same “label” to some records and different “labels” to other records. In other words, the tasks generally are not either all the same or all different (but it's okay if a particular task is all “the same” or all “not the same”).

If you are teaching your FindMatches transform using the **Upload labels from S3** option, try to include both examples of matching and nonmatching records. It's acceptable to have only one type. These labels help you build a more accurate FindMatches transform, but you still need to label some records that you generate using the **Generate labeling file** option.

## How can I enforce that the transform matches exactly as I taught it?

The FindMatches transform learns from the labels that you provide, so it might generate records pairs that don't respect the provided labels. To enforce that the FindMatches transform respects your labels, select **EnforceProvidedLabels** in **FindMatchesParameter**.

## What techniques can you use when an ML transform identifies items as matches that are not true matches?

You can use the following techniques:

- Increase the `precisionRecallTradeoff` to a higher value. This eventually results in finding fewer matches, but it should also break up your big cluster when it reaches a high enough value.
- Take the output rows corresponding to the incorrect results and reformat them as a labeling set (removing the `match_id` column and adding a `labeling_set_id` and `label` column). If necessary, break up (subdivide) into multiple labeling sets to ensure that the labeler can keep each labeling set in mind while assigning labels. Then, correctly label the matching sets and upload the label file and append it to your existing labels. This might teach your transformer enough about what it is looking for to understand the pattern.
- (Advanced) Finally, look at that data to see if there is a pattern that you can detect that the system is not noticing. Preprocess that data using standard AWS Glue functions to *normalize* the data. Highlight what you want the algorithm to learn from by separating data that you know to be differently important into their own columns. Or construct combined columns from columns whose data you know to be related.

## Working with machine learning transforms on the AWS Glue console

You can use AWS Glue to create custom machine learning transforms that can be used to cleanse your data. You can use these transforms when you create a job on the AWS Glue console.

For information about how to create a machine learning transform, see [Record matching with AWS Lake Formation FindMatches](#).

### Topics

- [Transform properties](#)
- [Adding and editing machine learning transforms](#)
- [Viewing transform details](#)

- [Teach transforms using labels](#)

## Transform properties

To view an existing machine learning transform, sign in to the AWS Management Console, and open the AWS Glue console at <https://console.aws.amazon.com/glue/>. In the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**.

The properties for each transform:

### Transform name

The unique name you gave the transform when you created it.

### ID

A unique identifier of the transform.

### Label count

The number of labels in the labeling file that was provided to help teach the transform.

### Status

Indicates whether the transform is **Ready** or **Needs training**. To run a machine learning transform successfully in a job, it must be **Ready**.

### Created

The date the transform was created.

### Modified

The date the transform was last updated.

### Description

The description supplied for the transform, if one was provided.

### AWS Glue version

The version of AWS Glue used.

### Run ID

The unique name you gave the transform when you created it.

## Task type

The type of machine learning transform; for example, **Find matching records**.

## Status

Indicates the status of the task run. Possible statuses include:

- Starting
- Running
- Stopping
- Stopped
- Succeeded
- Failed
- Timeout

## Error

If the status is Failed, an error message is displayed describing the reason for the failure.

## Adding and editing machine learning transforms

You can view, delete, set up and teach, or tune a transform on the AWS Glue console. Select the check box next to the transform in the list, choose **Action**, and then choose the action that you want to take.

### Creating a new ML transform

To add a new machine learning transform, choose **Create transform**. Follow the instructions in the **Add job** wizard. For more information, see [Record matching with AWS Lake Formation FindMatches](#).

#### Step 1. Set transform properties.

1. Enter the name and description (optional).
2. Optionally, set security configuration. See [Using data encryption with machine learning transforms](#).
3. Optionally, set Task execution settings. Task execution settings allow you to customize how the task is run. Select the Worker type, number of workers, task timeout (in minutes), the number of retries, and the AWS Glue version.

4. Optionally, set Tags. Tags are labels that you can assign to an AWS resource. Each tag consists of a key and an optional value. Tags can be used to search and filter your resource or track your AWS costs.

### Step 2. Choose table and primary key.

1. Choose the AWS Glue Catalog database and table.
2. Choose a primary key from the selected table. The primary key column typically contains a unique identifier for every record in the data source.

### Step 3. Select tuning options.

1. For **Recall vs. precision**, choose the tuning value to tune the transform to favor recall or precision. By default, **Balanced** is selected, but you can choose to favor recall or favor precision, or choose **Custom** and enter a value between 0.0 and 1.0 (inclusive).
2. For **Lower cost vs. accuracy**, choose the tuning value to favor lower cost or accuracy, or choose **Custom** and enter a value between 0.0 and 1.0 (inclusive).
3. For **Match enforcement**, choose **Force output to match labels** if you want to teach the ML transform by forcing the output to match the labels used.

### Step 4. Review and create.

1. Review the options for steps 1 – 3.
2. Choose **Edit** for any step that needs to be modified. Choose **Create transform** to complete the create transform wizard.

## Using data encryption with machine learning transforms

When adding a machine learning transform to AWS Glue, you can optionally specify a security configuration that is associated with the data source or data target. If the Amazon S3 bucket used to store the data is encrypted with a security configuration, specify the same security configuration when creating the transform.

You can also choose to use server-side encryption with AWS KMS (SSE-KMS) to encrypt the model and labels to prevent unauthorized persons from inspecting it. If you choose this option, you're

prompted to choose the AWS KMS key by name, or you can choose **Enter a key ARN**. If you choose to enter the ARN for the KMS key, a second field appears where you can enter the KMS key ARN.

 **Note**

Currently, ML transforms that use a custom encryption key aren't supported in the following Regions:

- Asia Pacific (Osaka) - `ap-northeast-3`

## Viewing transform details

### Viewing transform properties

The **Transform properties** page includes attributes of your transform. It shows you the details about the transform definition, including the following:

- **Transform name** shows the name of the transform.
- **Type** lists the type of the transform.
- **Status** displays whether the transform is ready to be used in a script or job.
- **Force output to match labels** displays whether the transform forces the output to match the labels provided by the user.
- **Spark version** is related to the AWS Glue version you chose in the **Task run properties** when adding the transform. AWS Glue 1.0 and Spark 2.4 is recommended for most customers. For more information, see [AWS Glue Versions](#).

### History, Estimate quality and Tags tabs

Transform details include the information that you defined when you created the transform. To view the details of a transform, select the transform in the **Machine learning transforms** list, and review the information on the following tabs:

- History
- Estimate quality
- Tags

## History

The **History** tab shows your transform task run history. Several types of tasks are run to teach a transform. For each task, the run metrics include the following:

- **Run ID** is an identifier created by AWS Glue for each run of this task.
- **Task type** shows the type of task run.
- **Status** shows the success of each task listed with the most recent run at the top.
- **Error** shows the details of an error message if the run was not successful.
- **Start time** shows the date and time (local time) that the task started.
- **End time** shows the date and time (local time) that the task ended.
- **Logs** links to the logs written to stdout for this job run.

The **Logs** link takes you to Amazon CloudWatch Logs. There you can view the details about the tables that were created in the AWS Glue Data Catalog and any errors that were encountered. You can manage your log retention period on the CloudWatch console. The default log retention is `Never Expire`. For more information about how to change the retention period, see [Change Log Data Retention in CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

- **Label file** shows a link to Amazon S3 for a generated labeling file.

## Estimate quality

The **Estimate quality** tab shows the metrics that you use to measure the quality of the transform. Estimates are calculated by comparing the transform match predictions using a subset of your labeled data against the labels you have provided. These estimates are approximate. You can invoke an **Estimate quality** task run from this tab.

The **Estimate quality** tab shows the metrics from the last **Estimate quality** run including the following properties:

- **Area under the Precision-Recall curve** is a single number estimating the upper bound of the overall quality of the transform. It is independent of the choice made for the precision-recall parameter. Higher values indicate that you have a more attractive precision-recall tradeoff.
- **Precision** estimates how often the transform is correct when it predicts a match.
- **Recall upper limit** estimates that for an actual match, how often the transform predicts the match.

- **F1** estimates the transform's accuracy between 0 and 1, where 1 is the best accuracy. For more information, see [F1 score](#) in Wikipedia.
- The **Column importance** table show the column names and importance score for each column. Column importance helps you understand how columns contribute to your model, by identifying which columns in your records are being used the most to do the matching. This data may prompt you to add to or change your labelset to raise or lower the importance of columns.

The Importance column provides a numerical score for each column, as a decimal not greater than 1.0.

For information about understanding quality estimates versus true quality, see [Quality estimates versus end-to-end \(true\) quality](#).

For more information about tuning your transform, see [Tuning machine learning transforms in AWS Glue](#).

### Quality estimates versus end-to-end (true) quality

AWS Glue estimates the quality of your transform by presenting the internal machine-learned model with a number of pairs of records that you provided matching labels for but that the model has not seen before. These quality estimates are a function of the quality of the machine-learned model (which is influenced by the number of records that you label to “teach” the transform). The end-to-end, or *true* recall (which is not automatically calculated by the ML transform) is also influenced by the ML transform filtering mechanism that proposes a wide variety of possible matches to the machine-learned model.

You can tune this filtering method primarily by specifying the **Lower Cost-Accuracy** tuning value. As the tuning value gets closer to favor **Accuracy**, the system does a more thorough and expensive search for pairs of records that might be matches. More pairs of records are fed to your machine-learned model, and your ML transform's end-to-end or true recall gets closer to the estimated recall metric. As a result, changes in the end-to-end quality of your matches as a result of changes in the cost/accuracy tradeoff for your matches will typically not be reflected in the quality estimate.

### Tags

Tags are labels that you can assign to an AWS resource. Each tag consists of a key and an optional value. Tags can be used to search and filter your resource or track your AWS costs.

## Teach transforms using labels

You can teach your ML transform using labels (examples) by choosing **Teach transform** from the ML transform details page. When you teach your machine learning algorithm by providing examples (called labels), you can choose existing labels to use, or create a labeling file.

### Teach the transform using labels

**Labeling**

Teach your machine learning algorithms by providing examples, called labels. For your transform, provide examples of matching and nonmatching records.

I do not have labels  
 I have labels  
[▶ How to label](#)

**Generate labeling file**

AWS Glue extracts records from your source data and suggests potential matching records. The file will contain approximately 100 data samples for you to work with. You can download the file once it has been generated.

S3 path to store the generated label file

**Upload labels from S3**

The completed labeling file must be in the correct format and in Amazon S3.

S3 path where the label file is stored

Existing labels

Append to my existing labels  
 Overwrite my existing labels

- **Labeling** – If you have labels, choose **I have labels**. If you do not have labels, you can still continue with the next step in generating a labeling file.
- **Generate labeling file** – AWS Glue extracts records from your source data and suggest potential matching records. You choose the Amazon S3 bucket to store the generated label file. Choose **Generate labeling file** to start the process. When done, choose **Download labeling file**. The downloaded file will have a column for labels where you can fill in the labels.
- **Upload labels from Amazon S3** – Choose the completed labeling file from the Amazon S3 bucket where the label file is stored. Then, choose to either append the labels to your existing labels or to overwrite your existing labels. Choose **Upload labeling file from Amazon S3**.

## Tutorial: Creating a machine learning transform with AWS Glue

This tutorial guides you through the actions to create and manage a machine learning (ML) transform using AWS Glue. Before using this tutorial, you should be familiar with using the AWS Glue console to add crawlers and jobs and edit scripts. You should also be familiar with finding and downloading files on the Amazon Simple Storage Service (Amazon S3) console.

In this example, you create a `FindMatches` transform to find matching records, teach it how to identify matching and nonmatching records, and use it in an AWS Glue job. The AWS Glue job writes a new Amazon S3 file with an additional column named `match_id`.

The source data used by this tutorial is a file named `dblp_acm_records.csv`. This file is a modified version of academic publications (DBLP and ACM) available from the original [DBLP ACM dataset](#). The `dblp_acm_records.csv` file is a comma-separated values (CSV) file in UTF-8 format with no byte-order mark (BOM).

A second file, `dblp_acm_labels.csv`, is an example labeling file that contains both matching and nonmatching records used to teach the transform as part of the tutorial.

### Topics

- [Step 1: Crawl the source data](#)
- [Step 2: Add a machine learning transform](#)
- [Step 3: Teach your machine learning transform](#)
- [Step 4: Estimate the quality of your machine learning transform](#)
- [Step 5: Add and run a job with your machine learning transform](#)
- [Step 6: Verify output data from Amazon S3](#)

### Step 1: Crawl the source data

First, crawl the source Amazon S3 CSV file to create a corresponding metadata table in the Data Catalog.

#### Important

To direct the crawler to create a table for only the CSV file, store the CSV source data in a different Amazon S3 folder from other files.

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Crawlers, Add crawler**.
3. Follow the wizard to create and run a crawler named `demo-crawl-dblp-acm` with output to database `demo-db-dblp-acm`. When running the wizard, create the database `demo-db-dblp-acm` if it doesn't already exist. Choose an Amazon S3 include path to sample data in the current AWS Region. For example, for `us-east-1`, the Amazon S3 include path to the source file is `s3://ml-transforms-public-datasets-us-east-1/dblp-acm/records/dblp_acm_records.csv`.

If successful, the crawler creates the table `dblp_acm_records_csv` with the following columns: `id`, `title`, `authors`, `venue`, `year`, and `source`.

## Step 2: Add a machine learning transform

Next, add a machine learning transform that is based on the schema of your data source table created by the crawler named `demo-crawl-dblp-acm`.

1. On the AWS Glue console, in the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**, then **Add transform**. Follow the wizard to create a `Find matches` transform with the following properties.
  - a. For **Transform name**, enter `demo-xform-dblp-acm`. This is the name of the transform that is used to find matches in the source data.
  - b. For **IAM role**, choose an IAM role that has permission to the Amazon S3 source data, labeling file, and AWS Glue API operations. For more information, see [Create an IAM Role for AWS Glue](#) in the *AWS Glue Developer Guide*.
  - c. For **Data source**, choose the table named `dblp_acm_records_csv` in database `demo-db-dblp-acm`.
  - d. For **Primary key**, choose the primary key column for the table, `id`.
2. In the wizard, choose **Finish** and return to the **ML transforms** list.

## Step 3: Teach your machine learning transform

Next, you teach your machine learning transform using the tutorial sample labeling file.

You can't use a machine language transform in an extract, transform, and load (ETL) job until its status is **Ready for use**. To get your transform ready, you must teach it how to identify matching and nonmatching records by providing examples of matching and nonmatching records. To teach your transform, you can **Generate a label file**, add labels, and then **Upload label file**. In this tutorial, you can use the example labeling file named `dblp_acm_labels.csv`. For more information about the labeling process, see [Labeling](#).

1. On the AWS Glue console, in the navigation pane, choose **Record Matching**.
2. Choose the `demo-xform-dblp-acm` transform, and then choose **Action, Teach**. Follow the wizard to teach your `Find matches` transform.
3. On the transform properties page, choose **I have labels**. Choose an Amazon S3 path to the sample labeling file in the current AWS Region. For example, for `us-east-1`, upload the provided labeling file from the Amazon S3 path `s3://ml-transforms-public-datasets-us-east-1/dblp-acm/labels/dblp_acm_labels.csv` with the option to **overwrite** existing labels. The labeling file must be located in Amazon S3 in the same Region as the AWS Glue console.

When you upload a labeling file, a task is started in AWS Glue to add or overwrite the labels used to teach the transform how to process the data source.

4. On the final page of the wizard, choose **Finish**, and return to the **ML transforms** list.

#### Step 4: Estimate the quality of your machine learning transform

Next, you can estimate the quality of your machine learning transform. The quality depends on how much labeling you have done. For more information about estimating quality, see [Estimate quality](#).

1. On the AWS Glue console, in the navigation pane under **Data Integration and ETL**, choose **Data classification tools > Record Matching**.
2. Choose the `demo-xform-dblp-acm` transform, and choose the **Estimate quality** tab. This tab displays the current quality estimates, if available, for the transform.
3. Choose **Estimate quality** to start a task to estimate the quality of the transform. The accuracy of the quality estimate is based on the labeling of the source data.
4. Navigate to the **History** tab. In this pane, task runs are listed for the transform, including the **Estimating quality** task. For more details about the run, choose **Logs**. Check that the run status is **Succeeded** when it finishes.

## Step 5: Add and run a job with your machine learning transform

In this step, you use your machine learning transform to add and run a job in AWS Glue. When the transform `demo-xform-dblp-acm` is **Ready for use**, you can use it in an ETL job.

1. On the AWS Glue console, in the navigation pane, choose **Jobs**.
2. Choose **Add job**, and follow the steps in the wizard to create an ETL Spark job with a generated script. Choose the following property values for your transform:
  - a. For **Name**, choose the example job in this tutorial, **demo-etl-dblp-acm**.
  - b. For **IAM role**, choose an IAM role with permission to the Amazon S3 source data, labeling file, and AWS Glue API operations. For more information, see [Create an IAM Role for AWS Glue](#) in the *AWS Glue Developer Guide*.
  - c. For **ETL language**, choose **Scala**. This is the programming language in the ETL script.
  - d. For **Script file name**, choose **demo-etl-dblp-acm**. This is the file name of the Scala script (same as the job name).
  - e. For **Data source**, choose **dbl\_p\_acm\_records\_csv**. The data source you choose must match the machine learning transform data source schema.
  - f. For **Transform type**, choose **Find matching records** to create a job using a machine learning transform.
  - g. Clear **Remove duplicate records**. You don't want to remove duplicate records because the output records written have an additional `match_id` field added.
  - h. For **Transform**, choose **demo-xform-dblp-acm**, the machine learning transform used by the job.
  - i. For **Create tables in your data target**, choose to create tables with the following properties:
    - **Data store type** — **Amazon S3**
    - **Format** — **CSV**
    - **Compression type** — **None**
    - **Target path** — The Amazon S3 path where the output of the job is written (in the current console AWS Region)
3. Choose **Save job and edit script** to display the script editor page.

4. Edit the script to add a statement to cause the job output to the **Target path** to be written to a single partition file. Add this statement immediately following the statement that runs the FindMatches transform. The statement is similar to the following.

```
val single_partition = findmatches1.repartition(1)
```

You must modify the `.writeDynamicFrame(findmatches1)` statement to write the output as `.writeDynamicFrame(single_partition)`.

5. After you edit the script, choose **Save**. The modified script looks similar to the following code, but customized for your environment.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.ml.FindMatches
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    // @type: DataSource
    // @args: [database = "demo-db-dblp-acm", table_name = "dblp_acm_records_csv",
transformation_ctx = "datasource0"]
    // @return: datasource0
    // @inputs: []
    val datasource0 = glueContext.getCatalogSource(database = "demo-db-dblp-acm",
tableName = "dblp_acm_records_csv", redshiftTmpDir = "", transformationContext =
"datasource0").getDynamicFrame()
    // @type: FindMatches
    // @args: [transformId = "tfm-123456789012", emitFusion = false,
survivorComparisonField = "<primary_id>", transformation_ctx = "findmatches1"]
    // @return: findmatches1
    // @inputs: [frame = datasource0]
```

```

val findmatches1 = FindMatches.apply(frame = datasource0, transformId
= "tfm-123456789012", transformationContext = "findmatches1",
computeMatchConfidenceScores = true)

// Repartition the previous DynamicFrame into a single partition.
val single_partition = findmatches1.repartition(1)

// @type: DataSink
// @args: [connection_type = "s3", connection_options = {"path": "s3://aws-
glue-ml-transforms-data/sal"}, format = "csv", transformation_ctx = "datasink2"]
// @return: datasink2
// @inputs: [frame = findmatches1]
val datasink2 = glueContext.getSinkWithFormat(connectionType =
"s3", options = JsonOptions("""{"path": "s3://aws-glue-ml-transforms-
data/sal"}"""), transformationContext = "datasink2", format =
"csv").writeDynamicFrame(single_partition)
    Job.commit()
}
}

```

6. Choose **Run job** to start the job run. Check the status of the job in the jobs list. When the job finishes, in the **ML transform, History** tab, there is a new **Run ID** row added of type **ETL job**.
7. Navigate to the **Jobs, History** tab. In this pane, job runs are listed. For more details about the run, choose **Logs**. Check that the run status is **Succeeded** when it finishes.

## Step 6: Verify output data from Amazon S3

In this step, you check the output of the job run in the Amazon S3 bucket that you chose when you added the job. You can download the output file to your local machine and verify that matching records were identified.

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. Download the target output file of the job demo-etl-db1p-acm. Open the file in a spreadsheet application (you might need to add a file extension `.csv` for the file to properly open).

The following image shows an excerpt of the output in Microsoft Excel.

	B	C	D	E	F	G	H	I
1	title	authors	venue	year	source	primary_id	match_id	match_confidence_score
2	Semantic Integration of Environmental Models for Application to Global Information S	D. Scott Mackay	SIGMOD Record	1999	DBLP	3092	0	0.830985237

The data source and target file both have 4,911 records. However, the Find matches transform adds another column named `match_id` to identify matching records in the output. Rows with the same `match_id` are considered matching records. The `match_confidence_score` is a number between 0 and 1 that provides an estimate of the quality of matches found by Find matches.

- Sort the output file by `match_id` to easily see which records are matches. Compare the values in the other columns to see if you agree with the results of the Find matches transform. If you don't, you can continue to teach the transform by adding more labels.

You can also sort the file by another field, such as `title`, to see if records with similar titles have the same `match_id`.

## Finding incremental matches

The Find matches feature allows you to identify duplicate or matching records in your dataset, even when the records don't have a common unique identifier and no fields match exactly. The initial release of the Find matches transform identified matching records within a single dataset. When you add new data to the dataset, you had to merge it with the existing clean dataset and rerun matching against the complete merged dataset.

The incremental matching feature makes it simpler to match to incremental records against existing matched datasets. Suppose that you want to match prospects data with existing customer datasets. The incremental match capability provides you the flexibility to match hundreds of thousands of new prospects with an existing database of prospects and customers by merging the results into a single database or table. By matching only between the new and existing datasets, the find incremental matches optimization reduces computation time, which also reduces cost.

The usage of incremental matching is similar to Find matches as described in [Tutorial: Creating a machine learning transform with AWS Glue](#). This topic identifies only the differences with incremental matching.

For more information, see the blog post on [Incremental data matching](#).

## Running an incremental matching job

For the following procedure, suppose the following:

- You have crawled the existing dataset into the table *first\_records*. The *first\_records* dataset must be a matched dataset, or the output of the matched job.
  - You have created and trained a Find matches transform with AWS Glue version 2.0. This is the only version of AWS Glue that supports incremental matches.
  - The ETL language is Scala. Note that Python is also supported.
  - The model already generated is called `demo-xform`.
1. Crawl the incremental dataset to the table *second\_records*.
  2. On the AWS Glue console, in the navigation pane, choose **Jobs**.
  3. Choose **Add job**, and follow the steps in the wizard to create an ETL Spark job with a generated script. Choose the following property values for your transform:
    - a. For **Name**, choose **demo-etl**.
    - b. For **IAM role**, choose an IAM role with permission to the Amazon S3 source data, labeling file, and [AWS Glue API operations](#).
    - c. For **ETL language**, choose **Scala**.
    - d. For **Script file name**, choose **demo-etl**. This is the file name of the Scala script.
    - e. For **Data source**, choose **first\_records**. The data source you choose must match the machine learning transform data source schema.
    - f. For **Transform type**, choose **Find matching records** to create a job using a machine learning transform.
    - g. Select the incremental matching option, and for **Data Source** select the table named **second\_records**.
    - h. For **Transform**, choose **demo-xform**, the machine learning transform used by the job.
    - i. Choose **Create tables in your data target** or **Use tables in the data catalog and update your data target**.

4. Choose **Save job and edit script** to display the script editor page.
5. Choose **Run job** to start the job run.

## Using FindMatches in a visual job

To use the **FindMatches** transform in AWS Glue Studio, you can use the **Custom Transform** node that invokes the FindMatches API. For more information on how to use a custom transform, see [Creating a custom transformation](#)

### Note

Currently, the FindMatches API only works with Glue 2.0. In order to run a job with the Custom transform that invokes the FindMatches API, ensure the AWS Glue version is Glue 2.0 in the **Job details** tab. If the version of AWS Glue is not Glue 2.0, the job will fail at runtime with the following error message: "cannot import name 'FindMatches' from 'awsglueml.transforms'".

## Prerequisites

- In order to use the **Find Matches** transform, open the AWS Glue Studio console at <https://console.aws.amazon.com/gluestudio/>.
- Create a machine learning transform. When created, a transformId is generated. You will need this ID for the steps below. For more information on how to create a machine learning transform, see [Adding and editing machine learning transforms](#).

## Adding a FindMatches transform

### To add a FindMatches transform:

1. In the AWS Glue Studio job editor, open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and choose a Data source by choosing the **Data tab**. This is the data source you want to check for matches.

2. Choose the data source node, then open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and search for 'custom transform'. Choose the **Custom Transform** node to add it to the graph. The **Custom Transform** is linked to the data source node. If it is not, you can click on the **Custom Transform** node and choose the **Node properties** tab, then under **Node parents**, choose the data source.
3. Click the **Custom Transform** node in the visual graph, then choose the **Node properties** tab and name the custom transform. It is recommended that you rename the transform so that the transform name is easily identifiable in the visual graph.
4. Choose the **Transform** tab, where you can edit the code block. This is where the code to invoke the FindMatches API can be added.

The screenshot displays the AWS Glue console interface. At the top, there are tabs for 'Visual', 'Script', 'Job details', 'Runs', 'Data quality New', 'Schedules', and 'Version Control'. The 'Visual' tab is active, showing a job graph with two nodes: 'Data source - S3 bucket Amazon S3' and 'Transform - Custom code ml transform'. A blue arrow points from the data source to the transform node. To the right of the graph is a 'Code block' editor with a search icon and a 'Transform' tab. The code block contains the following Python code:

```
1 - def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
2
```

The code block contains pre-populated code to get you started. Overwrite the pre-populated code with the template below. The template has a placeholder for the **transformId**, which you can provide.

```
def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
    dynf = dfc.select(list(dfc.keys())[0])
    from awsglueml.transforms import FindMatches
    findmatches = FindMatches.apply(frame = dynf, transformId = "<your id>")
    return(DynamicFrameCollection({"FindMatches": findmatches}, glueContext))
```

5. Click the **Custom Transform** node in the visual graph, then open the Resource panel by clicking on the cross symbol in the upper left-hand corner of the visual job graph and search for 'Select From Collection'. There is no need to change the default selection since there is only one DynamicFrame in the collection.

6. You can continue adding transformations or store the result, which is now enriched with the find matches additional columns. If you want to reference those new columns in downstream transforms, you need to add them to the transform output schema. the easiest way to do that is to choose the **Data preview** tab and then in the schema tab choose "Use datapreview schema".
7. To customize FindMatches, you can add additional parameters to pass to the 'apply' method. See [FindMatches class](#).

## Adding a FindMatches incrementally transformation

In the case of incremental matches, the process is the same as **Adding a FindMatches transformation** with the following differences:

- Instead of a parent node for the custom transform, you need two parent nodes.
- The first parent node should be the dataset.
- The second parent node should be the incremental dataset.

Replace the transformId with your transformId in the template code block:

```
def MyTransform (glueContext, dfc) -> DynamicFrameCollection:
    dfs = list(dfc.values())
    dynf = dfs[0]
    inc_dynf = dfs[1]
    from awsglueml.transforms import FindIncrementalMatches
    findmatches = FindIncrementalMatches.apply(existingFrame = dynf, incrementalFrame
    = inc_dynf,
                                           transformId = "<your id>")
    return(DynamicFrameCollection({"FindMatches": findmatches}, glueContext))
```

- For optional parameters, see [FindIncrementalMatches class](#).

## Migrate Apache Spark programs to AWS Glue

Apache Spark is an open-source platform for distributed computing workloads performed on large datasets. AWS Glue leverages Spark's capabilities to provide an optimized experience for ETL. You can migrate Spark programs to AWS Glue to take advantage of our features. AWS Glue provides the same performance enhancements you would expect from Apache Spark on Amazon EMR.

## Run Spark code

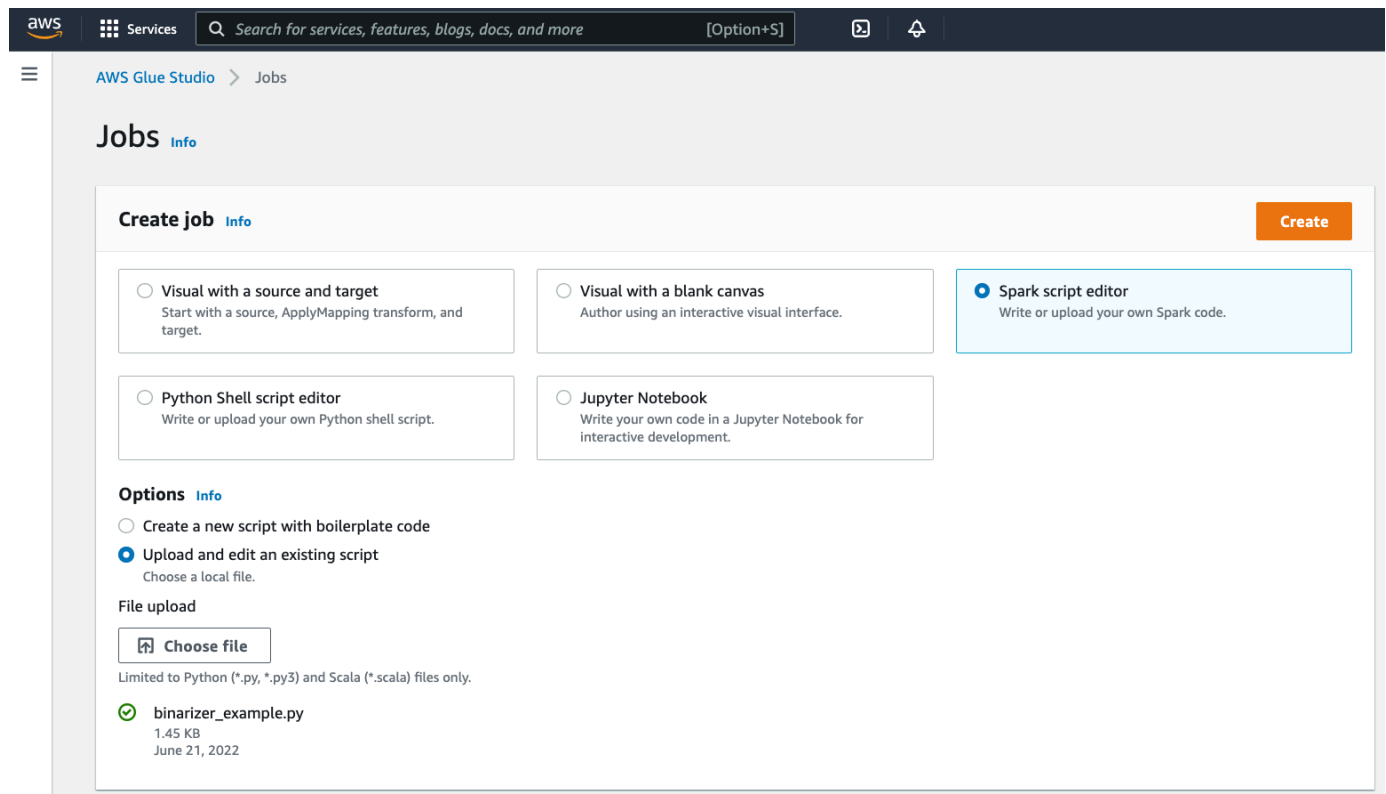

Native Spark code can be run in a AWS Glue environment out of the box. Scripts are often developed by iteratively changing a piece of code, a workflow suited for an Interactive Session. However, existing code is more suited to run in a AWS Glue job, which allows you to schedule and consistently get logs and metrics for each script run. You can upload and edit an existing script through the console.

1. Acquire the source to your script. For this example, you will use an example script from the Apache Spark repository. [Binarizer Example](#)
2. In the AWS Glue Console, expand the left-side navigation pane and select **ETL > Jobs**

In the **Create job** panel, select **Spark script editor**. An **Options** section will appear. Under **Options**, select **Upload and edit an existing script**.

A **File upload** section will appear. Under **File upload**, click **Choose file**. Your system file chooser will appear. Navigate to the location where you saved `binarizer_example.py`, select it and confirm your selection.

A **Create** button will appear on the header for the **Create job** panel. Click it.

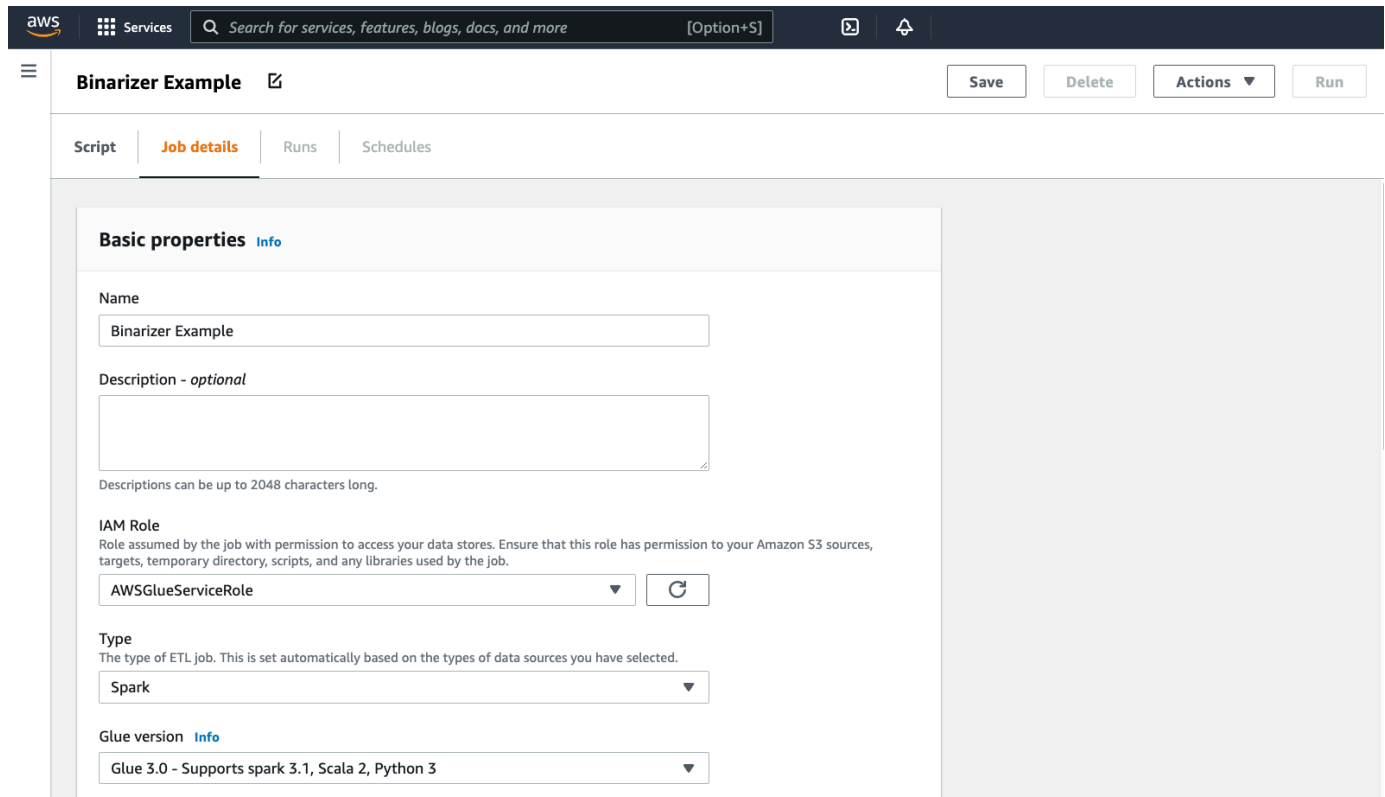

The screenshot shows the AWS Glue console interface for creating a job. At the top, there's a navigation bar with the AWS logo, 'Services', a search bar, and a keyboard shortcut '[Option+S]'. Below that, the breadcrumb 'AWS Glue Studio > Jobs' is visible. The main heading is 'Jobs Info'. The 'Create job Info' section has a 'Create' button in the top right. There are five options for creating a job: 'Visual with a source and target', 'Visual with a blank canvas', 'Spark script editor' (which is selected), 'Python Shell script editor', and 'Jupyter Notebook'. Below these is the 'Options Info' section with two options: 'Create a new script with boilerplate code' and 'Upload and edit an existing script' (which is selected). Under 'Upload and edit an existing script', there's a 'File upload' section with a 'Choose file' button. Below the button, it says 'Limited to Python (\*.py, \*.py3) and Scala (\*.scala) files only.' A file named 'binarizer\_example.py' (1.45 KB, June 21, 2022) is listed as uploaded.

3. Your browser will navigate to the script editor. On the header, click the **Job details** tab. Set the **Name** and **IAM Role**. For guidance around AWS Glue IAM roles, consult [the section called “Setting up IAM permissions”](#).

Optionally - set **Requested number of workers** to 2 and **Number of retries** to 1. These options are valuable when running production jobs, but turning them down will streamline your experience while testing out a feature.

In the title bar, click **Save**, then **Run**

The screenshot shows the AWS Glue console interface. At the top, there is a search bar with the text "Search for services, features, blogs, docs, and more" and a search icon. Below the search bar, the breadcrumb "Binarizer Example" is visible, along with buttons for "Save", "Delete", "Actions", and "Run". The "Job details" tab is selected, showing a form for configuring the job. The form includes the following fields:

- Name:** A text input field containing "Binarizer Example".
- Description - optional:** A text area for a description, with a note below it stating "Descriptions can be up to 2048 characters long."
- IAM Role:** A dropdown menu showing "AWSGlueServiceRole" and a refresh button.
- Type:** A dropdown menu showing "Spark".
- Glue version:** A dropdown menu showing "Glue 3.0 - Supports spark 3.1, Scala 2, Python 3".

4. Navigate to the **Runs** tab. You will see a panel corresponding to your job run. Wait a few minutes and the page should automatically refresh to show **Succeeded** under **Run status**.

**Binarizer Example** Last modified on 7/13/2022, 12:24:55 PM Save Delete Actions Run

Script | Job details | **Runs** | Schedules

**Recent job runs (1)** [Info](#) Refresh

< 1 >

July 13, 2022 12:24:58 PM Rewind job bookmark

Job name	Id	Run status	Glue version
Binarizer Example	<a href="#">jr_EXAMPLEID</a>	<span>✔ Succeeded</span>	3.0
Retry attempt number	Start time	End time	Start-up time
Initial run	July 13, 2022 12:24:58 PM	July 13, 2022 12:25:36 PM	7 seconds
Execution time	Last modified on	Trigger name	Security configuration
30 seconds	July 13, 2022 12:25:36 PM	-	-
Timeout	Max capacity	Number of workers	Worker type
2880 minutes	2 DPUs	2	G.1X
Execution class	Log group name	Cloudwatch logs	Performance and debugging recommendations
-	/aws-glue/jobs	<ul style="list-style-type: none"> <li><a href="#">All logs</a></li> <li><a href="#">Output logs</a></li> <li><a href="#">Error logs</a></li> </ul>	<ul style="list-style-type: none"> <li><a href="#">View in CloudWatch</a></li> </ul>

▶ **Input arguments (10)**  
Arguments used when this job run was executed.

- You will want to examine your output to confirm that the Spark script ran as intended. This Apache Spark sample script should write a string to the output stream. You can find that by navigating to **Output logs** under **Cloudwatch logs** in the panel for the successful job run. Note the job run id, a generated id under the **Id** label beginning with `jr_`.

This will open the CloudWatch console, set to visualize the contents of the default AWS Glue log group `/aws-glue/jobs/output`, filtered to the contents of the log streams for the job run id. Each worker will have generated a log stream, shown as rows under the **Log streams**. One worker should have run the requested code. You will need to open all the log streams to identify the correct worker. Once you find the right worker, you should see the output of the script, as seen in the following image:

The screenshot shows the AWS CloudWatch console interface. The breadcrumb navigation indicates the path: CloudWatch > Log groups > /aws-glue/jobs/output > jr\_EXAMPLEID. The main content area is titled "Log events" and includes a search bar, a "View as text" checkbox, and a "Create Metric Filter" button. Below this is a table of log events with columns for "Timestamp" and "Message".

Timestamp	Message
	No older events at this moment. <a href="#">Retry</a>
2022-07-13T13:27:33.060-07:00	2022-07-13 20:27:33,058 main WARN JNDI lookup class is not available because...

At the bottom of the log events section, it states: "No newer events at this moment. Auto retry paused. [Resume](#)".

## Common procedures needed for migrating Spark programs

### Assess Spark version support

AWS Glue release versions define the version of Apache Spark and Python available to the AWS Glue job. You can find our AWS Glue versions and what they support at [the section called "AWS Glue versions"](#). You may need to update your Spark program to be compatible with a newer version of Spark in order to access certain AWS Glue features.

### Include third-party libraries

Many existing Spark programs will have dependencies, both on private and public artifacts. AWS Glue supports JAR style dependencies for Scala Jobs as well as Wheel and source pure-Python dependencies for Python jobs.

**Python** - For information about Python dependencies, see [the section called "Python libraries"](#)

Common Python dependencies are provided in the AWS Glue environment, including the commonly requested [Pandas](#) library. Dependencies are included in AWS Glue Version 2.0+. For more information about provided modules, see [the section called "Python modules already provided in AWS Glue"](#). If you need to supply a Job with a different version of a dependency

included by default, you can use `--additional-python-modules`. For information about job arguments, see [the section called “Job parameters”](#).

You can supply additional Python dependencies with the `--extra-py-files` job argument. If you are migrating a job from a Spark program, this parameter is a good option because it is functionally equivalent to the `--py-files` flag in PySpark, and is subject to the same limitations. For more information about the `--extra-py-files` parameter, see [the section called “Including Python files with PySpark native features”](#)

For new jobs, you can manage Python dependencies with the `--additional-python-modules` job argument. Using this argument allows for a more thorough dependency management experience. This parameter supports Wheel style dependencies, including those with native code bindings compatible with Amazon Linux 2.

## Scala

You can supply additional Scala dependencies with the `--extra-jars` Job Argument. Dependencies must be hosted in Amazon S3 and the argument value should be a comma delimited list of Amazon S3 paths with no spaces. You may find it easier to manage your configuration by rebundling your dependencies before hosting and configuring them. AWS Glue JAR dependencies contain Java bytecode, which can be generated from any JVM language. You can use other JVM languages, such as Java, to write custom dependencies.

## Manage data source credentials

Existing Spark programs may come with complex or custom configuration to pull data from their datasources. Common datasource auth flows are supported by AWS Glue connections. For more information about AWS Glue connections, see [Connecting to data](#).

AWS Glue connections facilitate connecting your Job to a variety of types of data stores in two primary ways: through method calls to our libraries and setting the **Additional network connection** in the AWS console. You may also call the AWS SDK from within your job to retrieve information from a connection.

**Method calls** – AWS Glue Connections are tightly integrated with the AWS Glue Data Catalog, a service that allows you to curate information about your datasets, and the methods available to interact with AWS Glue connections reflect that. If you have an existing auth configuration you would like to reuse, for JDBC connections, you can access your AWS Glue connection configuration through the `extract_jdbc_conf` method on the `GlueContext`. For more information, see [the section called “extract\\_jdbc\\_conf”](#)

**Console configuration** – AWS Glue Jobs use associated AWS Glue connections to configure connections to Amazon VPC subnets. If you directly manage your security materials, you may need to provide a NETWORK type **Additional network connection** in the AWS console to configure routing. For more information about the AWS Glue connection API, see [the section called “Connections”](#)

If your Spark programs has a custom or uncommon auth flow, you may need to manage your security materials in a hands-on fashion. If AWS Glue connections do not seem like a good fit, you can securely host security materials in Secrets Manager and access them through the boto3 or AWS SDK, which are provided in the job.

## Configure Apache Spark

Complex migrations often alter Spark configuration to accommodate their workloads. Modern versions of Apache Spark allow runtime configuration to be set with the `SparkSession`. AWS Glue 3.0+ Jobs are provided a `SparkSession`, which can be modified to set runtime configuration. [Apache Spark Configuration](#). Tuning Spark is complex, and AWS Glue does not guarantee support for setting all Spark configuration. If your migration requires substantial Spark-level configuration, contact support.

## Set custom configuration

Migrated Spark programs may be designed to take custom configuration. AWS Glue allows configuration to be set on the job and job run level, through the job arguments. For information about job arguments, see [the section called “Job parameters”](#). You can access job arguments within the context of a job through our libraries. AWS Glue provides a utility function to provide a consistent view between arguments set on the job and arguments set on the job run. See [the section called “getResolvedOptions”](#) in Python and [the section called “GlueArgParser”](#) in Scala.

## Migrate Java code

As explained in [the section called “Third-party libraries”](#), your dependencies can contain classes generated by JVM languages, such as Java or Scala. Your dependencies can include a `main` method. You can use a `main` method in a dependency as the entrypoint for a AWS Glue Scala job. This allows you to write your `main` method in Java, or reuse a `main` method packaged to your own library standards.

To use a `main` method from a dependency, perform the following: Clear the contents of the editing pane providing the default `GlueApp` object. Provide the fully qualified name of a class in a dependency as a job argument with the key `--class`. You should then be able to trigger a Job run.

You cannot configure the order or structure of the arguments AWS Glue passes to the main method. If your existing code needs to read configuration set in AWS Glue, this will likely cause incompatibility with prior code. If you use `getResolvedOptions`, you will also not have a good place to call this method. Consider invoking your dependency directly from a main method generated by AWS Glue. The following AWS Glue ETL script shows an example of this.

```
import com.amazonaws.services.glue.util.GlueArgParser

object GlueApp {
  def main(sysArgs: Array[String]) {
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)

    // Invoke static method from JAR. Pass some sample arguments as a String[], one
    // defined inline and one taken from the job arguments, using getResolvedOptions
    com.mycompany.myproject.MyClass.myStaticPublicMethod(Array("string parameter1",
    args("JOB_NAME")))

    // Alternatively, invoke a non-static public method.
    (new com.mycompany.myproject.MyClass).someMethod()
  }
}
```

## Working with Ray jobs in AWS Glue

This section provides information about using AWS Glue for Ray jobs. For more information about writing AWS Glue for Ray scripts, consult the [the section called “AWS Glue for Ray”](#) section.

### Topics

- [Getting started with AWS Glue for Ray](#)
- [Supported Ray runtime environments](#)
- [Accounting for workers in Ray jobs](#)
- [Using job parameters in Ray jobs](#)
- [Monitoring Ray jobs with metrics](#)

## Getting started with AWS Glue for Ray

To work with AWS Glue for Ray, you use the same AWS Glue jobs and interactive sessions that you use with AWS Glue for Spark. AWS Glue jobs are designed for running the same script on

a recurring cadence, while interactive sessions are designed to let you run snippets of code sequentially against the same provisioned resources.

AWS Glue ETL and Ray are different underneath, so in your script, you have access to different tools, features, and configuration. As a new computation framework managed by AWS Glue, Ray has a different architecture and uses different vocabulary to describe what it does. For more information, see [Architecture Whitepapers](#) in the Ray documentation.

### Note

AWS Glue for Ray is available in US East (N. Virginia), US East (Ohio), US West (Oregon), Asia Pacific (Tokyo), and Europe (Ireland).

## Ray jobs in the AWS Glue Studio console

On the **Jobs** page in the AWS Glue Studio console, you can select a new option when you're creating a job in AWS Glue Studio—**Ray script editor**. Choose this option to create a Ray job in the console. For more information about jobs and how they're used, see [Building visual ETL jobs with AWS Glue Studio](#).

The screenshot shows the 'Jobs' page in the AWS Glue Studio console. At the top, there is a breadcrumb 'AWS Glue Studio > Jobs'. Below that is the 'Jobs' header with an 'Info' link. The main content area is titled 'Create job' with an 'Info' link and a 'Create' button. There are six radio button options for creating a job:

- Visual with a source and target  
Start with a source, ApplyMapping transform, and target.
- Visual with a blank canvas  
Author using an interactive visual interface.
- Spark script editor  
Write or upload your own Spark code.
- Python Shell script editor  
Write or upload your own Python shell script.
- Jupyter Notebook  
Write your own code in a Jupyter Notebook for interactive development.
- Ray script editor **New**  
Write your own code to run on Ray.

Below the options is an 'Options' section with an 'Info' link and two radio button options:

- Create a new script with boilerplate code
- Upload and edit an existing script  
Choose a local file.

## Ray jobs in the AWS CLI and SDK

Ray jobs in the AWS CLI use the same SDK actions and parameters as other jobs. AWS Glue for Ray introduces new values for certain parameters. For more information in the Jobs API, see [the section called "Jobs"](#).

## Supported Ray runtime environments

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python available in an AWS Glue for Spark job. The Python version indicates the version that is supported for jobs of type Spark. This is not how Ray runtime environments are configured.

For Ray jobs, you should set `GlueVersion` to `4.0` or greater. However, the versions of Ray, Python, and additional libraries that are available in your Ray job are determined by the `Runtime` field in the job definition.

The `Ray2.4` runtime environment will be available for a minimum of 6 months after release. As Ray rapidly evolves, you will be able to incorporate Ray updates and improvements through future runtime environment releases.

Valid values: `Ray2.4`

Runtime value	Ray and Python versions
<code>Ray2.4</code> (for AWS Glue 4.0+)	Ray 2.4.0 Python 3.9

### Additional information

- For release notes that accompany AWS Glue on Ray releases, see [the section called “AWS Glue versions”](#).
- For Python libraries that are provided in a runtime environment, see [the section called “Modules provided with Ray jobs”](#).

## Accounting for workers in Ray jobs

AWS Glue runs Ray jobs on new Graviton-based EC2 worker types, which are only available for Ray jobs. To appropriately provision these workers for the workloads Ray is designed for, we provide a different ratio of compute resources to memory resources from most workers. In order to account for these resources, we use the memory-optimized data processing unit (M-DPU) rather than the standard data processing unit (DPU).

- One M-DPU corresponds to 4 vCPUs and 32 GB of memory.

- One DPU corresponds to 4 vCPUs and 16 GB of memory. DPUs are used to account for resources in AWS Glue with Spark jobs and corresponding workers.

Ray jobs currently have access to one worker type, Z.2X. The Z.2X worker maps to 2 M-DPUs (8 vCPUs, 64 GB of memory) and has 128 GB of disk space. A Z.2X machine provides 8 Ray workers (one per vCPU).

The number of M-DPUs that you can use concurrently in an account is subject to a service quota. For more information about your AWS Glue account limits, see [AWS Glue endpoints and quotas](#).

You specify the number of worker nodes that are available to a Ray job with `--number-of-workers` (`NumberOfWorkers`) in the job definition. For more information about Ray values in the Jobs API, see [the section called "Jobs"](#).

You can further specify a minimum number of workers that a Ray job must allocate with the `--min-workers` job parameter. For more information about job parameters, see [the section called "Reference"](#).

## Using job parameters in Ray jobs

You set arguments for AWS Glue Ray jobs the same way you set arguments for AWS Glue for Spark jobs. For more information about the AWS Glue API, see [the section called "Jobs"](#). You can configure AWS Glue Ray jobs with different arguments, which are listed in this reference. You can also provide your own arguments.

You can configure a job through the console, on the **Job details** tab, under the **Job Parameters** heading. You can also configure a job through the AWS CLI by setting `DefaultArguments` on a job, or setting `Arguments` on a job run. Default arguments and job parameters stay with the job through multiple runs.

For example, the following is the syntax for running a job using `--arguments` to set a special parameter.

```
$ aws glue start-job-run --job-name "CSV to CSV" --arguments='--scriptLocation="s3://my_glue/libraries/test_lib.py",--test-environment="true"'
```

After you set the arguments, you can access job parameters from within your Ray job through environment variables. This gives you a way to configure your job for each run. The name of the environment variable will be the job argument name without the `--` prefix.

For instance, in the previous example, the variable names would be `scriptLocation` and `test-environment`. You would then retrieve the argument through methods available in the standard library: `test_environment = os.environ.get('test-environment')`. For more information about accessing environment variables with Python, see [os module](#) in the Python documentation.

## Configure how Ray jobs generate logs

By default, Ray jobs generate logs and metrics that are sent to CloudWatch and Amazon S3. You can use the `--logging_configuration` parameter to alter how logs are generated, currently you can use it to stop Ray jobs from generating various types of logs. This parameter takes a JSON object, whose keys correspond to the logs/behaviors you would like to alter. It supports the following keys:

- `CLOUDWATCH_METRICS` – Configures CloudWatch metrics series that can be used to visualize job health. For more information about metrics, see [the section called “Ray job metrics”](#).
- `CLOUDWATCH_LOGS` – Configures CloudWatch logs that provide Ray application level details about the status the job run. For more information about logs, see [the section called “Troubleshooting Ray errors”](#).
- `S3` – Configures what AWS Glue writes to Amazon S3, primarily similar information to CloudWatch logs but as files rather than log streams.

To disable a Ray logging behavior, provide the value `{"IS_ENABLED": "False"}`. For example, to disable CloudWatch metrics and CloudWatch logs, provide the following configuration:

```
--logging_configuration: "{\"CLOUDWATCH_METRICS\": {\"IS_ENABLED\": \"False\"},  
  \"CLOUDWATCH_LOGS\": {\"IS_ENABLED\": \"False\"}}"
```

## Reference

Ray jobs recognize the following argument names that you can use to set up the script environment for your Ray jobs and job runs:

- `--logging_configuration` – Used to stop the generation of various logs created by Ray jobs. These logs are generated by default on all Ray jobs. Format: String-escaped JSON object. For more information, see [the section called “Configure how Ray jobs generate logs”](#).
- `--min-workers` – The minimum number of worker nodes that are allocated to a Ray job. A worker node can run multiple replicas, one per virtual CPU. Format: integer. Minimum: 0.

Maximum: value specified in `--number-of-workers` (`NumberOfWorkers`) on the job definition. For more information about accounting for worker nodes, see [the section called "Accounting for workers in Ray jobs"](#).

- `--object_spilling_config` – AWS Glue for Ray supports using Amazon S3 as a way of extending the space available to Ray's object store. To enable this behavior, you can provide Ray an *object\_spilling* JSON config object with this parameter. For more information about Ray object spilling configuration, see [Object Spilling](#) in the Ray documentation. Format: JSON object.

AWS Glue for Ray only supports spilling to disk or spilling to Amazon S3 at once. You can provide multiple locations for spilling, as long as they respect this limitation. When spilling to Amazon S3, you will also need to add IAM permissions to your job for this bucket.

When providing a JSON object as configuration with the CLI, you must provide it as a string, with the JSON object string-escaped. For example, a string value for spilling to one Amazon S3 path would look like: `"{"type": "smart_open", "params": {"uri": "s3path"}}`. In AWS Glue Studio, provide this parameter as a JSON object with no extra formatting.

- `--object_store_memory_head` – The memory allocated to the Plasma object store on the Ray head node. This instance runs cluster management services, as well as worker replicas. The value represents a percentage of free memory on the instance after a warm start. You use this parameter to tune memory intensive workloads—defaults are acceptable for most use cases. Format: positive integer. Minimum: 1. Maximum: 100.

For more information about Plasma, see [The Plasma In-Memory Object Store](#) in the Ray documentation.

- `--object_store_memory_worker` – The memory allocated to the Plasma object store on the Ray worker nodes. These instances only run worker replicas. The value represents a percentage of free memory on the instance after a warm start. This parameter is used to tune memory intensive workloads—defaults are acceptable for most use cases. Format: positive integer. Minimum: 1. Maximum: 100.

For more information about Plasma, see [The Plasma In-Memory Object Store](#) in the Ray documentation.

- `--pip-install` – A set of Python packages to be installed. You can install packages from PyPI using this argument. Format: comma-delimited list.

A PyPI package entry is in the format `package==version`, with the PyPI name and version of your target package. Entries use Python version matching to match the package and version, such as `==`, not the single equals `=`. There are other version-matching operators. For more information, see [PEP 440](#) on the Python website. You can also provide custom modules with `--s3-py-modules`.

- `--s3-py-modules` – A set of Amazon S3 paths that host Python module distributions. Format: comma-delimited list.

You can use this to distribute your own modules to your Ray job. You can also provide modules from PyPI with `--pip-install`. Unlike with AWS Glue ETL, custom modules are not set up through pip, but are passed to Ray for distribution. For more information, see [the section called “Additional Python modules for Ray jobs”](#).

- `--working-dir` – A path to a .zip file hosted in Amazon S3 that contains files to be distributed to all nodes running your Ray job. Format: string. For more information, see [the section called “Providing files to your Ray job”](#).

## Monitoring Ray jobs with metrics

You can monitor Ray jobs using AWS Glue Studio and Amazon CloudWatch. CloudWatch collects and processes raw metrics from AWS Glue with Ray, which makes them available for analysis. These metrics are visualized in the AWS Glue Studio console, so you can monitor your job as it runs.

For a general overview of how to monitor AWS Glue, see [the section called “Using CloudWatch metrics”](#). For a general overview of how to use CloudWatch metrics that are published by AWS Glue, see [the section called “Monitoring with CloudWatch”](#).

## Monitoring Ray jobs in the AWS Glue console

On the details page for a job run, below the **Run details** section, you can view pre-built aggregated graphs that visualize your available job metrics. AWS Glue Studio sends job metrics to CloudWatch for every job run. With these, you can build a profile of your cluster and tasks, as well as access detailed information about each node.

For more information about available metrics graphs, see [the section called “Viewing Amazon CloudWatch metrics for a Ray job run”](#).

## Overview of Ray jobs metrics in CloudWatch

We publish Ray metrics when detailed monitoring is enabled in CloudWatch. Metrics are published to the `Glue/Ray` CloudWatch namespace.

- **Instance metrics**

We publish metrics about the CPU, memory and disk utilization of instances assigned to a job. These metrics are identified by features such as `ExecutorId`, `ExecutorType` and `host`. These metrics are a subset of the standard Linux CloudWatch agent metrics. You can find information about metric names and features in the CloudWatch documentation. For more information, see [Metrics collected by the CloudWatch agent](#).

- **Ray cluster metrics**

We forward metrics from the Ray processes that run your script to this namespace, then provide those most critical for you. The metrics that are available might differ by Ray version. For more information about which Ray version your job is running, see [the section called "AWS Glue versions"](#).

Ray collects metrics at the instance level. It also provides metrics for tasks and the cluster. For more information about Ray's underlying metric strategy, see [Metrics](#) in the Ray documentation.

 **Note**

We don't publish Ray metrics to the `Glue/Job Metrics/` namespace, which is only used for AWS Glue ETL jobs.

## Configuring job properties for Python shell jobs in AWS Glue

You can use a Python shell job to run Python scripts as a shell in AWS Glue. With a Python shell job, you can run scripts that are compatible with Python 3.6 or Python 3.9.

### Topics

- [Limitations](#)
- [Defining job properties for Python shell jobs](#)
- [Supported libraries for Python shell jobs](#)

- [Providing your own Python library](#)
- [Use AWS CloudFormation with Python shell jobs in AWS Glue](#)

## Limitations

Note the following limitations of Python Shell jobs:

- You can't use job bookmarks with Python shell jobs.
- You can't package any Python libraries as `.egg` files in Python 3.9+. Instead, use `.whl`.
- The `--extra-files` option cannot be used, because of a limitation on temporary copies of S3 data.

## Defining job properties for Python shell jobs

These sections describe defining job properties in AWS Glue Studio, or using the AWS CLI.

### AWS Glue Studio

When you define your Python shell job in AWS Glue Studio, you provide some of the following properties:

#### IAM role

Specify the AWS Identity and Access Management (IAM) role that is used for authorization to resources that are used to run the job and access data stores. For more information about permissions for running jobs in AWS Glue, see [Identity and access management for AWS Glue](#).

#### Type

Choose **Python shell** to run a Python script with the job command named `pythonshell`.

#### Python version

Choose the Python version. The default is Python 3.9. Valid versions are Python 3.6 and Python 3.9.

#### Load common analytics libraries (Recommended)

Choose this option to include common libraries for Python 3.9 in the Python shell.

If your libraries are either custom or they conflict with the pre-installed ones, you can choose not to install common libraries. However, you can install additional libraries besides the common libraries.

When you select this option, the `library-set` option is set to `analytics`. When you de-select this option, the `library-set` option is set to `none`.

## Script filename and Script path

The code in the script defines your job's procedural logic. You provide the script name and location in Amazon Simple Storage Service (Amazon S3). Confirm that there isn't a file with the same name as the script directory in the path. To learn more about using scripts, see [AWS Glue programming guide](#).

## Script

The code in the script defines your job's procedural logic. You can code the script in Python 3.6 or Python 3.9. You can edit a script in AWS Glue Studio.

## Data processing units

The maximum number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see [AWS Glue pricing](#).

You can set the value to 0.0625 or 1. The default is 0.0625. In either case, the local disk for the instance will be 20GB.

## CLI

You can also create a **Python shell** job using the AWS CLI, as in the following example.

```
aws glue create-job --name python-job-cli --role Glue_DefaultRole
  --command '{"Name" : "pythonshell", "PythonVersion": "3.9", "ScriptLocation" :
"s3://DOC-EXAMPLE-BUCKET/scriptname.py"}'
  --max-capacity 0.0625
```

**Note**

You don't need to specify the version of AWS Glue since the parameter `--glue-version` doesn't apply for AWS Glue shell jobs. Any version specified will be ignored.

Jobs that you create with the AWS CLI default to Python 3. Valid Python versions are 3 (corresponding to 3.6), and 3.9. To specify Python 3.6, add this tuple to the `--command` parameter: `"PythonVersion": "3"`

To specify Python 3.9, add this tuple to the `--command` parameter: `"PythonVersion": "3.9"`

To set the maximum capacity used by a Python shell job, provide the `--max-capacity` parameter. For Python shell jobs, the `--allocated-capacity` parameter can't be used.

## Supported libraries for Python shell jobs

In Python shell using Python 3.9, you can choose the library set to use pre-packaged library sets for your needs. You can use the `library-set` option to choose the library set. Valid values are `analytics`, and `none`.

The environment for running a Python shell job supports the following libraries:

Python version	Python 3.6	Python 3.9	
Library set	N/A	analytics	none
avro		1.11.0	
awscli	116.242	1.23.5	1.23.5
awswrangler		2.15.1	
botocore	1.12.232	1.24.21	1.23.5
boto3	1.9.203	1.21.21	
elasticsearch		8.2.0	
numpy	1.16.2	1.22.3	

Python version	Python 3.6	Python 3.9	
pandas	0.24.2	1.4.2	
psycopg2		2.9.3	
pyathena		2.5.3	
PyGreSQL	5.0.6		
PyMySQL		1.0.2	
pyodbc		4.0.32	
pyorc		0.6.0	
redshift-connector		2.0.907	
requests	2.22.0	2.27.1	
scikit-learn	0.20.3	1.0.2	
scipy	1.2.1	1.8.0	
SQLAlchemy		1.4.36	
s3fs		2022.3.0	

You can use the NumPy library in a Python shell job for scientific computing. For more information, see [NumPy](#). The following example shows a NumPy script that can be used in a Python shell job. The script prints "Hello world" and the results of several mathematical calculations.

```
import numpy as np
print("Hello world")

a = np.array([20,30,40,50])
print(a)

b = np.arange( 4 )
```

```
print(b)

c = a-b

print(c)

d = b**2

print(d)
```

## Providing your own Python library

### Using PIP

Python shell using Python 3.9 lets you provide additional Python modules or different versions at the job level. You can use the `--additional-python-modules` option with a list of comma-separated Python modules to add a new module or change the version of an existing module. You cannot provide custom Python modules hosted on Amazon S3 with this parameter when using Python shell jobs.

For example to update or to add a new `scikit-learn` module use the following key and value: `--additional-python-modules", "scikit-learn==0.21.3"`.

AWS Glue uses the Python Package Installer (`pip3`) to install the additional modules. You can pass additional `pip3` options inside the `--additional-python-modules` value. For example, `"scikit-learn==0.21.3 -i https://pypi.python.org/simple/"`. Any incompatibilities or limitations from `pip3` apply.

#### Note

To avoid incompatibilities in the future, we recommend that you use libraries built for Python 3.9.

### Using an Egg or Whl file

You might already have one or more Python libraries packaged as an `.egg` or a `.whl` file. If so, you can specify them to your job using the AWS Command Line Interface (AWS CLI) under the `--extra-py-files` flag, as in the following example.

```
aws glue create-job --name python-redshift-test-cli --role role --command '{"Name" :
"pythonshell", "ScriptLocation" : "s3://MyBucket/python/library/redshift_test.py"}'
--connections Connections=connection-name --default-arguments '{"--extra-py-
files" : ["s3://DOC-EXAMPLE-BUCKET/EGG-FILE", "s3://DOC-EXAMPLE-BUCKET/WHEEL-FILE"]}'
```

If you aren't sure how to create an `.egg` or a `.whl` file from a Python library, use the following steps. This example is applicable on macOS, Linux, and Windows Subsystem for Linux (WSL).

### To create a Python `.egg` or `.whl` file

1. Create an Amazon Redshift cluster in a virtual private cloud (VPC), and add some data to a table.
2. Create an AWS Glue connection for the VPC-SecurityGroup-Subnet combination that you used to create the cluster. Test that the connection is successful.
3. Create a directory named `redshift_example`, and create a file named `setup.py`. Paste the following code into `setup.py`.

```
from setuptools import setup

setup(
    name="redshift_module",
    version="0.1",
    packages=['redshift_module']
)
```

4. In the `redshift_example` directory, create a `redshift_module` directory. In the `redshift_module` directory, create the files `__init__.py` and `pygresql_redshift_common.py`.
5. Leave the `__init__.py` file empty. In `pygresql_redshift_common.py`, paste the following code. Replace `port`, `db_name`, `user`, and `password_for_user` with details specific to your Amazon Redshift cluster. Replace `table_name` with the name of the table in Amazon Redshift.

```
import pg

def get_connection(host):
    rs_conn_string = "host=%s port=%s dbname=%s user=%s password=%s" % (
        host, port, db_name, user, password_for_user)
```

```

rs_conn = pg.connect(dbname=rs_conn_string)
rs_conn.query("set statement_timeout = 1200000")
return rs_conn

def query(con):
    statement = "Select * from table_name;"
    res = con.query(statement)
    return res

```

6. If you're not already there, change to the `redshift_example` directory.
7. Do one of the following:
  - To create an `.egg` file, run the following command.

```
python setup.py bdist_egg
```

- To create a `.whl` file, run the following command.

```
python setup.py bdist_wheel
```

8. Install the dependencies that are required for the preceding command.
9. The command creates a file in the `dist` directory:
  - If you created an egg file, it's named `redshift_module-0.1-py2.7.egg`.
  - If you created a wheel file, it's named `redshift_module-0.1-py2.7-none-any.whl`.

Upload this file to Amazon S3.

In this example, the uploaded file path is either `s3://DOC-EXAMPLE-BUCKET/EGG-FILE` or `s3://DOC-EXAMPLE-BUCKET/WHEEL-FILE`.

10. Create a Python file to be used as a script for the AWS Glue job, and add the following code to the file.

```

from redshift_module import pygresql_redshift_common as rs_common

con1 = rs_common.get_connection(redshift_endpoint)
res = rs_common.query(con1)

```

```
print "Rows in the table cities are: "

print res
```

11. Upload the preceding file to Amazon S3. In this example, the uploaded file path is `s3://DOC-EXAMPLE-BUCKET/scriptname.py`.
12. Create a Python shell job using this script. On the AWS Glue console, on the **Job properties** page, specify the path to the `.egg/.whl` file in the **Python library path** box. If you have multiple `.egg/.whl` files and Python files, provide a comma-separated list in this box.

When modifying or renaming `.egg` files, the file names must use the default names generated by the "python setup.py bdist\_egg" command or must adhere to the Python module naming conventions. For more information, see the [Style Guide for Python Code](#).

Using the AWS CLI, create a job with a command, as in the following example.

```
aws glue create-job --name python-redshift-test-cli --role Role --command
'{"Name" : "pythonshell", "ScriptLocation" : "s3://DOC-EXAMPLE-BUCKET/
scriptname.py"}'
    --connections Connections="connection-name" --default-arguments '{"--extra-
py-files" : ["s3://DOC-EXAMPLE-BUCKET/EGG-FILE", "s3://DOC-EXAMPLE-BUCKET/WHEEL-
FILE"]}'
```

When the job runs, the script prints the rows created in the `table_name` table in the Amazon Redshift cluster.

## Use AWS CloudFormation with Python shell jobs in AWS Glue

You can use AWS CloudFormation with Python shell jobs in AWS Glue. The following is an example:

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  Python39Job:
    Type: 'AWS::Glue::Job'
    Properties:
      Command:
        Name: pythonshell
        PythonVersion: '3.9'
```

```
ScriptLocation: 's3://bucket/location'  
MaxRetries: 0  
Name: python-39-job  
Role: RoleName
```

The Amazon CloudWatch Logs group for Python shell jobs output is `/aws-glue/python-jobs/output`. For errors, see the log group `/aws-glue/python-jobs/error`.

## Monitoring AWS Glue

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS Glue and your other AWS solutions. AWS provides monitoring tools that you can use to watch AWS Glue, report when something is wrong, and take action automatically when appropriate:

You can use the following automated monitoring tools to watch AWS Glue and report when something is wrong:

- **Amazon CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events enables automated event-driven computing. You can write rules that watch for certain events and trigger automated actions in other AWS services when these events occur. For more information, see the [Amazon CloudWatch Events User Guide](#).
- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](#).
- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts call AWS, the source IP address from which the calls are made, and when the calls occur. For more information, see the [AWS CloudTrail User Guide](#).

Additionally, you have access to the following insights in the AWS Glue console to help you debug and profile jobs:

- Spark jobs – you can see a visualization of selected CloudWatch metrics series, and newer jobs have access to the Spark UI. For more information, see [the section called “Monitoring Spark jobs”](#).

- Ray jobs – you can see a visualization of selected CloudWatch metrics series. For more information, see [the section called “Ray job metrics”](#).

## Topics

- [AWS tags in AWS Glue](#)
- [Automating AWS Glue with CloudWatch Events](#)
- [AWS Glue resource monitoring](#)
- [Logging AWS Glue API calls with AWS CloudTrail](#)

## AWS tags in AWS Glue

To help you manage your AWS Glue resources, you can optionally assign your own tags to some AWS Glue resource types. A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define. You can use tags in AWS Glue to organize and identify your resources. Tags can be used to create cost accounting reports and restrict access to resources. If you're using AWS Identity and Access Management, you can control which users in your AWS account have permission to create, edit, or delete tags. In addition to the permissions to call the tag-related APIs, you also need the `glue:GetConnection` permission to call tagging APIs on connections, and the `glue:GetDatabase` permission to call tagging APIs on databases. For more information, see [ABAC with AWS Glue](#).

In AWS Glue, you can tag the following resources:

- Connection
- Database
- Crawler
- Interactive session
- Development endpoint
- Job
- Trigger
- Workflow
- Blueprint
- Machine learning transform
- Data quality ruleset

- Stream schemas
- Stream schema registries

**Note**

As a best practice, to allow tagging of these AWS Glue resources, always include the `glue:TagResource` action in your policies.

Consider the following when using tags with AWS Glue.

- A maximum of 50 tags are supported per entity.
- In AWS Glue, you specify tags as a list of key-value pairs in the format `{"string": "string" ...}`
- When you create a tag on an object, the tag key is required, and the tag value is optional.
- The tag key and tag value are case sensitive.
- The tag key and the tag value must not contain the prefix `aws`. No operations are allowed on such tags.
- The maximum tag key length is 128 Unicode characters in UTF-8. The tag key must not be empty or null.
- The maximum tag value length is 256 Unicode characters in UTF-8. The tag value may be empty or null.

## Tagging support for AWS Glue connections

You can restrict `CreateConnection`, `UpdateConnection`, `GetConnection` and, `DeleteConnection` action permission based on the resource tag. This enables you to implement the least privilege access control on AWS Glue jobs with JDBC data sources which need to fetch JDBC connection information from the Data Catalog.

### Example usage

Create an AWS Glue connection with the tag `["connection-category", "dev-test"]`.

Specify the tag condition for the `GetConnection` action in the IAM policy.

```
{
```

```

"Effect": "Allow",
"Action": [
  "glue:GetConnection"
],
"Resource": "*",
"Condition": {
  "ForAnyValue:StringEquals": {
    "aws:ResourceTag/tagKey": "dev-test"
  }
}
}

```

## Examples

The following examples create a job with assigned tags.

### AWS CLI

```

aws glue create-job --name job-test-tags --role MyJobRole --command
  Name=glueet1,ScriptLocation=S3://aws-glue-scripts//prod-job1
--tags key1=value1,key2=value2

```

### AWS CloudFormation JSON

For information about how to control access using tags, see [ABAC with AWS Glue](#).

## Automating AWS Glue with CloudWatch Events

You can use Amazon CloudWatch Events to automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to CloudWatch Events in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule. The actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an Amazon SQS queue

Some examples of using CloudWatch Events with AWS Glue include the following:

- Activating a Lambda function when an ETL job succeeds
- Notifying an Amazon SNS topic when an ETL job fails

The following CloudWatch Events are generated by AWS Glue.

- Events for "detail-type": "Glue Job State Change" are generated for SUCCEEDED, FAILED, TIMEOUT, and STOPPED.
- Events for "detail-type": "Glue Job Run Status" are generated for RUNNING, STARTING, and STOPPING job runs when they exceed the job delay notification threshold. You must set the job delay notification threshold property to receive these events.

Only one event is generated per job run status when the job delay notification threshold is exceeded.

- Events for "detail-type":"Glue Crawler State Change" are generated for Started, Succeeded, and Failed.
- Events for "detail-type":"Glue Data Catalog Database State Change" are generated for CreateDatabase, DeleteDatabase, CreateTable, DeleteTable and BatchDeleteTable. For example, if a table is created or deleted, a notification is sent to CloudWatch Events. Note that you cannot write a program that depends on the order or existence of notification events, as they might be out of sequence or missing. Events are emitted on a best effort basis. In the details of the notification:
  - The typeOfChange contains the name of the API operation.
  - The databaseName contains the name of the affected database.
  - The changedTables contains up to 100 names of affected tables per notification. When table names are long, multiple notifications might be created.
- Events for "detail-type":"Glue Data Catalog Table State Change" are generated for UpdateTable, CreatePartition, BatchCreatePartition, UpdatePartition, DeletePartition, BatchUpdatePartition and BatchDeletePartition. For example, if a table or partition is updated, a notification is sent to CloudWatch Events. Note that you cannot write a program that depends on the order or existence of notification events, as they might be out of sequence or missing. Events are emitted on a best effort basis. In the details of the notification:
  - The typeOfChange contains the name of the API operation.
  - The databaseName contains the name of the database that contains the affected resources.
  - The tableName contains the name of the affected table.
  - The changedPartitions specifies up to 100 affected partitions in one notification. When partition names are long, multiple notifications might be created.

For example if there are two partition keys, Year and Month, then "2018,01", "2018,02" modifies the partition where "Year=2018" and "Month=01" and the partition where "Year=2018" and "Month=02".

```
{
  "version":"0",
  "id":"abcdef00-1234-5678-9abc-def012345678",
  "detail-type":"Glue Data Catalog Table State Change",
  "source":"aws.glue",
  "account":"123456789012",
  "time":"2017-09-07T18:57:21Z",
```

```
"region": "us-west-2",
"resources": ["arn:aws:glue:us-west-2:123456789012:database/default/foo"],
"detail": {
  "changedPartitions": [
    "2018,01",
    "2018,02"
  ],
  "databaseName": "default",
  "tableName": "foo",
  "typeOfChange": "BatchCreatePartition"
}
}
```

For more information, see the [Amazon CloudWatch Events User Guide](#). For events specific to AWS Glue, see [AWS Glue Events](#).

## AWS Glue resource monitoring

AWS Glue has service limits to protect customers from unexpected excessive provisioning and from malicious actions intended to increase your bill. The limits also protect the service. Logging into the AWS Service Quota console, customers can view their current resource limits and request an increase (where appropriate).

AWS Glue allows you to view the service's resource usage as a percentage in Amazon CloudWatch and to configure CloudWatch alarms on it to monitor usage. Amazon CloudWatch provides monitoring for AWS resources and the customer applications running on the Amazon infrastructure. The metrics are free of charge to you. The following metrics are supported:

- Number of workflows per account
- Number of triggers per account
- Number of jobs per account
- Number of concurrent job runs per account
- Number of blueprints per account
- Number of interactive sessions per account

## Configuring and using resource metrics

To use this feature, you can go to the Amazon CloudWatch console to view the metrics and configure alarms. The metrics are under the AWS/Glue namespace and are a percentage of the actual resource usage count divided by the resource quota. The CloudWatch metrics are delivered to your accounts, which will be no cost for you. For example, if you have 10 workflows created, and your service quota allows you to have 200 workflows in maximum, then your usage is  $10/200 = 5\%$ , and in graph, you will see a datapoint of 5 as a percentage. To be more specific:

```
Namespace: AWS/Glue
Metric name: ResourceUsage
Type: Resource
Resource: Workflow (or Trigger, Job, JobRun, Blueprint, InteractiveSession)
Service: Glue
Class: None
```

To create an alarm on a metric in the CloudWatch console:

1. Once you locate the metric, go to **Graphed metrics**.
2. Click **Create alarm** under **Actions**.
3. Configure the alarm as needed.

We emit metrics whenever your resource usage has a change (such as an increase or decrease). But if your resource usage doesn't change, we emit metrics hourly, so that you have a continuous

CloudWatch graph. To avoid having missing data points, we do not recommend you to configure a period less than 1 hour.

You can also configure alarms using AWS CloudFormation as in the following example. In this example, once the workflow resource usage reaches 80%, it triggers an alarm to send a message to the existing SNS topic, where you can subscribe to it to get notifications.

```
{
  "Type": "AWS::CloudWatch::Alarm",
  "Properties": {
    "AlarmName": "WorkflowUsageAlarm",
    "ActionsEnabled": true,
    "OKActions": [],
    "AlarmActions": [
      "arn:aws:sns:af-south-1:085425700061:Default_CloudWatch_Alarms_Topic"
    ],
    "InsufficientDataActions": [],
    "MetricName": "ResourceUsage",
    "Namespace": "AWS/Glue",
    "Statistic": "Maximum",
    "Dimensions": [{
      "Name": "Type",
      "Value": "Resource"
    },
    {
      "Name": "Resource",
      "Value": "Workflow"
    },
    {
      "Name": "Service",
      "Value": "Glue"
    },
    {
      "Name": "Class",
      "Value": "None"
    }
  ],
  "Period": 3600,
  "EvaluationPeriods": 1,
  "DatapointsToAlarm": 1,
  "Threshold": 80,
  "ComparisonOperator": "GreaterThanThreshold",
  "TreatMissingData": "notBreaching"
}
```

```
}  
}
```

## Logging AWS Glue API calls with AWS CloudTrail

AWS Glue is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in AWS Glue. CloudTrail captures all API calls for AWS Glue as events. The calls captured include calls from the AWS Glue console and code calls to the AWS Glue API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for AWS Glue. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to AWS Glue, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

### AWS Glue information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in AWS Glue, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for AWS Glue, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Creating a trail for your AWS account](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All AWS Glue actions are logged by CloudTrail and are documented in the [AWS Glue API](#) . For example, calls to the `CreateDatabase`, `CreateTable` and `CreateScript` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#).

However, CloudTrail doesn't log all information regarding calls. For example, it doesn't log certain sensitive information, such as the `ConnectionProperties` used in connection requests, and it logs a `null` instead of the responses returned by the following APIs:

<code>BatchGetPartition</code>	<code>GetCrawlers</code>	<code>GetJobs</code>	<code>GetTable</code>
<code>CreateScript</code>	<code>GetCrawlerMetrics</code>	<code>GetJobRun</code>	<code>GetTables</code>
<code>GetCatalogImportStatus</code>	<code>GetDatabase</code>	<code>GetJobRuns</code>	<code>GetTableVersions</code>
<code>GetClassifier</code>	<code>GetDatabases</code>	<code>GetMapping</code>	<code>GetTrigger</code>
<code>GetClassifiers</code>	<code>GetDataflowGraph</code>	<code>GetObjects</code>	<code>GetTriggers</code>
<code>GetConnection</code>	<code>GetDevEndpoint</code>	<code>GetPartition</code>	<code>GetUserDefinedFunction</code>
<code>GetConnections</code>	<code>GetDevEndpoints</code>	<code>GetPartitions</code>	<code>GetUserDefinedFunctions</code>
<code>GetCrawler</code>	<code>GetJob</code>	<code>GetPlan</code>	

## Understanding AWS Glue log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `DeleteCrawler` action.

```
{
  "eventVersion": "1.05",
```

```

"userIdentity": {
  "type": "IAMUser",
  "principalId": "AKIAIOSFODNN7EXAMPLE",
  "arn": "arn:aws:iam::123456789012:user/johndoe",
  "accountId": "123456789012",
  "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
  "userName": "johndoe"
},
"eventTime": "2017-10-11T22:29:49Z",
"eventSource": "glue.amazonaws.com",
"eventName": "DeleteCrawler",
"awsRegion": "us-east-1",
"sourceIPAddress": "72.21.198.64",
"userAgent": "aws-cli/1.11.148 Python/3.6.1 Darwin/16.7.0 boto3/1.7.6",
"requestParameters": {
  "name": "tes-alpha"
},
"responseElements": null,
"requestID": "b16f4050-aed3-11e7-b0b3-75564a46954f",
"eventID": "e73dd117-cfd1-47d1-9e2f-d1271cad838c",
"eventType": "AwsApiCall",
"recipientAccountId": "123456789012"
}

```

This example shows a CloudTrail log entry that demonstrates a CreateConnection action.

```

{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2017-10-13T00:19:19Z",
  "eventSource": "glue.amazonaws.com",
  "eventName": "CreateConnection",
  "awsRegion": "us-east-1",
  "sourceIPAddress": "72.21.198.66",
  "userAgent": "aws-cli/1.11.148 Python/3.6.1 Darwin/16.7.0 boto3/1.7.6",
  "requestParameters": {

```

```

"connectionInput": {
  "name": "test-connection-alpha",
  "connectionType": "JDBC",
  "physicalConnectionRequirements": {
    "subnetId": "subnet-323232",
    "availabilityZone": "us-east-1a",
    "securityGroupIdList": [
      "sg-12121212"
    ]
  }
},
"responseElements": null,
"requestID": "27136ebc-afac-11e7-a7d6-ab217e5c3f19",
"eventID": "e8b3baeb-c511-4597-880f-c16210c60a4a",
"eventType": "AwsApiCall",
"recipientAccountId": "123456789012"
}

```

## AWS Glue job run statuses

You can view the status of an AWS Glue extract, transform, and load (ETL) job while it is running or after it has stopped. You can view the status using the AWS Glue console, the AWS Command Line Interface (AWS CLI), or the [GetJobRun action](#) in the AWS Glue API.

Possible job run statuses are STARTING, RUNNING, STOPPING, STOPPED, SUCCEEDED, FAILED, ERROR, WAITING and TIMEOUT.

The following table lists the statuses that indicate abnormal job termination.

Job run status	Description
FAILED	The job exceeded its maximum allowed concurrent runs, or terminated with an unknown exit code.
ERROR	A workflow, schedule trigger, or event trigger attempted to run a deleted job.
TIMEOUT	The job run time exceeded its specified timeout value.

The WAITING status indicates a job run is waiting for resources. The following table describes wait behavior for different classes of jobs.

Job type	Behavior
Spark jobs (Standard)	<p>Jobs that have not been configured to retry based on your <code>maxRetries</code> configuration may enter the WAITING state. A new job run will be in the WAITING state if the service is not able to acquire enough resources to start the run. This may occur due to service quotas for your account or capacity limits in your region encountering one of the following error cases:</p> <ul style="list-style-type: none"><li>• Max concurrent job runs per account exceeded</li><li>• Max concurrent job runs per job exceeded (includes the account level service quota as well as the limit you specify on the job with <code>MaxConcurrentRuns</code> )</li><li>• Max concurrent compute (DPU usage) exceeded</li><li>• Resource unavailable</li></ul> <p>For more information about AWS Glue service quotas, see <a href="#">AWS Glue endpoints and quotas</a>. The time AWS Glue will wait for resources may differ based on circumstances. A job may transition between non-terminal statuses as it attempts to acquire resources. Eventually, the job will transition to FAILED if it cannot acquire resources. AWS Glue will retry for a maximum of 15 minutes or 10 attempts, whichever comes first.</p>

Job type	Behavior
Spark jobs (Flex)	A new job run will be in the WAITING state if the service is not able acquire enough resources to start the run, which delays the starting of the run. The run will be in WAITING state for a maximum of 20 minutes (timeout controlled by the service). After 15 minutes, the service will try to do a force start and depending on available capacity the run may start or fail with an appropriate error message.
Python shell jobs	Same behavior as standard jobs using Spark.

The following state diagram outlines expected state transitions through the lifecycle of a AWS Glue job. This information is applicable to all job types.

# AWS Glue Streaming

AWS Glue Streaming, a component of AWS Glue, enables you to efficiently handle streaming data in near real-time, empowering you to carry out crucial tasks such as data ingestion, processing, and machine learning. Using the Apache Spark Streaming framework, AWS Glue Streaming provides a serverless service that can handle streaming data at scale. AWS Glue provides various optimizations on top of Apache Spark such as serverless infrastructure, auto-scaling, visual job development, instant-on notebooks for streaming jobs and other performance improvements.

## Use cases for streaming

Some common use cases for AWS Glue Streaming include:

**Near-real-time data processing:** AWS Glue Streaming allows organizations to process streaming data in near real-time, enabling them to derive insights and make timely decisions based on the latest information.

**Fraud detection:** You can utilize AWS Glue Streaming for real-time analysis of streaming data, making it valuable for detecting fraudulent activities, such as credit card fraud, network intrusion, or online scams. By continuously processing and analyzing incoming data, you can swiftly identify suspicious patterns or anomalies.

**Social media analytics:** AWS Glue Streaming can process real-time social media data, such as tweets, posts, or comments, enabling organizations to monitor trends, sentiment analysis, and manage brand reputation in real-time.

**Internet of Things (IoT) analytics:** AWS Glue Streaming is suitable for handling and analyzing high-velocity streams of data generated by IoT devices, sensors, and connected machinery. It allows for real-time monitoring, anomaly detection, predictive maintenance, and other IoT analytics use cases.

**Clickstream analysis:** AWS Glue Streaming can process and analyze real-time clickstream data from websites or mobile applications. This enables businesses to gain insights into user behavior, personalize user experiences, and optimize marketing campaigns based on real-time clickstream data.

**Log monitoring and analysis:** AWS Glue Streaming can continuously process and analyze log data from servers, applications, or network devices in real-time. This helps in detecting anomalies, troubleshooting issues, and monitoring system health and performance.

**Recommendation systems:** AWS Glue Streaming can process user activity data in real-time and update recommendation models dynamically. This allows for personalized and real-time recommendations based on user behavior and preferences.

These are some examples of the diverse range of use cases where AWS Glue Streaming can be applied. Its integration with the AWS ecosystem and managed services make it a convenient choice for real-time stream processing and analytics in the cloud.

## What are the benefits of using AWS Glue Streaming?

The benefits of using AWS Glue Streaming are as follows:

- **Serverless:** AWS Glue Streaming is serverless, eliminating the need to manage infrastructure. This reduces the operational overhead and allows users to focus on data processing and analytics tasks rather than infrastructure management.
- **Autoscaling:** AWS Glue Streaming provides autoscaling capabilities, dynamically adjusting the processing capacity based on the workload. It automatically scales out or in to handle fluctuations in data volume, ensuring optimal performance and resource utilization.
- **Visual development:** Streaming job development can be complex. AWS Glue Streaming addresses this challenge by offering AWS Glue Studio, a visual authoring tool. AWS Glue Studio simplifies the process of creating streaming workflows and enables developers to design and manage streaming applications visually, reducing the learning curve and increasing productivity.
- **Cost-effective:** As a serverless service, AWS Glue Streaming offers cost efficiency by eliminating the need for provisioning and maintaining infrastructure. Users are billed based on the resources consumed during the execution of streaming jobs, allowing for cost optimization and scaling based on actual usage.
- **Handles complex workloads:** AWS Glue Streaming is designed to handle complex streaming workloads. It can process and analyze large volumes of real-time data, support advanced transformations, and integrate with other AWS services, enabling sophisticated streaming data pipelines and analytics workflows.
- **No lock-in:** AWS Glue Streaming provides flexibility and avoids vendor lock-in. Users can leverage AWS Glue Streaming as part of the broader AWS ecosystem, integrating it with other AWS services seamlessly. This allows for easy integration with existing data sources, applications, and services without being tied to a specific technology or platform.

## When to use AWS Glue Streaming?

There are many options when it comes to streaming use cases. We recommend AWS Glue streaming in the following scenarios.

- 1. If you are already using AWS Glue or Spark for batch processing,** AWS Glue Streaming is the ideal choice for you. It provides a seamless transition to building streaming jobs without the need to learn a new language or framework. Leveraging your existing knowledge and infrastructure, AWS Glue Streaming simplifies the job development process and allows you to easily extend your data processing capabilities to real-time streaming scenarios.
- 2. If you require a unified service or product to handle batch, streaming, and event-driven workloads,** AWS Glue Streaming is the solution for you. With AWS Glue Streaming, you can consolidate your data processing needs into a single framework, eliminating the complexity of managing multiple systems. This enables efficient development and maintenance of diverse data workflows while ensuring consistency and compatibility across different workload types.
- 3. AWS Glue Streaming is well-suited for scenarios involving extremely large streaming data volumes and complex transformations,** such as joins between streams or relational databases. It can efficiently process and analyze massive streams of data, enabling you to tackle demanding workloads with ease. Whether it is high-velocity data ingestion or intricate data manipulations, AWS Glue Streaming's scalability and advanced processing capabilities ensure optimal performance and accurate results.
- 4. If you prefer a visual approach to building streaming jobs,** AWS Glue offers AWS Glue Studio, with which you can visually design and manage your streaming applications, simplifying the development process. This intuitive interface enables developers to create, configure, and monitor streaming workflows using a visual interface, reducing the learning curve and increasing productivity.
- 5. AWS Glue Streaming is an excellent choice for near-real-time use cases where there are stringent SLAs (Service Level Agreements) greater than 10 seconds.**
- 6. If you are building a transactional data lake using Apache Iceberg, Apache Hudi, or Delta Lake,** AWS Glue Streaming provides native support for these open table formats. This seamless integration enables you to process streaming data directly from these transactional data lakes, ensuring data consistency, integrity, and compatibility.
- 7. When needing to ingest streaming data for a variety of data targets:** AWS Glue Streaming provides native targets to a variety of data targets such as Amazon Redshift, Amazon RDS, Amazon Aurora, Oracle, SQL Server and other targets.

## Supported data sources

AWS Glue Streaming supports the following data sources:

- Amazon Kinesis
- Amazon MSK (Managed Streaming for Apache Kafka)
- Self-managed Apache Kafka

## Supported data targets

AWS Glue Streaming supports a variety of data targets such as:

- Data targets supported by AWS Glue Data Catalog
- Amazon S3
- Amazon Redshift
- MySQL
- PostgreSQL
- Oracle
- Microsoft SQL Server
- Snowflake
- Any database that can be connected using JDBC
- Apache Iceberg, Delta and Apache Hudi
- AWS Glue Marketplace connectors

## Tutorial: Build your first streaming workload using AWS Glue Studio

In this tutorial, you are going to learn how to create a streaming job using AWS Glue Studio. AWS Glue Studio is a visual interface to create AWS Glue jobs.

You can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources in Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

## Prerequisites

To follow this tutorial you'll need a user with AWS console permissions to use AWS Glue, Amazon Kinesis, Amazon S3, Amazon Athena, AWS CloudFormation, AWS Lambda and Amazon Cognito.

## Consume streaming data from Amazon Kinesis

### Topics

- [Generating mock data with Kinesis Data Generator](#)
- [Creating an AWS Glue streaming job with AWS Glue Studio](#)
- [Performing a transformation and storing the transformed result in Amazon S3](#)

### Generating mock data with Kinesis Data Generator

You can synthetically generate sample data in JSON format using the Kinesis Data Generator (KDG). You can find full instructions and details in the [tool documentation](#).

1. To get started, click

to run an AWS CloudFormation template on your AWS environment.

#### Note

You may encounter a CloudFormation template failure because some resources, such as the Amazon Cognito user for Kinesis Data Generator already exist in your AWS account. This could be because you already set that up from another tutorial or blog. To address this, you can either try the template in a new AWS account for a fresh start, or explore a different AWS Region. These options let you run the tutorial without conflicting with existing resources.

The template provisions a Kinesis data stream and a Kinesis Data Generator account for you. It also creates an Amazon S3 bucket to hold the data and a Glue Service Role with the required permission for this tutorial.

2. Enter a **Username** and **Password** that the KDG will use to authenticate. Note the username and password for further usage.

3. Select **Next** all the way to the last step. Acknowledge the creation of IAM resources. Check for any errors at the top of the screen, such as the password not meeting the minimum requirements, and deploy the template.
4. Navigate to the **Outputs** tab of the stack. Once the template is deployed, it will display the generated property **KinesisDataGeneratorUrl**. Click that URL.
5. Enter the **Username** and **Password** you noted down.
6. Select the Region you are using and select the Kinesis Stream `GlueStreamTest-  
{AWS::AccountId}`
7. Enter the following template:

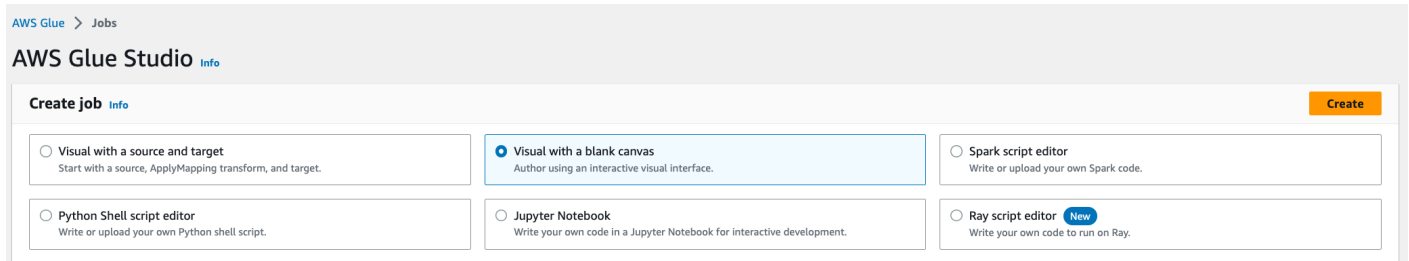

```
{
  "ventilatorid": {{random.number(100)}},
  "eventtime": "{{date.now("YYYY-MM-DD HH:mm:ss")}}",
  "serialnumber": "{{random.uuid}}",
  "pressurecontrol": {{random.number(
    {
      "min":5,
      "max":30
    }
  )}},
  "o2stats": {{random.number(
    {
      "min":92,
      "max":98
    }
  )}},
  "minutevolume": {{random.number(
    {
      "min":5,
      "max":8
    }
  )}},
  "manufacturer": "{{random.arrayElement(
    ["3M", "GE","Vyair", "Getinge"]
  )}}"
}
```

You can now view mock data with **Test template** and ingest the mock data to Kinesis with **Send data**.

8. Click **Send data** and generate 5-10K records to Kinesis.

## Creating an AWS Glue streaming job with AWS Glue Studio

1. Navigate to AWS Glue in the console on the same Region.
2. Select **ETL jobs** under the left side navigation bar under **Data Integration and ETL**.
3. Create an AWS Glue Job via **Visual with a blank canvas**.

4. Navigate to the **Job Details** tab.
5. For the AWS Glue job name, enter DemoStreamingJob.
6. For **IAM Role**, select the role provisioned by the CloudFormation template, glue-tutorial-role-\${AWS::AccountId}.
7. For **Glue version**, select **Glue 3.0**. Leave all other options as default.

**Basic properties** [Info](#)

## Name

DemoStreamingJob

Description - *optional*

Descriptions can be up to 2048 characters long.

## IAM Role

Role assumed by the job with permission to access your data stores. Ensure that this role has permission to your Amazon S3 sources, targets, temporary directory, scripts, and any libraries used by the job.

glue-tutorial-role-

## Type

The type of ETL job. This is set automatically based on the types of data sources you have selected.

Spark Streaming

Glue version [Info](#)

Glue 3.0 - Supports spark 3.1, Scala 2, Python 3

## Language

Python 3

## Worker type

Set the type of predefined worker that is allowed when a job runs.

G 1X

(4vCPU and 16GB RAM)

## Automatically scale the number of workers

- AWS Glue will optimize costs and resource usage by dynamically scaling the number of workers up and down throughout the job run. Requires Glue 3.0 or later.

8. Navigate to the **Visual tab**.

9. Click on the plus icon. Enter **Kinesis** in the search bar. Select the **Amazon Kinesis** data source.

10 Select **Stream details** for **Amazon Kinesis Source** under the tab **Data source properties - Kinesis Stream**.

11 Select **Stream is located in my account** for **Location of data stream**.

12 Select the Region you are using.

13 Select the `GlueStreamTest-{AWS::AccountId}` stream.

14 Keep all other settings as default.

**Data source properties - Kinesis Stream** | Output schema | Data preview

Start reading from the oldest available record in the stream.

Window size | [Info](#)  
Enter the time in seconds spent between batch calls.  
100

15 Navigate to the **Data preview** tab.

16 Click **Start data preview session**, which previews the mock data generated by KDG. Pick the Glue Service Role you previously created for the AWS Glue Streaming job.

It takes 30-60 seconds for the preview data to show up. If it shows **No data to display**, click the gear icon and change the **Number of rows to sample** to 100.

You can see the sample data as below:

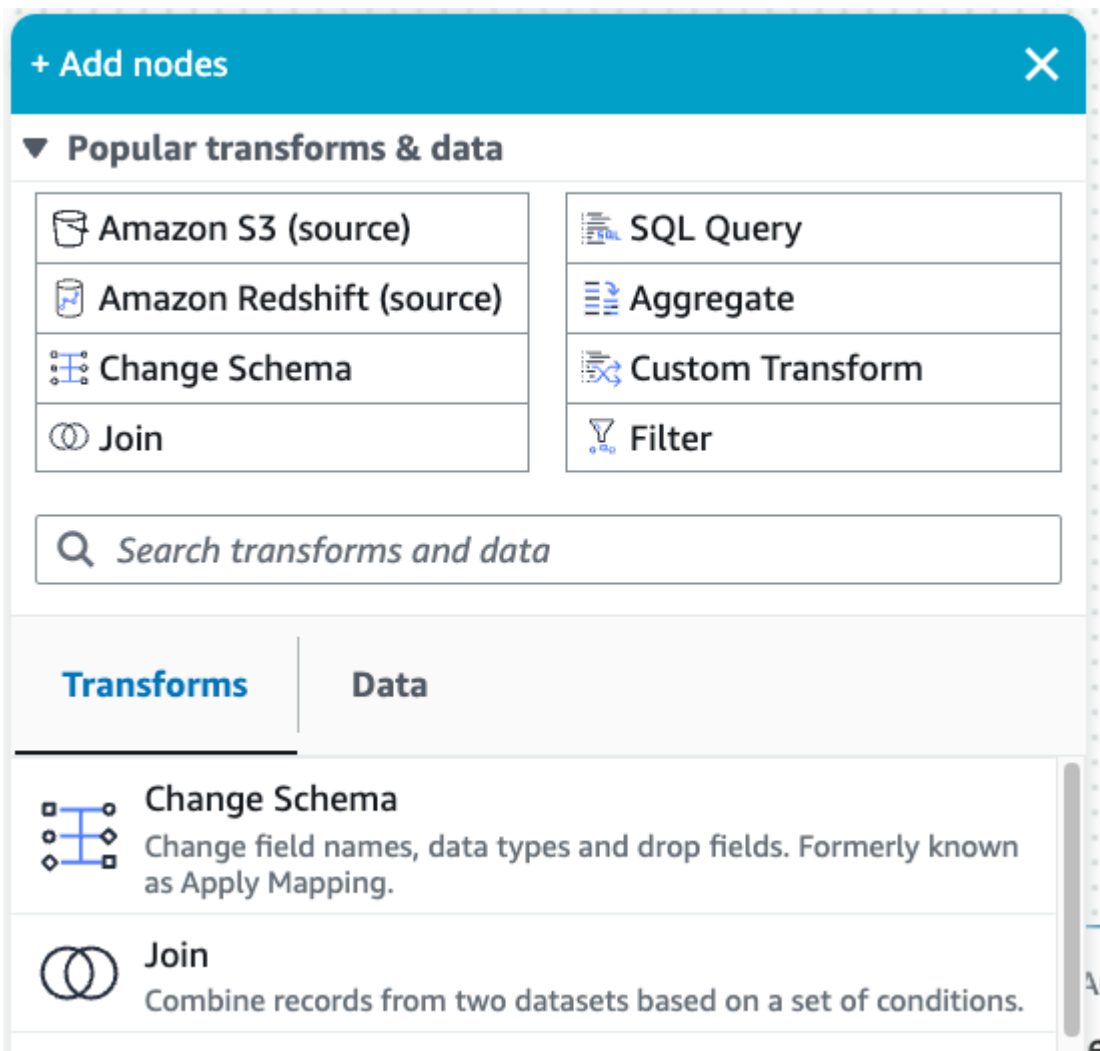

Data source properties - Kinesis Stream		Output schema	Data preview			
<b>Data preview (100)</b> <a href="#">Info</a>					Previewing 7 of 7 fields	
<input type="text" value="Filter sample dataset"/>

You can also see the inferred schema in the **Output schema** tab.

Data source properties - Kinesis Stream		Output schema	Data preview
<b>Schema</b> <a href="#">Info</a>			
Key			Data type
eventtime			string
manufacturer			string
minutevolume			long
o2stats			long
pressurecontrol			long
serialnumber			string
ventilatorid			long

## Performing a transformation and storing the transformed result in Amazon S3

1. With the source node selected, click on the plus icon on the top left to add a **Transforms** step.
2. Select the **Change Schema** step.

3. You can rename fields and convert the data type of fields in this step. Rename the `o2stats` column to `OxygenSaturation` and convert all `long` data type to `int`.

# Tutorial: Build your first streaming workload using AWS Glue Studio notebooks

In this tutorial, you will explore how to leverage AWS Glue Studio notebooks to interactively build and refine your ETL jobs for near real-time data processing. Whether you're new to AWS Glue or looking to enhance your skill set, this guide will walk you through the process, empowering you to harness the full potential of AWS Glue interactive session notebooks.

With AWS Glue Streaming, you can create streaming extract, transform, and load (ETL) jobs that run continuously and consume data from streaming sources such as Amazon Kinesis Data Streams, Apache Kafka, and Amazon Managed Streaming for Apache Kafka (Amazon MSK).

## Prerequisites

To follow this tutorial you'll need a user with AWS console permissions to use AWS Glue, Amazon Kinesis, Amazon S3, Amazon Athena, AWS CloudFormation, AWS Lambda and Amazon Cognito.

## Consume streaming data from Amazon Kinesis

### Topics

- [Generating mock data with Kinesis Data Generator](#)
- [Creating an AWS Glue streaming job with AWS Glue Studio](#)
- [Clean up](#)
- [Conclusion](#)

## Generating mock data with Kinesis Data Generator

### Note

If you have already completed our previous [Tutorial: Build your first streaming workload using AWS Glue Studio](#), you already have the Kinesis Data Generator installed on your account and you can skip steps 1-8 below and move on to the section [Creating an AWS Glue streaming job with AWS Glue Studio](#).

You can synthetically generate sample data in JSON format using the Kinesis Data Generator (KDG). You can find full instructions and details in the [tool documentation](#).

1. To get started, click

to run an AWS CloudFormation template on your AWS environment.

**Note**

You may encounter a CloudFormation template failure because some resources, such as the Amazon Cognito user for Kinesis Data Generator already exist in your AWS account. This could be because you already set that up from another tutorial or blog. To address this, you can either try the template in a new AWS account for a fresh start, or explore a different AWS Region. These options let you run the tutorial without conflicting with existing resources.

The template provisions a Kinesis data stream and a Kinesis Data Generator account for you.

2. Enter a **Username** and **Password** that the KDG will use to authenticate. Note the username and password for further usage.
3. Select **Next** all the way to the last step. Acknowledge the creation of IAM resources. Check for any errors at the top of the screen, such as the password not meeting the minimum requirements, and deploy the template.
4. Navigate to the **Outputs** tab of the stack. Once the template is deployed, it will display the generated property **KinesisDataGeneratorUrl**. Click that URL.
5. Enter the **Username** and **Password** you noted down.
6. Select the Region you are using and select the Kinesis Stream `GlueStreamTest-  
{AWS::AccountId}`
7. Enter the following template:

```
{
  "ventilatorid": {{random.number(100)}},
  "eventtime": "{{date.now("YYYY-MM-DD HH:mm:ss")}}",
  "serialnumber": "{{random.uuid}}",
  "pressurecontrol": {{random.number(
    {
      "min":5,
      "max":30
    }
  )}},
  "o2stats": {{random.number(
    {
      "min":92,
      "max":98
    }
  )}}
```

```
    }
  }},
  "minutevolume": {{random.number(
    {
      "min":5,
      "max":8
    }
  )}},
  "manufacturer": "{{random.arrayElement(
    ["3M", "GE","Vyair", "Getinge"]
  )}}"
}
```

You can now view mock data with **Test template** and ingest the mock data to Kinesis with **Send data**.

8. Click **Send data** and generate 5-10K records to Kinesis.

## Creating an AWS Glue streaming job with AWS Glue Studio

AWS Glue Studio is a visual interface that simplifies the process of designing, orchestrating, and monitoring data integration pipelines. It enables users to build data transformation pipelines without writing extensive code. Apart from the visual job authoring experience, AWS Glue Studio also includes a Jupyter notebook backed by AWS Glue Interactive sessions, which you will be using in the remainder of this tutorial.

### Set up the AWS Glue Streaming interactive sessions job

1. Download the provided [notebook file](#) and save it to a local directory
2. Open the AWS Glue Console and on the left pane click **Notebooks > Jupyter Notebook > Upload and edit an existing notebook**. Upload the notebook from the previous step and click **Create**.

The screenshot shows the AWS Glue Studio 'Create job' page. On the left is a navigation sidebar with 'Notebooks' highlighted. The main area is titled 'Create job' and offers several options: 'Visual with a source and target', 'Visual with a blank canvas', 'Spark script editor', 'Python Shell script editor', and 'Jupyter Notebook' (which is selected). Below these are 'Options' for creating a notebook: 'Create a new notebook from scratch' and 'Upload and edit an existing notebook' (selected). A 'File upload' section includes a 'Choose file' button and a list of files, with 'glue\_tutorial\_notebook.ipynb' selected. A 'Create' button is in the top right corner.

3. Provide the job a name, role and select the default Spark kernel. Next click **Start notebook**. For the **IAM Role**, select the role provisioned by the CloudFormation template. You can see this in the **Outputs** tab of CloudFormation.

The screenshot shows the 'Notebook setup' configuration page in AWS Glue. The page is titled 'Notebook setup' and has a section for 'Initial configuration'. It contains three main sections: 'Job name' with a text input field containing 'glue\_tutorial\_notebook'; 'IAM Role' with a dropdown menu showing 'glue-tutorial-role-62' and a refresh button; and 'Kernel' with a dropdown menu showing 'Spark'. At the bottom right, there are 'Cancel' and 'Start notebook' buttons.

The notebook has all necessary instructions to continue the tutorial. You can either run the instructions on the notebook or follow along with this tutorial to continue with the job development.

## Run the notebook cells

1. (Optional) The first code cell, %help lists all available notebook magics. You can skip this cell for now, but feel free to explore it.
2. Start with the next code block %streaming. This magic sets the job type to streaming which lets you develop, debug and deploy an AWS Glue streaming ETL job.
3. Run the next cell to create an AWS Glue interactive session. The output cell has a message that confirms the session creation.

Run this cell to set up and start your interactive session.

```
[1]: %glue_version 3.0

import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue import DynamicFrame
from datetime import datetime
from pyspark.sql.types import StructType, StructField, StringType, LongType
from pyspark.sql.functions import lit,col,from_json
import boto3

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)

Setting Glue version to: 3.0
Authenticating with environment variables and user-defined glue_role_arn: arn:aws:iam::624461903491:role/glue-tutorial-role
Trying to create a Glue session for the kernel.
Worker Type: G.1X
Number of Workers: 5
Session ID: j-48-af
Job Type: gluestreaming
Applying the following default arguments:
--glue_kernel_version 0.37.3
--enable-glue-datacatalog true
Waiting for session 48-af to get into ready status...
Session 48 has been created.
```

4. The next cell defines the variables. Replace the values with ones appropriate to your job and run the cell. For example:

```
output_database_name="default"
output_table_name="test_stream_001"

account_id = boto3.client("sts").get_caller_identity()["Account"]
region_name=boto3.client('s3').meta.region_name
stream_arn_name = "arn:aws:kinesis:{{region_name}}:{{account_id}}:stream/GlueStreamTest-{{account_id}}".format(region_name,account_id,account_id)
s3_bucket_name = "streaming-tutorial-s3-target-{{account_id}}".format(account_id)

output_location = "s3://{{s3_bucket_name}}/streaming_output/".format(s3_bucket_name)
checkpoint_location = "s3://{{s3_bucket_name}}/checkpoint_location/".format(s3_bucket_name)
```

5. Since the data is being streamed already to Kinesis Data Streams, your next cell will consume the results from the stream. Run the next cell. Since there are no print statements, there is no expected output from this cell.

6. In the following cell, you explore the incoming stream by taking a sample set and print its schema and the actual data. For example:

#### Sample and print the incoming records

the sampling is for debugging purpose. You may comment off the entire code cell below, before deploying the actual code

```
[4]: options = {
  -- "pollingTimeInMs": "20000",
  -- "windowSize": "5 seconds"
}
sampled_dynamic_frame = glueContext.getSampleStreamingDynamicFrame(data_frame, options, None)

count_of_sampled_records = sampled_dynamic_frame.count()

print(count_of_sampled_records)

sampled_dynamic_frame.printSchema()

sampled_dynamic_frame.toDF().show(10, False)
```

```
100
root
```

```
|-- eventtime: string
|-- manufacturer: string
|-- minutevolume: long
|-- o2stats: long
|-- pressurecontrol: long
|-- serialnumber: string
|-- ventilatorid: long
```

eventtime	manufacturer	minutevolume	o2stats	pressurecontrol	serialnumber	ventilatorid
2023-07-18 10:20:11	3M	6	92	24	a3e860ba-24b9-41c4-bc10-91c6b35e1406	6

2023-07-18 10:20:12	Getinge	7	98	30	25f425cd-b978-4953-9a03-4d607a639364	91
2023-07-18 10:20:12	GE	5	93	25	2cd7cdc2-f5f5-4ff2-ae32-45e5a8922d53	93

7. Next, define the actual data transformation logic. The cell consists of the `processBatch` method that is triggered during every micro-batch. Run the cell. At a high level, we do the following to the incoming stream:
- Select a subset of the input columns.
  - Rename a column (`o2stats` to `oxygen_stats`).
  - Derive new columns (`serial_identifier`, `ingest_year`, `ingest_month` and `ingest_day`).
  - Store the results into an Amazon S3 bucket and also create a partitioned AWS Glue catalog table
8. In the last cell, you trigger the process batch every 10 seconds. Run the cell and wait for about 30 seconds for it to populate the Amazon S3 bucket and the AWS Glue catalog table.
9. Finally, browse the stored data using the Amazon Athena query editor. You can see the renamed column and also the new partitions.

1 select \* from test\_stream\_001 limit 10

AWS Glue Streaming Tutorials - Working with Studio Notebook

## Clean up

To avoid incurring additional charges to your account, stop the streaming job that you started as part of the instructions. You can do this by stopping the notebook, which will end the session. Empty the Amazon S3 bucket and delete the AWS CloudFormation stack that you provisioned earlier.

## Conclusion

In this tutorial, we demonstrated how to do the following using the AWS Glue Studio notebook

- Author a streaming ETL job using notebooks
- Preview incoming data streams
- Code and fix issues without having to publish AWS Glue jobs
- Review the end-to-end working code, remove any debugging, and print statements or cells from the notebook
- Publish the code as an AWS Glue job

The goal of this tutorial is to give you hands-on experience working with AWS Glue Streaming and interactive sessions. We encourage you to use this as a reference for your individual AWS Glue Streaming use cases. For more information, see [Getting started with AWS Glue interactive sessions](#).

## AWS Glue Streaming concepts

The following sections provide information on concepts of AWS Glue Streaming.

### Topics

- [Anatomy of a AWS Glue streaming job](#)
- [Kafka connections](#)
- [Kinesis connections](#)
- [AWS Glue Streaming options](#)

## Anatomy of a AWS Glue streaming job

AWS Glue streaming jobs operate on the Spark streaming paradigm and leverage structured streaming from the Spark framework. Streaming jobs constantly poll on the streaming data source,

at a specific interval of time, to fetch records as micro batches. The following sections examine the different parts of a AWS Glue streaming job.

```
def processBatch(data_frame, batchId):
    if data_frame.count() > 0:
        AmazonKinesis_node1696872487972 = DynamicFrame.fromDF(
            glueContext.add_ingestion_time_columns(data_frame, "hour"),
            glueContext,
            "from_data_frame",
        )
        # Script generated for node Change Schema
        ChangeSchema_node1696872679326 = ApplyMapping.apply(
            frame=AmazonKinesis_node1696872487972,
            mappings=[
                ("eventtime", "string", "eventtime", "string"),
                ("manufacturer", "string", "manufacturer", "string"),
                ("minutevolume", "long", "minutevolume", "int"),
                ("o2stats", "long", "OxygenSaturation", "int"),
                ("pressurecontrol", "long", "pressurecontrol", "int"),
                ("serialnumber", "string", "serialnumber", "string"),
                ("ventilatorid", "long", "ventilatorid", "long"),
                ("ingest_year", "string", "ingest_year", "string"),
                ("ingest_month", "string", "ingest_month", "string"),
                ("ingest_day", "string", "ingest_day", "string"),
                ("ingest_hour", "string", "ingest_hour", "string"),
            ],
            transformation_ctx="ChangeSchema_node1696872679326",
        )
        # Script generated for node Amazon S3
        AmazonS3_node1696872743449_path = (
            "s3://streaming-tutorial-s3-target-"
        )
        AmazonS3_node1696872743449 = glueContext.getSink(
            path=AmazonS3_node1696872743449_path,
            connection_type="s3",
            update_behavior="UPDATE_IN_DATABASE",
            partition_keys=["ingest_year", "ingest_month", "ingest_day", "ingest_hour"],
            compression="snappy",
            enable_update_catalog=True,
            transformation_ctx="AmazonS3_node1696872743449",
        )
        AmazonS3_node1696872743449.setCatalogInfo(
            catalog_database="demo", catalog_table_name="demo_stream_transform_result"
        )
        AmazonS3_node1696872743449.setFormat("glueparquet")
        AmazonS3_node1696872743449.writeFrame(ChangeSchema_node1696872679326)

    glueContext.forEachBatch(
        frame=dataFrame_AmazonKinesis_node1696872487972,
        batch_function=processBatch,
        options={
            "windowSize": "100 seconds",
            "checkpointLocation": args["TempDir"] + "/" + args["JOB_NAME"] + "/checkpoint/",
        },
    )
job.commit()
```

1 ← Entry Point

## forEachBatch

The `forEachBatch` method is the entry point of a AWS Glue streaming job run. AWS Glue streaming jobs uses the `forEachBatch` method to poll data functioning like an iterator that remains active during the lifecycle of the streaming job and regularly polls the streaming source for new data and processes the latest data in micro batches.

```
glueContext.forEachBatch(
    frame=dataFrame_AmazonKinesis_node1696872487972,
    batch_function=processBatch,
    options={
        "windowSize": "100 seconds",
        "checkpointLocation": args["TempDir"] + "/" + args["JOB_NAME"] + "/
checkpoint/",
    },
)
```

Configure the `frame` property of `forEachBatch` to specify a streaming source. In this example, the source node that you created in the blank canvas during job creation is populated with the default DataFrame of the job. Set the `batch_function` property as the function that you decide to invoke for each micro batch operation. You must define a function to handle the batch transformation on the incoming data.

## Source

In the first step of the `processBatch` function, the program verifies the record count of the DataFrame that you defined as `frame` property of `forEachBatch`. The program appends an ingestion time stamp to a non-empty DataFrame. The `data_frame.count()>0` clause determines whether the latest micro batch is not empty and is ready for further processing.

```
def processBatch(data_frame, batchId):
    if data_frame.count() > 0:
        AmazonKinesis_node1696872487972 = DynamicFrame.fromDF(
            glueContext.add_ingestion_time_columns(data_frame, "hour"),
            glueContext,
            "from_data_frame",
        )
```

## Mapping

The next section of the program is to apply mapping. The `Mapping.apply` method on a spark DataFrame allows you to define transformation rule around data elements. Typically you can rename, change the data type, or apply a custom function on the source data column and map those to the target columns.

```
#Script generated for node ChangeSchema
ChangeSchema_node16986872679326 = ApplyMapping.apply(
    frame = AmazonKinesis_node1696872487972,
    mappings = [
        ("eventtime", "string", "eventtime", "string"),
        ("manufacturer", "string", "manufacturer", "string"),
        ("minutevolume", "long", "minutevolume", "int"),
        ("o2stats", "long", "OxygenSaturation", "int"),
```

```

        ("pressurecontrol", "long", "pressurecontrol", "int"),
        ("serialnumber", "string", "serialnumber", "string"),
        ("ventilatorid", "long", "ventilatorid", "long"),
        ("ingest_year", "string", "ingest_year", "string"),
        ("ingest_month", "string", "ingest_month", "string"),
        ("ingest_day", "string", "ingest_day", "string"),
        ("ingest_hour", "string", "ingest_hour", "string"),
    ],
    transformation_ctx="ChangeSchema_node16986872679326",
)
)

```

## Sink

In this section, the incoming data set from the streaming source are stored at a target location. In this example we will write the data to an Amazon S3 location. The `AmazonS3_node_path` property details is pre-populated as determined by the settings you used during job creation from the canvas. You can set the `updateBehavior` based on your use case and decide to either Not update the data catalog table, or Create data catalog and update data catalog schema on subsequent runs, or create a catalog table and not update the schema definition on subsequent runs.

The `partitionKeys` property defines the storage partition option. The default behavior is to partition the data per the `ingestion_time_columns` that was made available in the source section. The `compression` property allows you to set the compression algorithm to be applied during target write. You have options to set Snappy, LZO, or GZIP as the compression technique. The `enableUpdateCatalog` property controls whether the AWS Glue catalog table needs to be updated. Available options for this property are `True` or `False`.

```

#Script generated for node Amazon S3
AmazonS3_node1696872743449 = glueContext.getSink(
    path = AmazonS3_node1696872743449_path,
    connection_type = "s3",
    updateBehavior = "UPDATE_IN_DATABASE",
    partitionKeys = ["ingest_year", "ingest_month", "ingest_day", "ingest_hour"],
    compression = "snappy",
    enableUpdateCatalog = True,
    transformation_ctx = "AmazonS3_node1696872743449",
)

```

## AWS Glue Catalog sink

This section of the job controls the AWS Glue catalog table update behavior. Set `catalogDatabase` and `catalogTableName` property per your AWS Glue Catalog database name and the table name associated with the AWS Glue job that you are designing. You can define the file format of the target data via the `setFormat` property. For this example we will store the data in parquet format.

Once you set up and run the AWS Glue streaming job referring this tutorial, the streaming data produced at Amazon Kinesis Data Streams will be stored at the Amazon S3 location in a parquet format with snappy compression. On successful runs of the streaming job you will be able to query the data through Amazon Athena.

```
AmazonS3_node1696872743449 = setCatalogInfo(  
    catalogDatabase = "demo", catalogTableName = "demo_stream_transform_result"  
)  
AmazonS3_node1696872743449.setFormat("glueparquet")  
AmazonS3_node1696872743449.writeFormat("ChangeSchema_node16986872679326")  
)
```

## Kafka connections

Designates a connection to a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster.

You can read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kafka into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog`

to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- **Scala**
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- **Python**
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

## Configure Kafka

There are no AWS prerequisites to connecting to Kafka streams available through the internet.

You can create a AWS Glue Kafka connection to manage your connection credentials. For more information, see [the section called “Creating a connection for a Kafka data stream”](#). In your AWS Glue job configuration, provide `connectionName` as an **Additional network connection**, then, in your method call, provide `connectionName` to the `connectionName` parameter.

In certain cases, you will need to configure additional prerequisites:

- If using Amazon Managed Streaming for Apache Kafka with IAM authentication, you will need appropriate IAM configuration.

- If using Amazon Managed Streaming for Apache Kafka within an Amazon VPC, you will need appropriate Amazon VPC configuration. You will need to create a AWS Glue connection that provides Amazon VPC connection information. You will need your job configuration to include the AWS Glue connection as an **Additional network connection**.

For more information about Streaming ETL job prerequisites, consult [the section called “Streaming ETL jobs”](#).

## Example: Reading from Kafka streams

Used in conjunction with [the section called “forEachBatch”](#).

Example for Kafka streaming source:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "startingOffsets": "earliest",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

## Example: Writing to Kafka streams

Examples for writing to Kafka:

Example with the `getSink` method:

```
data_frame_datasource0 =
  glueContext.getSink(
    connectionType="kafka",
    connectionOptions={
      JsonObject("""{
        "connectionName": "ConfluentKafka",
        "classification": "json",
        "topic": "kafka-auth-topic",
        "typeOfData": "kafka"}
        """))},
```

```
transformationContext="dataframe_ApacheKafka_node1711729173428")
.getDataFrame()
```

Example with the `write_dynamic_frame.from_options` method:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.write_dynamic_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

## Kafka connection option reference

When reading, use the following connection options with `"connectionType": "kafka"`:

- `"bootstrap.servers"` (Required) A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.
- `"security.protocol"` (Required) The protocol used to communicate with brokers. The possible values are `"SSL"` or `"PLAINTEXT"`.
- `"topicName"` (Required) A comma-separated list of topics to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.
- `"assign"`: (Required) A JSON string specifying the specific `TopicPartitions` to consume. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

Example: `'{"topicA":[0,1],"topicB":[2,4]}'`

- `"subscribePattern"`: (Required) A Java regex string that identifies the topic list to subscribe to. You must specify one and only one of `"topicName"`, `"assign"` or `"subscribePattern"`.

Example: `'topic.*'`

- `"classification"` (Required) The file format used by the data in the record. Required unless provided through the Data Catalog.
- `"delimiter"` (Optional) The value separator used when `classification` is `CSV`. Default is `","`.

- `"startingOffsets"`: (Optional) The starting position in the Kafka topic to read data from. The possible values are `"earliest"` or `"latest"`. The default value is `"latest"`.
- `"startingTimestamp"`: (Optional, supported only for AWS Glue version 4.0 or later) The Timestamp of the record in the Kafka topic to read data from. The possible value is a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: `"2023-04-04T08:00:00-04:00"`.

Note: Only one of `'startingOffsets'` or `'startingTimestamp'` can be present in the Connection Options list of the AWS Glue streaming script, including both these properties will result in job failure.

- `"endingOffsets"`: (Optional) The end point when a batch query is ended. Possible values are either `"latest"` or a JSON string that specifies an ending offset for each `TopicPartition`.

For the JSON string, the format is `{"topicA":{"0":23,"1":-1},"topicB":{"0":-1}}`. The value `-1` as an offset represents `"latest"`.

- `"pollTimeoutMs"`: (Optional) The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is 512.
- `"numRetries"`: (Optional) The number of times to retry before failing to fetch Kafka offsets. The default value is 3.
- `"retryIntervalMs"`: (Optional) The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is 10.
- `"maxOffsetsPerTrigger"`: (Optional) The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across `topicPartitions` of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.
- `"minPartitions"`: (Optional) The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.
- `"includeHeaders"`: (Optional) Whether to include the Kafka headers. When the option is set to `"true"`, the data output will contain an additional column named `"glue_streaming_kafka_headers"` with type `Array[Struct(key: String, value: String)]`. The default value is `"false"`. This option is available in AWS Glue version 3.0 or later.
- `"schema"`: (Required when `inferSchema` set to false) The schema to use to process the payload. If classification is `avro` the provided schema must be in the Avro schema format. If the classification is not `avro` the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
'column1' INT, 'column2' STRING , 'column3' FLOAT
```

Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
        "name": "_id",
        "type": "string"
      },
      {
        "name": "index",
        "type":
        [
          "int",
          "string",
          "float"
        ]
      }
    ]
  }
}
}
```

- **"inferSchema"**: (Optional) The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within `foreachbatch`.
- **"avroSchema"**: (Deprecated) Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- **"addRecordTimestamp"**: (Optional) When this option is set to 'true', the data output will contain an additional column named `"__src_timestamp"` that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

- `"emitConsumerLagMetrics"`: (Optional) When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in AWS Glue to CloudWatch. The metric's name is `"glue.driver.streaming.maxConsumerLagInMs"`. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

When writing, use the following connection options with `"connectionType": "kafka"`:

- `"connectionName"` (Required) Name of the AWS Glue connection used to connect to the Kafka cluster (similar to Kafka source).
- `"topic"` (Required) If a topic column exists then its value is used as the topic when writing the given row to Kafka, unless the topic configuration option is set. That is, the `topic` configuration option overrides the topic column.
- `"partition"` (Optional) If a valid partition number is specified, that `partition` will be used when sending the record.

If no partition is specified but a key is present, a partition will be chosen using a hash of the key.

If neither key nor `partition` is present, a partition will be chosen based on sticky partitioning those changes when at least `batch.size` bytes are produced to the partition.

- `"key"` (Optional) Used for partitioning if `partition` is null.
- `"classification"` (Optional) The file format used by the data in the record. We only support JSON, CSV and Avro.

With Avro format, we can provide a custom `avroSchema` to serialize with, but note that this needs to be provided on the source for deserializing as well. Else, by default it uses the Apache `AvroSchema` for serializing.

Additionally, you can fine-tune the Kafka sink as required by updating the [Kafka producer configuration parameters](#). Note that there is no allow listing on connection options, all the key-value pairs are persisted on the sink as is.

However, there is a small deny list of options that will not take effect. For more information, see [Kafka specific configurations](#).

## Kinesis connections

You can read and write to Amazon Kinesis data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kinesis into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kinesis in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kinesis streaming source, the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kinesis streaming source. If you use `getSource`, `getSourceWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kinesis using the following arguments for the specified methods in the `GlueContext` class.

- Scala
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about Streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

## Configure Kinesis

To connect to a Kinesis data stream in an AWS Glue Spark job, you will need some prerequisites:

- If reading, the AWS Glue job must have Read access level IAM permissions to the Kinesis data stream.

- If writing, the AWS Glue job must have Write access level IAM permissions to the Kinesis data stream.

In certain cases, you will need to configure additional prerequisites:

- If your AWS Glue job is configured with **Additional network connections** (typically to connect to other datasets) and one of those connections provides Amazon VPC **Network options**, this will direct your job to communicate over Amazon VPC. In this case you will also need to configure your Kinesis data stream to communicate over Amazon VPC. You can do this by creating an interface VPC endpoint between your Amazon VPC and Kinesis data stream. For more information, see [Using Kinesis Data Streams with Interface VPC Endpoints](#).
- When specifying Amazon Kinesis Data Streams in another account, you must setup the roles and policies to allow cross-account access. For more information, see [Example: Read From a Kinesis Stream in a Different Account](#).

For more information about Streaming ETL job prerequisites, consult [the section called "Streaming ETL jobs"](#).

## Read from Kinesis

### Example: Reading from Kinesis streams

Used in conjunction with [the section called "forEachBatch"](#).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
    "startingPosition": "TRIM_HORIZON",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kinesis",
  connection_options=kinesis_options)
```

## Write to Kinesis

### Example: Writing to Kinesis streams

Used in conjunction with [the section called "forEachBatch"](#). Your DynamicFrame will be written to the stream in a JSON format. If the job cannot write after several retries, it will fail. By default, each DynamicFrame record will be sent to the Kinesis stream individually. You can configure this behavior using `aggregationEnabled` and associated parameters.

Example writing to Amazon Kinesis from a streaming job:

#### Python

```
glueContext.write_dynamic_frame.from_options(
    frame=frameToWrite
    connection_type="kinesis",
    connection_options={
        "partitionKey": "part1",
        "streamARN": "arn:aws:kinesis:us-east-1:111122223333:stream/streamName",
    }
)
```

#### Scala

```
glueContext.getSinkWithFormat(
    connectionType="kinesis",
    options=JsonOptions("""{
        "streamARN": "arn:aws:kinesis:us-
east-1:111122223333:stream/streamName",
        "partitionKey": "part1"
    }"""),
)
.writeDynamicFrame(frameToWrite)
```

## Kinesis connection parameters

Designates connection options for Amazon Kinesis Data Streams.

Use the following connection options for Kinesis streaming data sources:

- "streamARN" (Required) Used for Read/Write. The ARN of the Kinesis data stream.

- "classification" (Required for read) Used for Read. The file format used by the data in the record. Required unless provided through the Data Catalog.
- "streamName" – (Optional) Used for Read. The name of a Kinesis data stream to read from. Used with `endpointUrl`.
- "endpointUrl" – (Optional) Used for Read. Default: "https://kinesis.us-east-1.amazonaws.com". The AWS endpoint of the Kinesis stream. You do not need to change this unless you are connecting to a special region.
- "partitionKey" – (Optional) Used for Write. The Kinesis partition key used when producing records.
- "delimiter" (Optional) Used for Read. The value separator used when `classification` is CSV. Default is ",".
- "startingPosition": (Optional) Used for Read. The starting position in the Kinesis data stream to read data from. The possible values are "latest", "trim\_horizon", "earliest", or a Timestamp string in UTC format in the pattern yyyy-mm-ddTHH:MM:SSZ (where Z represents a UTC timezone offset with a +/-). For example "2023-04-04T08:00:00-04:00". The default value is "latest". Note: the Timestamp string in UTC Format for "startingPosition" is supported only for AWS Glue version 4.0 or later.
- "failOnDataLoss": (Optional) Fail the job if any active shard is missing or expired. The default value is "false".
- "awsSTSRoleARN": (Optional) Used for Read/Write. The Amazon Resource Name (ARN) of the role to assume using AWS Security Token Service (AWS STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSSessionName".
- "awsSTSSessionName": (Optional) Used for Read/Write. An identifier for the session assuming the role using AWS STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSRoleARN".
- "awsSTSEndpoint": (Optional) The AWS STS endpoint to use when connecting to Kinesis with an assumed role. This allows using the regional AWS STS endpoint in a VPC, which is not possible with the default global endpoint.
- "maxFetchTimeInMs": (Optional) Used for Read. The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple `GetRecords` API calls may be made within this time. The default value is 1000.

- "maxFetchRecordsPerShard": (Optional) Used for Read. The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same get-records call). If maxFetchRecordsPerShard needs to be strict then it needs to be a multiple of maxRecordPerRead. The default value is 100000.
- "maxRecordPerRead": (Optional) Used for Read. The maximum number of records to fetch from the Kinesis data stream in each getRecords operation. The default value is 10000.
- "addIdleTimeBetweenReads": (Optional) Used for Read. Adds a time delay between two consecutive getRecords operations. The default value is "False". This option is only configurable for Glue version 2.0 and above.
- "idleTimeBetweenReadsInMs": (Optional) Used for Read. The minimum time delay between two consecutive getRecords operations, specified in ms. The default value is 1000. This option is only configurable for Glue version 2.0 and above.
- "describeShardInterval": (Optional) Used for Read. The minimum time interval between two ListShards API calls for your script to consider resharding. For more information, see [Strategies for Resharding](#) in *Amazon Kinesis Data Streams Developer Guide*. The default value is 1s.
- "numRetries": (Optional) Used for Read. The maximum number of retries for Kinesis Data Streams API requests. The default value is 3.
- "retryIntervalMs": (Optional) Used for Read. The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is 1000.
- "maxRetryIntervalMs": (Optional) Used for Read. The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is 10000.
- "avoidEmptyBatches": (Optional) Used for Read. Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".
- "schema": (Required when inferSchema set to false) Used for Read. The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

The following are schema examples.

## Example in DDL schema format

```
`column1` INT, `column2` STRING , `column3` FLOAT
```

## Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
        "name": "_id",
        "type": "string"
      },
      {
        "name": "index",
        "type":
        [
          "int",
          "string",
          "float"
        ]
      }
    ]
  }
}
```

- **"inferSchema":** (Optional) Used for Read. The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within foreachbatch.
- **"avroSchema":** (Deprecated) Used for Read. Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the schema parameter.
- **"addRecordTimestamp":** (Optional) Used for Read. When this option is set to 'true', the data output will contain an additional column named "\_\_src\_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

- "emitConsumerLagMetrics": (Optional) Used for Read. When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- "fanoutConsumerARN": (Optional) Used for Read. The ARN of a Kinesis stream consumer for the stream specified in streamARN. Used to enable enhanced fan-out mode for your Kinesis connection. For more information on consuming a Kinesis stream with enhanced fan-out, see [the section called "Using enhanced fan-out in Kinesis streaming jobs"](#).
- "recordMaxBufferedTime" – (Optional) Used for Write. Default: 1000 (ms). Maximum time a record is buffered while waiting to be written.
- "aggregationEnabled" – (Optional) Used for Write. Default: true. Specifies if records should be aggregated before sending them to Kinesis.
- "aggregationMaxSize" – (Optional) Used for Write. Default: 51200 (bytes). If a record is larger than this limit, it will bypass the aggregator. Note Kinesis enforces a limit of 50KB on record size. If you set this beyond 50KB, oversize records will be rejected by Kinesis.
- "aggregationMaxCount" – (Optional) Used for Write. Default: 4294967295. Maximum number of items to pack into an aggregated record.
- "producerRateLimit" – (Optional) Used for Write. Default: 150 (%). Limits per-shard throughput sent from a single producer (such as your job), as a percentage of the backend limit.
- "collectionMaxCount" – (Optional) Used for Write. Default: 500. Maximum number of items to pack into an PutRecords request.
- "collectionMaxSize" – (Optional) Used for Write. Default: 5242880 (bytes). Maximum amount of data to send with a PutRecords request.

## AWS Glue Streaming options

Designates a connection to a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster.

You can read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kafka into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog` to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- **Scala**
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- **Python**
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

## AWS Glue streaming autoscaling

The following sections provide information on AWS Glue streaming autoscaling

### Enabling Auto Scaling in AWS Glue Studio

On the **Job details** tab in AWS Glue Studio, choose the type as **Spark** or **Spark Streaming**, and **Glue version** as **Glue 3.0** or **Glue 4.0**. Then a check box will show up below **Worker type**.

- Select the **Automatically scale the number of workers** option.

- Set the **Maximum number of workers** to define the maximum number of workers that can be vended to the job run.

Visual
Script
Job details
Runs
Data quality
Schedules

**Version Control**

---

**Type**  
The type of ETL job. This is set automatically based on the types of data sources you have selected.

Spark

**Glue version** [Info](#)

Glue 4.0 - Supports spark 3.3, Scala 2, Python 3 ▼

**Language**

Python 3 ▼

**Worker type**  
Set the type of predefined worker that is allowed when a job runs.

G 1X  
(4vCPU and 16GB RAM) ▼

**Automatically scale the number of workers**  
AWS Glue will optimize costs and resource usage by dynamically scaling the number of workers up and down throughout the job run. Requires Glue 3.0 or later.

**Maximum number of workers**  
The number of workers you want AWS Glue to allocate to this job.

10

## Enabling Auto Scaling with the AWS CLI or SDK

To enable Auto Scaling From the AWS CLI for your job run, run `start-job-run` with the following configuration:

```
{
  "JobName": "<your job name>",
```

```

"Arguments": {
  "--enable-auto-scaling": "true"
},
"WorkerType": "G.2X", // G.1X and G.2X are allowed for Auto Scaling Jobs
"NumberOfWorkers": 20, // represents Maximum number of workers
...other job run configurations...
}

```

Once an ETL job run is finished, you can also call `get-job-run` to check the actual resource usage of the job run in DPU-seconds. Note: the new field **DPUSecods** will only show up for your batch jobs on AWS Glue 3.0 or later enabled with Auto Scaling. This field is not supported for streaming jobs.

```

$ aws glue get-job-run --job-name your-job-name --run-id jr_xx --endpoint https://
glue.us-east-1.amazonaws.com --region us-east-1
{
  "JobRun": {
    ...
    "GlueVersion": "3.0",
    "DPUSecods": 386.0
  }
}

```

You can also configure job runs with Auto Scaling using the [AWS Glue SDK](#) with the same configuration.

## How it works

### Scaling across microbatch

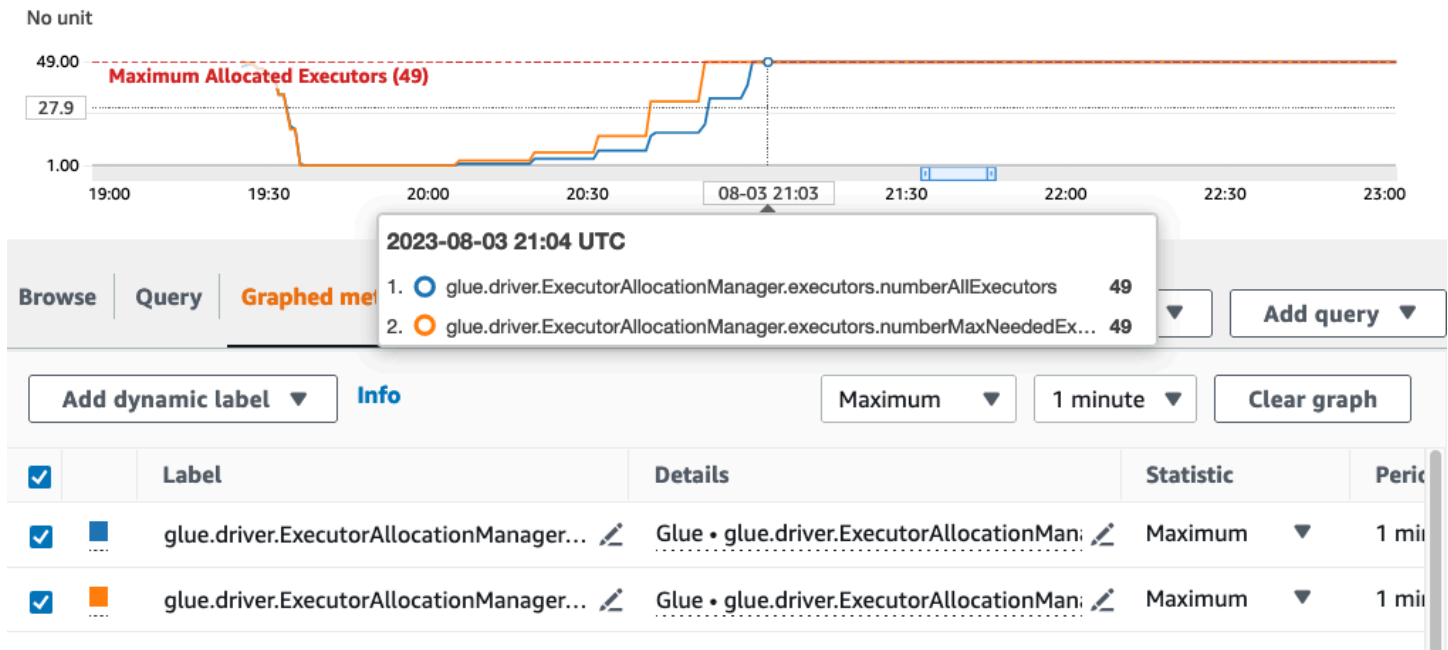

The following example is used to describe how autoscaling works.

- You have a AWS Glue job that starts with 50 DPUs.
- Autoscaling is enabled.

In this example, AWS Glue looks at the “batchProcessingTimeInMs” metric for a few micro batches and determines if your jobs are completing within the window size that you have established. If your jobs are completing sooner and depending on how soon they complete, AWS Glue may scale down. This metric, plotted with “numberAllExecutors” can be monitored in Amazon CloudWatch to see how autoscaling works.

The number of executors exponentially scales up or down only after each micro batch completes. As you can see from the Amazon CloudWatch Monitoring log, AWS Glue looks at the number of needed executors (Orange Line) and scales the executors (blue line) to match that automatically.

Once AWS Glue scales down the number of executors and observes that data volumes increase, consequently increasing the micro batch processing time, AWS Glue will scale up to 50 DPUs, which is the specified upper limit.

## Scaling within microbatch

In the above example, the system monitors a few completed micro-batches to make a decision on whether to scale up or down. Longer windows require autoscaling to respond more quickly within the microbatch, rather than waiting for a few micro batches. For these cases, you can use an additional configuration `--auto-scale-within-microbatch` to `true`. You can add this to the AWS Glue job properties in AWS Glue Studio as shown below.

### Job parameters [Info](#)

Key	Value - optional	
<input type="text" value="--auto-scale-within-microbatch"/>	<input type="text" value="true"/>	<input type="button" value="Remove"/>

You can add 49 more parameters.

# Maintenance windows for AWS Glue Streaming

AWS Glue periodically performs maintenance activities. During these maintenance windows, AWS Glue will need to restart your streaming jobs. You can control when the jobs are restarted by specifying maintenance windows. In this section, we outline where you can setup the maintenance window and specific behaviors you should consider.

## Topics

- [Setting up a maintenance window](#)
- [Maintenance window behavior](#)
- [Job monitoring](#)
- [Data loss handling](#)

## Setting up a maintenance window

You can set up a maintenance window using AWS Glue Studio or APIs.

### Setting up a maintenance windows in AWS Glue Studio

You can specify a maintenance window in the **Job Details** page of your AWS Glue Streaming job. You can specify the day and time in GMT. AWS Glue will restart your job within the specified time window.

#### Maintenance window

Restart on

at  hours (GMT)

For maintenance reasons, AWS Glue will restart streaming jobs within 3 hours of the specified maintenance window. You have the option to designate the start time in GMT for this maintenance. For more information, refer to documentation.

### Setting up a maintenance windows in the API

You can alternatively set up the maintenance window in the Create Job API. Here is an example of configuring a maintenance windows via the API.

```
aws glue create-job --name jobName --role roleArnForTheJob --command
Name=gluestreaming,ScriptLocation=s3-path-to-the-script --maintenance-window="Sun:10"
```

An example command is as follows:

```
aws glue create-job --name testMaintenance --role arn:aws:iam::012345678901:role/
Glue_DefaultRole --command Name=gluestreaming,ScriptLocation=s3://glue-example-test/
example.py --maintenance-window="Sun:10"
```

## Maintenance window behavior

AWS Glue goes through a series of steps to decide when to restart a job:

1. When a new streaming job is initiated, AWS Glue first checks if there is a timeout associated with the job run. A timeout allows you to configure the end time of the job. If the timeout is less than 7 days, then the job will not be restarted.
2. If the timeout is greater than 7 days, then AWS Glue checks if the maintenance window is configured for the job. If it is then that window is picked up and the window gets assigned to the job run. AWS Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.
3. If the maintenance window is not configured, AWS Glue automatically sets the restart time to 7 days past job run initiation time. For instance, if you initiated your job on 7/1/2024 12:00AM GMT and you did not specify maintenance windows, your job will be set to restart on 7/8/2024 at 12:00 AM GMT.

### Note

If you are already running streaming jobs, this change will impact you starting July 1, 2024. You will have time until June 30th to configure your maintenance windows. After July 1st, any streaming jobs that you start will be restarted per this documentation. If you require any additional support, you can reach out to AWS Support.

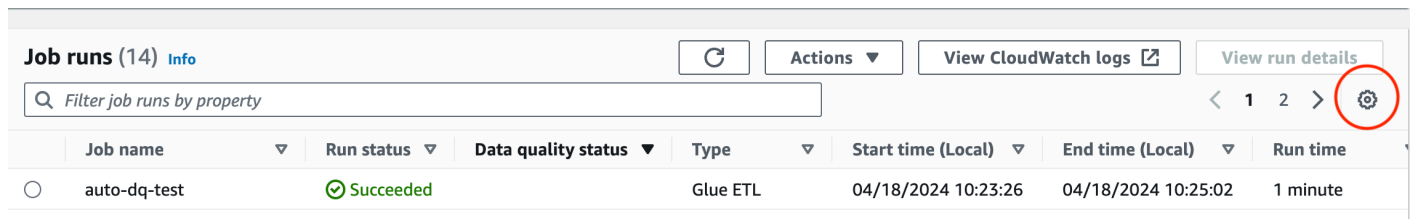

4. Sometimes, AWS Glue may not be able to restart the job, especially when the ongoing micro-batch is not processed. In these instances, the job will not be interrupted. In these instances, AWS Glue will restart the job after 14 days, and in this case, the maintenance window is not honored.

## Job monitoring

You can monitor the jobs in the AWS Glue Studio **Monitoring** page.

To see the expected next restart time of streaming jobs, show the column on the Job runs table on the **Monitoring** page.

1. Click the Gear icon in the top right of the table.

Job name	Run status	Data quality status	Type	Start time (Local)	End time (Local)	Run time
auto-dq-test	Succeeded		Glue ETL	04/18/2024 10:23:26	04/18/2024 10:25:02	1 minute

2. Scroll down, and turn on the **Expected restart time** column. Both UTC and Local time options are available.

worker type

DPU hours

Last modified (Local)

Worker utilization

Data skewness

Start time (UTC)

End time (UTC)

Last modified (UTC)

Data quality

**Expected restart time (UTC)**

**Expected restart time (Local)**

Cancel
Confirm

3. You can then view the columns in the table.

**Job runs (14)** [Info](#)

	Job name	Run status	Type	Start time (Local)	End time (Local)	Expected restart time (Local)
<input type="radio"/>	auto-dq-test	<span style="color: green;">✔ Succeeded</span>	Glue ETL	04/18/2024 10:23:26	04/18/2024 10:25:02	-
<input type="radio"/>	StreamingTest	<span style="color: blue;">🔄 Running</span>	Glue Streaming	04/16/2024 16:32:49	-	04/23/2024 02:00:00
<input type="radio"/>	StreamingProd	<span style="color: blue;">🔄 Running</span>	Glue Streaming	04/16/2024 13:45:10	-	04/25/2024 05:00:00

The original job will have an "EXPIRED" status and the new job instance will have a "RUNNING" status. The new job run that was restarted will have a job run ID as a concatenation of initial job run ID plus the prefix "restart\_" representing the restart count. For example, if the initial job run ID is `jr_1234`, then the restarted job run will have the ID `jr1234_restart_1` for the first restart. The second restart will be `jr1234_restart_2` for the second restart and so on.

Your retry attempt will not be impacted because of the restarts. If a run fails and a new run is started due to an automatic retry, the counter of restart will start from 1 again. For example, if a run fails at `jr_1234_attempt_3_restart_5`, then an automatic retry will start new run with ID: `jr_id1_attempt_4` and when this attempt is restarted after 7 days, the new run ID will be `jr_id1_attempt_4_restart_1`.

## Data loss handling

During maintenance restarts, AWS Glue Streaming follows a process that ensures data integrity and consistency between the previous job run and the restarted job run. Note that AWS Glue does not guarantee data integrity and consistency between job restarts and we recommend architecture considerations to handle duplicated data within streaming jobs.

1. Detecting maintenance restart conditions: AWS Glue Streaming monitors conditions that indicate when a maintenance restart should be triggered, such as when a maintenance window is reached after 7 days or a hard restart is necessary after 14 days.
2. Invoking a graceful termination: When the maintenance restart conditions are met, AWS Glue Streaming initiates a graceful termination process for the currently running job. This process involves the following steps:
  - a. Stopping the ingestion of new data: The streaming job stops consuming new data from the input sources (for example, Kafka topics, Kinesis streams, or files).
  - b. Processing pending data: The job continues to process any data that is already present in its internal buffers or queues.
  - c. Committing offsets and checkpoints: The job commits the latest offsets or checkpoints to external systems (for example, Kafka, Kinesis, or Amazon S3) to ensure that the restarted job can pick up from where the previous job left off.
3. Restarting the job: After the graceful termination process is complete, AWS Glue Streaming restarts the job using the preserved state and checkpoints. The restarted job picks up processing from the last committed offset or checkpoint, ensuring that no data is lost or duplicated.

4. Resuming data processing: The restarted job resumes data processing from the point where the previous job left off. It continues ingesting new data from the input sources, starting from the last committed offset or checkpoint, and processes the data according to the defined ETL logic.

## Advanced AWS Glue streaming concepts

In contemporary data-driven applications, the significance of data diminishes over time and its value transitions from being predictive to reactive. As a result, customers want to process data in real-time for making faster decisions. When dealing with real-time data feeds, such as from IoT sensors, the data may arrive unordered or experience delays in processing due to network latency and other source-related failures during ingestion. As part of the AWS Glue platform, AWS Glue Streaming builds on these capabilities to provide scalable, serverless streaming ETL, powered by Apache Spark structured streaming, empowering users with real-time data processing.

In this topic, we will explore advanced streaming concepts and capabilities of AWS Glue Streaming.

### Time considerations when processing streams

There are four notions of time when processing streams:

- **Event-time** – The time at which the event occurred. In most cases, this field is embedded into the event-data itself, at the source.
- **Event-time-window** – The time frame between two event-times. As shown in the above diagram, **W1** is an event-time-window from 17:00 to 17:10. Each event-time-window is a grouping of multiple events.
- **Trigger-time** – The trigger time controls how often the processing of data and updating of results occurs. This is the time when the micro-batch processing started.
- **Ingestion-time** – The time when the stream-data was ingested into the streaming service. If event-time is not embedded into the event itself, this time can be used for windowing in some cases.

## Windowing

Windowing is a technique where you group and aggregate multiple events by event-time-window. We will explore the benefits of windowing and when you would use it in the following examples.

Depending on the business use case, there are three types of time windows supported by spark.

- **Tumbling window** – a series of non-overlapping fixed size event-time-windows over which you aggregate.
- **Sliding window** – similar to the tumbling windows from the point of being “fixed-sized”, but windows can overlap or slide as long as the duration of slide is smaller than the duration of window itself.
- **Session window** – starts with an input data event and continues to expands itself as long as it receives input within a gap or duration of inactivity. A session window can have a static or dynamic size of the window length, depending on the inputs.

### Tumbling window

Tumbling window is a series of non-overlapping fixed size event-time-windows over which you aggregate. Lets understand this with a real world example.

Company ABC Auto wants to do a marketing campaign for a new brand of sports car. They want to pick a city where they have biggest sports car fans. To achieve this goal, they showcase a short 15 second advertisement introducing the car on their website. All the “clicks” and the corresponding “city” are recorded and streamed to Amazon Kinesis Data Streams. We want to count the number of clicks in a 10 minute window and group it by city to see which city has the highest demand. The following is the output of the aggregation.

window_start_time	window_end_time	city	total_clicks
2023-07-10 17:00:00	2023-07-10 17:10:00	Dallas	75

window_start_time	window_end_time	city	total_clicks
2023-07-10 17:00:00	2023-07-10 17:10:00	Chicago	10
2023-07-10 17:20:00	2023-07-10 17:30:00	Dallas	20
2023-07-10 17:20:00	2023-07-10 17:30:00	Chicago	50

As explained above, these event-time-windows are different from trigger-time intervals. For example, even if your trigger time is every minute, the output results will only show 10 minute non-overlapping aggregation windows. For optimization, its better to have the trigger interval aligned with the event-time-window.

In the table above, Dallas saw 75 clicks in the 17:00-17:10 window, while Chicago had 10 clicks. Also, there is no data for the 17:10 - 17:20 window for any city, so this window is omitted.

Now you can run further analysis on this data in the downstream analytics application to determine the most exclusive city to run the marketing campaign.

## Using tumbling windows in AWS Glue

1. Create a Amazon Kinesis Data Streams DataFrame and read from it. Example:

```
parsed_df = kinesis_raw_df \
    .selectExpr('CAST(data AS STRING)') \
    .select(from_json("data", ticker_schema).alias("data")) \
    .select('data.event_time', 'data.ticker', 'data.trade', 'data.volume',
'data.price')
```

2. Process data in a tumbling window. In the example below, data is grouped based on the input field "event\_time" in 10 minute tumbling windows and writing the output to an Amazon S3 data lake.

```
grouped_df = parsed_df \
    .groupBy(window("event_time", "10 minutes"), "city") \
    .agg(sum("clicks").alias("total_clicks"))

summary_df = grouped_df \
    .withColumn("window_start_time", col("window.start")) \
```

```

        .withColumn("window_end_time", col("window.end")) \
        .withColumn("year", year("window_start_time")) \
        .withColumn("month", month("window_start_time")) \
        .withColumn("day", dayofmonth("window_start_time")) \
        .withColumn("hour", hour("window_start_time")) \
        .withColumn("minute", minute("window_start_time")) \
        .drop("window")

write_result = summary_df \
    .writeStream \
    .format("parquet") \
    .trigger(processingTime="10 seconds") \
    .option("checkpointLocation", "s3a://bucket-stock-stream/stock-
stream-catalog-job/checkpoint/") \
    .option("path", "s3a://bucket-stock-stream/stock-stream-catalog-
job/summary_output/") \
    .partitionBy("year", "month", "day") \
    .start()

```

## Sliding window

Sliding windows are similar to the tumbling windows from the point of being “fixed-sized”, but windows can overlap or slide as long as the duration of slide is smaller than the duration of window itself. Due to the nature of sliding, an input can be bound to the multiple windows.

**Sliding Window (10 min window, sliding by 5 min)**

To better understand, let's consider the example of a bank that wants to detect potential credit card fraud. A streaming application could monitor a continuous stream of credit card transactions. These transactions could be aggregated into windows of 10 minutes duration and every 5 minutes, the window would slide forward, eliminating the oldest 5 minutes of data and adding the latest 5 minutes of new data. Within each window, the transactions could be grouped by country checking for suspicious patterns, such as a transaction in the US immediately followed by another in

Australia. For simplicity, let's categorize such transactions as fraud when the total transactions amount is greater than \$100. If such a pattern is detected, it signals potential fraud and the card could be frozen.

The credit card processing system is sending a stream of transaction events to Kinesis for each card-id along with the country. An AWS Glue job runs the analysis and produces the following aggregated output.

window_start_time	window_end_time	card_last_four	country	total_amount
2023-07-10 17:00:00	2023-07-10 17:10:00	6544	US	85
2023-07-10 17:00:00	2023-07-10 17:10:00	6544	Australia	10
2023-07-10 17:05:45	2023-07-10 17:15:45	6544	US	50
2023-07-10 17:10:45	2023-07-10 17:20:45	6544	US	50
2023-07-10 17:10:45	2023-07-10 17:20:45	6544	Australia	150

Based on the above aggregation, you can see the 10 minute window sliding every 5 minutes, summed by transaction amount. The anomaly is detected in the 17:10 - 17:20 window where there is an outlier, which is a transaction for \$150 in Australia. AWS Glue can detect this anomaly and push an alarm-event with the offending key to an SNS topic using boto3. Further a Lambda function can subscribe to this topic and take action.

### Process data in a sliding window

The `group-by` clause and the window function is used to implement the sliding window as shown below.

```
grouped_df = parsed_df \
```

```
.groupBy(window(col("event_time"), "10 minute", "5 min"), "country",
"card_last_four") \
.agg(sum("tx_amount").alias("total_amount"))
```

## Session window

Unlike the above two windows that have a fixed-size, session window can have a static or dynamic size of the window length, depending on the inputs. A session window starts with an input data event and continues to expand itself as long as it receives input within a gap or duration of inactivity.

Lets take an example. Company ABC hotel wants to find out when is the busiest time in a week and provide better deals for their guests. As soon as a guest checks-in, a session window is started and spark maintains a state with aggregation for that event-time-window. Every time a guests checks in, an event is generated and sent to Amazon Kinesis Data Streams. The hotel makes a decision that if there is no check-ins for a period of 15 minutes, the event-time-window can be closed. The next event-time-window will start again when there is a new check-in. The output looks as follows.

window_start_time	window_end_time	city	total_checkins
2023-07-10 17:02:00	2023-07-10 17:30:00	Dallas	50
2023-07-10 17:02:00	2023-07-10 17:30:00	Chicago	25
2023-07-10 17:40:00	2023-07-10 18:20:00	Dallas	75
2023-07-10 18:50:45	2023-07-10 19:15:45	Dallas	20

The first check-in occurred at event\_time=17:02. The aggregation event-time-window will start at 17:02. This aggregation will continue as long as we receive events within 15 minute duration. In

the above example, the last event we received was at 17:15 and then for the next 15 minutes there were no events. As a result, Spark closed that event-time-window at 17:15+15min = 17:30 and set it as 17:02 - 17:30. It started a new event-time-window at 17:47 when it received a new check-in data event.

## Process data in a session window

The group-by clause and the window function is used to implement the sliding window.

```
grouped_df = parsed_df \
    .groupBy(session_window(col("event_time"), "10 minute"), "city") \
    .agg(count("check_in").alias("total_checkins"))
```

## Output modes

Output mode is the mode in which the results from the unbounded table are written to the external sink. There are three modes available. In the following example you are counting occurrences of a word as lines of data are being streamed and processed in each micro batch.

- **Complete mode** – The whole result table will be written to the sink after every micro batch processing even though the word count was not updated in the current event-time-window.
- **Append mode** – This is the default mode, where only the new words and or rows added to the result table since the last trigger will be written to the sink. This mode is good for stateless streaming for queries like map, flatMap, filter, etc.
- **Update mode** – Only the words and or rows in the Result Table that were updated or added since the last trigger will be written to the sink.

### Note

Output mode = "update" is not supported for session windows.

## Handling late data and watermarks

When working with real-time data there could be delays in the arrival of data due to network latency and upstream failures and we need a mechanism to perform the aggregation again on the missed event-time-window. However, to do this, state needs to be maintained. At the same

time, the older data needs to be cleaned up to limit the size of the state. Spark version 2.1 added support for a feature called watermarking which maintains state and allows the user to specify the threshold for late data.

With reference to our stock ticker example above, let's consider the allowed threshold for the late data as no more than 10 minutes. To keep it simple we will assume tumbling window, ticker as AMZ, trade as BUY.

In the above diagram, we are calculating the total volume over a tumbling 10 minute window. We have the trigger at 17:00, 17:10 and 17:20. Above the timeline arrow, we have the input data stream and below is the unbounded results table.

In the first 10 minute tumbling window we aggregated based on event\_time and the total\_volume was calculated as 30. In the second event-time-window, spark got the first data event with event\_time=17:02. Since this is the max event\_time seen thus far by spark, the watermark threshold is set 10 minutes back (that is, watermark\_event\_time=16:52). Any data event with an event\_time after 16:52 will be considered for time bound aggregation and any data event before that will be dropped. This allows spark to maintain an intermediate state for additional 10 minutes to accommodate late data. Around wall clock time 17:08 Spark received an event with an event\_time=16:54 which was within threshold. Hence spark recalculated the "16:50 - 17:00" event-time-window and the total volume was updated from 30 to 60.

However, at the trigger time 17:20, when spark received event with event\_time=17:15 it set the watermark\_event\_time=17:05. Hence the late data event with event\_time=17:03 was considered "too late" and ignored.

$$\text{Watermark Boundary} = \text{Max(Event Time)} - \text{Watermark Threshold}$$

## Using watermarks in AWS Glue

Spark will not emit or write the data to the external sink until the watermark boundary is passed. To implement a watermark in AWS Glue, see the example below.

```
grouped_df = parsed_df \  
    .withWatermark("event_time", "10 minutes") \  
    .groupBy(window("event_time", "5 minutes"), "ticker") \  
    .agg(sum("volume").alias("total_volume"))
```

## Monitoring AWS Glue streaming jobs

Monitoring your streaming job is a critical part of building your ETL pipeline. Apart from using the Spark UI, you can also use Amazon CloudWatch to monitor the metrics. Below is a list of streaming metrics emitted by the AWS Glue framework. For a complete list of all the AWS Glue metrics, see [Monitoring AWS Glue using Amazon CloudWatch metrics](#).

AWS Glue uses a structured streaming framework to process the input events. You can either use the Spark API directly in your code or leverage the `ForEachBatch` provided by `GlueContext`, which publishes these metrics. To understand these metrics, we need to first understand `windowSize`.

**windowSize:** `windowSize` is the micro-batch interval that you provide. If you specify a window size of 60 seconds, the AWS Glue streaming job will wait for 60 seconds (or more if the previous batch hasn't completed by then) before it will read data in a batch from the streaming source and apply the transformations provided in `ForEachBatch`. This is also referred to as the trigger interval.

Lets review the metrics in greater detail to understand the health and performance characteristics.

### Note

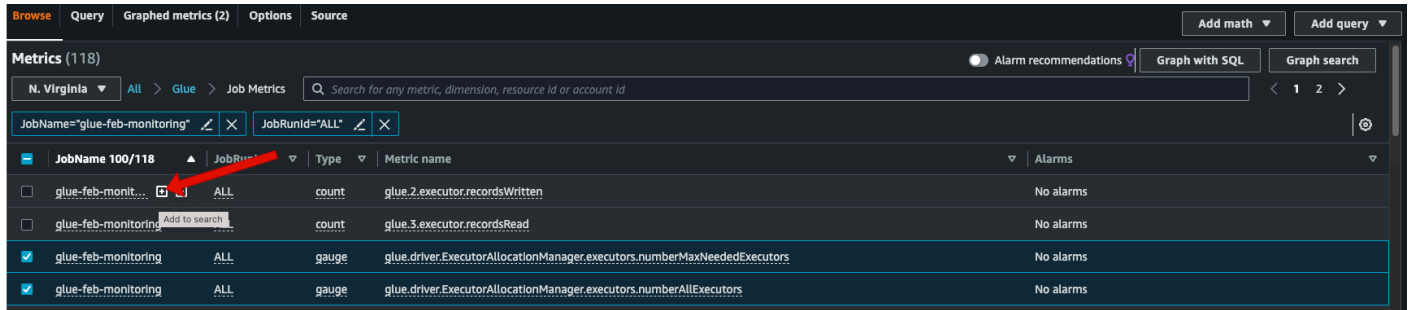

The metrics are emitted every 30 seconds. If your `windowSize` is less than 30 seconds then the reported metrics are an aggregation. For example say your `windowSize` is 10 seconds and you are steadily processing 20 records per micro-batch. In this scenario, the emitted metric value for `numRecords` would be 60.

A metric is not emitted if there is no data available for it. Also, in case of the consumer lag metric, you have to enable the feature to get metrics for it.

## Visualizing metrics

To plot visual metrics:

1. Go to **Metrics** in the Amazon CloudWatch console and then choose the **Browse** tab. Then choose **Glue** under "Custom namespaces".

2. Choose **Job Metrics** to show you the metrics for all your jobs.
3. Filter the metrics based on your JobName=glue-feb-monitoring and then JobRunId=ALL. You can click on the "+" sign as shown in the figure below to add it to the search filter.
4. Select the checkbox for the metrics that you are interested in. In the below figure we have selected numberAllExecutors and numberMaxNeededExecutors.

5. Once you have selected these metrics, you can go to the **Graphed metrics** tab and apply your statistics.
6. Since the metrics are emitted every min, you can apply the "average" over a minute for batchProcessingTimeInMs and maxConsumerLagInMs. For the numRecords you can apply the "sum" over every minute.
7. You can add a horizontal windowSize annotation to your graph using the **Options** tab.

Browse Query Graphed metrics (1) **Options** Source

Limits Min Auto Max Auto

Show units

8. Once you have your metrics selected, create a dashboard and add it. Here is a sample dashboard.

## Metrics deep dive

This section describes each of the metrics and how they co-relate with each other.

### Number of records (metric: streaming.numRecords)

This metric indicates how many records are being processed.

This streaming metric provides visibility into the number of records you are processing in a window. Along with the number of records being processed, it will also help you understand the behavior of the input traffic.

- Indicator #1 shows an example of stable traffic without any bursts. Typically this will be applications like IoT sensors that are collecting data at regular intervals and sending it to the streaming source.
- Indicator #2 shows an example of a sudden burst in traffic on an otherwise stable load. This could happen in a clickstream application when there is a marketing event like Black Friday and there is a burst in the number of clicks
- Indicator #3 shows an example of unpredictable traffic. Unpredictable traffic doesn't mean there is a problem. It is just the nature of the input data. Going back to the IoT sensor example, you can think of hundreds of sensors that are sending weather change events to the streaming source. As the weather change is not predictable, neither is the data. Understanding the traffic pattern is key to sizing your executors. If the input is very spiky, you may consider using autoscaling (more on that later).

You can combine this metric with the Kinesis PutRecords metric to make sure the number of events being ingested and the number of records being read are nearly the same. This is especially useful when you are trying to understand lag. As the ingestion rate increases, so do the numRecords read by AWS Glue.

## Batch processing time (metric: streaming.batchProcessingTimeInMs)

The batch processing time metric helps you determine if the cluster is underprovisioned or overprovisioned.

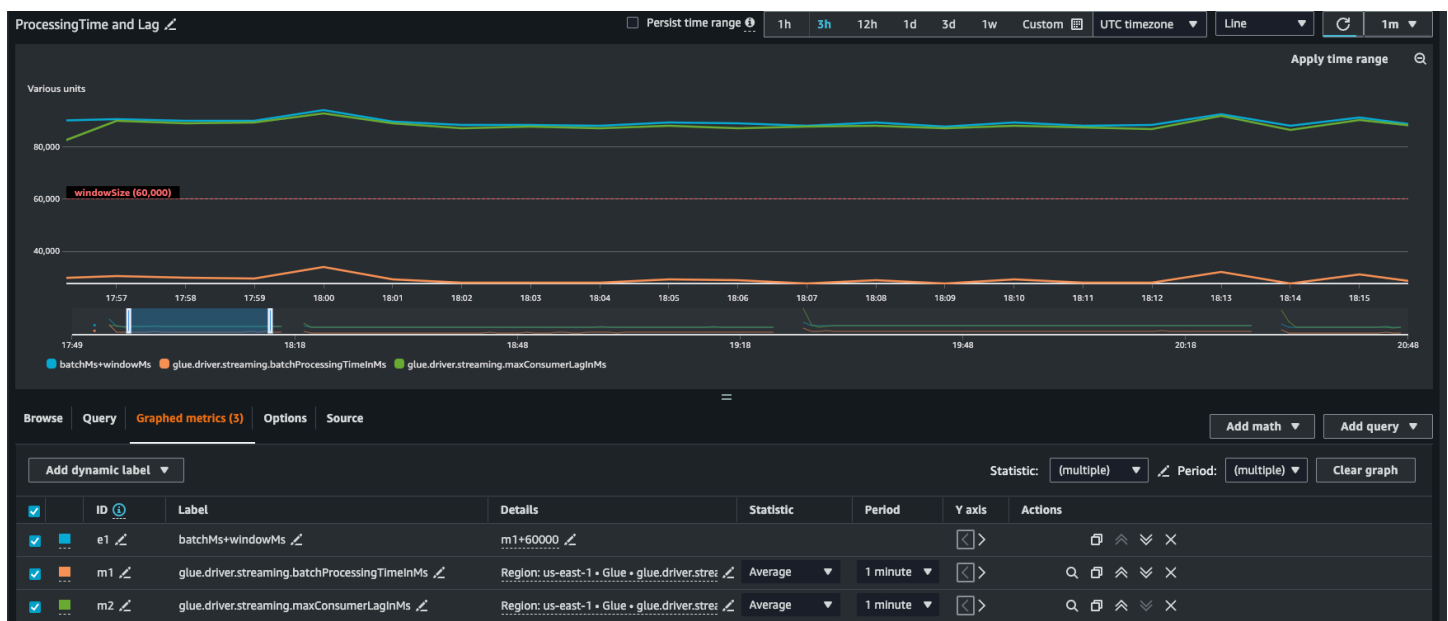

This metric indicates the number of milliseconds that it took to process each micro-batch of records. The main goal here is to monitor this time to make sure it less than the `windowSize` interval. It is okay if the `batchProcessingTimeInMs` goes over temporarily as long as it recovers in the following window interval. Indicator #1 shows a more or less stable time taken to process the job. However if the number of input records are increasing, the time it takes to process the job will increase as well as shown by indicator #2. If the `numRecords` is not going

up, but the processing time is going up, then you would need to take a deeper look into the job processing on the executors. It is a good practice to set a threshold and alarm to make sure the `batchProcessingTimeInMs` doesn't stay over 120% for more than 10 minutes. For more information on setting alarms, see [Using Amazon CloudWatch alarms](#).

## Consumer lag (metric: `streaming.maxConsumerLagInMs`)

The consumer lag metric helps you understand if there is a lag in processing events. If your lag is too high, then you could miss the processing SLA that your business depends on, even though you have a correct `windowSize`. You have to explicitly enable this metrics using the `emitConsumerLagMetrics` connection option. For more information, see [KinesisStreamingSourceOptions](#).

## Derived metrics

To gain deeper insights, you can create derived metrics to understand more about your streaming jobs in Amazon CloudWatch.

You can build a graph with derived metrics to decide if you need to use more DPUs. While autoscaling helps you do this automatically, you can use derived metrics to determine if autoscaling is working effectively.

- **InputRecordsPerSecond** indicates the rate at which you are getting input records. It is derived as follows: number of input records (`glue.driver.streaming.numRecords`)/ `WindowSize`.
- **ProcessingRecordsPerSecond** indicates the rate at which your records are being processed. It is derived as follows: number of input records (`glue.driver.streaming.numRecords`)/ `batchProcessingTimeInMs`.

If the input rate is higher than the processing rate, then you may need to add more capacity to process your job or increase the parallelism.

## Autoscaling metrics

When your input traffic is spiky, then you should consider enabling autoscaling and specify the max workers. With that you get two additional metrics, `numberAllExecutors` and `numberMaxNeededExecutors`.

- **numberAllExecutors** is the number of actively running job executors

- **numberMaxNeededExecutors** is the number of maximum (actively running and pending) job executors needed to satisfy the current load.

These two metrics will help you understand if your autoscaling is working correctly.

AWS Glue will monitor the `batchProcessingTimeInMs` metric over a few micro-batches and do one of two things. It will scale-out the executors, if `batchProcessingTimeInMs` is closer to the `windowSize`, or scale-in the executors, if `batchProcessingTimeInMs` is comparatively lower than `windowSize`. Also, it will use an algorithm for step-scaling the executors.

- indicator #1 shows you how the active executors scaled up to catch up with the max needed executors so as to process the load.
- indicator #2 shows you how the active executors scaled in since the `batchProcessingTimeInMs` was low.

You can use these metrics to monitor current executor-level parallelism and adjust the number of max workers in your auto-scaling configuration accordingly.

## How to get the best performance

Spark will try to create one task per shard, to read from, in the Amazon Kinesis stream. The data in each shard becomes a partition. It will then distribute these tasks across the executors/workers, depending of the number of cores on each worker (the number of cores per worker depends on the worker type you select G.025X, G.1X, etc). However it is non-deterministic how the tasks are

distributed. All tasks are executed in parallel on their respective cores. If there are more shards than the number of available executor cores, the tasks are queued up.

You can use a combination of the above metrics and the number of shards, to provision your executors for a stable load with some room for bursts. It is recommend that you run a few iterations of your job in order to determine the approximate number of workers. For an unstable/spiky workload you can do the same by setting up autoscaling and max workers.

Set the `windowSize` as per the SLA requirement of your business. For example, if your business requires that the processed data cannot be more than 120 seconds stale, then set your `windowSize` to at least 60 seconds such that your average consumer lag is less than 120 seconds (refer to the section on consumer lag above). From there depending on the `numRecords` and number of shards, plan for the capacity in DPUs making sure your `batchProcessingTimeInMs` is less than 70% of your `windowSize` most of the time.

 **Note**

Hot shards can cause data skew which means that some shards/partitions are much bigger than the others. This may cause some tasks that are running in parallel to take longer time causing straggler tasks. As a result, the next batch can't start until all tasks from the previous one complete, this will impact the `batchProcessingTimeInMillis` and the max lag.

# AWS Glue Data Quality

AWS Glue Data Quality allows you to measure and monitor the quality of your data so that you can make good business decisions. Built on top of the open-source DeeQu framework, AWS Glue Data Quality provides a managed, serverless experience. AWS Glue Data Quality works with Data Quality Definition Language (DQDL), which is a domain specific language that you use to define data quality rules. To learn more about DQDL and supported rule types, see [Data Quality Definition Language \(DQDL\) reference](#).

For additional product details and pricing, see the service page for [AWS Glue Data Quality](#).

## Benefits and key features

Benefits and key features of AWS Glue Data Quality include:

- **Serverless** – there is no installation, patching or maintenance.
- **Get started quickly** – AWS Glue Data Quality quickly analyzes your data and creates data quality rules for you. You can get started with two clicks: “Create Data Quality Rules → Recommend rules”.
- **Detect data quality issues** – Use machine learning (ML) to detect anomalies and hard-to-detect data quality issues.
- **Improvise your rules** – with 25+ out-of-the-box DQ rules to start from, you can create rules that suit your specific needs.
- **Evaluate quality and make confident business decisions** – Once you evaluate the rules, you get a Data Quality score that provides an overview of the health of your data. Use Data Quality score to make confident business decisions.
- **Zero in on bad data** – AWS Glue Data Quality helps you identify the exact records that caused your quality scores to go down. Easily identify them, quarantine and fix them.
- **Pay as you go** – There are no annual licenses you need to use AWS Glue Data Quality.
- **No lock-in** – AWS Glue Data Quality is built on open source DeeQu, allowing you to keep the rules you are authoring in an open language.
- **Data quality checks** – AWS Glue Data Quality You can enforce data quality checks on Data Catalog and AWS Glue ETL pipelines allowing you to manage data quality at rest and in transit.
- **ML-based data quality detection** – Use machine learning (ML) to detect anomalies and hard-to-detect data quality issues.

## How it works

There are two entry points for AWS Glue Data Quality: the AWS Glue Data Catalog and AWS Glue ETL jobs. This section provides an overview of the use cases and AWS Glue features that each entry point supports.

### Data quality for the AWS Glue Data Catalog

AWS Glue Data Quality evaluates objects that are stored in the AWS Glue Data Catalog. It offers non-coders an easy way to set up data quality rules. These personas include data stewards and business analysts.

You might choose this option for the following use cases:

- You want to perform data quality tasks on data sets that you've already cataloged in the AWS Glue Data Catalog.
- You work on data governance and need to identify or evaluate data quality issues in your data lake on an ongoing basis.

You can manage data quality for the Data Catalog using the following interfaces:

- The AWS Glue management console
- AWS Glue APIs

To get started with AWS Glue Data Quality for the AWS Glue Data Catalog see [Getting started with AWS Glue Data Quality for the Data Catalog](#).

### Data quality for AWS Glue ETL jobs

AWS Glue Data Quality for AWS Glue ETL jobs lets you perform *proactive* data quality tasks. Proactive tasks help you identify and filter out bad data *before* you load a data set into your data lake.

[Video: Introducing AWS Glue Data Quality for ETL Pipelines](#)

You might choose data quality for ETL jobs for the following use cases:

- You want to incorporate data quality tasks into your ETL jobs

- You want to write code that defines data quality tasks in ETL scripts
- You want to manage the quality of data that flows in your visual data pipelines

You can manage data quality for ETL jobs using the following interfaces:

- AWS Glue Studio, AWS Glue Studio notebooks, and AWS Glue interactive sessions
- AWS Glue libraries for ETL scripting
- AWS Glue APIs

To get started with data quality for ETL jobs, see [Tutorial: Getting started with Data Quality](#) in the *AWS Glue Studio User Guide*.

## Comparing data quality for the Data Catalog to data quality for ETL jobs

This table provides an overview of features that each entry point for AWS Glue Data Quality supports.

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
Data sources	Amazon S3, Amazon Redshift, JDBC sources compatible with the Data Catalog, and transactional data lake formats such as Apache Iceberg, Apache Hudi, and Delta Lake. Note that if tables are AWS Lake Formation managed, Iceberg, Delta and HUDI tables are not supported. Amazon Athena views that are cataloged in AWS Glue Data Catalog are not supported.	All data sources supported by AWS Glue, including custom connectors and third-party connectors.

Feature	Data quality for the Data Catalog	Data quality for ETL jobs
Data Quality rule recommendations	Supported	Not supported
Author and run DQDL rules	Supported	Supported
Auto scaling	Not supported	Supported
AWS Glue Flex support	Not supported	Supported
Scheduling	Supported when evaluating Data Quality rules and via Step Functions.	Supported when using Step Functions and workflows.
Identifying records that failed data quality checks	Not supported	Supported
Integration with Amazon Eventbridge	Supported	Supported
Integration with AWS Cloudwatch	Supported	Supported
Writing data quality results to Amazon S3	Supported	Supported
Incremental data quality	Supported via pushdown predicates	Supported via AWS Glue bookmarks
AWS CloudFormation support	Supported	Supported
ML-based anomaly detection	Not supported	Preview
Dynamic rules	Not supported	Supported

## Considerations

Consider the following items before you use AWS Glue Data Quality:

- Data quality rules can't evaluate nested or list-type data sources. See [Flatten nested structs](#).

## Terminology

The following list defines terms that are related to AWS Glue Data Quality.

### Data Quality Definition Language (DQDL)

A domain-specific language that you can use to write AWS Glue Data Quality rules.

To learn more about DQDL, see the [Data Quality Definition Language \(DQDL\) reference](#) guide.

### data quality

Describes how well a dataset serves its specific purpose. AWS Glue Data Quality evaluates rules against a dataset to measure data quality. Each rule checks for particular characteristics like data freshness or integrity. To quantify data quality, you can use a *data quality score*.

### data quality score

The percentage of data quality rules that pass (result in true) when you evaluate a ruleset with AWS Glue Data Quality.

### rule

A DQDL expression that checks your data for a specific characteristic and returns a Boolean value. For more information, see [Rule structure](#).

### analyzer

A DQDL expression that gathers data statistics. An analyzer gathers data statistics that can be used by ML algorithms to detect anomalies and hard-to-detect data quality issues over time.

### ruleset

An AWS Glue resource that comprises a set of data quality rules. A ruleset must be associated with a table in the AWS Glue Data Catalog. When you save a ruleset, AWS Glue assigns an Amazon Resource Name (ARN) to the ruleset.

## data quality score

The percentage of data quality rules that pass (result in true) when you evaluate a ruleset with AWS Glue Data Quality.

## observation

An unconfirmed insight generated by AWS Glue by analyzing data statistics gathered from rules and analyzers over time.

# Release notes for AWS Glue Data Quality

This topic describes features introduced in AWS Glue Data Quality.

## General availability: new features

The following new features are available with the general availability of AWS Glue Data Quality:

- The ability to identify which records failed data quality checks is now supported in AWS Glue Studio
- New data quality ruletypes such as validating referential integrity of data between two data sets, comparing data between two datasets, and data type checks
- Improved user experience in the AWS Glue Data Catalog
- Support for Apache Iceberg, Apache Hudi and Delta Lake
- Support for Amazon Redshift
- Simplified notification with Amazon Eventbridge
- AWS CloudFormation support for creating rulesets
- Performance improvements: caching option in ETL and AWS Glue Studio for faster performance when evaluating data quality

## Nov 27, 2023 (Preview)

- ML-powered anomaly detection capabilities are now available in AWS Glue ETL and AWS Glue Studio. With this, you can now detect anomalies and hard-to-detect data quality issues.
- [Dynamic Rules allows you to provide dynamic thresholds \(ex: RowCount > avg\(last\(10\)\)\)](#).

## Mar 12, 2024

- DQDL improvements
  - [Support for Keywords like NULL, BLANKS, WHITESPACES\\_ONLY](#)
  - [Options to specify how AWS Glue Data Quality must handle Composite rules](#)
  - [ColumnValues rule type will not allow NULL values to pass during comparisons](#)
  - [Support for NOT operator in DQDL](#)

## Mar 30, 2024

- DQDL improvements
  - DQDL now supports where clause so that you can filter data before applying DQ rules

## Anomaly detection in AWS Glue Data Quality

### Note

AWS Glue Data Quality is available in preview in the following regions:

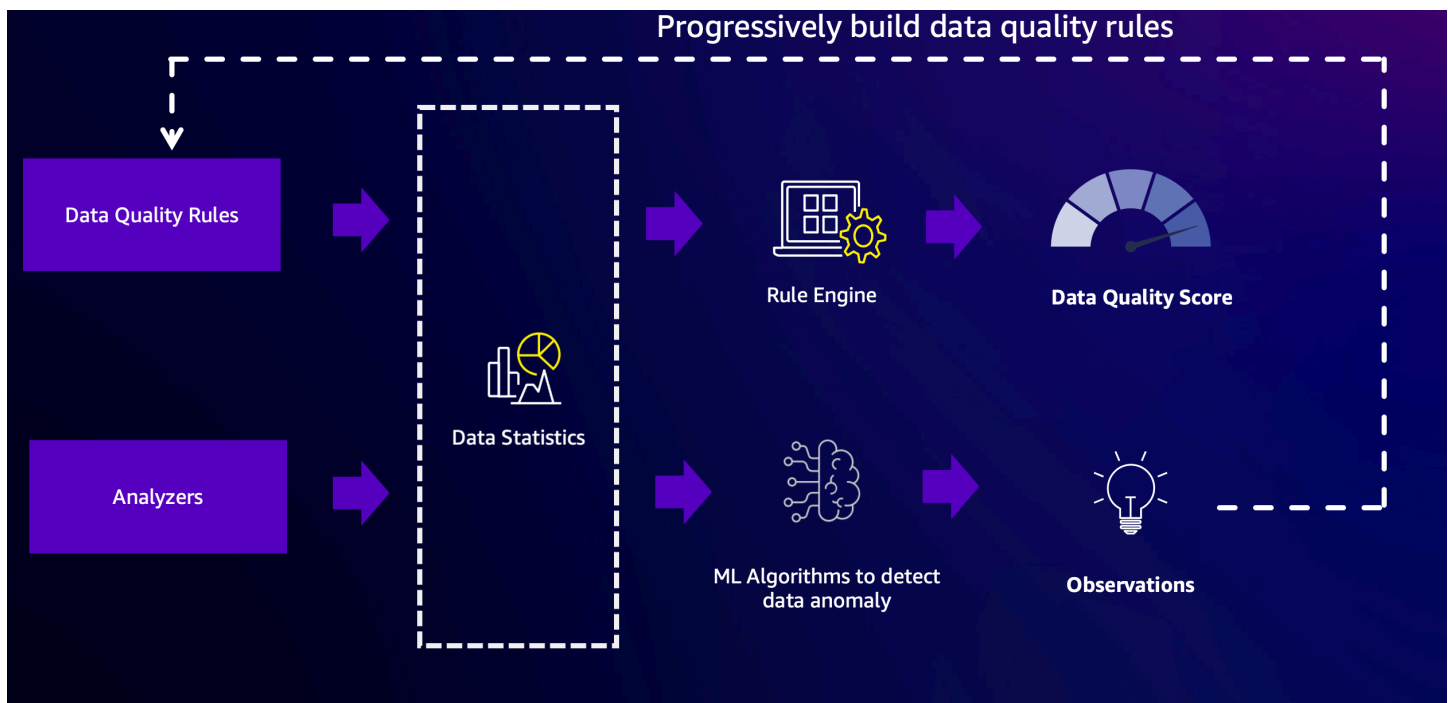

- US East (Ohio, N. Virginia)
- US West (Oregon)
- Asia Pacific (Tokyo)
- Europe (Ireland)

AWS Glue Data Quality anomaly detection applies machine learning (ML) algorithms on data statistics over time to detect abnormal patterns and hidden data quality issues that are hard to detect through rules. At present, anomaly detection is only available for AWS Glue 4.0. This feature is currently available only in AWS Glue Studio Visual ETL and AWS Glue ETL. This capability doesn't work on AWS Glue Studio Notebooks, AWS Glue Data Catalog, AWS Glue Interactive Sessions, and AWS Glue Data Previews.

## How it works

When evaluating Data Quality rules, AWS Glue captures data statistics needed to determine whether the data conforms with the rules. For example, Data Quality will compute the number of distinct values in a dataset, and then compare that value to the expectation.

The Data Quality rule engine compares the statistic value with the defined thresholds, and evaluates your quality requirements. As these statistics are collected over time, you can enable anomaly detection on your ETL pipelines to let AWS Glue learn from past statistics and report hidden patterns as Observations. Observations are unconfirmed insights that AWS Glue's ML algorithm identifies. They come with recommended Data Quality rules that you can apply to your ruleset for monitoring of the discovered pattern. We recommend running jobs at a regular schedule (for example, hourly and daily). Irregular runs might produce poor insights.

## Using analyzers to inspect your data

Sometimes, you might not have the time to author data quality rules. This is where analyzers come in handy. Analyzers are part of your ruleset and are very simple to configure. For example, you can write this in your ruleset:

```
Analzyers = [  
  RowCount,  
  Completeness "AllColumns"
```

```
]
```

This will gather the following statistics:

- Row Count for the entire dataset
- Completeness of every column in your dataset

We recommend using Analyzers because you won't have to worry about the thresholds. You can run your data pipelines and after three runs, AWS Glue Data Quality will start generating observations and rule recommendations when it notices any anomalies. You can review the observations, associated statistics and can easily incorporate the rule recommendations in your ruleset. To get started see [Configuring Anomaly detection and generating insights](#) . Note that Analyzers will not impact your data quality scores. They generate statistics that can be analyzed over time to generate observations.

## Using the DetectAnomaly Rule

Sometimes, you want your jobs to fail when it detects anomalies. To enforce a constraint, you must configure a rule. Analyzers won't stop a job. Instead, they will gather statistics and analyze the data. Configuring the DetectAnomaly rule in the rules section of the ruleset will confirm that the DQ scan reports the job has failed to pass all the rules in the scan.

## Benefits and use cases of Anomaly Detection

Engineers may manage hundreds of data pipelines at any given time. Each pipeline can extract data from different sources and load it into the data lake. Since each pipeline might extract data from a different source and load it into data lake, it is difficult to get immediate feedback on the data – whether its shape has changed significantly, or it has diverged from existing trends.

In the past, upstream data sources have changed without warning to data engineering teams, introducing hard-to-track “data bugs” into this process. By adding Data Quality nodes to jobs, this makes life much easier, as jobs fail when issues are spotted. However, this doesn't remove all the failure modes that data teams are worried about, which keeps the door open for other data bugs to come in.

One failure mode is around data volume. As a company's data store grows over time, the number of records produced by data pipelines may grow exponentially. Every week, data teams may need

to manually update ETL jobs to increase each Data Quality rule that sets a limit to the number of rows ingested.

Another failure mode is that some of the data quality rule limits are very wide to accommodate the fact that transaction volume varies by day of the week. On weekends, there are almost no transactions, and on Mondays there are about three times more transaction than on other weekdays. Data teams have two options - either implement logic to change the ruleset on the fly depending on the day, or set a very wide expectation.

Finally, data teams are also concerned with less well-defined data bugs. Models have been trained on data with specific characteristics, and if these start skewing in unexpected ways, the team wants to know. For example, in February a company may expand to Montana, and so transactions started containing the "MT" code appear more frequently. This may break the ML inference, and as a result the models falsely predicted that every single Montana transaction was fraudulent.

This is where Data quality anomaly detection can help solve these problems. Some of the benefits of Data Quality anomaly detection include:

- Scanning of data on a scheduled, event-driven, or manual basis.
- Detection of anomalies that can be indicative of an unintended event, seasonality, or statistical abnormality.
- Offer Rule Recommendations to take action on observations found by Data Quality anomaly detection.

This is useful if you:

- want to detect anomalies on your data automatically without the need to write data quality rules.
- want to catch potential problems in your data that data quality rules alone can't find.
- want to automate some tasks that evolve over time, such as limiting the number of rows ingested for data quality monitoring.

## Configure IAM permissions for AWS Glue Data Quality

This topic provides information to help you understand the actions and resources that you an IAM administrator can use in an AWS Identity and Access Management (IAM) policy for AWS Glue Data

Quality. It also includes sample IAM policies with the minimum permissions you need to use AWS Glue Data Quality with the AWS Glue Data Catalog.

For additional information about security in AWS Glue, see [Security in AWS Glue](#).

## IAM permissions for AWS Glue Data Quality

The following table lists the permissions that a user needs in order to perform specific AWS Glue Data Quality operations. To set fine-grained authorization for AWS Glue Data Quality, you can specify these actions in the Action element of an IAM policy statement.

### AWS Glue Data Quality actions

Action	Description	Resource types
<code>glue:CreateDataQualityRuleset</code>	Grants permission to create a data quality ruleset.	<code>::dataQualityRuleset/&lt;name&gt;</code>
<code>glue&gt;DeleteDataQualityRuleset</code>	Grants permission to delete a data quality ruleset.	<code>::dataQualityRuleset/&lt;name&gt;</code>
<code>glue:GetDataQualityRuleset</code>	Grants permission to retrieve a data quality ruleset.	<code>::dataQualityRuleset/&lt;name&gt;</code>
<code>glue:ListDataQualityRulesets</code>	Grants permission to retrieve all data quality rulesets.	<code>::dataQualityRuleset/*</code>
<code>glue:UpdateDataQualityRuleset</code>	Grants permission to update a data quality ruleset.	<code>::dataQualityRuleset/&lt;name&gt;</code>
<code>glue:GetDataQualityResult</code>	Grants permission to retrieve a data quality task run result.	<code>::dataQualityRuleset/&lt;name&gt;</code>
<code>glue:ListDataQualityResults</code>	Grants permission to retrieve all data quality task run results.	<code>::dataQualityRuleset/*</code>
<code>glue:CancelDataQualityRuleRecommendationRun</code>	Grants permission to stop an in-progress data quality recommendation task run.	<code>::dataQualityRuleset/*</code>

Action	Description	Resource types
<code>glue:GetDataQualityRuleRecommendationRun</code>	Grants permission to retrieve a data quality recommendation task run.	<code>::dataQualityRuleset/*</code>
<code>glue:ListDataQualityRuleRecommendationRuns</code>	Grants permission to retrieve all data quality recommendation task runs.	<code>::dataQualityRuleset/*</code>
<code>glue:StartDataQualityRuleRecommendationRun</code>	Grants permission to start a data quality recommendation task run.	<code>::dataQualityRuleset/*</code>
<code>glue:CancelDataQualityRulesetEvaluationRun</code>	Grants permission to stop an in-progress data quality task run.	<code>::dataQualityRuleset/*</code>
<code>glue:GetDataQualityRulesetEvaluationRun</code>	Grants permission to retrieve a data quality task run.	<code>::dataQualityRuleset/*</code>
<code>glue:ListDataQualityRulesetEvaluationRuns</code>	Grants permission to retrieve all data quality task runs.	<code>::dataQualityRuleset/*</code>
<code>glue:StartDataQualityRulesetEvaluationRun</code>	Grants permission to start a data quality task run.	<code>::dataQualityRuleset/&lt;name&gt;</code>
<code>glue:PublishDataQuality</code>	Grants permission to publish data quality results	<code>::dataQualityRuleset/&lt;name&gt;</code>

## IAM setup required for scheduling evaluation runs

### IAM permissions

To run scheduled Data Quality evaluation runs, you must add the `IAM:PassRole` action to the permissions policy.

### AWS EventBridge Scheduler required permissions

Action	Description	Resource types
<code>iam:PassRole</code>	Grants permission for IAM to allow the user to pass the approved roles.	ARN of the role used to call <code>StartDataQualityRuleSetEvaluationRun</code>

Without these permissions the following error occurs:

```
"errorCode": "AccessDenied"
"errorMessage": "User: arn:aws:sts::account_id:assumed-role/AWSGlueServiceRole is not
authorized to perform: iam:PassRole on resource: arn:aws:iam::account_id:role/service-
role/AWSGlueServiceRole
because no identity-based policy allows the iam:PassRole action"
```

### IAM trusted entities

The AWS Glue and AWS EventBridge Scheduler services need to be listed in the trusted entities in order to create and run a scheduled `StartDataQualityEvaluationRun`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Effect": "Allow",
      "Principal": {
```

```
        "Service": "scheduler.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

## Example IAM policies

An IAM role for AWS Glue Data Quality needs the following types of permissions:

- Permissions for AWS Glue Data Quality operations so that you can get recommended data quality rules and run a data quality task against a table in the AWS Glue Data Catalog. The example IAM policies in this section include the minimum permissions required for AWS Glue Data Quality operations.
- Permissions that grant access to your Data Catalog table and the underlying data. These permissions vary depending on your use case. For example, for data that you catalog in Amazon S3, the permissions should include access to Amazon S3.

### Note

You must configure Amazon S3 permissions in addition to the permissions described in this section.

## Minimum permissions to get recommended data quality rules

This example policy includes the permissions you need in order to generate recommended data quality rules.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGlueRuleRecommendationRunActions",
      "Effect": "Allow",
      "Action": [
        "glue:GetDataQualityRuleRecommendationRun",
        "glue:PublishDataQuality",
        "glue:CreateDataQualityRuleset"
      ]
    }
  ]
}
```

```

    ],
    "Resource": "arn:aws:glue:us-east-1:111122223333:dataQualityRuleset/*"
  },
  {
    "Sid": "AllowCatalogPermissions",
    "Effect": "Allow",
    "Action": [
      "glue:GetPartitions",
      "glue:GetTable"
    ],
    "Resource": [
      "*"
    ]
  },
  {
    "Sid": "AllowS3GetObjectToRunRuleRecommendationTask",
    "Effect": "Allow",
    "Action": [
      "s3:GetObject"
    ],
    "Resource": "arn:aws:s3:::aws-glue-*"
  },
  { // Optional for Logs
    "Sid": "AllowPublishingCloudwatchLogs",
    "Effect": "Allow",
    "Action": [
      "logs:CreateLogStream",
      "logs:CreateLogGroup",
      "logs:PutLogEvents"
    ],
    "Resource": "*"
  },
]
}

```

## Minimum permissions to run a data quality task

This example policy includes the permissions you need in order to run a data quality evaluation task.

The following policy statements are optional, depending on your use case:

- AllowCloudWatchPutMetricDataToPublishTaskMetrics - Required if you want to publish data quality run metrics to Amazon CloudWatch.
- AllowS3PutObjectToWriteTaskResults - Required if you want to write data quality run results to Amazon S3.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGlueGetDataQualityRuleset",
      "Effect": "Allow",
      "Action": [
        "glue:GetDataQualityRuleset"
      ],
      "Resource": "arn:aws:glue:us-east-1:111122223333:dataQualityRuleset/<YOUR-
RULESET-NAME>"
    },
    {
      "Sid": "AllowGlueRulesetEvaluationRunActions",

## Getting started with AWS Glue Data Quality for the Data Catalog

This getting started section provides instructions to help you get started with AWS Glue Data Quality on the AWS Glue console. You'll learn how to complete essential tasks such as generating data quality rule recommendations and evaluating a ruleset against your data.

### Topics

- [Prerequisites](#)
- [Step-by-step example](#)
- [Generating rule recommendations](#)
- [Monitoring rule recommendations](#)

- [Editing recommended rulesets](#)
- [Creating a new ruleset](#)
- [Running a ruleset to evaluate data quality](#)
- [Viewing the data quality score and results](#)
- [Related topics](#)

## Prerequisites

Before you use AWS Glue Data Quality, you should be familiar with using the Data Catalog and crawlers in AWS Glue. With AWS Glue Data Quality, you can evaluate quality for tables in a Data Catalog database. You also need the following:

- A table in the Data Catalog to evaluate your data quality ruleset against.
- An IAM role for AWS Glue that you supply when you generate rule recommendations or run a data quality task. This role must have permission to access resources that various AWS Glue Data Quality processes require to run on your behalf. These resources include AWS Glue, Amazon S3, and CloudWatch. To view example policies that include the minimum permissions for AWS Glue Data Quality, see [Example IAM policies](#).

To learn more about IAM roles for AWS Glue, see [Create an IAM policy for the AWS Glue service](#) and [Create an IAM role for the AWS Glue service](#). You can also view a list of all AWS Glue permissions that are specific to data quality in [Authorization for AWS Glue Data Quality actions](#).

- A database with at least one table that contains a variety of data. The table used in this tutorial is named `yyz-tickets`, with the table `tickets`. This data is a collection of publicly available information from the City of Toronto for parking citations. If you create your own table, make sure that it's populated with a variety of valid data to get the best set of recommended rules.

## Step-by-step example

For a step-by-step example with sample datasets, see the [AWS Glue Data Quality blog post](#).

## Generating rule recommendations

Rule recommendations make it easy to get started with data quality without writing code. With AWS Glue Data Quality, you can analyze your data, identify rules, and create a ruleset that you can evaluate in a data quality task. Recommendation runs are automatically deleted after 90 days.

## To generate data quality rule recommendations

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose **Tables** in the navigation pane. Then choose the table that you want to generate data quality rule recommendations for.
3. On the table details page, select the **Data quality** tab to access AWS Glue Data Quality rules and settings for your table.
4. On the **Data quality** tab, choose **Add rules and monitor data quality**.
5. On the **Ruleset builder** page, an alert at the top of the page will prompt you to start a recommendation task if there are no rule recommendation runs.
6. Choose **Recommend rules** to open the modal and input your parameters for the recommendation task.
7. Choose an IAM role with access to AWS Glue. This role must have permission to access resources that various AWS Glue Data Quality processes require to run on your behalf.
8. After the fields are completed according to your preferences, choose **Recommend rules** to start the recommendation task run. If recommendation runs are in progress or completed, you can manage your runs in this alert. You might need to refresh the alert to view the status change. Completed and in-progress recommendation task runs appear in the **Run history** page that lists all recommendation runs for the past 90 days.

## What the recommended rules mean

AWS Glue Data Quality generates rules based on the data from each column of the input table. It uses the rules to identify potential boundaries where data can be filtered to maintain quality requirements. The following list of generated rules includes examples that are useful for understanding what the rules mean and what they might do when applied to your data.

For a full list of the generated Data Quality Definition Language (DQDL) rule types, see [DQDL rule type reference](#).

- IsComplete "SET\_FINE\_AMOUNT" –The IsComplete rule verifies that the column is filled in for any given row. Use this rule to tag columns as non-optional in data.
- Uniqueness "TICKET\_NUMBER" > 0.95 – The Uniqueness rule verifies that the data within the column meets some threshold of uniqueness. In this example, the data that populates any given row for "TICKET\_NUMBER" was determined to be at most 95% identical in content to all other rows, which suggests this rule.

- `ColumnValues` "PROVINCE" in ["ON", "QC", "AB", "NY", ...] – The `ColumnValues` rule defines valid values for the column, based on existing column contents. In this example, the data for each row is a 2-letter license code plate for a state or province.
- `ColumnLength` "INFRACTION\_DESCRIPTION" between 15 and 31 – The `ColumnLength` rule enforces a length restriction on a column's data. This rule is generated from the sample data based on the minimum and maximum recorded lengths for a column of strings.

## Monitoring rule recommendations

When data quality rule recommendations are running, the **Add rules and monitor data quality** page displays information and additional actions that you can take in the top bar.

When rule recommendations are in progress, you can choose **Stop run** before the recommendation task is complete. While the task is in progress, you will see the status, **in progress**, and the date and time when the run started.

When the rule recommendations are complete, the rule recommendation bar displays the number of rules recommended, the status of the last recommendation run, and the date and timestamp when it finished.

You can add the recommended rules by choosing **Insert Rule Recommendation**. To view previously recommended rules, select a specific date. To run a new recommendation, choose **More actions**, and then choose **Recommended rules**.

Set default settings by choosing **Manage user settings**. You can set the default path for Amazon S3 to store rulesets or to set up a default role to run the Data Catalog.

## Editing recommended rulesets

Because AWS Glue Data Quality generates rules based on existing data that you have available, you might see some unexpected or undesirable rules in the automated suggestions. In order to get the most out of the recommended rulesets, you need to evaluate and modify them. For this step of the tutorial, you take the rules generated in the previous step and adjust them to enforce more restrictive qualities on some data. You also relax other rules to ensure that correct, unique data can be added later.

## Edit a suggested ruleset

1. In the AWS Glue console, choose **Data Catalog**, and then choose **Databases tables** in the navigation pane. Choose the table tickets.
2. On the table details page, choose the **Data quality** tab to access AWS Glue Data Quality rules and settings for the table.
3. In the **Rulesets** section, select the ruleset generated in [Generating rule recommendations](#).
4. Choose **Actions**, and then choose **Edit** in the console window. The ruleset editor loads in the console. It includes an editing pane for your rules and a quick reference for DQDL.
5. Remove line 2 of the script. This relaxes the requirement that the database size is constrained within a certain number of rows. After the edit, your file should contain the following on lines 1–3:

```
Rules = [
  IsComplete "TAG_NUMBER_MASKED",
  ColumnLength "TAG_NUMBER_MASKED" between 6 and 9,
```

6. Remove line 25 of the script. This relaxes the requirement that 96% of recorded provinces are ON. After the edit, your file should contain the following from line 24 to the end of the ruleset:

```
ColumnValues "PROVINCE" in ["ON", "QC", "AB", "NY", "AZ", "NS", "BC", "MI", "PQ",
  "MB", "PA", "FL", "SK", "NJ", "OH", "NB", "IL", "MA", "CA",
  "VA", "TX", "NF", "MD", "PE", "CT", "NC", "GA", "IN", "OR", "MN", "TN", "WI",
  "KY", "MO", "WA", "NH", "SC", "CO", "OK", "VT", "RI", "ME", "AL",
  "YT", "IA", "DE", "AR", "LA", "XX", "WV", "MT", "KS", "NT", "DC", "NV", "NE",
  "UT", "MS", "NM", "ID", "SD", "ND", "AK", "NU", "GO", "WY", "HI"],
ColumnLength "PROVINCE" = 2
]
```

7. Change line 14 to the following:

```
IsComplete "TIME_OF_INFRACTION",
```

This *strengthens* the requirement on the column by limiting the database to only tickets that contain a recorded time of infraction. You should always consider tickets without a recorded time of infraction to be invalid data in this dataset. This is different than situations where partitioning or transformation might be more appropriate for further data use or inspection to determine a quality rule.

8. Choose **Update Ruleset** at the bottom of the console page.

## Creating a new ruleset

A ruleset is a group of data quality rules that you evaluate against your data. In the AWS Glue console, you can author custom rulesets using Data Quality Definition Language (DQDL).

### To create a data quality ruleset

1. In the AWS Glue console, choose **Data Catalog**, choose **Databases**, and then choose **Tables** in the navigation pane. Select the table `tickets`.
2. Open the **Data quality** tab.
3. In the **Rulesets** section, choose **Create ruleset**. The DQDL editor launches in the console. It has a text area for direct editing, and a quick reference for DQDL rules and the table schema.
4. Start adding rules to the text area of the DQDL editor. You can either write rules directly from this tutorial, or use the **DQDL rule builder** feature of the data quality rules editor.

#### Note

##### How to use the DQDL rule builder

1. Select a rule type from the list, and select the plus sign to insert example syntax into the editor pane.
2. Exchange the placeholder column names with your own column names. Column names from the table are available in the **Schema** tab.
3. Update the expression parameter as you see fit. For a full list of expressions that DQDL supports, see [Expressions](#).

As an example, the following rules are constraints for data validation of the `ticket_number` column in the `tickets` table. To add the following rules, use the DQDL rule builder or directly edit your ruleset:

```
IsComplete "ticket_number",  
IsUnique "ticket_number",  
ColumnValues "ticket_number" > 9000000000
```

5. Provide a name for your new ruleset in the **Ruleset name** field.
6. Choose **Save ruleset**.

## Evaluating data quality across multiple datasets

You can set up data quality rules across multiple datasets using `ReferentialIntegrity` and `DatasetMatch` rulesets. `ReferentialIntegrity` checks to see if data in the primary dataset is present in other datasets.

To add a reference dataset, choose the **Schema** tab and then choose **Update reference tables**. You will be prompted to select a database and a table. You can add the table and then set up data quality rules. Rule types like `AggregateMatch`, `RowCountMatch`, `ReferentialIntegrity`, `SchemaMatch`, and `DatasetMatch` support the ability to perform data quality checks across multiple datasets.

## Running a ruleset to evaluate data quality

When you run a data quality task, AWS Glue Data Quality evaluates a ruleset against your data and calculates a data quality score. This score represents the percentage of data quality rules that passed for the input.

### To run a data quality task

1. In the AWS Glue console, choose **Data Catalog**, choose **Databases**, and then choose **Tables** in the navigation pane. Select the table tickets.
2. Choose the **Data quality** tab.
3. In the **Rulesets** list, select the ruleset that you want to evaluate against the table. For this step, we recommend using a ruleset that you've written or modified already rather than generated rules. Choose **Run**.
4. In the modal, choose your IAM role. This role must have permission to access resources that various AWS Glue Data Quality processes require to run on your behalf. You can save the IAM role as the default or modify it by going to the **Default Setting** page.
5. Under **Data quality actions**, choose whether you want to **Publish metrics to Amazon CloudWatch**. When this option is selected, AWS Glue Data Quality publishes metrics that indicate the number of rules that passed and the number of rules that failed. To take action on metrics stored this way, you can use CloudWatch alarms. Key metrics are also published to Amazon EventBridge for you to set up alerts. For more information, see [Setting up alerts, deployments, and scheduling](#).

6. In **Run Frequency**, choose run on demand or schedule the ruleset. When you schedule a ruleset, you're prompted for a task name. The schedule will be created in Amazon EventBridge. You can edit your schedule in Amazon EventBridge.
7. To save the data quality results in Amazon S3, select a **Data quality results location**. The IAM role that you previously selected for this task must have write access to this location.
8. Under **Additional Configurations**, enter the **Requested number of workers** that you want AWS Glue to allocate for your data quality task.
9. You can optionally set up a filter at the data source. This helps you reduce the data that you're reading. You can also use a filter to run incremental validations by selecting partition information and passing them as parameters via API calls. To improve performance, you can provide a partition predicate.
10. Choose **Run**. You should see your new task in the **Data quality task runs** list. When the **Run status** column for the task shows as **Completed**, you can view the quality score results. You might need to refresh your console window for the status to update correctly.
11. To view the column for the data quality result details, choose the "+" icon to expand the ruleset. The results show you the rules that passed and failed in the evaluation, and what triggered the rule failure.

## Viewing the data quality score and results

### To see the latest run on all created rulesets

1. In the AWS Glue console, choose **Tables** in the navigation pane. Then choose the table that you want to run a data quality task for.
2. Choose the **Data quality** tab.
3. The **Data quality snapshot** shows a general trend of runs over time. The last 10 runs over all rulesets are displayed by default. To filter by ruleset, select the desired one from the dropdown list. If there are less than 10 runs, all the completed runs that are available are displayed.
4. In the **Data quality** table, each ruleset with its latest run (if there is one) is shown, along with the score. Expanding the ruleset displays the rules that are in that ruleset, along with the rule results for that run.

## To see the latest run on a particular ruleset

1. In the AWS Glue console, choose **Tables** in the navigation pane. Then choose the table that you want to run a data quality task for.
2. Choose the **Data quality** tab.
3. In the **Data quality** table, choose on a specific ruleset.
4. On the **Ruleset details** page, choose the **Run history** tab.

All of the evaluation runs for this particular ruleset are listed in the table within this tab. You can see the history of the scores and the status of the runs.

5. To see more information about a particular run, choose the **Run ID** to go to the **Evaluation run details** page. On this page, you can see specifics about the run and more details about the status of individual rule results.

## Evaluating data quality with AWS Glue Studio

AWS Glue Data Quality evaluates and monitors the quality of your data based on rules that you define. This makes it easy to identify the data that needs action. In AWS Glue Studio, you can add data quality nodes to your visual job to create data quality rules on tables in your Data Catalog. You can then monitor and evaluate changes to your datasets as they evolve over time. For an overview of how to work with AWS Glue Data Quality in AWS Glue Studio, see the following video.

The following are the high-level steps for how you work with AWS Glue Data Quality:

1. **Create data quality rules** – Build a set of data quality rules using the DQDL builder by choosing built-in rulesets that you configure.
2. **Configure a data quality job** – Define actions based on the data quality results and output options.
3. **Save and run a data quality job** – Create and run a job. Saving the job will save the rulesets that you created for the job.

4. **Monitor and review the data quality results** – Review the data quality results after the job run is complete. Optionally, schedule the job for a future date.

## Benefits

Data analysts, data engineers, and data scientists can use the Evaluate Data Quality node in AWS Glue Studio to analyze, configure, monitor, and improve the quality of data from the visual job editor. The benefits of using the data quality node include the following:

- **You can detect data quality issues** - You can check for issues by creating rules that check characteristics of your datasets.
- **It's easy to get started** - You can start with pre-built rules and actions.
- **Tight integration** - You can use data quality nodes in AWS Glue Studio because AWS Glue Data Quality runs on top of the AWS Glue Data Catalog.

## Evaluating data quality for ETL jobs in AWS Glue Studio

In this tutorial, you get started with AWS Glue Data Quality in AWS Glue Studio. You will learn how to:

- Create rules using the Data Quality Definition Language (DQDL) rule builder.
- Specify data quality actions, data to output, and the output location of the data quality results.
- Review data quality results.

To practice with an example, review the blog post [Getting started with AWS Glue Data Quality for ETL pipelines](#).

### Step 1: Add the Evaluate Data Quality transform node to the visual job

In this step, you add the Evaluate Data Quality node to the visual job editor.

#### To add the data quality node

1. In the AWS Glue Studio console, choose **Visual with a source and target** from the **Create job** section, and then choose **Create**.
2. Choose a node that you want to apply the data quality transform to. Typically, this will be a transform node or a data source.

3. Open the resource panel on the left by choosing the "+" icon. Then search for **Evaluate Data Quality** in the search bar and choose **Evaluate Data Quality** from the search results.
4. The visual job editor shows the **Evaluate Data Quality** transform node branching from the node you selected. On the right side of the console, the **Transform** tab is automatically opened. If you need to change the parent node, choose the **Node properties** tab, and then choose the node parent from the dropdown menu.

When you choose a new node parent, a new connection is made between the parent node and the **Evaluate Data Quality** node. Remove any unwanted parent nodes. Only one parent node can be connected to one **Evaluate Data Quality** node.

5. The Evaluate Data Quality transform supports multiple parents so you can validate data quality rules across multiple datasets. Rules that support multiple datasets include ReferentialIntegrity, DatasetMatch, SchemaMatch, RowCountMatch, and AggregateMatch.

When you add multiple inputs to the Evaluate Data Quality transform, you need to select your "primary" input. Your primary input is the dataset that you want to validate data quality for. All other nodes or inputs are treated as references.

You can use the Evaluate Data Quality transform to identify specific records that failed data quality checks. We recommend that you choose your primary dataset because new columns that flag bad records are added to the primary dataset.

6. You can specify aliases for input data sources. Aliases provide another way to reference the input source when you're using the ReferentialIntegrity rule. Because only one data source can be designated as the primary source, each additional data source that you add will require an alias.

In the following example, the ReferentialIntegrity rule specifies the input data source by the alias name and performs a one-to-one comparison to the primary data source.

```
Rules = [  
  ReferentialIntegrity "Aliasname.name" = 1  
]
```

## Step 2: Create a rule using DQDL

In this step, you create a rule using DQDL. For this tutorial, you create a single rule using the **Completeness** rule type. This rule type checks the percentage of complete (non-null) values in a column against a given expression. For more information about using DQDL, see [DQDL](#).

1. On the **Transform** tab, add a **Rule type** by choosing the **Insert** button. This adds the rule type to the rule editor, where you can enter the parameters for the rule.

### Note

When you're editing rules, ensure that the rules are within the brackets and that the rules are separated by commas. For example, a complete rule expression will look like the following:

```
Rules= [  
    Completeness "year">0.8, Completeness "month">0.8  
]
```

This example specifies the parameter for completeness for the columns named 'year' and 'month'. For the rule to pass, these columns must be greater than 80% 'complete', or must have data in over 80% of instances for each respective column.

In this example, search for and insert the **Completeness** rule type. This adds the rule type to the rule editor. This rule type has the following syntax: `Completeness <COL_NAME> <EXPRESSION>`.

Most rule types require that you provide an expression as a parameter in order to create a Boolean response. For more information on supported DQDL expressions, see [DQDL expressions](#). Next, you'll add the column name.

2. In the DQDL rule builder, choose the **Schema** tab. Use the search bar to locate the column name in the input schema. The input schema displays the column name and data type.
3. In the rule editor, click to the right of the rule type to insert the cursor where the column will be inserted. Alternately, you can enter in the name of the column in the rule.

For example, from the list of columns in the input schema list, choose the **Insert** button next to the column (in this example, **year**). This adds the column to the rule.

4. Then, in the rule editor, add an expression to evaluate the rule. Because the **Completeness** rule type checks the percentage of complete (non-null) values in a column against a given expression, enter an expression such as  $> 0.8$ . This rule checks the column if it's greater than 80% complete (non-null) values.

### Step 3: Configure data quality outputs

After creating data quality rules, you can select additional options to specify data quality node output.

1. In **Data quality transform output**, choose from the following options:
  - **Original data** – Choose to output original input data. When you choose this option, a new child node “rowLevelOutcomes” is added to the job. The schema matches the schema of the primary dataset that was passed as input to the transform. This option is useful if you just want to pass the data through and fail the job when quality issues occur.

Another use case is when you want to detect bad records that failed data quality checks. To detect bad records, choose the option **Add new columns to indicate data quality errors**. This action adds four new columns to the schema of the “rowLevelOutcomes” transform.

- **DataQualityRulesPass** (string array) – Provides an array of rules that passed data quality checks.
- **DataQualityRulesFail** (string array) – Provides an array of rules that failed data quality checks.
- **DataQualityRulesSkip** (string array) – Provides an array of rules that were skipped. The following rules cannot identify error records because they're applied at the dataset level.
  - AggregateMatch
  - ColumnCount
  - ColumnExists
  - ColumnNamesMatchPattern
  - CustomSql
  - RowCount
  - RowCountMatch

- StandardDeviation
  - Mean
  - ColumnCorrelation
  - **DataQualityEvaluationResult** – Provides “Passed” or “Failed” status at the row level. Note that your overall results can be FAIL, but a certain record might pass. For example, the RowCount rule might have failed, but all other rules might have been successful. In such instances, this field status is 'Passed'.
2. **Data quality results** – Choose to output configured rules and their pass or fail status. This option is useful if you want to write your results to Amazon S3 or other databases.
  3. **Data quality output settings (Optional)** – Choose **Data quality output settings** to reveal the **Data quality result location** field. Then, choose **Browse** to search for an Amazon S3 location to set as the data quality output target.

## Step 4. Configure data quality actions

You can use actions to publish metrics to CloudWatch or to stop jobs based on specific criteria. Actions are only available after you create a rule. When you choose this option, the same metrics are also published to Amazon EventBridge. You can use these options to [create alerts for notification](#).

- **On ruleset failure** – You can choose what to do if a ruleset fails while the job is running. If you want the job to fail if data quality fails, choose when the job should fail by selecting one of the following options. By default, this action is not selected, and the job completes its run even if data quality rules fail.
  - **None** – If you choose **None** (default), the job does not fail and continues to run despite ruleset failures.
  - **Fail job after loading data to target** – The job fails and no data is saved. In order to save the results, choose an Amazon S3 location where the data quality results will be saved.
  - **Fail job without loading to target data** – This option fails the job immediately when a data quality error occurs. It does not load any data targets, including the results from the data quality transform.

## Step 5: View data quality results

After running the job, view the data quality results by choosing the **Data quality** tab.

1. For each job run, view the data quality results. Each node displays a data quality status and status detail. Choose a node to view all rules and the status of each rule.
2. Choose **Download results** to download a CSV file that contains information about the job run and data quality results.
3. If you have more than one job run with data quality results, you can filter the results by date and time range. Choose *Filter by a date and time range* to expand the filter window.
4. Choose a relative range or absolute range. For absolute ranges, use the calendar to select a date, and enter values for start time and end time. When you're done, choose **Apply**.

## Data Quality rule builder

With the Data Quality Definition Language (DQDL) rule builder, you can create data quality rules to evaluate your data. Start by selecting a rule type, and then specify the parameters in the rule editor. The rule editor also shows you any errors and warnings as you create rules.

The [DQDL guide](#) provides comprehensive documentation on how to construct rules using the DQDL syntax, built-in rule types, and examples.

## Evaluate Data Quality node

When you're working with the **Evaluate Data Quality** transform node and the DQDL rule builder, you can expand the working space.

- To expand the **Transform** tab to fill the entire screen, choose the expand icon in the upper-right hand corner of the node details panel.
- To expand the DQDL rule editor, choose the << icon to expand the rule editor and collapse the **Rule types** and **Schema** tabs.

The screenshot displays the AWS Glue Studio interface for configuring a data quality rule. The left pane shows a workflow diagram with the following nodes:

- Data source - Data Catalog: employees
- Data source - Data Catalog: customers
- Transform - Evaluate Data Quality (Multiframe)
- Transform - SelectFrom... rowLevelOutcomes
- Transform - SelectFrom... ruleOutcomes
- Data target - S3 bucket: Amazon S3
- Data target - Data Catalog: AWS Glue Data Catalog

The right pane shows the configuration for the 'Evaluate Data Quality' node:

- Name:** Evaluate Data Quality (Multiframe)
- Node parents:** employees, customers
- Aliases for referenced data sources:** employees (Primary source), customers
- Input sources:** employees, customers
- Helper:**

```

1 Rules = [
2   ReferentialIntegrity "employeeNumber" "customers
3     salesRepEmployeeNumber" between 0.6 and 0.7,
4   RowCount > 1000,
5   CustomSql "select count(*) from primary" between 10 and 200
]

```
- Data quality transform output info:**
  - Original data

## Components

There are 26 rule types that are built into AWS Glue Studio. Each rule type has a description and examples of how they can be used.

### Data quality rule types

AWS Glue Studio provides built-in rule types for ease in creating a rule. For more information on rule types, see [DQDL rule type reference](#).

### Schema

The **Schema** tab displays the column names and data type from the parent node. Schemas from multiple nodes are displayed. You can view the input schema, search by column name, and insert the column into the rule editor.

## Evaluate data quality [Info](#)

Evaluate data quality by defining your data quality rules and actions

## Data quality rules [Info](#)

- day int +
- fl\_date string +

```
1 Rules= [  
2   Completeness"year">0.8  
3 ]
```

Ln 1, Col 1 ⊗ Errors: 0 ⚠ Warnings: 0 ⚙

## Rule editor

The rule editor is a text editor where you can write and edit rules. If you select a rule type from the DQDL rule builder, the rule type is added to the rule editor. You can then specify parameters, add rules, and edit rules as needed by modifying the text. AWS Glue Studio validates the rules in the rule editor and displays errors and warnings if there are any.

## Errors and warnings

If a rule doesn't follow the DQDL rule syntax, the rule editor shows several visual indicators that there is an error:

- The rule editor displays an error icon and red color on the line with the error.
- The rule editor displays the number of errors next to the red error icon.
- When you choose the line with the error, descriptions of the error and location (line and column) are displayed at the bottom of the rule editor.

Ln 1, Col 18 ⊗ 1 ⚠ 0

Ln 1, Col 1 h is null

## Data quality actions

By default, this action is not selected and the job will complete its run even if the data quality rules fail.

Choose between the following actions. You can use actions to publish results to CloudWatch or stop jobs based on specific criteria. Actions are only available after you create a rule.

- **Publish results to CloudWatch** – When you run a job, add the results to CloudWatch.
- **Fail job when data quality fails** – If data quality rules fail, the job will also fail as a result.

### Data quality transform output

- **Original data** – Choose to output original input data. This option is ideal if you want to stop the job when quality issues are detected.
- **Data quality metrics** – Choose to output configured rules and their pass or fail status. This option is useful if you want to take a custom action.

### Data quality output settings

Set the data quality result location by specifying the Amazon S3 location as the data quality output target.

## Configuring Anomaly detection and generating insights

AWS Glue Data Quality (DQ) evaluates your data based on the data quality rules that you write and provides insights and observations about your data over time so that you can take immediate action. Since DQ scans your data, DQ computes statistical metrics such as row count, maximum or minimum, and then compares them against threshold expressions.

Some of the benefits of Data Quality anomaly detection include:

- continuous automated scanning of data
- detection of anomalies that can be indicative of an unintended event or statistical abnormality
- offer Rule Recommendations to take action on observations found by Data Quality anomaly detection

This is useful if you:

- want to detect anomalies on your data automatically, without the need to write data quality
- want to profile your data and view visual representations of what the data looks like
- want to track how your data changes over time

### What observations can I view about my data?

DQ identifies outliers in the data statistics gathered, changes in data formats, data drifts and schema changes. Based on observations, DQ recommends data quality rules that users can easily operationalize. Statistics include Completeness, Uniqueness, Mean, Sum, StandardDeviation, Entropy, DistinctValuesCount, and UniqueValueRatio.

## Enabling anomaly detection in AWS Glue Studio

To enable anomaly detection, you can open a AWS Glue Studio job and toggle on “Enable Anomaly Detection”. Turning this on enables anomaly detection on your data by analyzing your data over time and providing data statistics about your data and observations that you can act on.

### To enable anomaly detection in AWS Glue Studio:

1. Choose the **Data Quality** node in your job, then choose the **Anomaly detection** tab. Toggle on ‘Enable Anomaly Detection’.

The screenshot shows the 'Anomaly detection' configuration page in AWS Glue Studio. At the top, there are two tabs: 'Ruleset editor' and 'Anomaly detection New'. The 'Anomaly detection' tab is active. Below the tabs, there is a toggle switch for 'Enable anomaly detection Info' which is turned on. A descriptive text below the toggle states: 'Anomaly detection leverages machine learning algorithms to analyze statistics collected by rules and analyzers, allowing us to detect unanticipated and hidden data quality issues. Enable detect anomalies to generate observations on your data during a job run.'

Below this, there is a section titled 'Anomaly detection scope (0)' with a description: 'Scope of data statistics configured to be analyzed for anomalies.' To the right of this section are two buttons: 'Actions' with a dropdown arrow and 'Add analyzer'.

Underneath is a table with three columns: 'Scope of statistics', 'Scope of data', and 'Source'. The table is currently empty, displaying the message: 'No anomaly detection configuration. No configuration to display.'

At the bottom, there is a light blue summary box with the following text:
 

- Summary**
- 0 data quality rule(s). 0 analyzers.
- Anomaly detection enabled on data statistics from rules and analyzers.

2. Define the data to monitor for anomalies by choosing **Add analyzer**. There are two fields you can populate: Statistics and Data.

Statistics are information about your data’s shape and other properties. You can choose one or more statistics at a time, or choose All statistics. Statistics include: Completeness, Uniqueness, Mean, Sum, StandardDeviation, Entropy, DistinctValuesCount, and UniqueValueRatio.

Data is the columns in your data set. You can choose all columns or individual columns.

3. Choose **Add anomaly detection scope** to save your changes. When you've created analyzers, you can see them in the **Anomaly detection scope** section.

You can also use the **Actions** menu to edit your analyzers, or choose the **Ruleset editor** tab and edit the analyzer directly in the ruleset editor notepad. You will see the analyzers you saved just below any rules you've created.

```
Rules = [  
]  
  
Analyzers = [  
  Completeness "id"  
]
```

With the updated ruleset along with analyzers, Data Quality continuously monitors incoming data, signaling anomalies through alerts or job stops based on your settings.

## Note

Observations are generated when a minimum of three values per data statistics are observed in your data set. If there are no observations visible, Data quality does not have enough data to generate an observation. After several job runs, Data quality can provide insights into your data and will display them in the Observations section.

Analyzers generate observations by detecting anomalies in your data and provide you recommendations to progressively build rules. You can view the observations by choosing the Data Quality tab. Observations are specific to each job run. You can view the specific Data Quality node and job run at the top of the Observations section. Choose a new node or job run to view observations specific to that node and job.

The screenshot displays the AWS Glue Data Quality Observations section. At the top, there's a navigation bar with tabs for Visual, Script, Job details, Runs, Data quality - updated, Schedules, and Version Control. Below the navigation bar, there's a section for 'Getting started with data quality (DQ)' with a 'Give feedback' button. The main area is titled 'Data quality at EvaluateDataQuality\_node170057...' and includes a 'Go to node' button and a dropdown for job runs. Below this, there's a section for 'Observations (3) - new' with a search filter and a table of observations. The table has columns for Observation, Related metrics, Rule recommendations, and Observed data. Two observations are listed: one for RowCount and one for Completeness. Below the table is a line chart showing the trend of RowCount over time from Nov 21 10:10 to 10:18.

Observation	Related metrics	Rule recommendations	Observed data
<input checked="" type="radio"/> RowCount of 19999.0 is lower than the detected lower bound of 61509.0.	Dataset*.RowCount • ActualValue: 19999.00 • ExpectedValue: 72964.00 • LowerLimit: 61509.00 • UpperLimit: 84347.00	<input checked="" type="checkbox"/> RowCount between 61508.00 and 84348.00	RowCount
<input type="radio"/> Completeness for column fare_amount of 0.96 is lower than the detected lower bound of 1.0.	Column.fare_amount.Completeness • ActualValue: 0.96 • ExpectedValue: 1.00 • LowerLimit: 1.00	<input checked="" type="checkbox"/> Completeness "fare_amount" = 1.0	ColumnName: fare_amount

**Observation** – each insight is based for a specific job run configured by the rulesets and analyzers you specified.

**Related metrics** – When observations are generated, the Related metrics column shows you the rule and actual and expected values, as well as lower and upper limits.

**Rule recommendations** – AWS Glue then also recommends rules to address this. Each rule that is recommended can be copied by clicking the copy icon. You can copy all recommended rules by clicking the copy icon next to each rule and then clicking **Apply copied rules**.

**Monitored data** – The Monitored data column provides the column or row that was monitored and triggered the observation.

## Applying a recommend rule to your Data quality node

After an observation has been generated and a recommended rule is provided, you can apply that rule to your data quality node. To do this:

1. Click the copy icon next to each rule recommendation. This will add the rule recommendation to a notepad that you can retrieve later.
2. Click **Apply rule recommendations**. This opens the notepad where you can view the rules you previously copied.
3. Choose **Copy rules**.
4. Choose **Apply to ruleset editor**. This opens the ruleset editor where you can paste the copied rules.
5. Paste the copied rules to the ruleset editor.

## Data Quality for ETL jobs in AWS Glue Studio notebooks

In this tutorial, you learn how to use AWS Glue Data Quality for extract, transform, and load (ETL) jobs in AWS Glue Studio notebooks.

You can use notebooks in AWS Glue Studio to edit job scripts and view the output without having to run a full job. You can also add markdown and save notebooks as `.ipynb` files and job scripts. Note that you can start a notebook without installing software locally or managing servers. When you're satisfied with your code, you can use AWS Glue Studio to easily convert your notebook to an AWS Glue job.

The dataset that you use in this example consists of Medicare Provider payment data that was downloaded from two *Data.CMS.gov* datasets: "Inpatient Prospective Payment System Provider Summary for the Top 100 Diagnosis-Related Groups - FY2011" and "Inpatient Charge Data FY 2011".

After downloading the data, we modified the dataset to introduce a couple of erroneous records at the end of the file. This modified file is located in a public Amazon S3 bucket at `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv`.

## Prerequisites

- AWS Glue role with Amazon S3 permission to write to your destination Amazon S3 bucket
- A new notebook (see [Getting started with notebooks in AWS Glue Studio](#))

## Creating an ETL job in AWS Glue Studio

### To create an ETL job

1. Change the session version to AWS Glue 3.0.

To do this, remove all boilerplate code cells with the following magic and run the cell. Note that this boilerplate code is automatically provided in the first cell when a new notebook is created.

```
%glue_version 3.0
```

2. Copy the following code and run it in the cell.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
```

3. In the next cell, import the EvaluateDataQuality class that evaluates AWS Glue Data Quality.

```
from awsgluedq.transforms import EvaluateDataQuality
```

4. In the next cell, read in the source data by using the .csv file that's stored in the public Amazon S3 bucket.

```
medicare = spark.read.format(
    "csv").option(
    "header", "true").option(
    "inferSchema", "true").load(
    's3://aws glue-datasets/examples/medicare/Medicare_Hospital_Provider.csv')
medicare.printSchema()
```

5. Convert the data to an AWS Glue DynamicFrame.

```
from awsglue.dynamicframe import DynamicFrame
medicare_dyf = DynamicFrame.fromDF(medicare, glueContext, "medicare_dyf")
```

6. Create the ruleset using Data Quality Definition Language (DQDL).

```
EvaluateDataQuality_ruleset = """
    Rules = [
        ColumnExists "Provider Id",
        IsComplete "Provider Id",
        ColumnValues " Total Discharges " > 15
    ]
    """
```

7. Validate the dataset against the ruleset.

```
EvaluateDataQualityMultiframe = EvaluateDataQuality().process_rows(
    frame=medicare_dyf,
    ruleset=EvaluateDataQuality_ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "EvaluateDataQualityMultiframe",
        "enableDataQualityCloudWatchMetrics": False,
        "enableDataQualityResultsPublishing": False,
    },
    additional_options={"performanceTuning.caching": "CACHE_NOTHING"},
)
```

8. Review the results.

```
ruleOutcomes = SelectFromCollection.apply(
  dfc=EvaluateDataQualityMultiframe,
  key="ruleOutcomes",
  transformation_ctx="ruleOutcomes",
)

ruleOutcomes.toDF().show(truncate=False)
```

### Output:

```
-----+-----
+-----+-----
+-----+-----+
|Rule                                     |Outcome|FailureReason
      |EvaluatedMetrics                        |
+-----+-----+
+-----+-----+
|ColumnExists "Provider Id"             |Passed |null
      |{}                                       |
|IsComplete "Provider Id"               |Passed |null
      |{Column.Provider Id.Completeness -> 1.0} |
|ColumnValues " Total Discharges " > 15|Failed |Value: 11.0 does not meet the
      |constraint requirement!|{Column. Total Discharges .Minimum -> 11.0}|
+-----+-----+
+-----+-----+
+-----+-----+
```

### 9. Filter passed rows and review the failed rows from the Data Quality row-level results.

```
rowLevelOutcomes = SelectFromCollection.apply(
  dfc=EvaluateDataQualityMultiframe,
  key="rowLevelOutcomes",
  transformation_ctx="rowLevelOutcomes",
)

rowLevelOutcomes_df = rowLevelOutcomes.toDF() # Convert Glue DynamicFrame to
SparkSQL DataFrame
```

```

rowLevelOutcomes_df_passed =
  rowLevelOutcomes_df.filter(rowLevelOutcomes_df.DataQualityEvaluationResult ==
    "Passed") # Filter only the Passed records.
rowLevelOutcomes_df.filter(rowLevelOutcomes_df.DataQualityEvaluationResult ==
  "Failed").show(5, truncate=False) # Review the Failed records

```

## Output:

```

+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

only showing top 5 rows

```

Note that AWS Glue Data Quality added four new columns (`DataQualityRulesPass`, `DataQualityRulesFail`, `DataQualityRulesSkip`, and `DataQualityEvaluationResult`). This indicates the records that passed, the records that failed, rules skipped for row-level evaluation, and the overall row-level results.

#### 10. Write the output to an Amazon S3 bucket to analyze the data and visualize the results.

```

#Write the Passed records to the destination.

glueContext.write_dynamic_frame.from_options(
    frame = rowLevelOutcomes_df_passed,
    connection_type = "s3",
    connection_options = {"path": "s3://glue-sample-target/output-dir/
medicare_parquet"},
    format = "parquet")

```

# Data Quality Definition Language (DQDL) reference

Data Quality Definition Language (DQDL) is a domain specific language that you use to define rules for AWS Glue Data Quality.

This guide introduces key DQDL concepts to help you understand the language. It also provides a reference for DQDL rule types with syntax and examples. Before you use this guide, we recommend that you have familiarity with AWS Glue Data Quality. For more information, see [AWS Glue Data Quality](#).

## Note

DynamicRules are only supported in AWS Glue ETL.

## DQDL syntax

A DQDL document is case sensitive and contains a *ruleset*, which groups individual data quality rules together. To construct a ruleset, you must create a list named `Rules` (capitalized), delimited by a pair of square brackets. The list should contain one or more comma-separated DQDL rules like the following example.

```
Rules = [  
    IsComplete "order-id",  
    IsUnique "order-id"  
]
```

## Rule structure

The structure of a DQDL rule depends on the rule type. However, DQDL rules generally fit the following format.

```
<RuleType> <Parameter> <Parameter> <Expression>
```

RuleType is the case-sensitive name of the rule type that you want to configure. For example, IsComplete, IsUnique, or CustomSql. Rule parameters differ for each rule type. For a complete reference of DQDL rule types and their parameters, see [DQDL rule type reference](#).

## Composite rules

DQDL supports the following logical operators that you can use to combine rules. These rules are called Composite Rules.

### and

The logical and operator results in true if and only if the rules that it connects are true. Otherwise, the combined rule results in false. Each rule that you connect with the and operator must be surrounded by parentheses.

The following example uses the and operator to combine two DQDL rules.

```
(IsComplete "id") and (IsUnique "id")
```

### or

The logical or operator results in true if and only if one or more of the rules that it connects are true. Each rule that you connect with the or operator must be surrounded by parentheses.

The following example uses the or operator to combine two DQDL rules.

```
(RowCount "id" > 100) or (IsPrimaryKey "id")
```

You can use the same operator to connect multiple rules, so the following rule combination is allowed.

```
(Mean "Star_Rating" > 3) and (Mean "Order_Total" > 500) and (IsComplete "Order_Id")
```

However, you can't combine the logical operators into a single expression. For example, the following combination is not allowed.

```
(Mean "Star_Rating" > 3) and (Mean "Order_Total" > 500) or (IsComplete "Order_Id")
```

## How Composite rules work

By default, Composite Rules are evaluated as individual rules across the entire dataset or table and then the results are combined. In other words, it evaluates the entire column first and then applies the operator. This default behaviour is explained below with an example:

```
# Dataset

+-----+-----+
|myCol1|myCol2|
+-----+-----+
|      2|      1|
|      0|      3|
+-----+-----+

# Overall outcome

+-----+-----+-----+-----+-----+-----+
|Rule                                     |Outcome|
+-----+-----+-----+-----+-----+-----+
|(ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)|Failed |
+-----+-----+-----+-----+-----+-----+
```

In the above example, AWS Glue Data Quality first evaluates `(ColumnValues "myCol1" > 1)` which will result in a failure. Then it will evaluate `(ColumnValues "myCol2" > 2)` which will also fail. The combination of both results will be noted as FAILED.

However, if you prefer an SQL like behaviour, where you need the entire row to be evaluated, you have to explicitly set the `ruleEvaluation.scope` parameter as shown in `additionalOptions` in the code snippet below.

```
object GlueApp {
  val datasource = glueContext.getCatalogSource(
    database="<db>",
```

```

    tableName="<table>",
    transformationContext="datasource"
  ).getDynamicFrame()

val ruleset = """
  Rules = [
    (ColumnValues "age" >= 26) OR (ColumnLength "name" >= 4)
  ]
  """

val dq_results = EvaluateDataQuality.processRows(
  frame=datasource,
  ruleset=ruleset,
  additionalOptions=JsonOptions("""
    {
      "compositeRuleEvaluation.method":"ROW"
    }
  """)
)
}

```

Once set, the composite rules will behave as a single rule evaluating the entire row. The following example illustrates this behaviour.

```

# Row Level outcome

+-----+-----+-----+-----+
+-----+
|myCol1|myCol2|DataQualityRulesPass          |
DataQualityEvaluationResult|
+-----+-----+-----+-----+
+-----+
|2      |1      |[[ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)]|Passed
|      |      |      |
|0      |3      |[[ColumnValues "myCol1" > 1) OR (ColumnValues "myCol2" > 2)]|Passed
|      |      |      |
+-----+-----+-----+-----+
+-----+

```

Some rules cannot be supported in this feature because their overall outcome rely on thresholds or ratios. They are listed below.

Rules relying on ratios:

- Completeness
- DatasetMatch
- ReferentialIntegrity
- Uniqueness

Rules dependent on thresholds:

When the following rules include with threshold, they are not supported. However, rules that do not involve with threshold remain supported.

- ColumnDataType
- ColumnValues
- CustomSQL

## Expressions

### Note

The expressions, not and != are not supported in AWS Glue Data Catalog.

If a rule type doesn't produce a Boolean response, you must provide an expression as a parameter in order to create a Boolean response. For example, the following rule checks the mean (average) of all the values in a column against an expression to return a true or false result.

```
Mean "colA" between 80 and 100
```

Some rule types such as IsUnique and IsComplete already return a Boolean response.

The following table lists expressions that you can use in DQDL rules.

## Supported DQDL expressions

Expression	Description	Example
<code>=x</code>	Resolves to true if the rule type response is equal to <code>x</code> .	Completeness "colA" = "1.0", ColumnValues "colA" = "2022-06-30"
<code>!=x</code>	<code>x</code> Resolves to true if the rule type response is not equal to <code>x</code> .	ColumnValues "colA" != "a", ColumnValues "colA" != "2022-06-30"
<code>&gt; x</code>	Resolves to true if the rule type response is greater than <code>x</code> .	ColumnValues "colA" > 10
<code>&lt; x</code>	Resolves to true if the rule type response is less than <code>x</code> .	ColumnValues "colA" < 1000, ColumnValues "colA" < "2022-06-30"
<code>&gt;= x</code>	Resolves to true if the rule type response is greater than or equal to <code>x</code> .	ColumnValues "colA" >= 10
<code>&lt;= x</code>	Resolves to true if the rule type response is less than or equal to <code>x</code> .	ColumnValues "colA" <= 1000
<code>between x and y</code>	Resolves to true if the rule type response falls in a specified range (exclusive). Only use this expression type for numeric and date types.	Mean "colA" between 8 and 100, ColumnValues "colA" between "2022-05-31" and "2022-06-30"
<code>not between x and y</code>	Resolves to true if the rule type response does not fall in a specified range (inclusiv	ColumnValues "colA" not between "2022-05-31" and "2022-06-30"

Expression	Description	Example
	e). You should only use this expression type for numeric and date types.	
<code>in [a, b, c, ...]</code>	Resolves to true if the rule type response is in the specified set.	<pre>ColumnValues "colA" in [ 1, 2, 3 ], ColumnValues "colA" in [ "a", "b", "c" ]</pre>
<code>not in [a, b, c, ...]</code>	Resolves to true if the rule type response is not in the specified set.	<pre>ColumnValues "colA" not in [ 1, 2, 3 ], ColumnValues "colA" not in [ "a", "b", "c" ]</pre>
<code>matches /ab+c/i</code>	Resolves to true if the rule type response matches a regular expression.	<pre>ColumnValues "colA" matches "[a-zA-Z]*"</pre>
<code>not matches /ab+c/i</code>	Resolves to true if the rule type response does not match a regular expression.	<pre>ColumnValues "colA" not matches "[a-zA-Z]*"</pre>
<code>now()</code>	Works only with the ColumnValues rule type to create a date expression.	<pre>ColumnValues "load_date" &gt; (now() - 3 days)</pre>
<code>matches/in [...]/not matches/not in [...] with threshold</code>	Specifies the percentage of values that match the rule conditions. Works only with the ColumnValues, ColumnDataType, and CustomSQL rule types.	<pre>ColumnValues "colA" in ["A", "B"] with threshold &gt; 0.8, ColumnValues "colA" matches "[a-zA-Z]*" with threshold between 0.2 and 0.9 ColumnDataType "colA" = "Timestamp" with threshold &gt; 0.9</pre>

## Keywords for NULL, EMPTY and WHITESPACES\_ONLY

### Note

Keywords for NULL, EMPTY and WHITESPACES\_ONLY are not supported in AWS Glue Data Catalog.

If you want to validate if a string column has a null, empty or a string with only whitespaces you can use the following keywords:

- NULL / null – This keyword resolves to true for a null value in a string column.

`ColumnValues "colA" != NULL` with `threshold > 0.5` would return true if more than 50% of your data does not have null values.

`(ColumnValues "colA" = NULL) or (ColumnLength "colA" > 5)` would return true for all rows which either have a null value or have length >5. *Note that this will require the use of the "compositeRuleEvaluation.method" = "ROW" option.*

- EMPTY / empty – This keyword resolves to true for an empty string ("" ) value in a string column. Some data formats transform nulls in a string column to empty strings. This keyword helps filter out empty strings in your data.

`(ColumnValues "colA" = EMPTY) or (ColumnValues "colA" in ["a", "b"])` would return true if a row is either empty, "a" or "b". *Note that this requires the use of the "compositeRuleEvaluation.method" = "ROW" option.*

- WHITESPACES\_ONLY / whitespaces\_only – This keyword resolves to true for a string with only whitespaces (" ") value in a string column.

`ColumnValues "colA" not in ["a", "b", WHITESPACES_ONLY]` would return true if a row is neither "a" or "b" nor just whitespaces.

Supported rules:

- [ColumnValues](#)

For a numeric or date based expression, if you want to validate if a column has a null you can use the following keywords.

- `NULL / null` – This keyword resolves to true for a null value in a string column.

`ColumnValues "colA" in [NULL, "2023-01-01"]` would return true if a dates in your column are either `2023-01-01` or null.

`(ColumnValues "colA" = NULL)` or `(ColumnValues "colA" between 1 and 9)` would return true for all rows which either have a null value or have values between 1 and 9. *Note that this will require the use of the `"compositeRuleEvaluation.method" = "ROW"` option.*

Supported rules:

- [ColumnValues](#)

## Dynamic rules

You can now author dynamic rules to compare current metrics produced by your rules with their historical values. These historical comparisons are enabled by using the `last()` operator in expressions. For example, the rule `RowCount > last()` will succeed when the number of rows in the current run is greater than the most recent prior row count for the same dataset. `last()` takes an optional natural number argument describing how many prior metrics to consider; `last(k)` where  $k \geq 1$  will reference the last  $k$  metrics.

- If no data points are available, `last(k)` will return the default value 0.0.
- If fewer than  $k$  metrics are available, `last(k)` will return all prior metrics.

To form valid expressions use `last(k)`, where  $k > 1$  requires an aggregation function to reduce multiple historical results to a single number. For example, `RowCount > avg(last(5))` will check whether the current dataset's row count is strictly greater than the average of the last five row counts for the same dataset. `RowCount > last(5)` will produce an error because the current dataset row count can't be meaningfully compared to a list.

Supported aggregation functions:

- `avg`
- `median`
- `max`
- `min`
- `sum`

- `std` (standard deviation)
- `abs` (absolute value)
- `index(last(k), i)` will allow for selecting the *i*th most recent value out of the last *k*. *i* is zero-indexed, so `index(last(3), 0)` will return the most recent datapoint and `index(last(3), 3)` will result in an error as there are only three datapoints and we attempt to index the 4th most recent one.

## Sample expressions

### ColumnCorrelation

- `ColumnCorrelation "colA" "colB" < avg(last(10))`

### DistinctValuesCount

- `DistinctValuesCount "colA" between min(last(10))-1 and max(last(10))+1`

Most rule types with numeric conditions or thresholds support dynamic rules; see the provided table, [Analyzers and Rules](#), to determine whether dynamic rules are supported for your rule type.

## Analyzers

### Note

Analyzers are not supported in AWS Glue Data Catalog.

DQDL rules use functions called *analyzers* to gather information about your data. This information is employed by a rule's Boolean expression to determine whether the rule should succeed or fail. For example, the RowCount rule `RowCount > 5` will use a row count analyzer to discover the number of rows in your dataset, and compare that count with the expression `> 5` to check whether more than five rows exist in the current dataset.

Sometimes, instead of authoring rules, we recommend creating analyzers and then have them generate statistics that can be used to detect anomalies. For such instances, you can create analyzers. Analyzers differ from rules in the following ways.

Characteristic	Analyzers	Rules
Part of ruleset	Yes	Yes
Generates statistics	Yes	Yes
Generates observations	Yes	Yes
Can evaluate and assert a condition	No	Yes
You can configure actions such as stop the jobs on failure, continue processing job	No	Yes

Analyzers can independently exist without rules, so you can quickly configure them and progressively build data quality rules.

Some rule types can be input in the `Analyzers` block of your ruleset to run the rules required for analyzers and gather information without applying checks for any condition. Some analyzers aren't associated with rules and can only be input in the `Analyzers` block. The following table indicates whether each item is supported as a rule or a standalone analyzer, along with additional details for each rule type.

### Example Ruleset with Analyzer

The following ruleset uses:

- a dynamic rule to check whether a dataset is growing over its trailing average for the last three job runs
- a `DistinctValuesCount` analyzer to record the number of distinct values in the dataset's `Name` column
- a `ColumnLength` analyzer to track minimum and maximum `Name` size over time

Analyzer metric results can be viewed in the `Data Quality` tab for your job run.

```
Rules = [
```

```

    RowCount > avg(last(3))
]
Analyzers = [
    DistinctValuesCount "Name",
    ColumnLength "Name"
]

```

## Comments

You can use the '#' character to add a comment to your DQDL document. Anything after the '#' character and until the end of the line is ignored by DQDL.

```

Rules = [
    # More items should generally mean a higher price, so correlation should be
    positive
    ColumnCorrelation "price" "num_items" > 0
]

```

## DQDL rule type reference

This section provides a reference for each rule type that AWS Glue Data Quality supports.

### Note

- DQDL doesn't currently support nested or list-type column data.
- Bracketed values in the below table will be replaced with the information provided in rule arguments.
- Rules typically require an additional argument for expression.

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
Aggregate Match	Checks if two	One or more	When first	Yes	No	No	No	No

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
	<p>datasets match by comparing summary metrics like total sales amount. Useful for financial institutions to compare if all data is ingested from source systems.</p>	<p>aggregations</p>	<p>and second aggregation column names match:</p> <p>Column. [Column]. aggregation</p> <p>When first and second aggregation column names different:</p> <p>Column. [Column1, Column2]. aggregation</p>					

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
AllStatistics	Standard analyzer to gather multiple metrics for the provided column, or all columns in a dataset.	A single column name, OR "AllColumns"	For columns of all types: Dataset.RowCount Column.[Column].Completeness Column.[Column].Uniqueness Additional metrics for string-valued columns: ColumnLengthMetrics	No	Yes	No	No	No

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
			Additional metrics for numeric-valued columns:  ColumnValues metrics					
ColumnCorrelation	Checks how well two columns are correlated.	Exactly two column names	MultiColumnCorrelation. [Column1], [Column2].ColumnCorrelation	Yes	Yes	No	Yes	No
ColumnCount	Checks if any columns are dropped.	None	Dataset.ColumnCount	Yes	No	No	Yes	Yes

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
ColumnDataType	Checks if a column is compliant with a datatype.	Exactly one column name	Column.[Column].ColumnDataType.Compliance	Yes	No	No	Yes, in row-level threshold expression	No
ColumnExists	Checks if columns exist in a dataset. This allows customers building self service data platforms to ensure certain columns are made available.	Exactly one column name	N/A	Yes	No	No	No	No

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
ColumnLength	Checks if length of data is consistent.	Exactly one column name	<p>Column.[Column].MaximumLength</p> <p>Column.[Column].MinimumLength</p> <p>Additional metric when row-level threshold provided:</p> <p>Column.[Column].ColumnValues.Compliance</p>	Yes	Yes	Yes, when row-level threshold provided	No	Yes. Only generates observations by analyzing Minimum and Maximum length

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
ColumnNamesMatchPattern	Checks if column names match defined patterns. Useful for governance teams to enforce column name consistency.	A regex for column names	Dataset.ColumnNamesMatchRatio	Yes	No	No	No	No

Rule type	Description	Argument	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
ColumnValues	Checks if data is consistent per defined values. This rule supports regular expressions.	Exactly one column name	Column.[Column].Maximum  Column.[Column].Minimum  Additional metric when row-level threshold provided:  Column.[Column].ColumnValues.Compliance	Yes	Yes	Yes, when row-level threshold provided	No	Yes. Only generates observations by analyzing Minimum and Maximum values
Completeness	Checks for any blank or NULLs in data.	Exactly one column name	Column.[Column].Completeness	Yes	Yes	Yes	Yes	Yes

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
CustomScanner	Customer can implement almost any type of data quality checks in SQL.	A SQL statement (Optional) A row-level threshold	Dataset .CustomScanner.Additional metric when row-level threshold provided: Dataset .CustomScanner.Compliance	Yes	No	Yes, when row-level threshold provided	Yes	No
DataFreshness	Checks if data is fresh.	Exactly one column name	Column.[Column].DataFreshness.Compliance	Yes	No	Yes	No	No

Rule type	Description	Argument	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
DatasetMatch	Compares two datasets and identifies if they are in synch.	Name of a reference dataset A column mapping (Optional) Columns to check for matches	Dataset [ReferenceDatasetNames].DatasetMatch	Yes	No	Yes	Yes	No
DistinctValuesCount	Checks for duplicate values.	Exactly one column name	Column [Column].DistinctValuesCount	Yes	Yes	Yes	Yes	Yes
DetectAnomalies	Checks for anomalies in another rule type's reported metrics.	A rule type	Metric(s) reported by the rule type argument	Yes	No	No	No	No

Rule type	Description	Argument	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
Entropy	Checks for entropy of the data.	Exactly one column name	Column.[Column].entropy	Yes	Yes	No	Yes	No
IsComplete	Checks if 100% of the data is complete.	Exactly one column name	Column.[Column].completeness	Yes	No	Yes	No	No
IsPrimary Key	Checks if a column is a primary key (not NULL and unique).	Exactly one column name	For single column: Column.[Column].uniqueness  For multiple columns:  Multicolumn[Column[Comma delimited columns]].uniqueness	Yes	No	Yes	No	No

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
IsUnique	Checks if 100% of the data is unique.	Exactly one column name	Column.[Column].Uniqueness	Yes	No	Yes	No	No
Mean	Checks if the mean matches the set threshold.	Exactly one column name	Column.[Column].Mean	Yes	Yes	Yes	Yes	No
ReferentialIntegrity	Checks if two datasets have referential integrity.	One or more column names from dataset One or more column names from reference dataset	Column.[ReferenceDatasetAlias].ReferentialIntegrity	Yes	No	Yes	Yes	No

Rule type	Description	Arguments	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
RowCount	Checks if record counts match a threshold.	None	Dataset.RowCount	Yes	Yes	No	Yes	Yes
RowCountMatch	Checks if record counts between two datasets match.	Reference dataset alias	Dataset [ReferenceDatasetAlias].RowCountMatch	Yes	No	No	Yes	No
StandardDeviation	Checks if standard deviation matches the threshold.	Exactly one column name	Column [Column].StandardDeviation	Yes	Yes	Yes	Yes	No

Rule type	Description	Argument	Reported Metrics	Supported as Rule?	Supported as Analyzer?	Returns row-level Results?	Dynamic rule support?	Generates Observations
SchemaMatch	Checks if schema between two datasets match.	Reference dataset alias	Dataset [ReferenceDatasetAliases].SchemaMatch	Yes	No	No	Yes	No
Sum	Checks if sum matches a set threshold.	Exactly one column name	Column.[Column].Sum	Yes	Yes	No	Yes	No
Uniqueness	Checks if uniqueness of dataset matches threshold.	Exactly one column name	Column.[Column].Uniqueness	Yes	Yes	Yes	Yes	No
UniqueValueRatio	Checks if the unique value ratio matches threshold.	Exactly one column name	Column.[Column].UniqueValueRatio	Yes	Yes	Yes	Yes	No

## AggregateMatch

Checks the ratio of two column aggregations against a given expression. This rule type works on multiple datasets. The two column aggregations are evaluated and a ratio is produced by dividing the result of the first column aggregation with the result of the second column aggregation. The ratio is checked against the provided expression to produce a boolean response.

### Syntax

#### Column aggregation

```
ColumnExists <AGG_OPERATION> (<OPTIONAL_REFERENCE_ALIAS>.<COL_NAME>)
```

- **AGG\_OPERATION** – The operation to use for the aggregation. Currently, sum and avg are supported.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **OPTIONAL\_REFERENCE\_ALIAS** – This parameter needs to be provided if the column is from a reference dataset and not the primary dataset. If you are using this rule in the AWS Glue Data Catalog, your reference alias must follow the format "<database\_name>.<table\_name>.<column\_name>"

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **COL\_NAME** – The name of the column to aggregate.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

#### Example: Average

```
"avg(rating)"
```

#### Example: Sum

```
"sum(amount)"
```

#### Example: Average of column in reference dataset

```
"avg(reference.rating)"
```

## Rule

```
AggregateMatch <AGG_EXP_1> <AGG_EXP_2> <EXPRESSION>
```

- **AGG\_EXP\_1** – The first column aggregation.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **AGG\_EXP\_2** – The second column aggregation.

Supported column types: Byte, Decimal, Double, Float, Integer, Long, Short

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Aggregate Match using sum

The following example rule checks whether the sum of the values in the `amount` column is exactly equal to the sum of the values in the `total_amount` column.

```
AggregateMatch "sum(amount)" "sum(total_amount)" = 1.0
```

### Example: Aggregate Match using average

The following example rule checks whether the average of the values in the `ratings` column is equal to at least 90% of the average of the values in the `ratings` column in the reference dataset. The reference dataset is provided as an additional data source in the ETL or Data Catalog experience.

In AWS Glue ETL, you can use:

```
AggregateMatch "avg(ratings)" "avg(reference.ratings)" >= 0.9
```

In the AWS Glue Data Catalog, you can use:

```
AggregateMatch "avg(ratings)" "avg(database_name.tablename.ratings)" >= 0.9
```

## Null behavior

The AggregateMatch rule will ignore rows with NULL values in the calculation of the aggregation methods (sum/mean). For example:

```
+---+-----+
|id |units  |
+---+-----+
|100|0      |
|101|null  |
|102|20    |
|103|null  |
|104|40    |
+---+-----+
```

The mean of column units will be  $(0 + 20 + 40) / 3 = 20$ . Rows 101 and 103 are not considered in this calculation.

## ColumnCorrelation

Checks the *correlation* between two columns against a given expression. AWS Glue Data Quality uses the Pearson correlation coefficient to measure the linear correlation between two columns. The result is a number between -1 and 1 that measures the strength and direction of the relationship.

### Syntax

```
ColumnCorrelation <COL_1_NAME> <COL_2_NAME> <EXPRESSION>
```

- **COL\_1\_NAME** – The name of the first column that you want to evaluate the data quality rule against.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **COL\_2\_NAME** – The name of the second column that you want to evaluate the data quality rule against.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

## Example: Column correlation

The following example rule checks whether the correlation coefficient between the columns `height` and `weight` has a strong positive correlation (a coefficient value greater than 0.8).

```
ColumnCorrelation "height" "weight" > 0.8
```

## Sample dynamic rules

- `ColumnCorrelation "colA" "colB" between min(last(10)) and max(last(10))`
- `ColumnCorrelation "colA" "colB" < avg(last(5)) + std(last(5))`

## Null behavior

The `ColumnCorrelation` rule will ignore rows with NULL values in the calculation of the correlation. For example:

```
+---+-----+
|id |units  |
+---+-----+
|100|0      |
|101|null  |
|102|20    |
|103|null  |
|104|40    |
+---+-----+
```

Rows 101 and 103 will be ignored, and the `ColumnCorrelation` will be 1.0.

## ColumnCount

Checks the column count of the primary dataset against a given expression. In the expression, you can specify the number of columns or a range of columns using operators like `>` and `<`.

## Syntax

```
ColumnCount <EXPRESSION>
```

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

## Example: Column count numeric check

The following example rule checks whether the column count is within a given range.

```
ColumnCount between 10 and 20
```

## Sample dynamic rules

- `ColumnCount >= avg(last(10))`
- `ColumnCount between min(last(10))-1 and max(last(10))+1`

## ColumnDataType

Checks the inherent data type of the values in a given column against the provided expected type. Accepts a `with threshold` expression to check for a subset of the values in the column.

## Syntax

```
ColumnDataType <COL_NAME> = <EXPECTED_TYPE>
ColumnDataType <COL_NAME> = <EXPECTED_TYPE> with threshold <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

Supported column types: String type

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPECTED\_TYPE** – The expected type of the values in the column.

Supported values: Boolean, Date, Timestamp, Integer, Double, Float, Long

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An optional expression to specify the percentage of values that should be of the expected type.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

## Example: Column data type integers as strings

The following example rule checks whether the values in the given column, which is of type string, are actually integers.

```
ColumnDataType "colA" = "INTEGER"
```

### Example: Column data type integers as strings check for a subset of the values

The following example rule checks whether more than 90% of the values in the given column, which is of type string, are actually integers.

```
ColumnDataType "colA" = "INTEGER" with threshold > 0.9
```

## ColumnExists

Checks whether a column exists.

### Syntax

```
ColumnExists <COL_NAME>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

### Example: Column exists

The following example rule checks whether the column named `Middle_Name` exists.

```
ColumnExists "Middle_Name"
```

## ColumnLength

Checks whether the length of each row in a column conforms to a given expression.

### Syntax

```
ColumnLength <COL_NAME><EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** String

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Column row length

The following example rule checks whether the value in each row in the column named `Postal_Code` is 5 characters long.

```
ColumnLength "Postal_Code" = 5
```

### Null behavior

The `ColumnLength` rule treats NULLs as 0 length strings. For a NULL row:

```
ColumnLength "Postal_Code" > 4 # this will fail
```

```
ColumnLength "Postal_Code" < 6 # this will succeed
```

The following example compound rule provides a way to explicitly fail NULL values:

```
(ColumnLength "Postal_Code" > 4) AND (ColumnValues != NULL)
```

### ColumnNamesMatchPattern

Checks whether the names of all columns in the primary dataset match the given regular expression.

### Syntax

```
ColumnNamesMatchPattern <PATTERN>
```

- **PATTERN** – The pattern you want to evaluate the data quality rule against.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

### Example: Column names match pattern

The following example rule checks whether all columns start with the prefix "aws\_"

```
ColumnNamesMatchPattern "aws_.*"
```

## ColumnValues

Runs an expression against the values in a column.

### Syntax

```
ColumnValues <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Allowed values

The following example rule checks whether each value in the specified column is in a set of allowed values (including null, empty, and strings with only whitespaces).

```
ColumnValues "Country" in [ "US", "CA", "UK", NULL, EMPTY, WHITESPACES_ONLY ]
```

### Example: Regular expression

The following example rule checks the values in a column against a regular expression.

```
ColumnValues "First_Name" matches "[a-zA-Z]*"
```

### Example: Date values

The following example rule checks the values in a date column against a date expression.

```
ColumnValues "Load_Date" > (now() - 3 days)
```

## Example: Numeric values

The following example rule checks whether the column values match a certain numeric constraint.

```
ColumnValues "Customer_ID" between 1 and 2000
```

## Null behavior

For all `ColumnValues` rules (other than `!=` and `NOT IN`), `NULL` rows will fail the rule. If the rule fails due to a null value, the failure reason will display the following:

```
Value: NULL does not meet the constraint requirement!
```

The following example compound rule provides a way to explicitly allow for `NULL` values:

```
(ColumnValues "Age" > 21) OR (ColumnValues "Age" = NULL)
```

Negated `ColumnValues` rules using the `!=` and `not in` syntax will pass for `NULL` rows. For example:

```
ColumnValues "Age" != 21
```

```
ColumnValues "Age" not in [21, 22, 23]
```

The following examples provide a way to explicitly fail `NULL` values

```
(ColumnValues "Age" != 21) AND (ColumnValues "Age" != NULL)
```

```
ColumnValues "Age" not in [21, 22, 23, NULL]
```

## Completeness

Checks the percentage of complete (non-null) values in a column against a given expression.

### Syntax

```
Completeness <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Null value percentage

The following example rules check if more than 95 percent of the values in a column are complete.

```
Completeness "First_Name" > 0.95
```

### Sample dynamic rules

- Completeness "colA" between  $\min(\text{last}(5)) - 1$  and  $\max(\text{last}(5)) + 1$
- Completeness "colA"  $\leq \text{avg}(\text{last}(10))$

### Null behavior

Note on CSV Data Formats: Blank rows on CSV columns can display multiple behaviors.

- If a column is of `String` type, the blank row will be recognized as an empty string and will not fail the Completeness rule.
- If a column is of another data type like `Int`, the blank row will be recognized as `NULL` and will fail the Completeness rule.

### CustomSQL

This rule type has been extended to support two use cases:

- Run a custom SQL statement against a dataset and checks the return value against a given expression.
- Run a custom SQL statement where you specify a column name in your `SELECT` statement against which you compare with some condition to get row-level results.

### Syntax

```
CustomSql <SQL_STATEMENT> <EXPRESSION>
```

- **SQL\_STATEMENT** – A SQL statement that returns a single numeric value, surrounded by double quotes.
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Custom SQL to retrieve an overall rule outcome

This example rule uses a SQL statement to retrieve the record count for a data set. The rule then checks that the record count is between 10 and 20.

```
CustomSql "select count(*) from primary" between 10 and 20
```

### Example: Custom SQL to retrieve row-level results

This example rule uses a SQL statement wherein you specify a column name in your SELECT statement against which you compare with some condition to get row level results. A threshold condition expression defines a threshold of how many records should fail for the entire rule to fail. Note that a rule may not contain both a condition and keyword together.

```
CustomSql "select Name from primary where Age > 18"
```

or

```
CustomSql "select Name from primary where Age > 18" with threshold > 3
```

#### Important

The `primary` alias stands in for the name of the data set that you want to evaluate. When you work with visual ETL jobs on the console, `primary` always represents the `DynamicFrame` being passed to the `EvaluatedDataQuality.apply()` transform. When you use the AWS Glue Data Catalog to run data quality tasks against a table, `primary` represents the table.

If you are in AWS Glue Data Catalog, you can also use the actual table names:

```
CustomSql "select count(*) from database.table" between 10 and 20
```

You can also join multiple tables to compare different data elements:

```
CustomSql "select count(*) from database.table inner join database.table2 on id1 = id2"
between 10 and 20
```

In AWS Glue ETL, CustomSQL can identify records that failed the data quality checks. For this to work, you will need to return records that are part of the primary table that you are evaluating data quality. Records that are returned as part of the query are considered successful and records that are not returned are considered failed.

The following rule will ensure that records with age < 100 are identified as successful and records that are above are marked as failed.

```
CustomSql "select id from primary where age < 100"
```

This CustomSQL rule will pass when 50% of the records have age > 10 and will also identify records that failed. The records returned by this CustomSQL will be considered passed while the ones not returned will be considered failed.

```
CustomSQL "select ID, CustomerID from primary where age > 10" with threshold > 0.5
```

Note: CustomSQL rule will fail if you return records that are not available in the dataset.

## DataFreshness

Checks the freshness of data in a column by evaluating the difference between the current time and the values of a date column. You can specify a time-based expression for this rule type to make sure that column values are up to date.

### Syntax

```
DataFreshness <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Date

- **EXPRESSION** – A numeric expression in hours or days. You must specify the time unit in your expression.

### Example: Data freshness

The following example rules check for data freshness.

```
DataFreshness "Order_Date" <= 24 hours
DataFreshness "Order_Date" between 2 days and 5 days
```

### Null behavior

The `DataFreshness` rules will fail for rows with `NULL` values. If the rule fails due to a null value, the failure reason will display the following:

```
80.00 % of rows passed the threshold
```

where 20% of the rows that failed include the rows with `NULL`.

The following example compound rule provides a way to explicitly allow for `NULL` values:

```
(DataFreshness "Order_Date" <= 24 hours) OR (ColumnValues "Order_Date" = NULL)
```

### Data Freshness for Amazon S3 objects

Sometimes you will need to validate the freshness of data based on the Amazon S3 file creating time. To do this, you can use the following code to get the timestamp and add it to your dataframe, and then apply Data Freshness checks.

```
df = glueContext.create_data_frame.from_catalog(database = "default", table_name =
  "mytable")
df = df.withColumn("file_ts", df["_metadata.file_modification_time"])

Rules = [
  DataFreshness "file_ts" < 24 hours
]
```

### DatasetMatch

Checks if the data in the primary dataset matches the data in a reference dataset. The two datasets are joined using the provided key column mappings. Additional column mappings can be

provided should you wish to check for the equality of the data in only those columns. Note that for **DataSetMatch** to work, your join keys should be unique and should not be NULL (must be a primary key). If you don't satisfy these conditions, you will get the error message, "Provided key map not suitable for given data frames". In cases where you can't have joined keys that are unique, consider using other rule types such as **AggregateMatch** to match on summary data.

## Syntax

```
DataSetMatch <REFERENCE_DATASET_ALIAS> <JOIN_CONDITION_WITH  
MAPPING> <OPTIONAL_MATCH_COLUMN_MAPPINGS> <EXPRESSION>
```

- **REFERENCE\_DATASET\_ALIAS** – The alias of the reference dataset with which you compare data from the primary dataset.
- **KEY\_COLUMN\_MAPPINGS** – A comma-separated list of column names that form a key in the datasets. If the column names are not the same in both datasets, you must separate them with a ->
- **OPTIONAL\_MATCH\_COLUMN\_MAPPINGS** – You can supply this parameter if you want to check for matching data only in certain columns. It uses the same syntax as the key column mappings. If this parameter is not provided, we will match the data in all remaining columns. The remaining, non-key columns must have the same names in both datasets.
- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Match set datasets using ID column

The following example rule checks that more than 90% of the primary dataset matches the reference dataset, using the "ID" column to join the two datasets. It compares all columns in this case.

```
DataSetMatch "reference" "ID" >= 0.9
```

### Example: Match set datasets using multiple key columns

In the following example, the primary dataset and the reference dataset have different names for the key columns. ID\_1 and ID\_2 together form a composite key in the primary dataset. ID\_ref1 and ID\_ref2 together form a composite key in the reference dataset. In this scenario, you can use the special syntax to supply the column names.

```
DatasetMatch "reference" "ID_1->ID_ref1,ID_ref2->ID_ref2" >= 0.9
```

### Example: Match set datasets using multiple key columns and check that specific column matches

This example builds on the previous example. We want to check that only the column containing the amounts match. This column is named Amount1 in the primary dataset and Amount2 in the reference dataset. You want an exact match.

```
DatasetMatch "reference" "ID_1->ID_ref1,ID_ref2->ID_ref2" "Amount1->Amount2" >= 0.9
```

## DistinctValuesCount

Checks the number of distinct values in a column against a given expression.

### Syntax

```
DistinctValuesCount <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Distinct column value count

The following example rule checks that the column named State contains more than 3 distinct values.

```
DistinctValuesCount "State" > 3
```

### Sample dynamic rules

- `DistinctValuesCount "colA" between avg(last(10))-1 and avg(last(10))+1`
- `DistinctValuesCount "colA" <= index(last(10),2) + std(last(5))`

## Entropy

Checks whether the *entropy* value of a column matches a given expression. Entropy measures the level of information that's contained in a message. Given the probability distribution over values in a column, entropy describes how many bits are required to identify a value.

### Syntax

```
Entropy <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Column entropy

The following example rule checks that the column named Feedback has an entropy value greater than one.

```
Entropy "Star_Rating" > 1
```

### Sample dynamic rules

- Entropy "colA" < max(last(10))
- Entropy "colA" between min(last(10)) and max(last(10))

## IsComplete

Checks whether all of the values in a column are complete (non-null).

### Syntax

```
IsComplete <COL_NAME>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

### Example: Null values

The following example checks whether all of the values in a column named `email` are non-null.

```
IsComplete "email"
```

### Null behavior

Note on CSV Data Formats: Blank rows on CSV columns can display multiple behaviors.

- If a column is of `String` type, the blank row will be recognized as an empty string and will not fail the `Completeness` rule.
- If a column is of another data type like `Int`, the blank row will be recognized as `NULL` and will fail the `Completeness` rule.

### IsPrimaryKey

Checks whether a column contains a primary key. A column contains a primary key if all of the values in the column are unique and complete (non-null).

### Syntax

```
IsPrimaryKey <COL_NAME>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

### Example: Primary key

The following example rule checks whether the column named `Customer_ID` contains a primary key.

```
IsPrimaryKey "Customer_ID"
```

**Example: Primary key with multiple columns. Any of the following examples are valid.**

```
IsPrimaryKey "colA" "colB"  
IsPrimaryKey "colA" "colB" "colC"  
IsPrimaryKey colA "colB" "colC"
```

## IsUnique

Checks whether all of the values in a column are unique, and returns a Boolean value.

### Syntax

```
IsUnique <COL_NAME>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

### Example: Unique column values

The following example rule checks whether all of the values in a column named `email` are unique.

```
IsUnique "email"
```

## Mean

Checks whether the mean (average) of all the values in a column matches a given expression.

### Syntax

```
Mean <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Average value

The following example rule checks whether the average of all of the values in a column exceeds a threshold.

```
Mean "Star_Rating" > 3
```

### Sample dynamic rules

- Mean "colA" > avg(last(10)) + std(last(2))
- Mean "colA" between min(last(5)) - 1 and max(last(5)) + 1

### Null behavior

The Mean rule will ignore rows with NULL values in the calculation of the mean. For example:

```
+---+-----+
|id |units  |
+---+-----+
|100|0      |
|101|null  |
|102|20    |
|103|null  |
|104|40    |
+---+-----+
```

The mean of column units will be  $(0 + 20 + 40) / 3 = 20$ . Rows 101 and 103 are not considered in this calculation.

## ReferentialIntegrity

Checks to what extent the values of a set of columns in the primary dataset are a subset of the values of a set of columns in a reference dataset.

### Syntax

```
ReferentialIntegrity <PRIMARY_COLS> <REFERENCE_DATASET_COLS> <EXPRESSION>
```

- **PRIMARY\_COLS** – A comma-separated list of column names in the primary dataset.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **REFERENCE\_DATASET\_COLS** – This parameter contains two parts separated by a period. The first part is the alias of the reference dataset. The second part is the comma-separated list of column names in the reference dataset enclosed in braces.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Check the referential integrity of a zip code column

The following example rule checks that more than 90% of the values in the zipcode column in the primary dataset, are present in the zipcode column in the reference dataset.

```
ReferentialIntegrity "zipcode" "reference.zipcode" >= 0.9
```

### Example: Check the referential integrity of the city and state columns

In the following example, columns containing city and state information exist in the primary dataset and the reference dataset. The names of the columns are different in both datasets. The rule checks if the set of values of the columns in the primary dataset is exactly equal to the set of values of the columns in the reference dataset.

```
ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" = 1.0
```

### Sample dynamic rules

- `ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" > avg(last(10))`
- `ReferentialIntegrity "city,state" "reference.{ref_city,ref_state}" between min(last(10)) - 1 and max(last(10)) + 1`

### RowCount

Checks the row count of a dataset against a given expression. In the expression, you can specify the number of rows or a range of rows using operators like > and <.

### Syntax

```
RowCount <EXPRESSION>
```

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Row count numeric check

The following example rule checks whether the row count is within a given range.

```
RowCount between 10 and 100
```

### Sample dynamic rules

```
RowCount > avg(lats(10)) *0.8
```

## RowCountMatch

Checks the ratio of the row count of the primary dataset and the row count of a reference dataset against the given expression.

### Syntax

```
RowCountMatch <REFERENCE_DATASET_ALIAS> <EXPRESSION>
```

- **REFERENCE\_DATASET\_ALIAS** – The alias of the reference dataset against which to compare row counts.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Row count check against a reference dataset

The following example rule checks whether the row count of the primary dataset is at least 90% of the row count of the reference dataset.

```
RowCountMatch "reference" >= 0.9
```

## StandardDeviation

Checks the standard deviation of all of the values in a column against a given expression.

### Syntax

```
StandardDeviation <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Standard deviation

The following example rule checks whether the standard deviation of the values in a column named colA is less than a specified value.

```
StandardDeviation "Star_Rating" < 1.5
```

### Sample dynamic rules

- StandardDeviation "colA" > avg(last(10)) + 0.1
- StandardDeviation "colA" between min(last(10)) - 1 and max(last(10)) + 1

### Null behavior

The StandardDeviation rule will ignore rows with NULL values in the calculation of standard deviation. For example:

```
+---+-----+-----+
|id |units1  |units2  |
+---+-----+-----+
|100|0       |0       |
|101|null   |0       |
|102|20      |20      |
|103|null   |0       |
|104|40      |40      |
```

```
+---+-----+-----+
```

The standard deviation of column `units1` will not consider rows 101 and 103 and result to 16.33. The standard deviation for column `units2` will result in 16.

## Sum

Checks the sum of all the values in a column against a given expression.

### Syntax

```
Sum <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Sum

The following example rule checks whether the sum of all of the values in a column exceeds a given threshold.

```
Sum "transaction_total" > 500000
```

### Sample dynamic rules

- `Sum "ColA" > avg(last(10))`
- `Sum "colA" between min(last(10)) - 1 and max(last(10)) + 1`

### Null behavior

The Sum rule will ignore rows with NULL values in the calculation of sum. For example:

```
+---+-----+
|id |units   |
+---+-----+
```

```
|100|0      |
|101|null   |
|102|20     |
|103|null   |
|104|40     |
+---+-----+
```

The sum of column units will not consider rows 101 and 103 and result to  $(0 + 20 + 40) = 60$ .

## SchemaMatch

Checks if the schema of the primary dataset matches the schema of a reference dataset. The schema check is done column by column. The schema of two columns match if the names are identical and the types are identical. The order of the columns does not matter.

### Syntax

```
SchemaMatch <REFERENCE_DATASET_ALIAS> <EXPRESSION>
```

- **REFERENCE\_DATASET\_ALIAS** – The alias of the reference dataset against which to compare schemas.

**Supported column types:** Byte, Decimal, Double, Float, Integer, Long, Short

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: SchemaMatch

The following example rule checks whether the schema of the primary dataset exactly matches the schema of a reference dataset.

```
SchemaMatch "reference" = 1.0
```

## Uniqueness

Checks the percentage of unique values in a column against a given expression. Unique values occur exactly once.

### Syntax

```
Uniqueness <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

### Example: Uniqueness percentage

The following example rule checks whether the percentage of unique values in a column matches certain numeric criteria.

```
Uniqueness "email" = 1.0
```

### Sample dynamic rules

- Uniqueness "colA" between min(last(10)) and max(last(10))
- Uniqueness "colA" >= avg(last(10))

## UniqueValueRatio

Checks the *unique value ratio* of a column against a given expression. A unique value ratio is the fraction of unique values divided by the number of all distinct values in a column. Unique values occur exactly one time, while distinct values occur *at least* once.

For example, the set [a, a, b] contains one unique value (b) and two distinct values (a and b). So the unique value ratio of the set is  $\frac{1}{2} = 0.5$ .

### Syntax

```
UniqueValueRatio <COL_NAME> <EXPRESSION>
```

- **COL\_NAME** – The name of the column that you want to evaluate the data quality rule against.

**Supported column types:** Any column type

- **EXPRESSION** – An expression to run against the rule type response in order to produce a Boolean value. For more information, see [Expressions](#).

## Example: Unique value ratio

This example checks the unique value ratio of a column against a range of values.

```
UniqueValueRatio "test_score" between 0 and 0.5
```

## Sample dynamic rules

- `UniqueValueRatio "colA" > avg(last(10))`
- `UniqueValueRatio "colA" <= index(last(10),2) + std(last(5))`

## DetectAnomalies

Detects anomalies for a given data quality rule. Every execution of DetectAnomalies rule result in saving evaluated value for the given rule. When there is enough data gathered, anomaly detection algorithm takes all historical data for that given rule and runs anomaly detection. DetectAnomalies rule fails when anomaly is detected. More info about what anomaly was detected can be obtained from Observations.

## Syntax

```
DetectAnomalies <RULE_NAME> <RULE_PARAMETERS>
```

**RULE\_NAME** – The name of the rule that you want to evaluate and detect anomalies for. Supported rules:

- "RowCount"
- "Completeness"
- "Uniqueness"
- "Mean"
- "Sum"
- "StandardDeviation"
- "Entropy"
- "DistinctValuesCount"
- "UniqueValueRatio"

- "ColumnLength"
- "ColumnValues"
- "ColumnCorrelation"

RULE\_PARAMETERS – some rules require additional parameters to run. Refer to the given rule documentation to see required parameters.

### Example: Anomalies for RowCount

For example, if we want to detect RowCount anomalies, we provide RowCount as a rule name.

```
DetectAnomalies "RowCount"
```

### Example: Anomalies for ColumnLength

For example, if we want to detect ColumnLength anomalies, we provide ColumnLength as a rule name and the column name.

```
DetectAnomalies "ColumnLength" "id"
```

## Using APIs to measure and manage data quality

This topic describes how to use APIs to measure and manage data quality.

### Contents

- [Prerequisites](#)
- [Working with AWS Glue Data Quality recommendations](#)
- [Working with AWS Glue Data Quality rulesets](#)
- [Working with AWS Glue Data Quality runs](#)
- [Working with AWS Glue Data Quality results](#)

### Prerequisites

- Make sure your boto3 version is up to date so that it includes the latest AWS Glue Data Quality API.
- Make sure your AWS CLI version is up to date, so as to include the latest CLI.

If you're using an AWS Glue job to run these APIs, you can use the following option to update the boto3 library to the latest version:

```
-additional-python-modules boto3==<version>
```

## Working with AWS Glue Data Quality recommendations

To start an AWS Glue Data Quality recommendation run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 Glue client.
        """
        self.glue_client = glue_client

    def start_data_quality_rule_recommendation_run(self, database_name, table_name,
        role_arn):
        """
        Starts a recommendation run that is used to generate rules when you don't
        know what rules to write. AWS Glue Data Quality analyzes the data and comes up with
        recommendations for a potential ruleset. You can then triage the ruleset and modify
        the generated ruleset to your liking.

        :param database_name: The name of the AWS Glue database which contains the
        dataset.
        :param table_name: The name of the AWS Glue table against which we want a
        recommendation
        :param role_arn: The Amazon Resource Name (ARN) of an AWS Identity and Access
        Management (IAM) role that grants permission to let AWS Glue access the resources it
        needs.

        """
        try:
            response = self.client.start_data_quality_rule_recommendation_run(
                DataSource={
                    'GlueTable': {
                        'DatabaseName': database_name,
                        'TableName': table_name
                    }
                },

```

```

        Role=role_arn
    )
except ClientError as err:
    logger.error(
        "Couldn't start data quality recommendation run %s. Here's why: %s:
%s", name,
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response['RunId']

```

For a recommendation run, you are able to use your `pushDownPredicates` or `catalogPartitionPredicates` to improve performance and run recommendations only on specific partitions of your catalog sources.

```

client.start_data_quality_rule_recommendation_run(
    DataSource={
        'GlueTable': {
            'DatabaseName': database_name,
            'TableName': table_name,
            'AdditionalOptions': {
                'pushDownPredicate': "year=2022"
            }
        }
    },
    Role=role_arn,
    NumberOfWorkers=2,
    CreatedRulesetName='<rule_set_name>'
)

```

### To get results of an AWS Glue Data Quality recommendation run:

```

class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_rule_recommendation_run(self, run_id):
        """

```

```

Gets the specified recommendation run that was used to generate rules.

:param run_id: The id of the data quality recommendation run

"""
try:
    response =
self.client.get_data_quality_rule_recommendation_run(RunId=run_id)
except ClientError as err:
    logger.error(
        "Couldn't get data quality recommendation run %. Here's why: %s: %s",
run_id,
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response

```

From the above response object, you can extract the RuleSet that was recommended by the run, to use in further steps:

```

print(response['RecommendedRuleset'])

Rules = [
    RowCount between 2000 and 8000,
    IsComplete "col1",
    IsComplete "col2",
    StandardDeviation "col3" between 58138330.8 and 64258155.09,
    ColumnValues "col4" between 1000042965 and 1214474826,
    IsComplete "col5"
]

```

**To get a list of all your recommendation runs that can be filtered and listed:**

```

response = client.list_data_quality_rule_recommendation_runs(
    Filter={
        'DataSource': {
            'GlueTable': {
                'DatabaseName': '<database_name>',
                'TableName': '<table_name>'
            }
        }
    }
)

```

## To cancel existing AWS Glue Data Quality recommendation tasks:

```
response = client.cancel_data_quality_rule_recommendation_run(  
    RunId='dqrun-d4b6b01957fdd79e59866365bf9cb0e40fxxxxxxx'  
)
```

## Working with AWS Glue Data Quality rulesets

### To create an AWS Glue Data Quality ruleset:

```
response = client.create_data_quality_ruleset(  
    Name='<ruleset_name>',  
    Ruleset='Rules = [IsComplete "col1", IsPrimaryKey "col2", RowCount between 2000 and  
8000]',  
    TargetTable={  
        'TableName': '<table_name>',  
        'DatabaseName': '<database_name>'  
    }  
)
```

### To get a data quality ruleset:

```
response = client.get_data_quality_ruleset(  
    Name='<ruleset_name>'  
)  
print(response)
```

You can use this API to then extract the rule set:

```
print(response['Ruleset'])
```

### To list all the data quality rulesets for a table:

```
response = client.list_data_quality_rulesets()
```

You can use the filter condition within the API to filter all rulesets attached to a specific database or table:

```
response = client.list_data_quality_rulesets(  
    Filter={
```

```

        'TargetTable': {
            'TableName': '<table_name>',
            'DatabaseName': '<database_name>'
        }
    },
)

```

### To update a data quality ruleset:

```

class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def update_data_quality_ruleset(self, ruleset_name, ruleset_string):
        """
        Update an AWS Glue Data Quality Ruleset

        :param ruleset_name: The name of the AWS Glue Data Quality ruleset to update
        :param ruleset_string: The DQDL ruleset string to update the ruleset with

        """
        try:
            response = self.client.update_data_quality_ruleset(
                Name=ruleset_name,
                Ruleset=ruleset_string
            )
        except ClientError as err:
            logger.error(
                "Couldn't update the AWS Glue Data Quality ruleset. Here's why: %s:
%s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response

```

### To delete a data quality ruleset:

```

class GlueWrapper:
    """Encapsulates AWS Glue actions."""

```

```
def __init__(self, glue_client):
    """
    :param glue_client: A Boto3 AWS Glue client.
    """
    self.glue_client = glue_client

def delete_data_quality_ruleset(self, ruleset_name):
    """
    Delete a AWS Glue Data Quality Ruleset

    :param ruleset_name: The name of the AWS Glue Data Quality ruleset to delete
    """
    try:
        response = self.client.delete_data_quality_ruleset(
            Name=ruleset_name
        )
    except ClientError as err:
        logger.error(
            "Couldn't delete the AWS Glue Data Quality ruleset. Here's why: %s:
%s",
            err.response['Error']['Code'], err.response['Error']['Message'])
        raise
    else:
        return response
```

## Working with AWS Glue Data Quality runs

### To start an AWS Glue Data Quality run:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def start_data_quality_ruleset_evaluation_run(self, database_name, table_name,
role_name, ruleset_list):
        """
        Start an AWS Glue Data Quality evaluation run
```

```

        :param database_name: The name of the AWS Glue database which contains the
dataset.
        :param table_name: The name of the AWS Glue table against which we want to
evaluate.
        :param role_arn: The Amazon Resource Name (ARN) of an AWS Identity and Access
Management (IAM) role that grants permission to let AWS Glue access the resources it
needs.
        :param ruleset_list: The list of AWS Glue Data Quality ruleset names to
evaluate.

"""
try:
    response = client.start_data_quality_ruleset_evaluation_run(
        DataSource={
            'GlueTable': {
                'DatabaseName': database_name,
                'TableName': table_name
            }
        },
        Role=role_name,
        RulesetNames=ruleset_list
    )
except ClientError as err:
    logger.error(
        "Couldn't start the AWS Glue Data Quality Run. Here's why: %s: %s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response['RunId']

```

Remember that you can pass a `pushDownPredicate` or `catalogPartitionPredicate` parameter to ensure your data quality run only targets a specific set of partition within your catalog table. For example:

```

response = client.start_data_quality_ruleset_evaluation_run(
    DataSource={
        'GlueTable': {
            'DatabaseName': '<database_name>',
            'TableName': '<table_name>',
            'AdditionalOptions': {
                'pushDownPredicate': 'year=2023'
            }
        }
    }
)

```

```

    },
    Role='<role_name>',
    NumberOfWorkers=5,
    Timeout=123,
    AdditionalRunOptions={
        'CloudWatchMetricsEnabled': False
    },
    RulesetNames=[
        '<ruleset_name>',
    ]
)

```

## To get information about an AWS Glue Data Quality run:

```

class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_ruleset_evaluation_run(self, run_id):
        """
        Get details about an AWS Glue Data Quality Run

        :param run_id: The AWS Glue Data Quality run ID to look up

        """
        try:
            response = self.client.get_data_quality_ruleset_evaluation_run(
                RunId=run_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't look up the AWS Glue Data Quality run ID. Here's why: %s:
%s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response

```

## To get the results from an AWS Glue Data Quality run:

For a given AWS Glue Data Quality run, you can extract the results of the run's evaluation using the following method:

```
response = client.get_data_quality_ruleset_evaluation_run(
    RunId='d4b6b01957fdd79e59866365bf9cb0e40fxxxxxxx'
)

resultID = response['ResultIds'][0]

response = client.get_data_quality_result(
    ResultId=resultID
)

print(response['RuleResults'])
```

### To list all your AWS Glue Data Quality runs:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def list_data_quality_ruleset_evaluation_runs(self, database_name, table_name):
        """
        Lists all the AWS Glue Data Quality runs against a given table

        :param database_name: The name of the database where the data quality runs
        :param table_name: The name of the table against which the data quality runs
        were created

        """
        try:
            response = self.client.list_data_quality_ruleset_evaluation_runs(
                Filter={
                    'DataSource': {
                        'GlueTable': {
                            'DatabaseName': database_name,
                            'TableName': table_name
                        }
                    }
                }
            )
```

```

        }
    )
except ClientError as err:
    logger.error(
        "Couldn't list the AWS Glue Quality runs. Here's why: %s: %s",
        err.response['Error']['Code'], err.response['Error']['Message'])
    raise
else:
    return response

```

You can modify the filter clause to only show results between specific times or running against specific tables.

### To stop an ongoing AWS Glue Data Quality run:

```

class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def cancel_data_quality_ruleset_evaluation_run(self, result_id):
        """
        Cancels a given AWS Glue Data Quality run

        :param result_id: The result id of a AWS Glue Data Quality run to cancel

        """
        try:
            response = self.client.cancel_data_quality_ruleset_evaluation_run(
                ResultId=result_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't cancel the AWS Glue Data Quality run. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response

```

## Working with AWS Glue Data Quality results

### To get your AWS Glue Data Quality run results:

```
class GlueWrapper:
    """Encapsulates AWS Glue actions."""
    def __init__(self, glue_client):
        """
        :param glue_client: A Boto3 AWS Glue client.
        """
        self.glue_client = glue_client

    def get_data_quality_result(self, result_id):
        """
        Outputs the result of an AWS Glue Data Quality Result

        :param result_id: The result id of an AWS Glue Data Quality run

        """
        try:
            response = self.client.get_data_quality_result(
                ResultId=result_id
            )
        except ClientError as err:
            logger.error(
                "Couldn't get the AWS Glue Data Quality result. Here's why: %s: %s",
                err.response['Error']['Code'], err.response['Error']['Message'])
            raise
        else:
            return response
```

### To cancel existing AWS Glue Data Quality recommendation tasks:

Given an AWS Glue Data Quality run ID, you can extract the result ID to then get the actual results, as shown below:

```
response = client.get_data_quality_ruleset_evaluation_run(
    RunId='dqrn-abca77ee126abe1378c1da1ae0750xxxxxxxx'
)

resultID = response['ResultIds'][0]

response = client.get_data_quality_result(
```

```
    ResultId=resultID
  )

print(resp['RuleResults'])
```

## Setting up alerts, deployments, and scheduling

This topic describes how to set up alerts, deployments, and scheduling for AWS Glue Data Quality.

### Contents

- [Setting up alerts and notifications in Amazon EventBridge integration](#)
  - [Additional configuration options for the event pattern](#)
  - [Formatting notifications as emails](#)

- [Deploying data quality rules using AWS CloudFormation](#)
- [Scheduling data quality rules](#)

## Setting up alerts and notifications in Amazon EventBridge integration

AWS Glue Data Quality supports the publishing of EventBridge events, which are emitted upon completion of a Data Quality ruleset evaluation run. With this, you can easily setup alerts when data quality rules fail.

Here is a sample event when you evaluate data quality rulesets in the Data Catalog. With this information, you can review the data that is made available with Amazon EventBridge. You can issue additional API calls to get more details. For example, call the `get_data_quality_result` API with the result ID to get the details of a particular execution.

```
{
  "version": "0",
  "id": "abcdef00-1234-5678-9abc-def012345678",
  "detail-type": "Data Quality Evaluation Results Available",
  "source": "aws.glue-dataquality",
  "account": "123456789012",
  "time": "2017-09-07T18:57:21Z",
  "region": "us-west-2",
```

```

"resources":[],
"detail":{
  "context": {
    "contextType": "GLUE_DATA_CATALOG",
    "runId":"dqrun-12334567890",
    "databaseName": "db-123",
    "tableName": "table-123",
    "catalogId": "123456789012"
  },
  "resultID": "dqresult-12334567890",
  "rulesetNames": ["rulset1"],
  "state":"SUCCEEDED",
  "score": 1.00,
  "rulesSucceeded": 100,
  "rulesFailed": 0,
  "rulesSkipped": 0
}
}

```

Here is a sample event that gets published when you evaluate data quality rulesets in AWS Glue ETL or AWS Glue Studio notebooks.

```

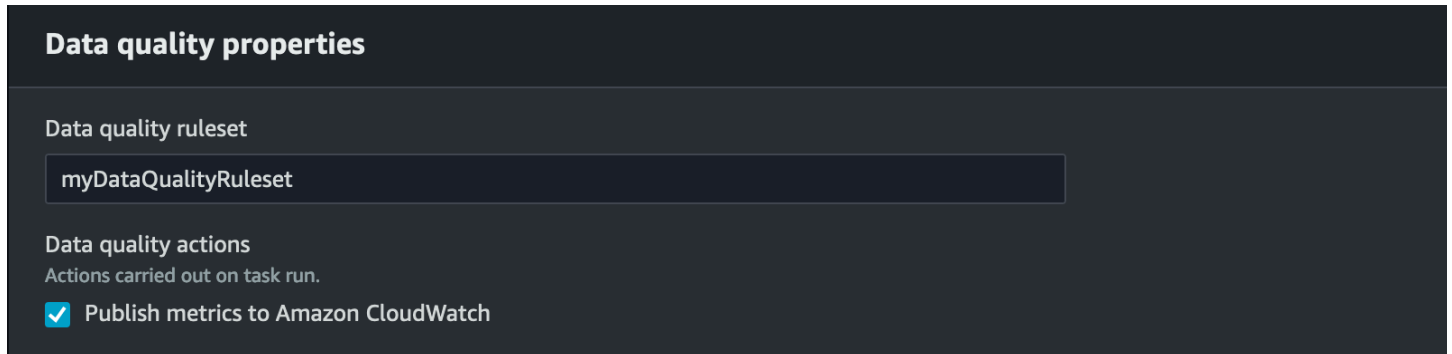

{
  "version":"0",
  "id":"abcdef00-1234-5678-9abc-def012345678",
  "detail-type":"Data Quality Evaluation Results Available",
  "source":"aws.glue-dataquality",
  "account":"123456789012",
  "time":"2017-09-07T18:57:21Z",
  "region":"us-west-2",
  "resources":[],
  "detail":{
    "context": {
      "contextType": "GLUE_JOB",
      "jobId": "jr-12334567890",
      "jobName": "dq-eval-job-1234",
      "evaluationContext": "",
    }
    "resultID": "dqresult-12334567890",
    "rulesetNames": ["rulset1"],
    "state":"SUCCEEDED",
    "score": 1.00
    "rulesSucceeded": 100,

```

```
    "rulesFailed": 0,  
    "rulesSkipped": 0  
  }  
}
```

For Data Quality evaluation runs both in the Data Catalog and in ETL jobs, the **Publish metrics to Amazon Cloudwatch** option, which is selected by default, must remain selected for EventBridge publishing to work.

## Setting up EventBridge notifications

To receive the emitted events and define targets, you must configure Amazon EventBridge rules. To create rules:

1. Open the Amazon EventBridge console.
2. Choose **Rules** under the **Buses** section of the navigation bar.
3. Choose **Create Rule**.
4. On **Define Rule Detail**:
  - a. For Name, enter myDQRu1e.
  - b. Enter the description (optional).
  - c. For event bus, select your event bus. If you don't have one, leave it as default.
  - d. For Rule type select **Rule with an event pattern** then choose **Next**.
5. On **Build Event Pattern**:
  - a. For event source select **AWS events or EventBridge partner events**.
  - b. Skip the sample event section.
  - c. For creation method select **Use pattern form**.
  - d. For event pattern:
    - i. Select **AWS services** for Event source.

- ii. Select **Glue Data Quality** for AWS service.
- iii. Select **Data Quality Evaluation Results Available** for Event type.
- iv. Select **FAILED** for Specific state(s). Then you see an event pattern similar to the following:

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "state": ["FAILED"]
  }
}
```

- v. For more configuration options see [Additional configuration options for the event pattern](#).

## 6. On **Select Target(s)**:

- a. For **Target Types** select **AWS service**.
- b. Use the **Select a target** dropdown to choose your desired AWS service to connect to (SNS, Lambda, SQS, etc.), then choose **Next**.

## 7. On **Configure tag(s)** click **Add new tags** to add optional tags then choose **Next**.

## 8. You see a summary page of all the selections. Choose **Create rule** at the bottom.

## Additional configuration options for the event pattern

In addition to filtering your event on success or failure, you may want to further filter events on different parameters.

To do this, go to the Event Pattern section, and select **Edit pattern** to specify additional parameters. Note that fields in the event pattern are case sensitive. The following are examples of configuring the event pattern.

To capture events from a particular table evaluating specific rulesets use this type of pattern:

```
{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "context": {
      "contextType": ["GLUE_DATA_CATALOG"],
      "databaseName": "db-123",

```

```

    "tableName": "table-123",
  },
  "rulesetNames": ["ruleset1", "ruleset2"]
  "state": ["FAILED"]
}
}

```

To capture events from specific jobs in the ETL experience use this type of pattern:

```

{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "context": {
      "contextType": ["GLUE_JOB"],
      "jobName": ["dq_evaluation_job1", "dq_evaluation_job2"]
    },
    "state": ["FAILED"]
  }
}
}

```

To capture events with a score under a specific threshold (e.g. 70%):

```

{
  "source": ["aws.glue-dataquality"],
  "detail-type": ["Data Quality Evaluation Results Available"],
  "detail": {
    "score": [{
      "numeric": ["<=", 0.7]
    }]
  }
}
}

```

## Formatting notifications as emails

Sometimes you need to send a well-formatted email notification to your business teams. You can use Amazon EventBridge and AWS Lambda to achieve this.

## Glue Data Quality rulesets **Glue\_DQ\_RULESET\_CUSTOM\_20de29c13537** run details

AWS Notifications <no-reply@sns.amazonaws.com>

Thursday, 11. May 2023 at 15:01

response = glue_client.get_data_quality_result(ResultId=resultID)
RuleResults = response['RuleResults']
message_text += "\n\nruleset details evaluation steps results:\n\n"
subresult_info = []

for dic in RuleResults:
    subresult = "Name: {}\t\tResult: {}\t\tDescription: \t{}".format(dic['Name'],
dic['Result'], dic['Description'])
    if 'EvaluationMessage' in dic:
        subresult += "\t\tEvaluationMessage: {}".format(dic['EvaluationMessage'])
    subresult_info.append({
        'Name': dic['Name'],
        'Result': dic['Result'],
        'Description': dic['Description'],
        'EvaluationMessage': dic.get('EvaluationMessage', '')
    })
    message_text += "\n" + subresult

log_metadata['resultrun'] = subresult_info

sns_client.publish(
    TopicArn=sns_topic_arn,
    Message=message_text,
    Subject=subject_text
)

return {

```

```
'statusCode': 200,  
'body': json.dumps('Message published to SNS topic')  
}
```

## Set up alerts and notifications in CloudWatch integration

Our recommended approach is to set up data quality alerts using Amazon EventBridge, because Amazon EventBridge requires a one-time setup to alert customers. However, some customers prefer Amazon CloudWatch due to familiarity. For such customers, we offer integration with Amazon CloudWatch.

Each AWS Glue Data Quality evaluation emits a pair of metrics named `glue.data.quality.rules.passed` (indicating a number of rules that passed) and `glue.data.quality.rules.failed` (indicating the number of failed rules) per data quality run. You can use this emitted metric to create alarms to alert users if a given data quality run falls below a threshold. To get started with setting up an alarm that would send an email via an Amazon SNS notification, follow the steps below:

To get started with setting up an alarm that would send an email via an Amazon SNS notification, follow the steps below:

1. Open the Amazon CloudWatch console.
2. Choose **All metrics** under **Metrics**. You will see an additional namespace under Custom namespaces titled Glue Data Quality.

### Note

When starting an AWS Glue Data Quality run, make sure the **Publish metrics to Amazon CloudWatch** checkbox is enabled. Otherwise, metrics for that particular run will not be published to Amazon CloudWatch.

Under the Glue Data Quality namespace, you can see metrics being emitted per table, per ruleset. For the purpose of this topic, we will use the `glue.data.quality.rules.failed` rule and alarm if this value goes over 1 (indicating that, if we see a number of failed rule evaluations greater than 1, we want to be notified).

3. To create the alarm, choose **All alarms** under **Alarms**.

4. Choose **Create alarm**.
5. Choose **Select metric**.
6. Select the `glue.data.quality.rules.failed` metric corresponding to the table you've created, then choose **Select metric**.
7. Under the **Specify metric and conditions** tab, under the **Metrics** section:
  - a. For **Statistic**, choose **Sum**.
  - b. For **Period**, choose **1 minute**.
8. Under the **Conditions** section:
  - a. For **Threshold type**, choose **Static**.
  - b. For **Whenever glue.data.quality.rules.failed is...**, select **Greater/Equal**.
  - c. For **than...**, enter **1** as the threshold value.

These selections imply that if the `glue.data.quality.rules.failed` metric emits a value greater than or equal to 1, we will trigger an alarm. However, if there is no data, we will treat it as acceptable.

9. Choose **Next**.
10. On **Configure actions**:
  - a. For the **Alarm state trigger** section, choose **In alarm**.
  - b. For **Send a notification to the following SNS topic** section, choose **Create a new topic to send a notification via a new SNS topic**.
  - c. For **Email endpoints that will receive the notification** enter your email address. Then click **Create Topic**.
  - d. Choose **Next**.

11. For **Alarm name**, enter `myFirstDQAlarm`, then choose **Next**.

12. You see a summary page of all the selections. Choose **Create alarm** at the bottom.

You can now see the alarm being created from the Amazon CloudWatch alarms dashboard.

## Querying data quality results to build dashboards

You may want to build a dashboard to display your data quality results. There are two ways to do this:

**Set up Amazon EventBridge with the following code to write the data to Amazon S3:**

```
import boto3
import json
from datetime import datetime

s3_client = boto3.client('s3')
glue_client = boto3.client('glue')

s3_bucket = 's3-bucket-name'

def write_logs(log_metadata):
    try:
        filename = datetime.now().strftime("%m%d%Y%H%M%S") + ".json"
        key_opts = {
            'year': datetime.now().year,
            'month': "{:02d}".format(datetime.now().month),
            'day': "{:02d}".format(datetime.now().day),
            'filename': filename
        }
        s3key = "gluedataqualitylogs/year={year}/month={month}/day={day}/
{filename}".format(**key_opts)
        s3_client.put_object(Bucket=s3_bucket, Key=s3key,
Body=json.dumps(log_metadata))
    except Exception as e:
        print(f'Error writing logs to S3: {e}')

def lambda_handler(event, context):
    log_metadata = {}
    message_text = ""
    subject_text = ""

    if event['detail']['context']['contextType'] == 'GLUE_DATA_CATALOG':
        log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
        log_metadata['tableName'] = str(event['detail']['context']['tableName'])
        log_metadata['databaseName'] = str(event['detail']['context']['databaseName'])
        log_metadata['runId'] = str(event['detail']['context']['runId'])
        log_metadata['resultId'] = str(event['detail']['resultId'])
        log_metadata['state'] = str(event['detail']['state'])
        log_metadata['score'] = str(event['detail']['score'])
        log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
        log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
```

```

log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

message_text += "Glue Data Quality run details:\n"
message_text += "ruleset_name: {}".format(log_metadata['ruleset_name'])
message_text += "glue_table_name: {}".format(log_metadata['tableName'])
message_text += "glue_database_name: {}".format(log_metadata['databaseName'])
message_text += "run_id: {}".format(log_metadata['runId'])
message_text += "result_id: {}".format(log_metadata['resultId'])
message_text += "state: {}".format(log_metadata['state'])
message_text += "score: {}".format(log_metadata['score'])
message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
message_text += "numRulesFailed: {}".format(log_metadata['numRulesFailed'])
message_text += "numRulesSkipped: {}".format(log_metadata['numRulesSkipped'])

subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

else:
log_metadata['ruleset_name'] = str(event['detail']['rulesetNames'][0])
log_metadata['jobName'] = str(event['detail']['context']['jobName'])
log_metadata['jobId'] = str(event['detail']['context']['jobId'])
log_metadata['resultId'] = str(event['detail']['resultId'])
log_metadata['state'] = str(event['detail']['state'])
log_metadata['score'] = str(event['detail']['score'])

log_metadata['numRulesSucceeded'] = str(event['detail']['numRulesSucceeded'])
log_metadata['numRulesFailed'] = str(event['detail']['numRulesFailed'])
log_metadata['numRulesSkipped'] = str(event['detail']['numRulesSkipped'])

message_text += "Glue Data Quality run details:\n"
message_text += "ruleset_name: {}".format(log_metadata['ruleset_name'])
message_text += "glue_job_name: {}".format(log_metadata['jobName'])
message_text += "job_id: {}".format(log_metadata['jobId'])
message_text += "result_id: {}".format(log_metadata['resultId'])
message_text += "state: {}".format(log_metadata['state'])
message_text += "score: {}".format(log_metadata['score'])
message_text += "numRulesSucceeded:
{}\n".format(log_metadata['numRulesSucceeded'])
message_text += "numRulesFailed: {}".format(log_metadata['numRulesFailed'])
message_text += "numRulesSkipped: {}".format(log_metadata['numRulesSkipped'])

subject_text = "Glue Data Quality ruleset {} run
details".format(log_metadata['ruleset_name'])

```

```

resultID = str(event['detail']['resultId'])
response = glue_client.get_data_quality_result(ResultId=resultID)
RuleResults = response['RuleResults']
message_text += "\n\nruleset details evaluation steps results:\n\n"
subresult_info = []

for dic in RuleResults:
    subresult = "Name: {} \t \t Result: {} \t \t Description: \t {}".format(dic['Name'],
dic['Result'], dic['Description'])
    if 'EvaluationMessage' in dic:
        subresult += "\t \t EvaluationMessage: {}".format(dic['EvaluationMessage'])
    subresult_info.append({
        'Name': dic['Name'],
        'Result': dic['Result'],
        'Description': dic['Description'],
        'EvaluationMessage': dic.get('EvaluationMessage', '')
    })
    message_text += "\n" + subresult

log_metadata['resultrun'] = subresult_info

write_logs(log_metadata)

return {
    'statusCode': 200,
    'body': json.dumps('Message published to SNS topic')
}

```

After writing to Amazon S3, you can use AWS Glue crawlers to register to Athena and query the tables.

### Configure an Amazon S3 location during a data quality evaluation::

When running data quality tasks in the AWS Glue Data Catalog or AWS Glue ETL, you can provide an Amazon S3 location to write the data quality results to Amazon S3. You can use the syntax below to create a table by referencing the target to read the data quality results.

Note that you must run the `CREATE EXTERNAL TABLE` and `MSCK REPAIR TABLE` queries separately.

```
CREATE EXTERNAL TABLE <my_table_name>(
  catalogid string,
  databasename string,
  tablename string,
  dqrunid string,
  evaluationstartedon timestamp,
  evaluationcompletedon timestamp,
  rule string,
  outcome string,
  failurereason string,
  evaluatedmetrics string)
PARTITIONED BY (
  `year` string,
  `month` string,
  `day` string)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
WITH SERDEPROPERTIES (

  'paths'='catalogId,databaseName,dqRunId,evaluatedMetrics,evaluationCompletedOn,evaluationStart
STORED AS INPUTFORMAT 'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT 'org.apache.hadoop.hive ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION 's3://glue-s3-dq-bucket-us-east-2-results/'
TBLPROPERTIES (
  'classification'='json',
  'compressionType'='none',
  'typeOfData'='file');
```

```
MSCK REPAIR TABLE <my_table_name>;
```

Once you create the above table, you can run analytical queries using Amazon Athena.

## Deploying data quality rules using AWS CloudFormation

You can use AWS CloudFormation to create data quality rules. For more information, see [AWS CloudFormation for AWS Glue](#).

## Scheduling data quality rules

You can schedule data quality rules using the following methods:

- Schedule data quality rules from the Data Catalog: no code users can use this option to easily schedule their data quality scans. AWS Glue Data Quality will create the schedule in Amazon EventBridge. To schedule data quality rules:
  - Navigate to the ruleset and click **Run**.
  - In the **Run frequency**, select the desired schedule and provide a **Task Name**. This Task Name is the name of your schedule in EventBridge.
- Use Amazon EventBridge and AWS Step Functions to orchestrate evaluations and recommendations for data quality rules.

## Troubleshooting AWS Glue Data Quality errors

If you encounter errors in AWS Glue Data Quality, use the following solutions to help you find the source of the problems and fix them.

### Contents

- [Error: missing AWS Glue Data Quality module](#)
- [Error: insufficient AWS Lake Formation permissions](#)
- [Error: rulesets are not uniquely named](#)
- [Error: tables with special characters](#)
- [Error: overflow error with a large ruleset](#)
- [Error: overall rule status is failed](#)
- [AnalysisException: Unable to verify existence of default database](#)
- [Error Message: Provided key map not suitable for given data frames](#)
- [Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details](#)
- [LAUNCH ERROR: Error downloading from S3 for bucket](#)
- [InvalidInputException \(status: 400\): DataQuality rules cannot be parsed](#)
- [Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup](#)
- [CustomSQL errors](#)
- [Dynamic Rules](#)
- [Exception in User Class: org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException](#)

## Error: missing AWS Glue Data Quality module

**Error message:** No module named 'awsgluedq'.

**Resolution:** This error occurs when you run AWS Glue Data Quality in an unsupported version. AWS Glue Data Quality is supported only in Glue version 3.0 and later.

## Error: insufficient AWS Lake Formation permissions

**Error message:** Exception in User Class:

```
com.amazonaws.services.glue.model.AccessDeniedException: Insufficient Lake Formation permission(s) on impact_sdg_involvement (Service: AWS Glue; Status Code: 400; Error Code: AccessDeniedException; Request ID: 465ae693-b7ba-4df0-a4e4-6b17xxxxxxx; Proxy: null).
```

**Resolution:** You must provide sufficient permissions in AWS Lake Formation.

## Error: rulesets are not uniquely named

**Error message:** Exception in User Class: ...services.glue.model.AlreadyExistsException: Another ruleset with the same name already exists.

**Resolution:** Rulesets are global and must be unique.

## Error: tables with special characters

**Error message:** Exception in User Class: org.apache.spark.sql.AnalysisException: cannot resolve "C" given input columns: [primary.data\_end\_time, primary.data\_start\_time, primary.end\_time, primary.last\_updated, primary.message, primary.process\_date, primary.rowhash, primary.run\_by, primary.run\_id, primary.start\_time, primary.status]; line 1 pos 44;.

**Resolution:** There is a current limitation that AWS Glue Data Quality cannot be executed on tables that have special characters such as ".".

## Error: overflow error with a large ruleset

**Error message:** Exception in User Class: java.lang.StackOverflowError.

**Resolution:** If you have a large ruleset of greater than 2K rules, you may encounter this issue. Break your rules into multiple rulesets.

## Error: overall rule status is failed

**Error condition:** My Ruleset is successful, but my overall rule status is failed.

**Resolution:** This error most likely occurred because you chose the option to publish metrics to Amazon CloudWatch while publishing. If your dataset is in a VPC, your VPC may not allow AWS Glue to publish metrics to Amazon CloudWatch. In this case, you must set up an endpoint for your VPC to access Amazon CloudWatch.

## AnalysisException: Unable to verify existence of default database

**Error condition:** AnalysisException: Unable to verify existence of default database: com.amazonaws.services.glue.model.AccessDeniedException: Insufficient Lake Formation permission(s) on default (Service: AWS Glue; Status Code: 400; Error Code: AccessDeniedException; Request ID: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX; Proxy: null)

**Resolution:** In AWS Glue job's catalog integration, AWS Glue always tries to check whether default database exists or not using AWS Glue GetDatabase API. When the DESCRIBE Lake Formation permission is not granted, or GetDatabase IAM permission is granted, then the job fails when verifying existence of the default database.

To resolve:

1. Add the DESCRIBE permission in Lake Formation for the default database.
2. Configure the IAM role attached to the AWS Glue job as Database Creator in Lake Formation. This will automatically create a default database and grant required Lake Formation permissions for the role.
3. Disable `--enable-data-catalog` option. (It is shown as **Use Data Catalog as the Hive metastore** in AWS Glue Studio).

If you do not need Spark SQL Data Catalog integration in the job, you can disable it.

## Error Message: Provided key map not suitable for given data frames

**Error condition:** Provided key map not suitable for given data frames.

**Resolution:** You are using **DataSetMatch** ruletype and the join keys have duplicates. Your join keys must be unique and must not be NULL. In cases where you can't have join keys that are unique, consider using other ruletypes such as **AggregateMatch** to match on summary data.

## Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details

**Error condition:** Exception in User Class: java.lang.RuntimeException : Failed to fetch data. Check the logs in CloudWatch to get more details.

**Resolution:** This happens when you are creating DQ rules on an Amazon S3-based table that compares against Amazon RDS or Amazon Redshift. In these cases, AWS Glue cannot load the connection. Instead, try to set up DQ rule on the Amazon Redshift or Amazon RDS dataset. This is a known bug.

## LAUNCH ERROR: Error downloading from S3 for bucket

**Error condition:** LAUNCH ERROR: Error downloading from S3 for bucket: aws-glue-ml-data-quality-assets-us-east-1, key: jars/aws-glue-ml-data-quality-etl.jar.Access Denied (Service: Amazon S3; Status Code: 403; Please refer logs for details) .

**Resolution:** The permissions in the role passed to AWS Glue Data Quality must permit reading from the preceding Amazon S3 location. This IAM policy should be attached to the role:

```
{
  "Sid": "allowS3",
  "Effect": "Allow",
  "Action": "s3:GetObject",
  "Resource": "arn:aws:s3:::aws-glue-ml-data-quality-assets-<region>/*"
}
```

Refer to [Data Quality authorization](#) for detailed permissions. These libraries are required to evaluate data quality for your datasets.

## InvalidInputException (status: 400): DataQuality rules cannot be parsed

**Error condition:** InvalidInputException (status: 400): DataQuality rules cannot be parsed.

**Resolution:** There are many possibilities for this error. One possibility is that your rules may have single quotes. Verify that they are in double quotes. For example:

```
Rules = [
```

```
ColumnValues "tipo_vinculo" in ["COD0", "DOC0", "COC0", "DOD0"] AND "categoria" = 'ES'  
AND "cod_bandera" = 'CEP'
```

Change this to:

```
Rules = [  
(ColumnValues "tipovinculo" in [ "COD0", "DOC0", "COC0", "DOD0"]) AND (ColumnValues  
"categoria" = "ES")  
AND (ColumnValues "codbandera" = "CEP")  
]
```

## Error: Eventbridge is not triggering Glue DQ jobs based on the schedule I setup

**Error condition:** Eventbridge is not triggering AWS Glue Data Quality jobs based on the schedule I setup.

**Resolution:** The role triggering the job may not have the right permissions. Make sure that the role that you are using to start the jobs has the permissions mentioned in [IAM setup required for scheduling evaluation runs](#).

## CustomSQL errors

**Error condition:** The output from CustomSQL must contain at least one column that matches the input dataset for AWS Glue Data Quality to provide row level results. The SQL query is a valid query but no columns from the SQL result are present in the Input Dataset. Ensure that matching columns are returned from the SQL.

**Resolution:** The SQL query is valid but verify that you're selecting only columns from the primary table. Selecting aggregate functions like sum, count on the columns from the primary can result in this error.

**Error condition:** There was a problem when executing your SQL statement: cannot resolve "Col".

**Resolution:** This column is not present in the primary table.

**Error condition:** The columns that are returned from the SQL statement should only belong to the primary table. "In this case, some columns ( Col ) belong to reference table".

**Resolution:** In SQL queries when you're joining the primary table with other reference tables, verify that your select statement has only column names from your primary table to generate row level results for the primary table.

## Dynamic Rules

**Error condition:** Dynamic rules require job context, and cannot be evaluated in interactive session or data preview..

**Cause:** This error message might appear in your data preview results, or in other interactive sessions, when dynamic DQ rules are present in your ruleset. Dynamic rules reference historical metrics associated with a particular job name and evaluation context, so they can't be evaluated in interactive sessions.

**Resolution:** Running your AWS Glue job will produce historical metrics, which can be referenced in later job runs for the same job.

**Error condition:**

- [RuleType] rule only supports simple atomic operands in thresholds..
- Function last not yet implemented for [RuleType] rule.

**Resolution:** Dynamic rules are generally supported for all DQDL ruletypes in numeric expressions (see [DQDL Reference](#)). However, some rules that produce multiple metrics, ColumnValues and ColumnLength, are not yet supported.

**Error condition:** Binary expression operands must resolve to a single number..

**Cause:** Dynamic rules support binary expressions, like `RowCount > avg(last(5)) * 0.9`. Here, the binary expression is `avg(last(5)) * 0.9`. This rule is valid because both operands `avg(last(5))` and `0.9` resolve to a single number. An incorrect example is `RowCount > last(5) * 0.9`, because `last(5)` will produce a list that can't be meaningfully compared to the current row count.

**Resolution:** Use aggregation functions to reduce a list-valued operand to a single number.

**Error condition:**

- Rule threshold results in list, and a single value is expected. Use aggregation functions to produce a single value. Valid example: `sum(last(10))`, `avg(last(10))`.
- Rule threshold results in empty list, and a single value is expected.

**Cause:** Dynamic rules can be used to compare some feature of your dataset with its historical values. The last function allows for the retrieval of multiple historical values, if a positive integer argument is provided. For example, `last(5)` will retrieve the last five most recent values observed in job runs for your rule.

**Resolution:** An aggregation function must be used to reduce these values to a single number to make a meaningful comparison with the value observed in the current job run.

Valid examples:

- `RowCount >= avg(last(5))`
- `RowCount > last(1)`
- `RowCount < last()`

Invalid example: `RowCount > last(5)`.

**Error condition:**

- Function index used in threshold requires positive integer argument.
- Index argument must be an integer. Valid syntax example: `RowCount > index(last(10, 2))`, which means RowCount must be greater than third most recent execution from last 10 job runs.

**Resolution:** When authoring dynamic rules, you can use the `index` aggregation function to select one historical value from a list. For example, `RowCount > index(last(5), 1)` will check whether the row count observed in the current job is strictly greater than the second most recent row count observed for your job. `index` is zero-indexed.

**Error condition:** `IllegalArgumentException: Parsing Error: Rule Type: DetectAnomalies is not valid.`

**Resolution:** Anomaly detection is only available in AWS Glue 4.0.

**Error condition:** `IllegalArgumentException: Parsing Error: Unexpected condition for rule of type ... no viable alternative at input ....`

Note: ... is dynamic. Example: `IllegalArgumentException: Parsing Error: Unexpected condition for rule of type RowCount with number return type, line 4:19 no viable alternative at input '>last'.`

**Resolution:** Anomaly detection is only available in AWS Glue 4.0.

## **Exception in User Class: `org.apache.spark.sql.AnalysisException: org.apache.hadoop.hive.ql.metadata.HiveException`**

**Error condition:** Exception in User Class:

`org.apache.spark.sql.AnalysisException:`

`org.apache.hadoop.hive.ql.metadata.HiveException: Unable to fetch table mailpiece_submitted. StorageDescriptor#InputFormat cannot be null for table: mailpiece_submitted (Service: null; Status Code: 0; Error Code: null; Request ID: null; Proxy: null)`

**Cause:** You are using Apache Iceberg in AWS Glue Data Catalog and the Input Format attribute in AWS Glue Data Catalog is empty.

**Resolution:** This issue occurs when you are using CustomSQL ruletype in your DQ rule. One way to fix this is to use "primary" or add catalog name `glue_catalog.` to `<database>.<table>` in Custom ruletype.

# Amazon Q data integration in AWS Glue

Amazon Q data integration in AWS Glue is a new generative AI capability of AWS Glue that enables data engineers and ETL developers to build data integration jobs using natural language. Engineers and developers can ask Amazon Q to author jobs, troubleshoot issues, and answer questions about AWS Glue and data integration.

## What is Amazon Q?

### Note

Powered by Amazon Bedrock: AWS implements [automated abuse detection](#). Because Amazon Q data integration is built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

Amazon Q is a generative artificial intelligence (AI) powered conversational assistant that can help you understand, build, extend, and operate AWS applications. The model that powers Amazon Q has been augmented with high quality AWS content to get you more complete, actionable, and referenced answers to accelerate your building on AWS. For more information, see [What is Amazon Q?](#)

## What is Amazon Q data integration in AWS Glue?

Amazon Q data integration in AWS Glue includes the following capabilities:

- **Chat** – Amazon Q data integration in AWS Glue can answer natural language questions in English about AWS Glue and data integration domains like AWS Glue source and destination connectors, AWS Glue ETL jobs, Data Catalog, crawlers and AWS Lake Formation, and other feature documentation, and best practices. Amazon Q data integration in AWS Glue responds with step-by-step instructions, and includes references to its information sources.
- **Data integration code generation** – Amazon Q data integration in AWS Glue can answer questions about AWS Glue ETL scripts, and generate new code given a natural language question in English.

- **Troubleshoot** – Amazon Q data integration in AWS Glue is purpose built to help you understand errors in AWS Glue jobs and provides step-by-step instructions, to root cause and resolve your issues.

 **Note**

Amazon Q data integration in AWS Glue does not use the context of your conversation to inform future responses for the duration of your conversation. Each conversation with Amazon Q data integration in AWS Glue is independent of your prior or future conversations.

## Working with Amazon Q data integration in AWS Glue?

In the Amazon Q panel you can request Amazon Q generate code for an AWS Glue ETL script, or answer a question on AWS Glue features or troubleshooting an error. The response is an ETL script in PySpark with step-by-step instructions to customize the script, review and execute it. For questions, the response is generated based on the data integration knowledge base with a summary and source URL for references.

For example, you can ask Amazon Q to *"Please provide a Glue script that reads from Snowflake, renames the fields, and writes to Redshift"* and in response, Amazon Q data integration in AWS Glue will return an AWS Glue job script that can perform the requested action. You can review the generated code to ensure that it fulfills the requested intent. If satisfied, you can deploy it as an AWS Glue job in production. You can troubleshoot jobs by asking the integration to explain errors and failures, and to propose solutions. Amazon Q can answer questions about AWS Glue or data integration best practices.

The screenshot displays the AWS Glue Studio 'Jobs' page. The left sidebar contains navigation links for 'Getting started', 'ETL jobs' (with sub-links for Visual ETL, Notebooks, Job run monitoring, Data Catalog tables, Data connections, and Workflows), 'Data Catalog', 'Data Integration and ETL', and 'Legacy pages'. Below the sidebar are 'What's New' and 'Documentation' links, and two toggle switches for 'Enable compact mode' and 'Enable new navigation'. The main content area is titled 'AWS Glue Studio' and features a 'Create job' section with three options: 'Visual ETL' (visual interface), 'Notebook' (interactive code notebook), and 'Script editor' (code with a script editor). Below this is an 'Example jobs' section with a 'Create example job' button. The 'Your jobs (2)' section shows a search for 'demo' with 2 matches. A table lists the jobs:

<input type="checkbox"/>	Job name	Type	Last modified	AWS Glue version
<input type="checkbox"/>	q-demo-taxi	Glue ETL	4/26/2024, 1:19:07 PM	4.0
<input type="checkbox"/>	q-demo	Glue ETL	4/25/2024, 3:41:38 PM	4.0

The following are example questions that demonstrate how Amazon Q data integration in AWS Glue can help you build on AWS Glue:

AWS Glue ETL code generation:

- Write an AWS Glue script that reads JSON from S3, transforms fields using apply mapping and writes to Amazon Redshift
- How do I write an AWS Glue script for reading from DynamoDB, applying the DropNullFields transform and writing to S3 as Parquet?
- Give me an AWS Glue script that reads from MySQL, drops some fields based on my business logic, and writes to Snowflake
- Write an AWS Glue job to read from DynamoDB and write to S3 as JSON
- Help me develop an AWS Glue script for AWS Glue Data Catalog to S3
- Write an AWS Glue job to read JSON from S3, drop nulls and write to Redshift

AWS Glue feature explanations:

- How do I use AWS Glue Data Quality?
- How to use AWS Glue job bookmarks?
- How do I enable AWS Glue autoscaling?

- What is the difference between AWS Glue dynamic frames and Spark data frames?
- What are the different types of connections supported by AWS Glue?

AWS Glue troubleshooting:

- How to troubleshoot Out Of Memory (OOM) errors on AWS Glue jobs?
- What are some error messages you may see when setting up AWS Glue Data Quality and how can you fix them?
- How do I fix an AWS Glue job with the error Amazon S3 access denied?
- How do I resolve issues with data shuffle on AWS Glue jobs?

## Best practices for interacting with Amazon Q data integration

The following are best practices for interacting with Amazon Q data integration:

- When interacting with Amazon Q data integration, ask specific questions, iterate when you have complex requests, and verify the answers for accuracy.
- When providing data integration prompts in natural language, be as specific as possible to help the assistant understand exactly what you need. Instead of asking "extract data from S3," provide more details like "write an AWS Glue script that extracts JSON files from S3."
- Review the generated script before running it to ensure accuracy. If the generated script has errors or does not match your intent, provide instructions to the assistant on how to correct it.
- Generative AI technology is new and there can be mistakes, sometimes called hallucinations, in the responses. Test and review all code for errors and vulnerabilities before using it in your environment or workload.

## Amazon Q data integration in AWS Glue service improvement

To help Amazon Q data integration in AWS Glue provide the most relevant information about AWS services, we may use certain content from Amazon Q, such as questions that you ask Amazon Q and its responses, for service improvement.

For information about what content we use and how to opt out, see [Amazon Q Developer service improvement](#) in the *Amazon Q Developer User Guide*.

## Considerations

Consider the following items before you use Amazon Q data integration in AWS Glue:

- Currently, the code generation only works with PySpark kernel. The generated code is for AWS Glue jobs based on Python Spark.
- For information about the supported combinations of code generation abilities of Amazon Q data integration in AWS Glue, see [Supported code generation abilities](#).

## Setting up Amazon Q data integration in AWS Glue

The following sections provide information setting up Amazon Q data integration in AWS Glue.

### Topics

- [Configuring IAM permissions](#)

## Configuring IAM permissions

This topic describes the IAM permissions that you configure for the Amazon Q chat experience, and the AWS Glue Studio notebook experience.

### Topics

- [Configuring IAM permissions for Amazon Q chat](#)
- [Configuring IAM permissions for AWS Glue Studio notebooks](#)

## Configuring IAM permissions for Amazon Q chat

Granting permissions to the APIs used by Amazon Q data integration in AWS Glue requires appropriate AWS Identity and Access Management (IAM) permissions. You can obtain permissions by attaching the following custom AWS policy to your IAM identity (such as a user, role, or group):

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```

        "Action": [
            "glue:StartCompletion",
            "glue:GetCompletion"
        ],
        "Resource": [
            "arn:aws:glue:*:*:completion/*"
        ]
    }
]
}

```

## Configuring IAM permissions for AWS Glue Studio notebooks

To enable Amazon Q data integration in AWS Glue Studio notebooks, ensure the following permission is attached to the notebook IAM role:

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:StartCompletion",
        "glue:GetCompletion"
      ],
      "Resource": [
        "arn:aws:glue:*:*:completion/*"
      ]
    },
    {
      "Sid": "CodeWhispererPermissions",
      "Effect": "Allow",
      "Action": [
        "codewhisperer:GenerateRecommendations"
      ],
      "Resource": "*"
    }
  ]
}

```

### Note

Amazon Q data integration in AWS Glue does not have APIs available through the AWS SDK that you can use programmatically. The following two APIs are used in the IAM policy for enabling this experience through the Amazon Q chat panel or AWS Glue Studio notebooks: `StartCompletion` and `GetCompletion`.

## Assigning permissions

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center: Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider: Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

## Supported code generation abilities

The following are the combinations of the code generation abilities of Amazon Q data integration in AWS Glue.

Source	Transformation	Target
S3 with the following format types: json, csv, parquet, hudi, delta	ApplyMapping	S3 with the following format types: json, csv, avro, orc, parquet, hudi, delta
Glue Data Catalog	RenameField	Glue Data Catalog
Amazon Redshift	DropFields	Amazon Redshift

Source	Transformation	Target
MySQL	SelectFields	MySQL
Postgres	DropNullFields	Postgres
Oracle	Filter	Oracle
SQL Server	Spigot	SQL Server
DynamoDB	Custom SQL Code	DynamoDB
Snowflake	Aggregate	Snowflake
MongoDB	DropDuplicates	MongoDB
Custom JDBC Connector	Join	Custom JDBC Connector
Custom Spark Connector	Union	Custom Spark Connector
Google BigQuery		Google BigQuery
Teradata		Teradata
Amazon OpenSearch Service		Amazon OpenSearch Service
Vertica		Vertica
Azure SQL		Azure DQL
SAP HANA		SAP HANA
Azure Cosmos		Azure Cosmos

## Example interactions

Amazon Q data integration in AWS Glue allows you enter your question in the Amazon Q panel. You can enter a question regarding data integration functionality provided by AWS Glue. A detailed answer, together with reference documents, will be returned.

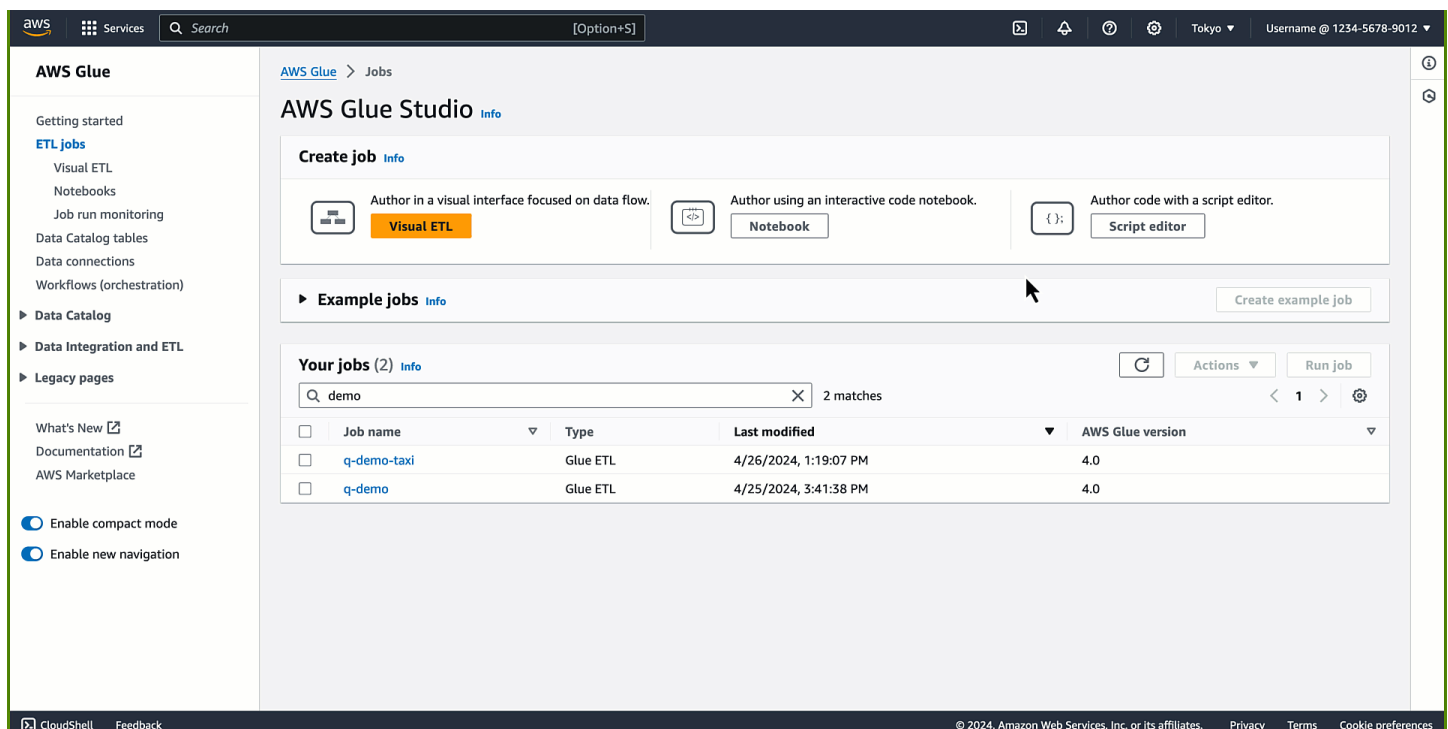

Another use case is generating AWS Glue ETL job scripts. You can ask a question regarding how to perform a data extract, transform, load job. A generated PySpark script will be returned.

## Topics

- [Amazon Q chat interactions](#)
- [AWS Glue Studio notebook interactions](#)

## Amazon Q chat interactions

On the AWS Glue console, start authoring a new job, and ask Amazon Q: *"Please provide a Glue script that reads from Snowflake, renames the fields, and writes to Redshift."*

The screenshot shows the AWS Glue Studio console. The main content area is titled 'AWS Glue Studio' and features a 'Create job' section with three options: 'Visual ETL' (Author in a visual interface focused on data flow), 'Notebook' (Author using an interactive code notebook), and 'Script editor' (Author code with a script editor). Below this is an 'Example jobs' section with a 'Create example job' button. The 'Your jobs (2)' section displays a table with the following data:

Job name	Type	Last modified	AWS Glue version
q-demo-taxi	Glue ETL	4/26/2024, 1:19:07 PM	4.0
q-demo	Glue ETL	4/25/2024, 3:41:38 PM	4.0

You will notice that the code is generated. With this response, you can learn and understand how you can author AWS Glue code for your purpose. You can copy/paste the generated code to the script editor and configure placeholders. After you configure an AWS Identity and Access Management (IAM) role and AWS Glue connections on the job, save and run the job. When the job is complete, you can start querying the table exported from Snowflake in Amazon Redshift.

The following prompt reads data from two different sources, filters and projects them individually, joins on a common key, and writes the output to a third target. Ask Amazon Q: *"I want to read data from S3 in Parquet format, and select some fields. I also want to read data from DynamoDB,*

select some fields, and filter some rows. I want to union these two datasets and write the results to OpenSearch.

The screenshot shows the AWS Glue Studio interface. The left sidebar contains navigation options like 'Getting started', 'ETL jobs', 'Data Catalog', and 'Data Integration and ETL'. The main content area is titled 'AWS Glue Studio' and 'Jobs'. It features a 'Create job' section with three options: 'Visual ETL' (highlighted in orange), 'Notebook', and 'Script editor'. Below this is an 'Example jobs' section with a 'Create example job' button. The 'Your jobs (5)' section shows a search bar with 'demo' and a table of jobs.

Job name	Type	Last modified	AWS Glue version
q-demo-snowflake-to-redshift	Glue ETL	4/26/2024, 1:28:55 PM	4.0
q-demo-taxi	Glue ETL	4/26/2024, 1:19:07 PM	4.0
q-demo	Glue ETL	4/25/2024, 3:41:38 PM	4.0

The code is generated. When the job is complete, your index is available in OpenSearch and can be used by your downstream workloads.

## AWS Glue Studio notebook interactions

Add a new cell and enter your comment to describe what you want to achieve. After you press **Tab** and **Enter**, the recommended code is shown.

First intent is to extract the data: "Give me code that reads a Glue Data Catalog table", followed by "Give me code to apply a filter transform with `star_rating>3`" and "Give me code that writes the frame into S3 as Parquet".

The screenshot shows the AWS Glue Studio notebook interface. At the top, there are navigation tabs: Notebook, Script, Job details, Runs, Data quality - updated, Schedules, and Version Control. Below the tabs is a toolbar with buttons for Stop notebook, Download Notebook, Actions, Save, and Run. The main area displays a data table with the following content:

Marine end-to-e... Lake maracaibo in...	2013	25	US 2013-01-27 00:00:00	207443 white gold anklet...	Jewelry	5 Re
23008 RDYS06F9USEZLSG	N	6				
gular supply al... Amongst other neg...	2013					
89950 RBJPZWSA0NG285W	N	2	US 2013-01-11 00:00:00	352961 silver-plated hai...	Jewelry	5 Gr
oundwater recha... Not exactly were ...	2013					

Below the table, it says "only showing top 20 rows". The interface also shows a code editor with a cursor and a status bar at the bottom indicating "Mode: Command" and "Ln 1, Col 1".

Similar to the Amazon Q chat experience, the code is recommended. If you press **Tab**, then the recommended code is chosen.

You can run each cell by filling in the appropriate options for your sources in the generated code. At any point in the runs, you can also preview a sample of your dataset by using the `show()` method.

## Complex prompts

You can generate a full script with a single complex prompt. *"I have JSON data in S3 and data in Oracle that needs combining. Please provide a Glue script that reads from both sources, does a join, and then writes results to Redshift."*

The screenshot displays the AWS Glue Studio Notebook interface. At the top, the notebook is titled "q-note" and shows it was last modified on 4/29/2024 at 11:40:12 AM. Action buttons include "Stop notebook", "Download Notebook", "Actions", "Save", and "Run". The notebook content area shows a message: "AWS Glue Studio Notebook. You are now running a AWS Glue Studio notebook; To start using your notebook you need to start an AWS Glue Interactive Session." Below the message is a code editor area with a toolbar and a status bar at the bottom showing "Mode: Edit", "Ln 1, Col 1", and "Untitled.ipynb".

You may notice that, on the notebook, Amazon Q data integration in AWS Glue generated the same code snippet that was generated in the Amazon Q chat.

You can run the notebook as a job, either by choosing **Run** or programmatically.

# Orchestration in AWS Glue

The following sections provide information on orchestration of jobs in AWS Glue.

## Topics

- [Starting jobs and crawlers using triggers](#)
- [Performing complex ETL activities using blueprints and workflows in AWS Glue](#)
- [Developing blueprints in AWS Glue](#)

## Starting jobs and crawlers using triggers

In AWS Glue, you can create Data Catalog objects called triggers, which you can use to either manually or automatically start one or more crawlers or extract, transform, and load (ETL) jobs. Using triggers, you can design a chain of dependent jobs and crawlers.

### Note

You can accomplish the same thing by defining *workflows*. Workflows are preferred for creating complex multi-job ETL operations. For more information, see [the section called “Performing complex ETL activities using blueprints and workflows”](#).

## Topics

- [AWS Glue triggers](#)
- [Adding triggers](#)
- [Activating and deactivating triggers](#)

## AWS Glue triggers

When *fired*, a trigger can start specified jobs and crawlers. A trigger fires on demand, based on a schedule, or based on a combination of events.

**Note**

Only two crawlers can be activated by a single trigger. If you want to crawl multiple data stores, use multiple sources for each crawler instead of running multiple crawlers simultaneously.

A trigger can exist in one of several states. A trigger is either `CREATED`, `ACTIVATED`, or `DEACTIVATED`. There are also transitional states, such as `ACTIVATING`. To temporarily stop a trigger from firing, you can deactivate it. You can then reactivate it later.

There are three types of triggers:

**Scheduled**

A time-based trigger based on `cron`.

You can create a trigger for a set of jobs or crawlers based on a schedule. You can specify constraints, such as the frequency that the jobs or crawlers run, which days of the week they run, and at what time. These constraints are based on `cron`. When you're setting up a schedule for a trigger, consider the features and limitations of `cron`. For example, if you choose to run your crawler on day 31 each month, keep in mind that some months don't have 31 days. For more information about `cron`, see [Time-based schedules for jobs and crawlers](#).

**Conditional**

A trigger that fires when a previous job or crawler or multiple jobs or crawlers satisfy a list of conditions.

When you create a conditional trigger, you specify a list of jobs and a list of crawlers to watch. For each watched job or crawler, you specify a status to watch for, such as `succeeded`, `failed`, `timed out`, and so on. The trigger fires if the watched jobs or crawlers end with the specified statuses. You can configure the trigger to fire when any or all of the watched events occur.

For example, you could configure a trigger T1 to start job J3 when both job J1 and job J2 successfully complete, and another trigger T2 to start job J4 if either job J1 or job J2 fails.

The following table lists the job and crawler completion states (events) that triggers watch for.

Job completion states	Crawler completion states
<ul style="list-style-type: none"> <li>• SUCCEEDED</li> <li>• STOPPED</li> <li>• FAILED</li> <li>• TIMEOUT</li> </ul>	<ul style="list-style-type: none"> <li>• SUCCEEDED</li> <li>• FAILED</li> <li>• CANCELLED</li> </ul>

## On-demand

A trigger that fires when you activate it. On-demand triggers never enter the ACTIVATED or DEACTIVATED state. They always remain in the CREATED state.

So that they are ready to fire as soon as they exist, you can set a flag to activate scheduled and conditional triggers when you create them.

### Important

Jobs or crawlers that run as a result of other jobs or crawlers completing are referred to as *dependent*. Dependent jobs or crawlers are only started if the job or crawler that completes was started by a trigger. All jobs or crawlers in a dependency chain must be descendants of a single **scheduled** or **on-demand** trigger.

## Passing job parameters with triggers

A trigger can pass parameters to the jobs that it starts. Parameters include job arguments, timeout value, security configuration, and more. If the trigger starts multiple jobs, the parameters are passed to each job.

The following are the rules for job arguments passed by a trigger:

- If the key in the key-value pair matches a default job argument, the passed argument overrides the default argument. If the key doesn't match a default argument, then the argument is passed as an additional argument to the job.
- If the key in the key-value pair matches a non-overridable argument, the passed argument is ignored.

For more information, see [the section called “Triggers”](#) in the AWS Glue API.

## Adding triggers

You can add a trigger using the AWS Glue console, the AWS Command Line Interface (AWS CLI), or the AWS Glue API.

### Note

Currently, the AWS Glue console supports only jobs, not crawlers, when working with triggers. You can use the AWS CLI or AWS Glue API to configure triggers with both jobs and crawlers.

### To add a trigger (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **ETL**, choose **Triggers**. Then choose **Add trigger**.
3. Provide the following properties:

#### Name

Give your trigger a unique name.

#### Trigger type

Specify one of the following:

- **Schedule:** The trigger fires at a specific frequency and time.
  - **Job events:** A conditional trigger. The trigger fires when any or all jobs in the list match their designated statuses. For the trigger to fire, the watched jobs must have been started by triggers. For any job you choose, you can only watch one job event (completion status).
  - **On-demand:** The trigger fires when it is activated.
4. Complete the trigger wizard. On the **Review** page, you can activate **Schedule** and **Job events** (conditional) triggers immediately by selecting **Enable trigger on creation**.

## To add a trigger (AWS CLI)

- Enter a command similar to the following.

```
aws glue create-trigger --name MyTrigger --type SCHEDULED --schedule "cron(0 12 * * ? *)" --actions CrawlerName=MyCrawler --start-on-creation
```

This command creates a schedule trigger named `MyTrigger`, which runs every day at 12:00pm UTC and starts a crawler named `MyCrawler`. The trigger is created in the activated state.

For more information, see [the section called "AWS Glue triggers"](#).

## Time-based schedules for jobs and crawlers

You can define a time-based schedule for your crawlers and jobs in AWS Glue. The definition of these schedules uses the Unix-like [cron](#) syntax. You specify time in [Coordinated Universal Time \(UTC\)](#), and the minimum precision for a schedule is 5 minutes.

To learn more about configuring jobs and crawlers to run using a schedule, see [Starting jobs and crawlers using triggers](#).

### Cron expressions

Cron expressions have six required fields, which are separated by white space.

### Syntax

```
cron(Minutes Hours Day-of-month Month Day-of-week Year)
```

Fields	Values	Wildcards
Minutes	0–59	, - * /
Hours	0–23	, - * /
Day-of-month	1–31	, - * ? / L W
Month	1–12 or JAN-DEC	, - * /

Fields	Values	Wildcards
Day-of-week	1–7 or SUN-SAT	, - * ? / L
Year	1970–2199	, - * /

## Wildcards

- The , (comma) wildcard includes additional values. In the Month field, JAN , FEB , MAR would include January, February, and March.
- The - (dash) wildcard specifies ranges. In the Day field, 1–15 would include days 1 through 15 of the specified month.
- The \* (asterisk) wildcard includes all values in the field. In the Hours field, \* would include every hour.
- The / (forward slash) wildcard specifies increments. In the Minutes field, you could enter **1/10** to specify every 10th minute, starting from the first minute of the hour (for example, the 11th, 21st, and 31st minute).
- The ? (question mark) wildcard specifies one or another. In the Day-of-month field you could enter **7**, and if you didn't care what day of the week the seventh was, you could enter **?** in the Day-of-week field.
- The **L** wildcard in the Day-of-month or Day-of-week fields specifies the last day of the month or week.
- The **W** wildcard in the Day-of-month field specifies a weekday. In the Day-of-month field, **3W** specifies the day closest to the third weekday of the month.

## Limits

- You can't specify the Day-of-month and Day-of-week fields in the same cron expression. If you specify a value in one of the fields, you must use a ? (question mark) in the other.
- Cron expressions that lead to rates faster than 5 minutes are not supported.

## Examples

When creating a schedule, you can use the following sample cron strings.

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
0	10	*	*	?	*	Run at 10:00 am (UTC) every day
15	12	*	*	?	*	Run at 12:15 pm (UTC) every day
0	18	?	*	MON-FRI	*	Run at 6:00 pm (UTC) every Monday through Friday
0	8	1	*	?	*	Run at 8:00 am (UTC) every first day of the month
0/15	*	*	*	?	*	Run every 15 minutes
0/10	*	?	*	MON-FRI	*	Run every 10 minutes Monday through Friday

Minutes	Hours	Day of month	Month	Day of week	Year	Meaning
0/5	8–17	?	*	MON-FRI	*	Run every 5 minutes Monday through Friday between 8:00 am and 5:55 pm (UTC)

For example to run on a schedule of every day at 12:15 UTC, specify:

```
cron(15 12 * * ? *)
```

## Activating and deactivating triggers

You can activate or deactivate a trigger using the AWS Glue console, the AWS Command Line Interface (AWS CLI), or the AWS Glue API.

### Note

Currently, the AWS Glue console supports only jobs, not crawlers, when working with triggers. You can use the AWS CLI or AWS Glue API to configure triggers with both jobs and crawlers.

### To activate or deactivate a trigger (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **ETL**, choose **Triggers**.
3. Select the check box next to the desired trigger, and on the **Action** menu choose **Enable trigger** to activate the trigger or **Disable trigger** to deactivate the trigger.

## To activate or deactivate a trigger (AWS CLI)

- Enter one of the following commands.

```
aws glue start-trigger --name MyTrigger
```

```
aws glue stop-trigger --name MyTrigger
```

Starting a trigger activates it, and stopping a trigger deactivates it. When you activate an on-demand trigger, it fires immediately.

For more information, see [the section called “AWS Glue triggers”](#).

## Performing complex ETL activities using blueprints and workflows in AWS Glue

Some of your organization's complex extract, transform, and load (ETL) processes might best be implemented by using multiple, dependent AWS Glue jobs and crawlers. Using AWS Glue *workflows*, you can design a complex multi-job, multi-crawler ETL process that AWS Glue can run and track as single entity. After you create a workflow and specify the jobs, crawlers, and triggers in the workflow, you can run the workflow on demand or on a schedule.

### Topics

- [Overview of workflows in AWS Glue](#)
- [Creating and building out a workflow manually in AWS Glue](#)
- [Starting an AWS Glue workflow with an Amazon EventBridge event](#)
- [Viewing the EventBridge events that started a workflow](#)
- [Running and monitoring a workflow in AWS Glue](#)
- [Stopping a workflow run](#)
- [Repairing and resuming a workflow run](#)
- [Getting and setting workflow run properties in AWS Glue](#)
- [Querying workflows using the AWS Glue API](#)
- [Blueprint and workflow restrictions in AWS Glue](#)
- [Troubleshooting blueprint errors in AWS Glue](#)

- [Permissions for personas and roles for AWS Glue blueprints](#)

## Overview of workflows in AWS Glue

In AWS Glue, you can use workflows to create and visualize complex extract, transform, and load (ETL) activities involving multiple crawlers, jobs, and triggers. Each workflow manages the execution and monitoring of all its jobs and crawlers. As a workflow runs each component, it records execution progress and status. This provides you with an overview of the larger task and the details of each step. The AWS Glue console provides a visual representation of a workflow as a graph.

You can create a workflow from an AWS Glue blueprint, or you can manually build a workflow a component at a time using the AWS Management Console or the AWS Glue API. For more information about blueprints, see [the section called "Overview of blueprints"](#).

*Triggers* within workflows can start both jobs and crawlers and can be fired when jobs or crawlers complete. By using triggers, you can create large chains of interdependent jobs and crawlers. In addition to triggers within a workflow that define job and crawler dependencies, each workflow has a *start trigger*. There are three types of start triggers:

- **Schedule** – The workflow is started according to a schedule that you define. The schedule can be daily, weekly, monthly, and so on, or can be a custom schedule based on a cron expression.
- **On demand** – The workflow is started manually from the AWS Glue console, API, or AWS CLI.
- **EventBridge event** – The workflow is started upon the occurrence of a single Amazon EventBridge event or a batch of Amazon EventBridge events. With this trigger type, AWS Glue can be an event consumer in an event-driven architecture. Any EventBridge event type can start a workflow. A common use case is the arrival of a new object in an Amazon S3 bucket (the S3 PutObject operation).

Starting a workflow with a batch of events means waiting until a specified number of events have been received or until a specified amount of time has passed. When you create the EventBridge event trigger, you can optionally specify batch conditions. If you specify batch conditions, you must specify the batch size (number of events), and can optionally specify a batch window (number of seconds). The default and maximum batch window is 900 seconds (15 minutes). The batch condition that is met first starts the workflow. The batch window starts when the first event arrives. If you don't specify batch conditions when creating a trigger, the batch size defaults to 1.

When the workflow starts, the batch conditions are reset and the event trigger begins watching for the next batch condition to be met to start the workflow again.

The following table shows how batch size and batch window operate together to trigger a workflow.

Batch size	Batch window	Resulting triggering condition
10		The workflow is triggered upon the arrival of 10 EventBridge events, or 15 minutes after the arrival of the first event, whichever occurs first. (If windows size isn't specified, it defaults to 15 minutes.)
10	2 mins	The workflow is triggered upon the arrival of 10 EventBridge events, or 2 minutes after the arrival of the first event, whichever occurs first.
1		The workflow is triggered upon the arrival of the first event. Window size is irrelevant. The batch size defaults to 1 if you don't specify batch conditions when you create the EventBridge event trigger.

The `GetWorkflowRun` API operation returns the batch condition that triggered the workflow.

Regardless of how a workflow is started, you can specify the maximum number of concurrent workflow runs when you create the workflow.

If an event or batch of events starts a workflow run that eventually fails, that event or batch of events is no longer considered for starting a workflow run. A new workflow run is started only when the next event or batch of events arrives.

### Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

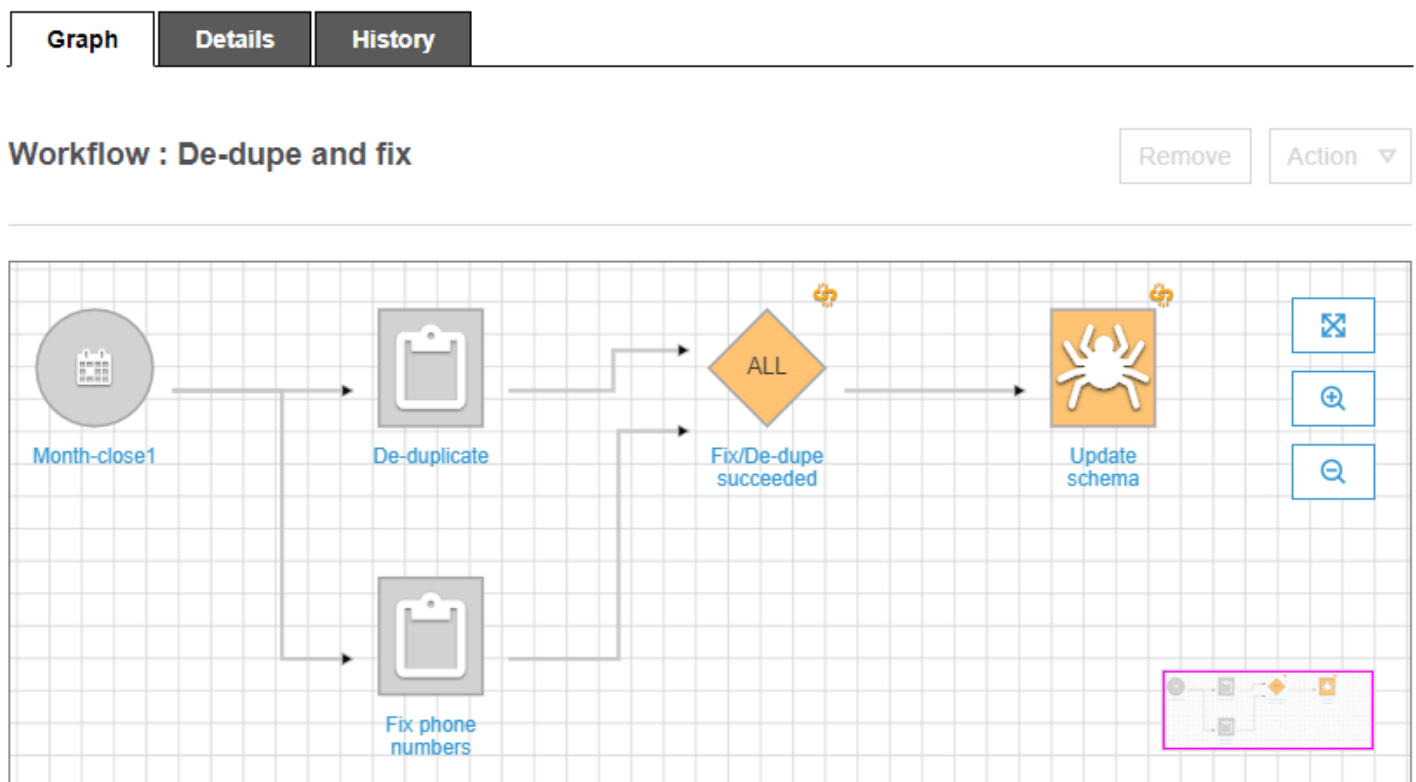

A workflow run will not be started if it would exceed the concurrency limit set for the workflow, even though the event condition is met. It's advisable to adjust workflow concurrency limits based on the expected event volume. AWS Glue does not retry workflow runs that fail due to exceeded concurrency limits. Likewise, it's advisable to adjust concurrency limits for jobs and crawlers within workflows based on expected event volume.

## Workflow run properties

To share and manage state throughout a workflow run, you can define default workflow run properties. These properties, which are name/value pairs, are available to all the jobs in the workflow. Using the AWS Glue API, jobs can retrieve the workflow run properties and modify them for jobs that come later in the workflow.

## Workflow graph

The following image shows the graph of a very basic workflow on the AWS Glue console. Your workflow could have dozens of components.

This workflow is started by a schedule trigger, `Month-close1`, which starts two jobs, `De-duplicate` and `Fix phone numbers`. Upon successful completion of both jobs, an event trigger, `Fix/De-dupe succeeded`, starts a crawler, `Update schema`.

## Static and dynamic workflow views

For each workflow, there is the notion of *static view* and *dynamic view*. The static view indicates the design of the workflow. The dynamic view is a runtime view that includes the latest run information for each of the jobs and crawlers. Run information includes success status and error details.

When a workflow is running, the console displays the dynamic view, graphically indicating the jobs that have completed and that are yet to be run. You can also retrieve a dynamic view of a running workflow using the AWS Glue API. For more information, see [Querying workflows using the AWS Glue API](#).

### See also

- [the section called “Creating a workflow from a blueprint”](#)
- [the section called “Creating and building out a workflow manually”](#)
- [Workflows](#) (for the workflows API)

## Creating and building out a workflow manually in AWS Glue

You can use the AWS Glue console to manually create and build out a workflow one node at a time.

A workflow contains jobs, crawlers, and triggers. Before manually creating a workflow, create the jobs and crawlers that the workflow is to include. It's best to specify run-on-demand crawlers for workflows. You can create new triggers while you are building out your workflow, or you can *clone* existing triggers into the workflow. When you clone a trigger, all the catalog objects associated with the trigger—the jobs or crawlers that fire it and the jobs or crawlers that it starts—are added to the workflow.

### Important

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

You build out your workflow by adding triggers to the workflow graph, and defining the watched events and actions for each trigger. You begin with a *start trigger*, which can be either an on-demand or schedule trigger, and complete the graph by adding event (conditional) triggers.

## Step 1: Create the workflow

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Choose **Add workflow** and complete the **Add a new ETL workflow** form.

Any optional default run properties that you add are made available as arguments to all jobs in the workflow. For more information, see [Getting and setting workflow run properties in AWS Glue](#).

4. Choose **Add workflow**.

The new workflow appears in the list on the **Workflows** page.

## Step 2: Add a start trigger

1. On the **Workflows** page, select your new workflow. Then, at the bottom of the page, ensure that the **Graph** tab is selected.
2. Choose **Add trigger**, and in the **Add trigger** dialog box, do one of the following:
  - Choose **Clone existing**, and choose a trigger to clone. Then choose **Add**.

The trigger appears on the graph, along with the jobs and crawlers that it watches and the jobs and crawlers that it starts.

If you mistakenly selected the wrong trigger, select the trigger on the graph, and then choose **Remove**.

- Choose **Add new**, and complete the **Add trigger** form.
  1. For **Trigger type**, select **Schedule**, **On demand**, or **EventBridge event**.

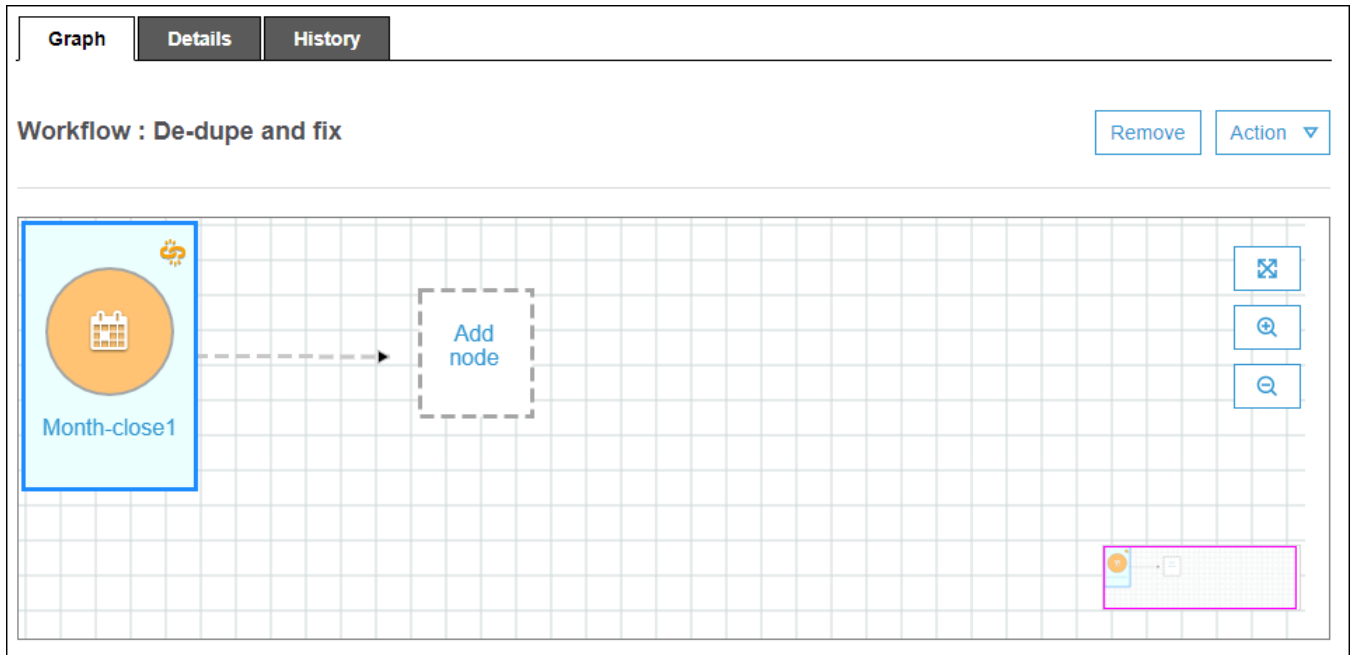

For trigger type **Schedule**, choose one of the **Frequency** options. Choose **Custom** to enter a cron expression.

For trigger type **EventBridge event**, enter **Number of events** (batch size), and optionally enter **Time delay** (batch window). If you omit **Time delay**, the batch window defaults to 15 minutes. For more information, see [Overview of workflows in AWS Glue](#).

## 2. Choose **Add**.

The trigger appears on the graph, along with a placeholder node (labeled **Add node**). In the example below, the start trigger is a schedule trigger named `Month-close1`.

At this point, the trigger isn't saved yet.

## 3. If you added a new trigger, complete these steps:

- a. Do one of the following:
  - Choose the placeholder node (**Add node**).
  - Ensure that the start trigger is selected, and on the **Action** menu above the graph, choose **Add jobs/crawlers to trigger**.
- b. In the **Add job(s) and crawler(s) to trigger** dialog box, select one or more jobs or crawlers, and then choose **Add**.

The trigger is saved, and the selected jobs or crawlers appear on the graph with connectors from the trigger.

If you mistakenly added the wrong jobs or crawlers, you can select either the trigger or a connector and choose **Remove**.

### Step 3: Add more triggers

Continue to build out your workflow by adding more triggers of type **Event**. To zoom in or out or to enlarge the graph canvas, use the icons to the right of the graph. For each trigger to add, complete the following steps:

#### Note

There is no action to save the workflow. After you add your last trigger and assign actions to the trigger, the workflow is complete and saved. You can always come back later and add more nodes.

1. Do one of the following:
  - To clone an existing trigger, ensure that no node on the graph is selected, and on the **Action** menu, choose **Add trigger**.
  - To add a new trigger that watches a particular job or crawler on the graph, select the job or crawler node, and then choose the **Add trigger** placeholder node.

You can add more jobs or crawlers to watch for this trigger in a later step.

2. In the **Add trigger** dialog box, do one of the following:
  - Choose **Add new**, and complete the **Add trigger** form. Then choose **Add**.

The trigger appears on the graph. You will complete the trigger in a later step.

  - Choose **Clone existing**, and choose a trigger to clone. Then choose **Add**.

The trigger appears on the graph, along with the jobs and crawlers that it watches and the jobs and crawlers that it starts.

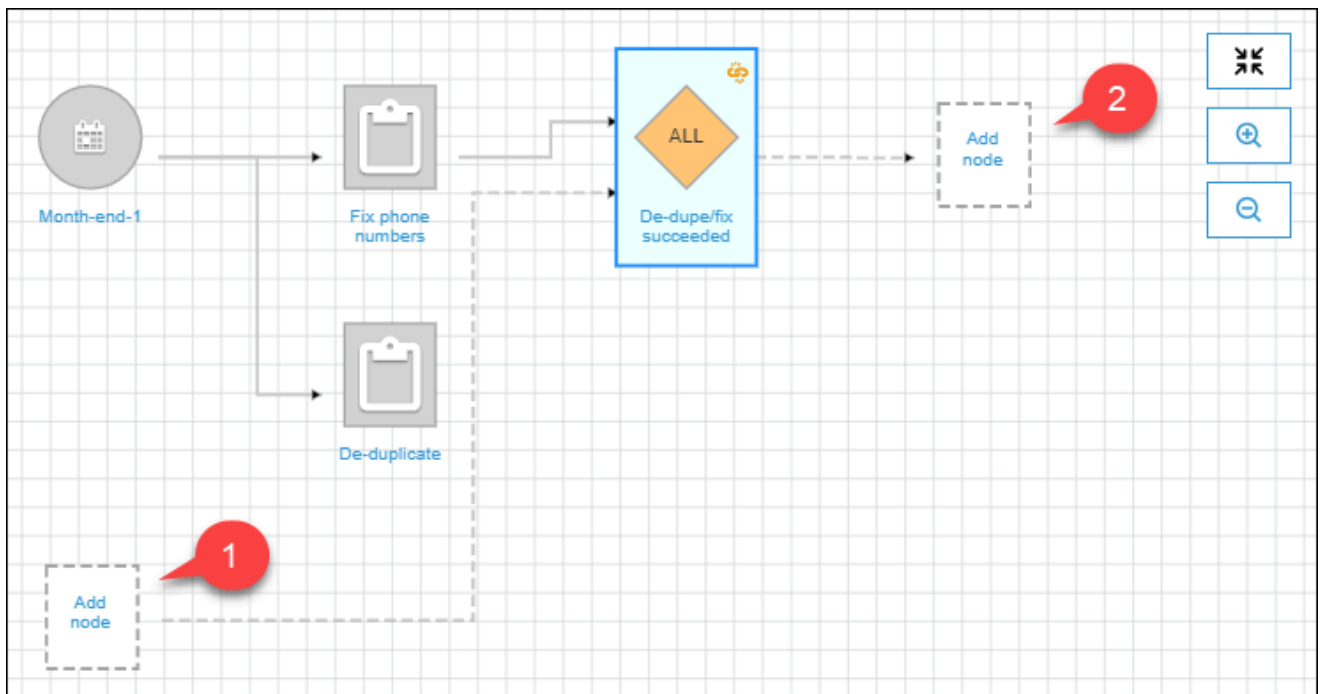

If you mistakenly chose the wrong trigger, select the trigger on the graph, and then choose **Remove**.

3. If you added a new trigger, complete these steps:

- a. Select the new trigger.

As the following graph shows, the trigger `De-dupe/fix succeeded` is selected, and placeholder nodes appear for (1) events to watch and (2) actions.

- b. (Optional if the trigger already watches an event and you want to add more jobs or crawlers to watch.) Choose the events-to-watch placeholder node, and in the **Add job(s) and crawler(s) to watch** dialog box, select one or more jobs or crawlers. Choose an event to watch (SUCCEEDED, FAILED, etc.), and choose **Add**.
- c. Ensure that the trigger is selected, and choose the actions placeholder node.
- d. In the **Add job(s) and crawler(s) to watch dialog** box, select one or more jobs or crawlers, and choose **Add**.

The selected jobs and crawlers appear on the graph, with connectors from the trigger.

For more information on workflows and blueprints, see the following topics.

- [Overview of workflows in AWS Glue](#)
- [Running and monitoring a workflow in AWS Glue](#)
- [Creating a workflow from a blueprint in AWS Glue](#)

## Starting an AWS Glue workflow with an Amazon EventBridge event

Amazon EventBridge, also known as CloudWatch Events, enables you to automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule.

With EventBridge support, AWS Glue can serve as an event producer and consumer in an event-driven architecture. For workflows, AWS Glue supports any type of EventBridge event as a consumer. The likely most common use case is the arrival of a new object in an Amazon S3 bucket. If you have data arriving in irregular or undefined intervals, you can process this data as close to its arrival as possible.

### Note

AWS Glue does not provide guaranteed delivery of EventBridge messages. AWS Glue performs no deduplication if EventBridge delivers duplicate messages. You must manage idempotency based on your use case.

Be sure to configure EventBridge rules correctly to avoid sending unwanted events.

### Before you begin

If you want to start a workflow with Amazon S3 data events, you must ensure that events for the S3 bucket of interest are logged to AWS CloudTrail and EventBridge. To do so, you must create a CloudTrail trail. For more information, see [Creating a trail for your AWS account](#).

### To start a workflow with an EventBridge event

### Note

In the following commands, replace:

- *<workflow-name>* with the name to assign to the workflow.
- *<trigger-name>* with the name to assign to the trigger.
- *<bucket-name>* with the name of the Amazon S3 bucket.
- *<account-id>* with a valid AWS account ID.

- *<region>* with the name of the Region (for example, us-east-1).
- *<rule-name>* with the name to assign to the EventBridge rule.

1. Ensure that you have AWS Identity and Access Management (IAM) permissions to create and view EventBridge rules and targets. The following is a sample policy that you can attach. You might want to scope it down to put limits on the operations and resources.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "events:PutRule",
        "events:DisableRule",
        "events>DeleteRule",
        "events:PutTargets",
        "events:RemoveTargets",
        "events:EnableRule",
        "events:List*",
        "events:Describe*"
      ],
      "Resource": "*"
    }
  ]
}
```

2. Create an IAM role that the EventBridge service can assume when passing an event to AWS Glue.
  - a. On the **Create role** page of the IAM console, choose **AWS Service**. Then choose the service **CloudWatch Events**.
  - b. Complete the **Create role** wizard. The wizard automatically attaches the `CloudWatchEventsBuiltInTargetExecutionAccess` and `CloudWatchEventsInvocationAccess` policies.
  - c. Attach the following inline policy to the role. This policy allows the EventBridge service to direct events to AWS Glue.

```
{
```

```

"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "glue:notifyEvent"
    ],
    "Resource": [
      "arn:aws:glue:<region>:<account-id>:workflow/<workflow-name>"
    ]
  }
]
}

```

3. Enter the following command to create the workflow.

See [create-workflow](#) in the *AWS CLI Command Reference* for information about additional optional command-line parameters.

```
aws glue create-workflow --name <workflow-name>
```

4. Enter the following command to create an EventBridge event trigger for the workflow. This will be the start trigger for the workflow. Replace *<actions>* with the actions to perform (the jobs and crawlers to start).

See [create-trigger](#) in the *AWS CLI Command Reference* for information about how to code the actions argument.

```
aws glue create-trigger --workflow-name <workflow-name> --type EVENT --
name <trigger-name> --actions <actions>
```

If you want the workflow to be triggered by a batch of events instead of a single EventBridge event, enter the following command instead.

```
aws glue create-trigger --workflow-name <workflow-name> --type EVENT
--name <trigger-name> --event-batching-condition BatchSize=<number-of-
events>,BatchWindow=<seconds> --actions <actions>
```

For the event-batching-condition argument, BatchSize is required and BatchWindow is optional. If BatchWindow is omitted, the window defaults to 900 seconds, which is the maximum window size.

## Example

The following example creates a trigger that starts the `eventtest` workflow after three EventBridge events have arrived, or five minutes after the first event arrives, whichever comes first.

```
aws glue create-trigger --workflow-name eventtest --type EVENT --name objectArrival
--event-batching-condition BatchSize=3,BatchWindow=300 --actions JobName=test1
```

5. Create a rule in Amazon EventBridge.
  - a. Create the JSON object for the rule details in your preferred text editor.

The following example specifies Amazon S3 as the event source, `PutObject` as the event name, and the bucket name as a request parameter. This rule starts a workflow when a new object arrives in the bucket.

```
{
  "source": [
    "aws.s3"
  ],
  "detail-type": [
    "AWS API Call via CloudTrail"
  ],
  "detail": {
    "eventSource": [
      "s3.amazonaws.com"
    ],
    "eventName": [
      "PutObject"
    ],
    "requestParameters": {
      "bucketName": [
        "<bucket-name>"
      ]
    }
  }
}
```

To start the workflow when a new object arrives in a folder within the bucket, you can substitute the following code for `requestParameters`.

```

"requestParameters": {
  "bucketName": [
    "<bucket-name>"
  ]
  "key" : [{ "prefix" : "<folder1>/<folder2>/*"}]}
}

```

- b. Use your preferred tool to convert the rule JSON object to an escaped string.

```

{\n  \"source\": [\n    \"aws.s3\"\n  ],\n  \"detail-type\": [\n    \"AWS API\n    Call via CloudTrail\"\n  ],\n  \"detail\": {\n    \"eventSource\": [\n      \"s3.amazonaws.com\"\n    ],\n    \"eventName\": [\n      \"PutObject\"\n    ],\n    \"requestParameters\": {\n      \"bucketName\": [\n        \"<bucket-  
name>\"\n      ]\n    }\n  }\n}

```

- c. Run the following command to create a JSON parameter template that you can edit to specify input parameters to a subsequent `put-rule` command. Save the output in a file. In this example, the file is called `ruleCommand`.

```
aws events put-rule --name <rule-name> --generate-cli-skeleton >ruleCommand
```

For more information about the `--generate-cli-skeleton` parameter, see [Generating AWS CLI skeleton and input parameters from a JSON or YAML input file](#) in the *AWS Command Line Interface User Guide*.

The output file should look like the following.

```

{
  "Name": "",
  "ScheduleExpression": "",
  "EventPattern": "",
  "State": "ENABLED",
  "Description": "",
  "RoleArn": "",
  "Tags": [
    {
      "Key": "",
      "Value": ""
    }
  ],
  "EventBusName": ""
}

```

```
}

```

- d. Edit the file to optionally remove parameters and to specify at a minimum the Name, EventPattern, and State parameters. For the EventPattern parameter, provide the escaped string for the rule details that you created in a previous step.

```
{
  "Name": "<rule-name>",
  "EventPattern": "{\n  \"source\": [\n    \"aws.s3\"\n  ],\n  \"detail-
type\": [\n    \"AWS API Call via CloudTrail\"\n  ],\n  \"detail\": {\n
  \"eventSource\": [\n    \"s3.amazonaws.com\"\n  ],\n  \"eventName\": [\n
    \"PutObject\"\n  ],\n  \"requestParameters\": {\n    \"bucketName
\": [\n      \"<bucket-name>\"\n    ]\n  }\n}",
  "State": "DISABLED",
  "Description": "Start an AWS Glue workflow upon new file arrival in an
Amazon S3 bucket"
}
```

 **Note**

It is best to leave the rule disabled until you finish building out the workflow.

- e. Enter the following `put-rule` command, which reads input parameters from the file `ruleCommand`.

```
aws events put-rule --name <rule-name> --cli-input-json file://ruleCommand
```

The following output indicates success.

```
{
  "RuleArn": "<rule-arn>"
}
```

6. Enter the following command to attach the rule to a target. The target is the workflow in AWS Glue. Replace `<role-name>` with the role that you created at the beginning of this procedure.

```
aws events put-targets --rule <rule-name> --targets
  "Id"="1", "Arn"="arn:aws:glue:<region>:<account-id>:workflow/<workflow-
name>", "RoleArn"="arn:aws:iam::<account-id>:role/<role-name>" --region <region>
```

The following output indicates success.

```
{
  "FailedEntryCount": 0,
  "FailedEntries": []
}
```

7. Confirm successful connection of the rule and target by entering the following command.

```
aws events list-rule-names-by-target --target-arn arn:aws:glue:<region>:<account-id>:workflow/<workflow-name>
```

The following output indicates success, where *<rule-name>* is the name of the rule that you created.

```
{
  "RuleNames": [
    "<rule-name>"
  ]
}
```

8. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
9. Select the workflow, and verify that the start trigger and its actions—the jobs or crawlers that it starts—appear on the workflow graph. Then continue with the procedure in [Step 3: Add more triggers](#). Or add more components to the workflow by using the AWS Glue API or AWS Command Line Interface.
10. When the workflow is completely specified, enable the rule.

```
aws events enable-rule --name <rule-name>
```

The workflow is now ready to be started by an EventBridge event or event batch.

## Viewing the EventBridge events that started a workflow

You can view the event ID of the Amazon EventBridge event that started your workflow. If your workflow was started by a batch of events, you can view the event IDs of all events in the batch.

For workflows with a batch size greater than one, you can also see which batch condition started the workflow: the arrival of the number of events in the batch size, or the expiration of the batch window.

### To view the EventBridge events that started a workflow (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **Workflows**.
3. Select the workflow. Then at the bottom, choose the **History** tab.
4. Select a workflow run, and then choose **View run details**.
5. On the run details page, locate the **Run properties** field, and look for the **aws:eventIds** key.

The value for that key is a list of EventBridge event IDs.

### To view the EventBridge events that started a workflow (AWS API)

- Include the following code in your Python script.

```
workflow_params =  
    glue_client.get_workflow_run_properties(Name=workflow_name, RunId=workflow_run_id)  
batched_events = workflow_params['aws:eventIds']
```

`batched_events` will be a list of strings, where each string is an event ID.

## Running and monitoring a workflow in AWS Glue

If the start trigger for a workflow is an on-demand trigger, you can start the workflow from the AWS Glue console. Complete the following steps to run and monitor a workflow. If the workflow fails, you can view the run graph to determine the node that failed. To help troubleshoot, if the workflow was created from a blueprint, you can view the blueprint run to see the blueprint parameter values that were used to create the workflow. For more information, see [the section called “Viewing blueprint runs”](#).

You can run and monitor a workflow by using the AWS Glue console, API, or AWS Command Line Interface (AWS CLI).

### To run and monitor a workflow (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Select a workflow. On the **Actions** menu, choose **Run**.
4. Check the **Last run status** column in the workflows list. Choose the refresh button to view ongoing workflow status.
5. While the workflow is running or after it has completed (or failed), view the run details by completing the following steps.
  - a. Ensure that the workflow is selected, and choose the **History** tab.
  - b. Choose the current or most recent workflow run, and then choose **View run details**.

The workflow runtime graph shows the current run status.

- c. Choose any node in the graph to view details and status of the node.

**Graph**

Select the graph nodes to resume and then choose Resume run.

**Legend:** ✔ Completed 🔄 Running ✘ Failed ⚠ Warning ❌ Error

**Job details**

**Selected run**

Tue, 21 Jul 2020 19:55:10 GMT - FAILED

Name	myDemoBPWorkflow1_etl_jo
Description	-
Job run id	jr_8e74182b093deea6bf63d
Status	Failed
Resume	<input type="checkbox"/>
Retry attempt	-
Job run error	Error: Invalid argument type

Execution time: 28  
Start time: Tue, 21 Jul 2020 19:55:10 G  
End time: Tue, 21 Jul 2020 20:21:17 G

## To run and monitor a workflow (AWS CLI)

1. Enter the following command. Replace *<workflow-name>* with the workflow to run.

```
aws glue start-workflow-run --name <workflow-name>
```

If the workflow is successfully started, the command returns the run ID.

2. View workflow run status by using the `get-workflow-run` command. Supply the workflow name and run ID.

```
aws glue get-workflow-run --name myWorkflow --run-id
wr_d2af14217e8eae775ba7b1fc6fc7a42c795aed3cbcd8763f9415452e2dbc8705
```

The following is sample command output.

```
{
  "Run": {
    "Name": "myWorkflow",
    "WorkflowRunId":
"wr_d2af14217e8eae775ba7b1fc6fc7a42c795aed3cbcd8763f9415452e2dbc8705",
    "WorkflowRunProperties": {
      "run_state": "COMPLETED",
      "unique_id": "fee63f30-c512-4742-a9b1-7c8183bdaae2"
    },
    "StartedOn": 1578556843.049,
    "CompletedOn": 1578558649.928,
    "Status": "COMPLETED",
```

```
    "Statistics": {
      "TotalActions": 11,
      "TimeoutActions": 0,
      "FailedActions": 0,
      "StoppedActions": 0,
      "SucceededActions": 9,
      "RunningActions": 0,
      "ErroredActions": 0
    }
  }
}
```

- [the section called “Overview of blueprints”](#)

## Stopping a workflow run

You can use the AWS Glue console, AWS Command Line Interface (AWS CLI) or AWS Glue API to stop a workflow run. When you stop a workflow run, all running jobs and crawlers are immediately terminated, and jobs and crawlers that are not yet started never start. It might take up to a minute for all running jobs and crawlers to stop. The workflow run status goes from **Running** to **Stopping**, and when the workflow run is completely stopped, the status goes to **Stopped**.

After the workflow run is stopped, you can view the run graph to see which jobs and crawlers completed and which never started. You can then determine if you must perform any steps to ensure data integrity. Stopping a workflow run causes no automatic rollback operations to be performed.

### To stop a workflow run (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, under **ETL**, choose **Workflows**.
3. Choose a running workflow, and then choose the **History** tab.
4. Choose the workflow run, and then choose **Stop run**.

The run status changes to **Stopping**.

5. (Optional) Choose the workflow run, choose **View run details**, and review the run graph.

### To stop a workflow run (AWS CLI)

- Enter the following command. Replace *<workflow-name>* with the name of the workflow and *<run-id>* with the run ID of the workflow run to stop.

```
aws glue stop-workflow-run --name <workflow-name> --run-id <run-id>
```

The following is an example of the **stop-workflow-run** command.

```
aws glue stop-workflow-run --name my-workflow --run-id  
wr_137b88917411d128081069901e4a80595d97f719282094b7f271d09576770354
```

## Repairing and resuming a workflow run

If one or more nodes (jobs or crawlers) in a workflow do not successfully complete, this means that the workflow only partially ran. After you find the root causes and make corrections, you can select one or more nodes to resume the workflow run from, and then resume the workflow run. The selected nodes and all nodes that are downstream from those nodes are then run.

### Topics

- [Resuming a workflow run: How it works](#)
- [Resuming a workflow run](#)
- [Notes and limitations for resuming workflow runs](#)

### Resuming a workflow run: How it works

Consider the workflow W1 in the following diagram.

The workflow run proceeds as follows:

1. Trigger T1 starts job J1.
2. Successful completion of J1 fires triggers T2 and T3, which run jobs J2 and J3, respectively.
3. Jobs J2 and J3 fail.
4. Triggers T4 and T5 depend on the successful completion of J2 and J3, so they don't fire, and jobs J4 and J5 don't run. Workflow W1 is only partially run.

Now assume that the issues that caused J2 and J3 to fail are corrected. J2 and J3 are selected as the starting points to resume the workflow run from.

The workflow run resumes as follows:

1. Jobs J2 and J3 run successfully.
2. Triggers T4 and T5 fire.
3. Jobs J4 and J5 run successfully.

The resumed workflow run is tracked as a separate workflow run with a new run ID. When you view the workflow history, you can view the previous run ID for any workflow run. In the example in the following screenshot, the workflow run with run ID `wr_c7a22...` (the second row) had a node that did not complete. The user fixed the problem and resumed the workflow run, which resulted in run ID `wr_a07e55...` (the first row).

Graph   Details   History				
View run details   Stop run   				
Run ID	Previous run ID	Run status	Execution time	
 wr_a07e55f2087afdd415a404403f644a4265278...	wr_c7a2219a8dc412f1366a5b30df3c58be30b9...	Completed	17 Minutes	
 wr_c7a2219a8dc412f1366a5b30df3c58be30b9...	-	Completed	8 Minutes	

### Note

For the rest of this discussion, the term "resumed workflow run" refers to the workflow run that was created when the previous workflow run was resumed. The "original workflow run" refers to the workflow run that only partially ran and that needed to be resumed.

## Resumed workflow run graph

In a resumed workflow run, although only a subset of nodes are run, the run graph is a complete graph. That is, the nodes that didn't run in the resumed workflow are copied from the run graph of the original workflow run. Copied job and crawler nodes that ran in the original workflow run include run details.

Consider again the workflow W1 in the previous diagram. When the workflow run is resumed starting with J2 and J3, the run graph for the resumed workflow run shows all jobs, J1 through J5, and all triggers, T1 through T5. The run details for J1 are copied from the original workflow run.

## Workflow run snapshots

When a workflow run is started, AWS Glue takes a snapshot of the workflow design graph at that point in time. That snapshot is used for the duration of the workflow run. If you make changes to any triggers after the run starts, those changes don't affect the current workflow run. Snapshots ensure that workflow runs proceed in a consistent manner.

Snapshots make only triggers immutable. Changes that you make to downstream jobs and crawlers during the workflow run take effect for the current run.

## Resuming a workflow run

Follow these steps to resume a workflow run. You can resume a workflow run by using the AWS Glue console, API, or AWS Command Line Interface (AWS CLI).

## To resume a workflow run (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.

Sign in as a user who has permissions to view workflows and resume workflow runs.

### Note

To resume workflow runs, you need the `glue:ResumeWorkflowRun` AWS Identity and Access Management (IAM) permission.

2. In the navigation pane, choose **Workflows**.
3. Select a workflow, and then choose the **History** tab.
4. Select the workflow run that only partially ran, and then choose **View run details**.
5. In the run graph, select the first (or only) node that you want to restart and that you want to resume the workflow run from.
6. In the details pane to the right of the graph, select the **Resume** check box.

The screenshot displays the AWS Glue console interface. On the left, a workflow graph is shown with three nodes: a green circle (Completed), a red square with a clipboard icon (Failed), and a grey diamond labeled 'ALL'. The red node is highlighted with a blue border and has a small resume icon at its top right. A 'Resume run' button is visible above the graph. Below the graph is a legend with icons for Completed, Running, Failed, Warning, and Error. On the right, the 'Job details' pane shows the selected run as 'Tue, 21 Jul 2020 19:55:10 GMT - FAILED'. The 'Status' is 'Failed' and the 'Resume' checkbox is checked. The 'Job run error' is 'Error: Invalid argument type'.

The node changes color and shows a small resume icon at the upper right.

The screenshot displays the AWS Glue console interface. On the left, a workflow graph is shown with three nodes: a green circle labeled 'myDemoBPWorkflow1\_starti...', a purple square labeled 'myDemoBPWorkflow1\_eti\_j...', and a grey diamond labeled 'myDemoBPWorkflow1\_myD...'. The purple square node is highlighted with a blue border and a 'C' icon. A legend above the graph indicates: Completed (green checkmark), Running (blue refresh icon), Failed (red X), Warning (yellow triangle), and Error (red circle with X). A 'Resume run' button is visible in the top right of the graph area. On the right, the 'Job details' panel shows the 'Selected run' as 'Tue, 21 Jul 2020 19:55:10 GMT - RESUME'. Below this, the job details include: Name (myDemoBPWorkflow1\_eti\_jo), Description (-), Job run id (jr\_8e74182b093deea6bf63d), Status (Resume), Resume (checked), Retry attempt (-), and Job run error (Error: Invalid argument type). The execution time is 28, and the start and end times are 'Tue, 21 Jul 2020 19:55:10 G' and 'Tue, 21 Jul 2020 20:21:17 G' respectively.

7. Complete the previous two steps for any additional nodes to restart.
8. Choose **Resume run**.

### To resume a workflow run (AWS CLI)

1. Ensure that you have the `glue:ResumeWorkflowRun` IAM permission.
2. Retrieve the node IDs for the nodes that you want to restart.
  - a. Run the `get-workflow-run` command for the original workflow run. Supply the workflow name and run ID, and add the `--include-graph` option, as shown in the following example. Get the run ID from the **History** tab on the console, or by running the `get-workflow` command.

```
aws glue get-workflow-run --name cloudtrailtest1 --run-id
wr_a07e55f2087afdd415a404403f644a4265278f68b13ba3da08c71924ebe3c3a8 --include-
graph
```

The command returns the nodes and edges of the graph as a large JSON object.

- b. Locate the nodes of interest by the `Type` and `Name` properties of the node objects.

The following is an example node object from the output.

```
{
  "Type": "JOB",
  "Name": "test1_post_failure_4592978",
  "UniqueId":
  "wnode_d1b2563c503078b153142ee76ce545fe5ceef66e053628a786ddd74a05da86fd",
```

```

    "JobDetails": {
      "JobRuns": [
        {
          "Id":
"jr_690b9f7fc5cb399204bc542c6c956f39934496a5d665a42de891e5b01f59e613",
          "Attempt": 0,
          "TriggerName": "test1_aggregate_failure_649b2432",
          "JobName": "test1_post_failure_4592978",
          "StartedOn": 1595358275.375,
          "LastModifiedOn": 1595358298.785,
          "CompletedOn": 1595358298.785,
          "JobRunState": "FAILED",
          "PredecessorRuns": [],
          "AllocatedCapacity": 0,
          "ExecutionTime": 16,
          "Timeout": 2880,
          "MaxCapacity": 0.0625,
          "LogGroupName": "/aws-glue/python-jobs"
        }
      ]
    }
  }
}

```

- c. Get the node ID from the UniqueId property of the node object.
3. Run the `resume-workflow-run` command. Provide the workflow name, run ID, and list of node IDs separated by spaces, as shown in the following example.

```

aws glue resume-workflow-run --name cloudtrailtest1 --run-id
wr_a07e55f2087afdd415a404403f644a4265278f68b13ba3da08c71924ebe3c3a8 --node-
ids wnode_ca1f63e918fb855e063aed2f42ec5762ccf71b80082ae2eb5daeb8052442f2f3
wnode_d1b2563c503078b153142ee76ce545fe5ceef66e053628a786ddd74a05da86fd

```

The command outputs the run ID of the resumed (new) workflow run and a list of nodes that will be started.

```

{
  "RunId": "wr_2ada0d3209a262fc1156e4291134b3bd643491bcfb0ceead30bd3e4efac24de9",
  "NodeIds": [
    "wnode_ca1f63e918fb855e063aed2f42ec5762ccf71b80082ae2eb5daeb8052442f2f3"
  ]
}

```

Note that although the example `resume-workflow-run` command listed two nodes to restart, the example output indicated that only one node would be restarted. This is because one node was downstream of the other node, and the downstream node would be restarted anyway by the normal flow of the workflow.

## Notes and limitations for resuming workflow runs

Keep the following notes and limitations in mind when resuming workflow runs.

- You can resume a workflow run only if it's in the COMPLETED state.

### Note

Even if one or more nodes in a workflow run don't complete, the workflow run state is shown as COMPLETED. Be sure to check the run graph to discover any nodes that didn't successfully complete.

- You can resume a workflow run from any job or crawler node that the original workflow run attempted to run. You can't resume a workflow run from a trigger node.
- Restarting a node does not reset its state. Any data that was partially processed is not rolled back.
- You can resume the same workflow run multiple times. If a resumed workflow run only partially runs, you can address the issue and resume the resumed run.
- If you select two nodes to restart and they're dependent upon each other, the upstream node is run before the downstream node. In fact, selecting the downstream node is redundant, because it will be run according to the normal flow of the workflow.

## Getting and setting workflow run properties in AWS Glue

Use workflow run properties to share and manage state among the jobs in your AWS Glue workflow. You can set default run properties when you create the workflow. Then, as your jobs run, they can retrieve the run property values and optionally modify them for input to jobs that are later in the workflow. When a job modifies a run property, the new value exists only for the workflow run. The default run properties aren't affected.

If your AWS Glue job is not part of a workflow, these properties will not be set.

The following sample Python code from an extract, transform, and load (ETL) job demonstrates how to get the workflow run properties.

```
import sys
import boto3
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from awsglue.context import GlueContext
from pyspark.context import SparkContext

glue_client = boto3.client("glue")
args = getResolvedOptions(sys.argv, ['JOB_NAME', 'WORKFLOW_NAME', 'WORKFLOW_RUN_ID'])
workflow_name = args['WORKFLOW_NAME']
workflow_run_id = args['WORKFLOW_RUN_ID']
workflow_params = glue_client.get_workflow_run_properties(Name=workflow_name,
                                                         RunId=workflow_run_id)["RunProperties"]

target_database = workflow_params['target_database']
target_s3_location = workflow_params['target_s3_location']
```

The following code continues by setting the `target_format` run property to 'csv'.

```
workflow_params['target_format'] = 'csv'
glue_client.put_workflow_run_properties(Name=workflow_name, RunId=workflow_run_id,
                                       RunProperties=workflow_params)
```

For more information, see the following:

- [GetWorkflowRunProperties action \(Python: `get\_workflow\_run\_properties`\)](#)
- [PutWorkflowRunProperties action \(Python: `put\_workflow\_run\_properties`\)](#)

## Querying workflows using the AWS Glue API

AWS Glue provides a rich API for managing workflows. You can retrieve a static view of a workflow or a dynamic view of a running workflow using the AWS Glue API. For more information, see [Workflows](#).

### Topics

- [Querying static views](#)
- [Querying dynamic views](#)

## Querying static views

Use the `GetWorkflow` API operation to get a static view that indicates the design of a workflow. This operation returns a directed graph consisting of nodes and edges, where a node represents a trigger, a job, or a crawler. Edges define the relationships between nodes. They are represented by connectors (arrows) on the graph in the AWS Glue console.

You can also use this operation with popular graph-processing libraries such as NetworkX, igraph, JGraphT, and the Java Universal Network/Graph (JUNG) Framework. Because all these libraries represent graphs similarly, minimal transformations are needed.

The static view returned by this API is the most up-to-date view according to the latest definition of triggers associated with the workflow.

### Graph definition

A workflow graph  $G$  is an ordered pair  $(N, E)$ , where  $N$  is a set of nodes and  $E$  a set of edges. *Node* is a vertex in the graph identified by a unique number. A node can be of type trigger, job, or crawler. For example: `{name:T1, type:Trigger, uniqueId:1}`, `{name:J1, type:Job, uniqueId:2}`.

*Edge* is a 2-tuple of the form  $(src, dest)$ , where  $src$  and  $dest$  are nodes and there is a directed edge from  $src$  to  $dest$ .

### Example of querying a static view

Consider a conditional trigger  $T$ , which triggers job  $J2$  upon completion of job  $J1$ .

```
J1 ----> T ----> J2
```

Nodes:  $J1, T, J2$

Edges:  $(J1, T), (T, J2)$

## Querying dynamic views

Use the `GetWorkflowRun` API operation to get a dynamic view of a running workflow. This operation returns the same static view of the graph along with metadata related to the workflow run.

For run, nodes representing jobs in the `GetWorkflowRun` call have a list of job runs initiated as part of the latest run of the workflow. You can use this list to display the run status of each job in the graph itself. For downstream dependencies that are not yet run, this field is set to `null`. The graphed information makes you aware of the current state of any workflow at any point of time.

The dynamic view returned by this API is based on the static view that was present when the workflow run was started.

*Runtime nodes example:* `{name:T1, type: Trigger, uniqueId:1},{name:J1, type:Job, uniqueId:2, jobDetails:{jobRuns}},{name:C1, type:Crawler, uniqueId:3, crawlerDetails:{crawls}}`

### Example 1: Dynamic view

The following example illustrates a simple two-trigger workflow.

- Nodes: t1, j1, t2, j2
- Edges: (t1, j1), (j1, t2), (t2, j2)

The `GetWorkflow` response contains the following.

```
{
  Nodes : [
    {
      "type" : Trigger,
      "name" : "t1",
      "uniqueId" : 1
    },
    {
      "type" : Job,
      "name" : "j1",
      "uniqueId" : 2
    },
    {
      "type" : Trigger,
      "name" : "t2",
      "uniqueId" : 3
    },
    {
      "type" : Job,
      "name" : "j2",
```

```
        "uniqueId" : 4
      }
    ],
    Edges : [
      {
        "sourceId" : 1,
        "destinationId" : 2
      },
      {
        "sourceId" : 2,
        "destinationId" : 3
      },
      {
        "sourceId" : 3,
        "destinationId" : 4
      }
    ]
  }
}
```

The `GetWorkflowRun` response contains the following.

```
{
  Nodes : [
    {
      "type" : Trigger,
      "name" : "t1",
      "uniqueId" : 1,
      "jobDetails" : null,
      "crawlerDetails" : null
    },
    {
      "type" : Job,
      "name" : "j1",
      "uniqueId" : 2,
      "jobDetails" : [
        {
          "id" : "jr_12334",
          "jobRunState" : "SUCCEEDED",
          "errorMessage" : "error string"
        }
      ],
      "crawlerDetails" : null
    },
    {

```

```

        "type" : Trigger,
        "name" : "t2",
        "uniqueId" : 3,
        "jobDetails" : null,
        "crawlerDetails" : null
    },
    {
        "type" : Job,
        "name" : "j2",
        "uniqueId" : 4,
        "jobDetails" : [
            {
                "id" : "jr_1233sdf4",
                "jobRunState" : "SUCCEEDED",
                "errorMessage" : "error string"
            }
        ],
        "crawlerDetails" : null
    }
],
Edges : [
    {
        "sourceId" : 1,
        "destinationId" : 2
    },
    {
        "sourceId" : 2,
        "destinationId" : 3
    },
    {
        "sourceId" : 3,
        "destinationId" : 4
    }
]
}

```

## Example 2: Multiple jobs with a conditional trigger

The following example shows a workflow with multiple jobs and a conditional trigger (t3).

Consider Flow:

```

T(t1) ----> J(j1) ----> T(t2) ----> J(j2)
      |                |
      |                |
      >+-----> T(t3) <-----+

```

```
  |
  |
J(j3)
```

Graph generated:

Nodes: t1, t2, t3, j1, j2, j3

Edges: (t1, j1), (j1, t2), (t2, j2), (j1, t3), (j2, t3), (t3, j3)

## Blueprint and workflow restrictions in AWS Glue

The following are restrictions for blueprints and workflows.

### Blueprint restrictions

Keep the following blueprint restrictions in mind:

- The blueprint must be registered in the same AWS Region where the Amazon S3 bucket resides in.
- To share blueprints across AWS accounts you must give the read permissions on the blueprint ZIP archive in Amazon S3. Customers who have read permission on a blueprint ZIP archive can register the blueprint in their AWS account and use it.
- The set of blueprint parameters is stored as a single JSON object. The maximum length of this object is 128 KB.
- The maximum uncompressed size of the blueprint ZIP archive is 5 MB. The maximum compressed size is 1 MB.
- Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

### Workflow restrictions

Keep the following workflow restrictions in mind. Some of these comments are directed more at a user creating workflows manually.

- The maximum batch size for an Amazon EventBridge event trigger is 100. The maximum window size is 900 seconds (15 minutes).
- A trigger can be associated with only one workflow.
- Only one starting trigger (on-demand or schedule) is permitted.

- If a job or crawler in a workflow is started by a trigger that is outside the workflow, any triggers inside the workflow that depend on job or crawler completion (succeeded or otherwise) do not fire.
- Similarly, if a job or crawler in a workflow has triggers that depend on job or crawler completion (succeeded or otherwise) both within the workflow and outside the workflow, and if the job or crawler is started from within a workflow, only the triggers inside the workflow fire upon job or crawler completion.

## Troubleshooting blueprint errors in AWS Glue

If you encounter errors when using AWS Glue blueprints, use the following solutions to help you find the source of the problems and fix them.

### Topics

- [Error: missing PySpark module](#)
- [Error: missing blueprint config file](#)
- [Error: missing imported file](#)
- [Error: not authorized to perform iamPassRole on resource](#)
- [Error: invalid cron schedule](#)
- [Error: a trigger with the same name already exists](#)
- [Error: workflow with name: foo already exists.](#)
- [Error: module not found in specified layoutGenerator path](#)
- [Error: validation error in Connections field](#)

### Error: missing PySpark module

AWS Glue returns the error "Unknown error executing layout generator function ModuleNotFoundError: No module named 'pyspark'".

When you unzip the blueprint archive it could be like either of the following:

```
$ unzip compaction.zip
Archive:  compaction.zip
  creating: compaction/
  inflating: compaction/blueprint.cfg
  inflating: compaction/layout.py
```

```
inflating: compaction/README.md
inflating: compaction/compaction.py

$ unzip compaction.zip
Archive:  compaction.zip
  inflating: blueprint.cfg
  inflating: compaction.py
  inflating: layout.py
  inflating: README.md
```

In the first case, all the files related to the blueprint were placed under a folder named `compaction` and it was then converted into a zip file named `compaction.zip`.

In the second case, all the files required for the blueprint were not included into a folder and were added as root files under the zip file `compaction.zip`.

Creating a file in either of the above formats is allowed. However make sure that `blueprint.cfg` has the correct path to the name of the function in the script that generates the layout.

## Examples

In case 1: `blueprint.cfg` should have `layoutGenerator` as the following:

```
layoutGenerator": "compaction.layout.generate_layout"
```

In case 2: `blueprint.cfg` should have `layoutGenerator` as the following

```
layoutGenerator": "layout.generate_layout"
```

If this path is not included correctly, you could see an error as indicated. For example, if you have the folder structure as mentioned in case 2 and you have the `layoutGenerator` indicated as in case 1, you can see the above error.

## Error: missing blueprint config file

AWS Glue returns the error "Unknown error executing layout generator function `FileNotFoundException: [Errno 2] No such file or directory: '/tmp/compaction/blueprint.cfg'`".

The `blueprint.cfg` should be placed at the root level of the ZIP archive or within a folder which has the same name as the ZIP archive.

When we extract the blueprint ZIP archive, `blueprint.cfg` is expected to be found in one of the following paths. If it is not found in one of the following paths, you can see the above error.

```
$ unzip compaction.zip
Archive:  compaction.zip
  creating: compaction/
  inflating: compaction/blueprint.cfg

$ unzip compaction.zip
Archive:  compaction.zip
  inflating: blueprint.cfg
```

### **Error: missing imported file**

AWS Glue returns the error "Unknown error executing layout generator function `FileNotFoundException: [Errno 2] No such file or directory: * *demo-project/foo.py`".

If your layout generation script has functionality to read other files, make sure you give a full path for the file to be imported. For example, the `Conversion.py` script may be referenced in `Layout.py`. For more information, see [Sample blueprint Project](#).

### **Error: not authorized to perform iamPassRole on resource**

AWS Glue returns the error "User: `arn:aws:sts::123456789012:assumed-role/AWSGlueServiceRole/GlueSession` is not authorized to perform: `iam:PassRole` on resource: `arn:aws:iam::123456789012:role/AWSGlueServiceRole`"

If the jobs and crawlers in the workflow assume the same role as the role passed to create workflow from the blueprint, then the blueprint role needs to include the `iam:PassRole` permission on itself.

If the jobs and crawlers in the workflow assume a role other than the role passed to create the entities of the workflow from the blueprint, then the blueprint role needs to include the `iam:PassRole` permission on that other role instead of on the blueprint role.

For more information, see [Permissions for blueprint Roles](#).

### **Error: invalid cron schedule**

AWS Glue returns the error "The schedule `cron(0 0 * * * *)` is invalid."

Provide a valid [cron](#) expression. For more information, see [Time-Based Schedules for Jobs and Crawlers](#).

### **Error: a trigger with the same name already exists**

AWS Glue returns the error "Trigger with name 'foo\_starting\_trigger' already submitted with different configuration".

A blueprint does not require you to define triggers in the layout script for workflow creation. Trigger creation is managed by the blueprint library based on the dependencies defined between two actions.

The naming for the triggers is as follows:

- For the starting trigger in the workflow the naming is <workflow\_name>\_starting\_trigger.
- For a node(job/crawler) in the workflow that depends on the completion of either one or multiple upstream nodes; AWS Glue defines a trigger with the name <workflow\_name>\_<node\_name>\_trigger

This error means a trigger with same name already exists. You can delete the existing trigger and re-run the workflow creation.

#### **Note**

Deleting a workflow doesn't delete the nodes within the workflow. It is possible that though the workflow is deleted, triggers are left behind. Due to this, you may not receive a 'workflow already exists' error, but you may receive a 'trigger already exists' error in a case where you create a workflow, delete it and then try to re-create it with the same name from same blueprint.

### **Error: workflow with name: foo already exists.**

The workflow name should be unique. Please try with a different name.

### **Error: module not found in specified layoutGenerator path**

AWS Glue returns the error "Unknown error executing layout generator function ModuleNotFoundError: No module named 'crawl\_s3\_locations'".

```
layoutGenerator": "crawl_s3_locations.layout.generate_layout"
```

For example, if you have the above `layoutGenerator` path, then when you unzip the blueprint archive, it needs to look like the following:

```
$ unzip crawl_s3_locations.zip
Archive:  crawl_s3_locations.zip
  creating: crawl_s3_locations/
  inflating: crawl_s3_locations/blueprint.cfg
  inflating: crawl_s3_locations/layout.py
  inflating: crawl_s3_locations/README.md
```

When you unzip the archive, if the blueprint archive looks like the following, then you can get the above error.

```
$ unzip crawl_s3_locations.zip
Archive:  crawl_s3_locations.zip
  inflating: blueprint.cfg
  inflating: layout.py
  inflating: README.md
```

You can see that there is no folder named `crawl_s3_locations` and when the `layoutGenerator` path refers to the layout file via the module `crawl_s3_locations`, you can get the above error.

## Error: validation error in Connections field

AWS Glue returns the error "Unknown error executing layout generator function TypeError: Value ['foo'] for key Connections should be of type <class 'dict'>!".

This is a validation error. The `Connections` field in the `Job` class is expecting a dictionary and instead a list of values are provided causing the error.

```
User input was list of values
Connections= ['string']

Should be a dict like the following
Connections*={'Connections': ['string']}
```

To avoid these run time errors while creating a workflow from a blueprint, you can validate the workflow, job and crawler definitions as outlined in [Testing a blueprint](#).

Refer to the syntax in [AWS Glue blueprint Classes Reference](#) for defining the AWS Glue job, crawler and workflow in the layout script.

## Permissions for personas and roles for AWS Glue blueprints

The following are the typical personas and suggested AWS Identity and Access Management (IAM) permissions policies for personas and roles for AWS Glue blueprints.

### Topics

- [Blueprint personas](#)
- [Permissions for blueprint personas](#)
- [Permissions for blueprint roles](#)

## Blueprint personas

The following are the personas typically involved in the lifecycle of AWS Glue blueprints.

Persona	Description
AWS Glue developer	Develops, tests, and publishes blueprints.
AWS Glue administrator	Registers, maintains, and grants permissions on blueprints.
Data analyst	Runs blueprints to create workflows.

For more information, see [the section called “Overview of blueprints”](#).

## Permissions for blueprint personas

The following are the suggested permissions for each blueprint persona.

### AWS Glue developer permissions for blueprints

The AWS Glue developer must have write permissions on the Amazon S3 bucket that is used to publish the blueprint. Often, the developer registers the blueprint after uploading it. In that

case, the developer needs the permissions listed in [the section called “AWS Glue administrator permissions for blueprints”](#). Additionally, if the developer wishes to test the blueprint after its registered, he or she also needs the permissions listed in [the section called “Data analyst permissions for blueprints”](#).

## AWS Glue administrator permissions for blueprints

The following policy grants permissions to register, view, and maintain AWS Glue blueprints.

### Important

In the following policy, replace *<s3-bucket-name>* and *<prefix>* with the Amazon S3 path to uploaded blueprint ZIP archives to register.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateBlueprint",
        "glue:UpdateBlueprint",
        "glue>DeleteBlueprint",
        "glue:GetBlueprint",
        "glue:ListBlueprints",
        "glue:BatchGetBlueprints"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::<s3-bucket-name>/<prefix>/*"
    }
  ]
}
```

## Data analyst permissions for blueprints

The following policy grants permissions to run blueprints and to view the resulting workflow and workflow components. It also grants PassRole on the role that AWS Glue assumes to create the workflow and workflow components.

The policy grants permissions on any resource. If you want to configure fine-grained access to individual blueprints, use the following format for blueprint ARNs:

```
arn:aws:glue:<region>:<account-id>:blueprint/<blueprint-name>
```

### Important

In the following policy, replace *<account-id>* with a valid AWS account and replace *<role-name>* with the name of the role used to run a blueprint. See [the section called "Permissions for blueprint roles"](#) for the permissions that this role requires.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListBlueprints",
        "glue:GetBlueprint",
        "glue:StartBlueprintRun",
        "glue:GetBlueprintRun",
        "glue:GetBlueprintRuns",
        "glue:GetCrawler",
        "glue:ListTriggers",
        "glue:ListJobs",
        "glue:BatchGetCrawlers",
        "glue:GetTrigger",
        "glue:BatchGetWorkflows",
        "glue:BatchGetTriggers",
        "glue:BatchGetJobs",
        "glue:BatchGetBlueprints",
        "glue:GetWorkflowRun",
        "glue:GetWorkflowRuns",
        "glue:ListCrawlers",
```

```

        "glue:ListWorkflows",
        "glue:GetJob",
        "glue:GetWorkflow",
        "glue:StartWorkflowRun"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "arn:aws:iam::<account-id>:role/<role-name>"
}
]
}

```

## Permissions for blueprint roles

The following are the suggested permissions for the IAM role used to create a workflow from a blueprint. The role has to have a trust relationship with `glue.amazonaws.com`.

### Important

In the following policy, replace `<account-id>` with a valid AWS account, and replace `<role-name>` with the name of the role.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateJob",
        "glue:GetCrawler",
        "glue:GetTrigger",
        "glue>DeleteCrawler",
        "glue:CreateTrigger",
        "glue>DeleteTrigger",
        "glue>DeleteJob",
        "glue:CreateWorkflow",
        "glue>DeleteWorkflow",
        "glue:GetJob",

```

```
        "glue:GetWorkflow",
        "glue:CreateCrawler"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "arn:aws:iam::<account-id>:role/<role-name>"
  }
]
```

### Note

If the jobs and crawlers in the workflow assume a role other than this role, this policy must include the `iam:PassRole` permission on that other role instead of on the blueprint role.

## Developing blueprints in AWS Glue

Your organization might have a set of similar ETL use cases that could benefit from being able to parametrize a single workflow to handle them all. To address this need, AWS Glue enables you to define *blueprints*, which you can use to generate workflows. A blueprint accepts parameters, so that from a single blueprint, a data analyst can create different workflows to handle similar ETL use cases. After you create a blueprint, you can reuse it for different departments, teams, and projects.

# Overview of blueprints in AWS Glue

## Note

The blueprints feature is currently unavailable in the following Regions in the AWS Glue console: Asia Pacific (Jakarta) and Middle East (UAE).

AWS Glue blueprints provide a way to create and share AWS Glue workflows. When there is a complex ETL process that could be used for similar use cases, rather than creating an AWS Glue workflow for each use case, you can create a single blueprint.

The blueprint specifies the jobs and crawlers to include in a workflow, and specifies parameters that the workflow user supplies when they run the blueprint to create a workflow. The use of parameters enables a single blueprint to generate workflows for the various similar use cases. For more information about workflows, see [Overview of workflows in AWS Glue](#).

The following are example use cases for blueprints:

- You want to partition an existing dataset. The input parameters to the blueprint are Amazon Simple Storage Service (Amazon S3) source and target paths and a list of partition columns.
- You want to snapshot an Amazon DynamoDB table into a SQL data store like Amazon Redshift. The input parameters to the blueprint are the DynamoDB table name and an AWS Glue connection, which designates an Amazon Redshift cluster and destination database.
- You want to convert CSV data in multiple Amazon S3 paths to Parquet. You want the AWS Glue workflow to include a separate crawler and job for each path. The input parameters are the destination database in the AWS Glue Data Catalog and a comma-delimited list of Amazon S3 paths. Note that in this case, the number of crawlers and jobs that the workflow creates is variable.

## Blueprint components

A blueprint is a ZIP archive that contains the following components:

- A Python layout generator script

Contains a function that specifies the workflow *layout*—the crawlers and jobs to create for the workflow, the job and crawler properties, and the dependencies between the jobs and crawlers.

The function accepts blueprint parameters and returns a workflow structure (JSON object) that AWS Glue uses to generate the workflow. Because you use a Python script to generate the workflow, you can add your own logic that is suitable for your use cases.

- A configuration file

Specifies the fully qualified name of the Python function that generates the workflow layout. Also specifies the names, data types, and other properties of all blueprint parameters used by the script.

- (Optional) ETL scripts and supporting files

As an advanced use case, you can parameterize the location of the ETL scripts that your jobs use. You can include job script files in the ZIP archive and specify a blueprint parameter for an Amazon S3 location where the scripts are to be copied to. The layout generator script can copy the ETL scripts to the designated location and specify that location as the job script location property. You can also include any libraries or other supporting files, provided that your script handles them.

## Blueprint runs

When you create a workflow from a blueprint, AWS Glue runs the blueprint, which starts an asynchronous process to create the workflow and the jobs, crawlers, and triggers that the workflow encapsulates. AWS Glue uses the blueprint run to orchestrate the creation of the workflow and its components. You view the status of the creation process by viewing the blueprint run status. The blueprint run also stores the values that you supplied for the blueprint parameters.

You can view blueprint runs using the AWS Glue console or AWS Command Line Interface (AWS CLI). When viewing or troubleshooting a workflow, you can always return to the blueprint run to view the blueprint parameter values that were used to create the workflow.

### Lifecycle of a blueprint

blueprints are developed, tested, registered with AWS Glue, and run to create workflows. There are typically three personas involved in the blueprint lifecycle.

Persona	Tasks
AWS Glue developer	<ul style="list-style-type: none"> <li>Writes the workflow layout script and creates the configuration file.</li> <li>Tests the blueprint locally using libraries provided by the AWS Glue service.</li> <li>Creates a ZIP archive of the script, configuration file, and supporting files and publishes the archive to a location in Amazon S3.</li> <li>Adds a bucket policy to the Amazon S3 bucket that grants read permissions on bucket objects to the AWS Glue administrator's AWS account.</li> <li>Grants IAM read permissions on the ZIP archive in Amazon S3 to the AWS Glue administrator.</li> </ul>
AWS Glue administrator	<ul style="list-style-type: none"> <li><i>Registers</i> the blueprint with AWS Glue. AWS Glue makes a copy of the ZIP archive into a reserved Amazon S3 location.</li> </ul>

Persona	Tasks
	<ul style="list-style-type: none"><li>• Grants IAM permissions on the blueprint to data analysts.</li></ul>
Data analyst	<ul style="list-style-type: none"><li>• Runs the blueprint to create a workflow, and provides blueprint parameter values. Checks the blueprint run status to ensure that the workflow and workflow components were successfully generated.</li><li>• Runs and troubleshoots the workflow. Before running the workflow, can verify the workflow by viewing the workflow design graph on the AWS Glue console.</li></ul>

## Overview of developing blueprints

The first step in your development process is to identify a common use case that would benefit from a blueprint. A typical use case involves a recurring ETL problem that you believe should be solved in a general manner. Next, design a blueprint that implements the generalized use case, and define the blueprint input parameters that together can define a specific use case from the generalized use case.

A blueprint consists of a project that contains a blueprint parameter configuration file and a script that defines the *layout* of the workflow to generate. The layout defines the jobs and crawlers (or *entities* in blueprint script terminology) to create.

You do not directly specify any triggers in the layout script. Instead you write code to specify the dependencies between the jobs and crawlers that the script creates. AWS Glue generates the triggers based on your dependency specifications. The output of the layout script is a workflow object, which contains specifications for all workflow entities.

You build your workflow object using the following AWS Glue blueprint libraries:

- `awsglue.blueprint.base_resource` – A library of base resources used by the libraries.
- `awsglue.blueprint.workflow` – A library for defining a `Workflow` class.
- `awsglue.blueprint.job` – A library for defining a `Job` class.
- `awsglue.blueprint.crawler` – A library for defining a `Crawler` class.

The only other libraries that are supported for layout generation are those libraries that are available for the Python shell.

Before publishing your blueprint, you can use methods defined in the blueprint libraries to test the blueprint locally.

When you're ready to make the blueprint available to data analysts, you package the script, the parameter configuration file, and any supporting files, such as additional scripts and libraries, into

a single deployable asset. You then upload the asset to Amazon S3 and ask an administrator to register it with AWS Glue.

For information about more sample blueprint projects, see [Sample blueprint project](#) and [Blueprint samples](#).

## Prerequisites for developing blueprints

To develop blueprints, you should be familiar with using AWS Glue and writing scripts for Apache Spark ETL jobs or Python shell jobs. In addition, you must complete the following setup tasks.

- Download four AWS Python libraries to use in your blueprint layout scripts.
- Set up the AWS SDKs.
- Set up the AWS CLI.

### Download the Python libraries

Download the following libraries from GitHub, and install them into your project:

- [https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/base\\_resource.py](https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/base_resource.py)
- <https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/workflow.py>
- <https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/crawler.py>
- <https://github.com/awslabs/aws-glue-blueprint-libs/tree/master/awsglue/blueprint/job.py>

### Set up the AWS Java SDK

For the AWS Java SDK, you must add a `jar` file that includes the API for blueprints.

1. If you haven't already done so, set up the AWS SDK for Java.
  - For Java 1.x, follow the instructions in [Set up the AWS SDK for Java](#) in the *AWS SDK for Java Developer Guide*.
  - For Java 2.x, follow the instructions in [Setting up the AWS SDK for Java 2.x](#) in the *AWS SDK for Java 2.x Developer Guide*.
2. Download the client `jar` file that has access to the APIs for blueprints.

- For Java 1.x: `s3://awsglue-custom-blueprints-preview-artifacts/awsglue-java-sdk-preview/AWSGlueJavaClient-1.11.x.jar`
  - For Java 2.x: `s3://awsglue-custom-blueprints-preview-artifacts/awsglue-java-sdk-v2-preview/AwsJavaSdk-Glue-2.0.jar`
3. Add the client jar to the front of the Java classpath to override the AWS Glue client provided by the AWS Java SDK.

```
export CLASSPATH=<path-to-preview-client-jar>:$CLASSPATH
```

4. (Optional) Test the SDK with the following Java application. The application should output an empty list.

Replace `accessKey` and `secretKey` with your credentials, and replace `us-east-1` with your Region.

```
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.AWSCredentialsProvider;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.services.glue.AWSGlue;
import com.amazonaws.services.glue.AWSGlueClientBuilder;
import com.amazonaws.services.glue.model.ListBlueprintsRequest;

public class App{
    public static void main(String[] args) {
        AWSCredentials credentials = new BasicAWSCredentials("accessKey",
"secretKey");
        AWSCredentialsProvider provider = new
AWSStaticCredentialsProvider(credentials);
        AWSGlue glue = AWSGlueClientBuilder.standard().withCredentials(provider)
.withRegion("us-east-1").build();
        ListBlueprintsRequest request = new
ListBlueprintsRequest().withMaxResults(2);
        System.out.println(glue.listBlueprints(request));
    }
}
```

## Set up the AWS Python SDK

The following steps assume that you have Python version 2.7 or later, or version 3.6 or later installed on your computer.

1. Download the following boto3 wheel file. If prompted to open or save, save the file. `s3://awsglue-custom-blueprints-preview-artifacts/aws-python-sdk-preview/boto3-1.17.31-py2.py3-none-any.whl`
2. Download the following botocore wheel file: `s3://awsglue-custom-blueprints-preview-artifacts/aws-python-sdk-preview/botocore-1.20.31-py2.py3-none-any.whl`
3. Check your Python version.

```
python --version
```

4. Depending on your Python version, enter the following commands (for Linux):

- For Python 2.7 or later.

```
python3 -m pip install --user virtualenv  
source env/bin/activate
```

- For Python 3.6 or later.

```
python3 -m venv python-sdk-test  
source python-sdk-test/bin/activate
```

5. Install the botocore wheel file.

```
python3 -m pip install <download-directory>/botocore-1.20.31-py2.py3-none-any.whl
```

6. Install the boto3 wheel file.

```
python3 -m pip install <download-directory>/boto3-1.17.31-py2.py3-none-any.whl
```

7. Configure your credentials and default region in the `~/.aws/credentials` and `~/.aws/config` files. For more information, see [Configuring the AWS CLI](#) in the *AWS Command Line Interface User Guide*.
8. (Optional) Test your setup. The following commands should return an empty list.

Replace `us-east-1` with your Region.

```
$ python
>>> import boto3
>>> glue = boto3.client('glue', 'us-east-1')
>>> glue.list_blueprints()
```

## Set up the preview AWS CLI

1. If you haven't already done so, install and/or update the AWS Command Line Interface (AWS CLI) on your computer. The easiest way to do this is with `pip`, the Python installer utility:

```
pip install awscli --upgrade --user
```

You can find complete installation instructions for the AWS CLI here: [Installing the AWS Command Line Interface](#).

2. Download the AWS CLI wheel file from: `s3://awsglue-custom-blueprints-preview-artifacts/awscli-preview-build/awscli-1.19.31-py2.py3-none-any.whl`
3. Install the AWS CLI wheel file.

```
python3 -m pip install awscli-1.19.31-py2.py3-none-any.whl
```

4. Run the `aws configure` command. Configure your AWS credentials (including access key, and secret key) and AWS Region. You can find information on configuring the AWS CLI here: [Configuring the AWS CLI](#).
5. Test the AWS CLI. The following command should return an empty list.

Replace `us-east-1` with your Region.

```
aws glue list-blueprints --region us-east-1
```

## Writing the blueprint code

Each blueprint project that you create must contain at a minimum the following files:

- A Python layout script that defines the workflow. The script contains a function that defines the entities (jobs and crawlers) in a workflow, and the dependencies between them.
- A configuration file, `blueprint.cfg`, which defines:

- The full path of the workflow layout definition function.
- The parameters that the blueprint accepts.

## Topics

- [Creating the blueprint layout script](#)
- [Creating the configuration file](#)
- [Specifying blueprint parameters](#)

## Creating the blueprint layout script

The blueprint layout script must include a function that generates the entities in your workflow. You can name this function whatever you like. AWS Glue uses the configuration file to determine the fully qualified name of the function.

Your layout function does the following:

- (Optional) Instantiates the `Job` class to create `Job` objects, and passes arguments such as `Command` and `Role`. These are job properties that you would specify if you were creating the job using the AWS Glue console or API.
- (Optional) Instantiates the `Crawler` class to create `Crawler` objects, and passes `name`, `role`, and `target` arguments.
- To indicate dependencies between the objects (workflow entities), passes the `DependsOn` and `WaitForDependencies` additional arguments to `Job()` and `Crawler()`. These arguments are explained later in this section.
- Instantiates the `Workflow` class to create the workflow object that is returned to AWS Glue, passing a `Name` argument, an `Entities` argument, and an optional `OnSchedule` argument. The `Entities` argument specifies all of the jobs and crawlers to include in the workflow. To see how to construct an `Entities` object, see the sample project later in this section.
- Returns the `Workflow` object.

For definitions of the `Job`, `Crawler`, and `Workflow` classes, see [AWS Glue blueprint classes reference](#).

The layout function must accept the following input arguments.

Argument	Description
user_params	Python dictionary of blueprint parameter names and values. For more information, see <a href="#">Specifying blueprint parameters</a> .
system_params	Python dictionary containing two properties: region and accountId .

Here is a sample layout generator script in a file named Layout . py:

```
import argparse
import sys
import os
import json
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *

def generate_layout(user_params, system_params):

    etl_job = Job(Name="{}_etl_job".format(user_params['WorkflowName']),
                  Command={
                      "Name": "glueetl",
                      "ScriptLocation": user_params['ScriptLocation'],
                      "PythonVersion": "2"
                  },
                  Role=user_params['PassRole'])
    post_process_job = Job(Name="{}_post_process".format(user_params['WorkflowName']),
                           Command={
                               "Name": "pythonshell",
                               "ScriptLocation": user_params['ScriptLocation'],
                               "PythonVersion": "2"
                           },
                           Role=user_params['PassRole'],
                           DependsOn={
                               etl_job: "SUCCEEDED"
                           },
                           WaitForDependencies="AND")
    sample_workflow = Workflow(Name=user_params['WorkflowName'],
                               Entities=Entities(Jobs=[etl_job, post_process_job]))
```

```
return sample_workflow
```

The sample script imports the required blueprint libraries and includes a `generate_layout` function that generates a workflow with two jobs. This is a very simple script. A more complex script could employ additional logic and parameters to generate a workflow with many jobs and crawlers, or even a variable number of jobs and crawlers.

## Using the `DependsOn` argument

The `DependsOn` argument is a dictionary representation of a dependency that this entity has on other entities within the workflow. It has the following form.

```
DependsOn = {dependency1 : state, dependency2 : state, ...}
```

The keys in this dictionary represent the object reference, not the name, of the entity, while the values are strings that correspond to the state to watch for. AWS Glue infers the proper triggers. For the valid states, see [Condition Structure](#).

For example, a job might depend on the successful completion of a crawler. If you define a crawler object named `crawler2` as follows:

```
crawler2 = Crawler(Name="my_crawler", ...)
```

Then an object depending on `crawler2` would include a constructor argument such as:

```
DependsOn = {crawler2 : "SUCCEEDED"}
```

For example:

```
job1 = Job(Name="Job1", ..., DependsOn = {crawler2 : "SUCCEEDED", ...})
```

If `DependsOn` is omitted for an entity, that entity depends on the workflow start trigger.

## Using the `WaitForDependencies` argument

The `WaitForDependencies` argument defines whether a job or crawler entity should wait until *all* entities on which it depends complete or until *any* completes.

The allowable values are "AND" or "ANY".

## Using the OnSchedule argument

The OnSchedule argument for the Workflow class constructor is a cron expression that defines the starting trigger definition for a workflow.

If this argument is specified, AWS Glue creates a schedule trigger with the corresponding schedule. If it isn't specified, the starting trigger for the workflow is an on-demand trigger.

## Creating the configuration file

The blueprint configuration file is a required file that defines the script entry point for generating the workflow, and the parameters that the blueprint accepts. The file must be named `blueprint.cfg`.

Here is a sample configuration file.

```
{
  "layoutGenerator": "DemoBlueprintProject.Layout.generate_layout",
  "parameterSpec" : {
    "WorkflowName" : {
      "type": "String",
      "collection": false
    },
    "WorkerType" : {
      "type": "String",
      "collection": false,
      "allowedValues": ["G1.X", "G2.X"],
      "defaultValue": "G1.X"
    },
    "Dpu" : {
      "type" : "Integer",
      "allowedValues" : [2, 4, 6],
      "defaultValue" : 2
    },
    "DynamoDBTableName": {
      "type": "String",
      "collection" : false
    },
    "ScriptLocation" : {
      "type": "String",
      "collection": false
    }
  }
}
```

```
    }  
  }  
}
```

The `layoutGenerator` property specifies the fully qualified name of the function in the script that generates the layout.

The `parameterSpec` property specifies the parameters that this blueprint accepts. For more information, see [Specifying blueprint parameters](#).

### Important

Your configuration file must include the workflow name as a blueprint parameter, or you must generate a unique workflow name in your layout script.

## Specifying blueprint parameters

The configuration file contains blueprint parameter specifications in a `parameterSpec` JSON object. `parameterSpec` contains one or more parameter objects.

```
"parameterSpec": {  
  "<parameter_name>": {  
    "type": "<parameter-type>",  
    "collection": true|false,  
    "description": "<parameter-description>",  
    "defaultValue": "<default value for the parameter if value not specified>",  
    "allowedValues": "<list of allowed values>"  
  },  
  "<parameter_name>": {  
    ...  
  }  
}
```

The following are the rules for coding each parameter object:

- The parameter name and type are mandatory. All other properties are optional.
- If you specify the `defaultValue` property, the parameter is optional. Otherwise the parameter is mandatory and the data analyst who is creating a workflow from the blueprint must provide a value for it.

- If you set the `collection` property to `true`, the parameter can take a collection of values. Collections can be of any data type.
- If you specify `allowedValues`, the AWS Glue console displays a dropdown list of values for the data analyst to choose from when creating a workflow from the blueprint.

The following are the permitted values for type:

Parameter data type	Notes
String	-
Integer	-
Double	-
Boolean	Possible values are <code>true</code> and <code>false</code> . Generates a check box on the <b>Create a workflow from &lt;blueprint&gt;</b> page on the AWS Glue console.
S3Uri	Complete Amazon S3 path, beginning with <code>s3://</code> . Generates a text field and <b>Browse</b> button on the <b>Create a workflow from &lt;blueprint&gt;</b> page.
S3Bucket	Amazon S3 bucket name only. Generates a bucket picker on the <b>Create a workflow from &lt;blueprint&gt;</b> page.
IAMRoleArn	Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role. Generates a role picker on the <b>Create a workflow from &lt;blueprint&gt;</b> page.
IAMRoleName	Name of an IAM role. Generates a role picker on the <b>Create a workflow from &lt;blueprint&gt;</b> page.

## Sample blueprint project

Data format conversion is a frequent extract, transform, and load (ETL) use case. In typical analytic workloads, column-based file formats like Parquet or ORC are preferred over text formats like CSV or JSON. This sample blueprint enables you to convert data from CSV/JSON/etc. into Parquet for files on Amazon S3.

This blueprint takes a list of S3 paths defined by a blueprint parameter, converts the data to Parquet format, and writes it to the S3 location specified by another blueprint parameter. The layout script creates a crawler and job for each path. The layout script also uploads the ETL script in `Conversion.py` to an S3 bucket specified by another blueprint parameter. The layout script then specifies the uploaded script as the ETL script for each job. The ZIP archive for the project contains the layout script, the ETL script, and the blueprint configuration file.

For information about more sample blueprint projects, see [Blueprint samples](#).

The following is the layout script, in the file `Layout.py`.

```
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *
import boto3

s3_client = boto3.client('s3')

# Ingesting all the S3 paths as Glue table in parquet format
def generate_layout(user_params, system_params):
    #Always give the full path for the file
    with open("ConversionBlueprint/Conversion.py", "rb") as f:
        s3_client.upload_fileobj(f, user_params['ScriptsBucket'], "Conversion.py")
    etlScriptLocation = "s3://{}/Conversion.py".format(user_params['ScriptsBucket'])

    crawlers = []
    jobs = []
    workflowName = user_params['WorkflowName']
    for path in user_params['S3Paths']:
        tablePrefix = "source_"
        crawler = Crawler(Name="{}_crawler".format(workflowName),
                          Role=user_params['PassRole'],
                          DatabaseName=user_params['TargetDatabase'],
                          TablePrefix=tablePrefix,
                          Targets= {"S3Targets": [{"Path": path}]})
        crawlers.append(crawler)
    transform_job = Job(Name="{}_transform_job".format(workflowName),
                        Command={"Name": "glueetl",
                                "ScriptLocation": etlScriptLocation,
                                "PythonVersion": "3"},
                        Role=user_params['PassRole'],
                        DefaultArguments={"--database_name":
user_params['TargetDatabase']},
```

```

        "--table_prefix": tablePrefix,
        "--region_name": system_params['region'],
        "--output_path":
user_params['TargetS3Location']},
        DependsOn={crawler: "SUCCEEDED"},
        WaitForDependencies="AND")
    jobs.append(transform_job)
    conversion_workflow = Workflow(Name=workflowName, Entities=Entities(Jobs=jobs,
Crawlers=crawlers))
    return conversion_workflow

```

The following is the corresponding blueprint configuration file `blueprint.cfg`.

```

{
  "layoutGenerator": "ConversionBlueprint.Layout.generate_layout",
  "parameterSpec" : {
    "WorkflowName" : {
      "type": "String",
      "collection": false,
      "description": "Name for the workflow."
    },
    "S3Paths" : {
      "type": "S3Uri",
      "collection": true,
      "description": "List of Amazon S3 paths for data ingestion."
    },
    "PassRole" : {
      "type": "IAMRoleName",
      "collection": false,
      "description": "Choose an IAM role to be used in running the job/crawler"
    },
    "TargetDatabase": {
      "type": "String",
      "collection" : false,
      "description": "Choose a database in the Data Catalog."
    },
    "TargetS3Location": {
      "type": "S3Uri",
      "collection" : false,
      "description": "Choose an Amazon S3 output path: ex:s3://<target_path>/."
    },
    "ScriptsBucket": {
      "type": "S3Bucket",

```

```
        "collection": false,
        "description": "Provide an S3 bucket name(in the same AWS Region) to store
the scripts."
    }
}
}
```

The following script in the file `Conversion.py` is the uploaded ETL script. Note that it preserves the partitioning scheme during conversion.

```
import sys
from pyspark.sql.functions import *
from pyspark.context import SparkContext
from awsglue.transforms import *
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions
import boto3

args = getResolvedOptions(sys.argv, [
    'JOB_NAME',
    'region_name',
    'database_name',
    'table_prefix',
    'output_path'])
databaseName = args['database_name']
tablePrefix = args['table_prefix']
outputPath = args['output_path']

glue = boto3.client('glue', region_name=args['region_name'])

glue_context = GlueContext(SparkContext.getOrCreate())
spark = glue_context.spark_session
job = Job(glue_context)
job.init(args['JOB_NAME'], args)

def get_tables(database_name, table_prefix):
    tables = []
    paginator = glue.get_paginator('get_tables')
    for page in paginator.paginate(DatabaseName=database_name, Expression=table_prefix
+"""):
        tables.extend(page['TableList'])
    return tables
```

```
for table in get_tables(databaseName, tablePrefix):
    tableName = table['Name']
    partitionList = table['PartitionKeys']
    partitionKeys = []
    for partition in partitionList:
        partitionKeys.append(partition['Name'])

    # Create DynamicFrame from Catalog
    dyf = glue_context.create_dynamic_frame.from_catalog(
        name_space=databaseName,
        table_name=tableName,
        additional_options={
            'useS3ListImplementation': True
        },
        transformation_ctx='dyf'
    )

    # Resolve choice type with make_struct
    dyf = ResolveChoice.apply(
        frame=dyf,
        choice='make_struct',
        transformation_ctx='resolvechoice_' + tableName
    )

    # Drop null fields
    dyf = DropNullFields.apply(
        frame=dyf,
        transformation_ctx="dropnullfields_" + tableName
    )

    # Write DynamicFrame to S3 in glueparquet
    sink = glue_context.getSink(
        connection_type="s3",
        path=outputPath,
        enableUpdateCatalog=True,
        partitionKeys=partitionKeys
    )
    sink.setFormat("glueparquet")

    sink.setCatalogInfo(
        catalogDatabase=databaseName,
        catalogTableName=tableName[len(tablePrefix):]
    )
```

```
sink.writeFrame(dyf)

job.commit()
```

### Note

Only two Amazon S3 paths can be supplied as an input to the sample blueprint. This is because AWS Glue triggers are limited to invoking only two crawler actions.

## Testing a blueprint

While you develop your code, you should perform local testing to verify that the workflow layout is correct.

Local testing doesn't generate AWS Glue jobs, crawlers, or triggers. Instead, you run the layout script locally and use the `to_json()` and `validate()` methods to print objects and find errors. These methods are available in all three classes defined in the libraries.

There are two ways to handle the `user_params` and `system_params` arguments that AWS Glue passes to your layout function. Your test-bench code can create a dictionary of sample blueprint parameter values and pass that to the layout function as the `user_params` argument. Or, you can remove the references to `user_params` and replace them with hardcoded strings.

If your code makes use of the `region` and `accountId` properties in the `system_params` argument, you can pass in your own dictionary for `system_params`.

### To test a blueprint

1. Start a Python interpreter in a directory with the libraries, or load the blueprint files and the supplied libraries into your preferred integrated development environment (IDE).
2. Ensure that your code imports the supplied libraries.
3. Add code to your layout function to call `validate()` or `to_json()` on any entity or on the `Workflow` object. For example, if your code creates a `Crawler` object named `mycrawler`, you can call `validate()` as follows.

```
mycrawler.validate()
```

You can print `mycrawler` as follows:

```
print(mycrawler.to_json())
```

If you call `to_json` on an object, there is no need to also call `validate()`, because `to_json()` calls `validate()`.

It is most useful to call these methods on the workflow object. Assuming that your script names the workflow object `my_workflow`, validate and print the workflow object as follows.

```
print(my_workflow.to_json())
```

For more information about `to_json()` and `validate()`, see [Class methods](#).

You can also import `pprint` and pretty-print the workflow object, as shown in the example later in this section.

4. Run the code, fix errors, and finally remove any calls to `validate()` or `to_json()`.

## Example

The following example shows how to construct a dictionary of sample blueprint parameters and pass it in as the `user_params` argument to layout function `generate_compaction_workflow`. It also shows how to pretty-print the generated workflow object.

```
from pprint import pprint
from awsglue.blueprint.workflow import *
from awsglue.blueprint.job import *
from awsglue.blueprint.crawler import *

USER_PARAMS = {"WorkflowName": "compaction_workflow",
               "ScriptLocation": "s3://awsexamplebucket1/scripts/threaded-
compaction.py",
               "PassRole": "arn:aws:iam::111122223333:role/GlueRole-ETL",
               "DatabaseName": "cloudtrial",
               "TableName": "ct_cloudtrail",
               "CoalesceFactor": 4,
               "MaxThreadWorkers": 200}

def generate_compaction_workflow(user_params: dict, system_params: dict) -> Workflow:
    compaction_job = Job(Name=f"{user_params['WorkflowName']}_etl_job",
```

```

        Command={"Name": "glueetl",
                "ScriptLocation": user_params['ScriptLocation'],
                "PythonVersion": "3"},
        Role="arn:aws:iam::111122223333:role/
AWSGlueServiceRoleDefault",
        DefaultArguments={"DatabaseName": user_params['DatabaseName'],
                "TableName": user_params['TableName'],
                "CoalesceFactor":
user_params['CoalesceFactor'],
                "max_thread_workers":
user_params['MaxThreadWorkers']})

        catalog_target = {"CatalogTargets": [{"DatabaseName": user_params['DatabaseName'],
"Tables": [user_params['TableName']]}]}

        compacted_files_crawler = Crawler(Name=f"{user_params['WorkflowName']}_post_crawl",
                Targets = catalog_target,
                Role=user_params['PassRole'],
                DependsOn={compaction_job: "SUCCEEDED"},
                WaitForDependencies="AND",
                SchemaChangePolicy={"DeleteBehavior": "LOG"})

        compaction_workflow = Workflow(Name=user_params['WorkflowName'],
                Entities=Entities(Jobs=[compaction_job],

Crawlers=[compacted_files_crawler]))
        return compaction_workflow

generated = generate_compaction_workflow(user_params=USER_PARAMS, system_params={})
gen_dict = generated.to_json()

pprint(gen_dict)

```

## Publishing a blueprint

After you develop a blueprint, you must upload it to Amazon S3. You must have write permissions on the Amazon S3 bucket that you use to publish the blueprint. You must also make sure that the AWS Glue administrator, who will register the blueprint, has read access to the Amazon S3 bucket. For the suggested AWS Identity and Access Management (IAM) permissions policies for personas and roles for AWS Glue blueprints, see [Permissions for personas and roles for AWS Glue blueprints](#).

## To publish a blueprint

1. Create the necessary scripts, resources, and blueprint configuration file.
2. Add all files to a ZIP archive and upload the ZIP file to Amazon S3. Use an S3 bucket that is in the same Region as the Region in which users will register and run the blueprint.

You can create a ZIP file from the command line using the following command.

```
zip -r folder.zip folder
```

3. Add a bucket policy that grants read permissions to the AWS desired account. The following is a sample policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::my-blueprints/*"
    }
  ]
}
```

4. Grant the IAM `s3:GetObject` permission on the Amazon S3 bucket to the AWS Glue administrator or to whoever will be registering blueprints. For a sample policy to grant to administrators, see [AWS Glue administrator permissions for blueprints](#).

After you have completed local testing of your blueprint, you may also want to test a blueprint on AWS Glue. To test a blueprint on AWS Glue, it must be registered. You can limit who sees the registered blueprint using IAM authorization, or by using separate testing accounts.

### See also:

- [Registering a blueprint in AWS Glue](#)

## AWS Glue blueprint classes reference

The libraries for AWS Glue blueprints define three classes that you use in your workflow layout script: `Job`, `Crawler`, and `Workflow`.

### Topics

- [Job class](#)
- [Crawler class](#)
- [Workflow class](#)
- [Class methods](#)

### Job class

The `Job` class represents an AWS Glue ETL job.

### Mandatory constructor arguments

The following are mandatory constructor arguments for the `Job` class.

Argument name	Type	Description
Name	str	Name to assign to the job. AWS Glue adds a randomly generated suffix to the name to distinguish the job from those created by other blueprint runs.
Role	str	Amazon Resource Name (ARN) of the role that the job should assume while executing.
Command	dict	Job command, as specified in the <a href="#">JobCommand structure</a> in the API documentation.

### Optional constructor arguments

The following are optional constructor arguments for the `Job` class.

Argument name	Type	Description
DependsOn	dict	List of workflow entities that the job depends on. For more information, see <a href="#">Using the DependsOn argument</a> .
WaitForDependencies	str	Indicates whether the job should wait until <i>all</i> entities on which it depends complete before executing or until <i>any</i> completes. For more information, see <a href="#">Using the WaitForDependencies argument</a> . Omit if the job depends on only one entity.
(Job properties)	-	Any of the job properties listed in <a href="#">Job structure</a> in the AWS Glue API documentation (except CreatedOn and LastModifiedOn ).

## Crawler class

The `Crawler` class represents an AWS Glue crawler.

### Mandatory constructor arguments

The following are mandatory constructor arguments for the `Crawler` class.

Argument name	Type	Description
Name	str	Name to assign to the crawler. AWS Glue adds a randomly generated suffix to the name to distinguish the crawler from those created by other blueprint runs.
Role	str	ARN of the role that the crawler should assume while running.
Targets	dict	Collection of targets to crawl. Targets class constructor arguments are defined in the <a href="#">CrawlerTargets structure</a> in the API documenta

Argument name	Type	Description
		tion. All Targets constructor arguments are optional, but you must pass at least one.

## Optional constructor arguments

The following are optional constructor arguments for the `Crawler` class.

Argument name	Type	Description
<code>DependsOn</code>	<code>dict</code>	List of workflow entities that the crawler depends on. For more information, see <a href="#">Using the DependsOn argument</a> .
<code>WaitForDependencies</code>	<code>str</code>	Indicates whether the crawler should wait until <i>all</i> entities on which it depends complete before running or until <i>any</i> completes. For more information, see <a href="#">Using the WaitForDependencies argument</a> . Omit if the crawler depends on only one entity.
(Crawler properties)	-	Any of the crawler properties listed in <a href="#">Crawler structure</a> in the AWS Glue API documentation, with the following exceptions: <ul style="list-style-type: none"> <li>• <code>State</code></li> <li>• <code>CrawlElapsedTime</code></li> <li>• <code>CreationTime</code></li> <li>• <code>LastUpdated</code></li> <li>• <code>LastCrawl</code></li> <li>• <code>Version</code></li> </ul>

## Workflow class

The `Workflow` class represents an AWS Glue workflow. The workflow layout script returns a `Workflow` object. AWS Glue creates a workflow based on this object.

### Mandatory constructor arguments

The following are mandatory constructor arguments for the `Workflow` class.

Argument name	Type	Description
Name	str	Name to assign to the workflow.
Entities	Entities	A collection of entities (jobs and crawlers) to include in the workflow. The <code>Entities</code> class constructor accepts a <code>Jobs</code> argument, which is a list of <code>Job</code> objects, and a <code>Crawlers</code> argument, which is a list of <code>Crawler</code> objects.

### Optional constructor arguments

The following are optional constructor arguments for the `Workflow` class.

Argument name	Type	Description
Description	str	See <a href="#">Workflow structure</a> .
DefaultRunProperties	dict	See <a href="#">Workflow structure</a> .
OnSchedule	str	A cron expression.

### Class methods

All three classes include the following methods.

## **validate()**

Validates the properties of the object and if errors are found, outputs a message and exits. Generates no output if there are no errors. For the `Workflow` class, calls itself on every entity in the workflow.

## **to\_json()**

Serializes the object to JSON. Also calls `validate()`. For the `Workflow` class, the JSON object includes job and crawler lists, and a list of triggers generated by the job and crawler dependency specifications.

## **Blueprint samples**

There are a number of sample blueprint projects available on the [AWS Glue blueprint Github repository](#). These samples are for reference only and are not intended for production use.

The titles of the sample projects are:

- **Compaction:** this blueprint creates a job that compacts input files into larger chunks based on desired file size.
- **Conversion:** this blueprint converts input files in various standard file formats into Apache Parquet format, which is optimized for analytic workloads.
- **Crawling Amazon S3 locations:** this blueprint crawls multiple Amazon S3 locations to add metadata tables to the Data Catalog.
- **Custom connection to Data Catalog:** this blueprint accesses data stores using AWS Glue custom connectors, reads the records, and populates the table definitions in the AWS Glue Data Catalog based on the record schema.
- **Encoding:** this blueprint converts your non-UTF files into UTF encoded files.
- **Partitioning:** this blueprint creates a partitioning job that places output files into partitions based on specific partition keys.
- **Importing Amazon S3 data into a DynamoDB table:** this blueprint imports data from Amazon S3 into a DynamoDB table.
- **Standard table to governed:** this blueprint imports an AWS Glue Data Catalog table into a Lake Formation table.

## Registering a blueprint in AWS Glue

After the AWS Glue developer has coded the blueprint and uploaded a ZIP archive to Amazon Simple Storage Service (Amazon S3), an AWS Glue administrator must register the blueprint. Registering the blueprint makes it available for use.

When you register a blueprint, AWS Glue copies the blueprint archive to a reserved Amazon S3 location. You can then delete the archive from the upload location.

To register a blueprint, you need read permissions on the Amazon S3 location that contains the uploaded archive. You also need the AWS Identity and Access Management (IAM) permission `glue:CreateBlueprint`. For the suggested permissions for an AWS Glue administrator who must register, view, and maintain blueprints, see [AWS Glue administrator permissions for blueprints](#).

You can register a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

### To register a blueprint (console)

1. Ensure that you have read permissions (`s3:GetObject`) on the blueprint ZIP archive in Amazon S3.
2. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.

Sign in as a user that has permissions to register a blueprint. Switch to the same AWS Region as the Amazon S3 bucket that contains the blueprint ZIP archive.

3. In the navigation pane, choose **blueprints**. Then on the **blueprints** page, choose **Add blueprint**.
4. Enter a blueprint name and optional description.
5. For **ZIP archive location (S3)**, enter the Amazon S3 path of the uploaded blueprint ZIP archive. Include the archive file name in the path and begin the path with `s3://`.
6. (Optional) Add tag one or more tags.
7. Choose **Add blueprint**.

The **blueprints** page returns and shows that the blueprint status is **CREATING**. Choose the refresh button until the status changes to **ACTIVE** or **FAILED**.

8. If the status is **FAILED**, select the blueprint, and on the **Actions** menu, choose **View**.

The detail page shows the reason for the failure. If the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
  - The Amazon S3 bucket that contains the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see [Developing blueprints in AWS Glue](#).
  - The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.
9. Ensure that data analysts have permissions on the blueprint.

The suggested IAM policy for data analysts is shown in [Data analyst permissions for blueprints](#). This policy grants `glue:GetBlueprint` on any resource. If your policy is more fine-grained at the resource level, then grant data analysts permissions on this newly created resource.

### To register a blueprint (AWS CLI)

1. Enter the following command.

```
aws glue create-blueprint --name <blueprint-name> [--description <description>] --  
blueprint-location s3://<s3-path>/<archive-filename>
```

2. Enter the following command to check the blueprint status. Repeat the command until the status goes to ACTIVE or FAILED.

```
aws glue get-blueprint --name <blueprint-name>
```

If the status is FAILED and the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
- The Amazon S3 bucket containing the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see [Publishing a blueprint](#).

- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

### See also:

- [Overview of blueprints in AWS Glue](#)

## Viewing blueprints in AWS Glue

View a blueprint to review the blueprint description, status, and parameter specifications, and to download the blueprint ZIP archive.

You can view a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

### To view a blueprint (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **blueprints**.
3. On the **blueprints** page, select a blueprint. Then on the **Actions** menu, choose **View**.

### To view a blueprint (AWS CLI)

- Enter the following command to view just the blueprint name, description, and status. Replace *<blueprint-name>* with the name of the blueprint to view.

```
aws glue get-blueprint --name <blueprint-name>
```

The command output looks something like the following.

```
{
  "Blueprint": {
    "Name": "myDemoBP",
    "CreatedOn": 1587414516.92,
    "LastModifiedOn": 1587428838.671,
    "BlueprintLocation": "s3://awsexamplebucket1/demo/
DemoBlueprintProject.zip",
```

```

    "Status": "ACTIVE"
  }
}

```

Enter the following command to also view the parameter specifications.

```
aws glue get-blueprint --name <blueprint-name> --include-parameter-spec
```

The command output looks something like the following.

```

{
  "Blueprint": {
    "Name": "myDemoBP",
    "CreatedOn": 1587414516.92,
    "LastModifiedOn": 1587428838.671,
    "ParameterSpec": "{\"WorkflowName\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},\"PassRole\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},\"DynamoDBTableName\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null},\"ScriptLocation\":{\"type\":\"String\",\"collection\":false,\"description\":null,\"defaultValue\":null,\"allowedValues\":null}}",
    "BlueprintLocation": "s3://awsexamplebucket1/demo/DemoBlueprintProject.zip",
    "Status": "ACTIVE"
  }
}

```

Add the `--include-blueprint` argument to include a URL in the output that you can paste into your browser to download the blueprint ZIP archive that AWS Glue stored.

#### See also:

- [Overview of blueprints in AWS Glue](#)

## Updating a blueprint in AWS Glue

You can update a blueprint if you have a revised layout script, a revised set of blueprint parameters, or revised supporting files. Updating a blueprint creates a new version.

Updating a blueprint doesn't affect existing workflows created from the blueprint.

You can update a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

The following procedure assumes that the AWS Glue developer has created and uploaded an updated blueprint ZIP archive to Amazon S3.

### To update a blueprint (console)

1. Ensure that you have read permissions (`s3:GetObject`) on the blueprint ZIP archive in Amazon S3.
2. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.

Sign in as a user that has permissions to update a blueprint. Switch to the same AWS Region as the Amazon S3 bucket that contains the blueprint ZIP archive.

3. In the navigation pane, choose **blueprints**.
4. On the **blueprints** page, select a blueprint, and on the **Actions** menu, choose **Edit**.
5. On the **Edit a blueprint** page, update the blueprint **Description** or **ZIP archive location (S3)**. Be sure to include the archive file name in the path.
6. Choose **Save**.

The **blueprints** page returns and shows that the blueprint status is UPDATING. Choose the refresh button until the status changes to ACTIVE or FAILED.

7. If the status is FAILED, select the blueprint, and on the **Actions** menu, choose **View**.

The detail page shows the reason for the failure. If the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.

- The Amazon S3 bucket that contains the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see [Publishing a blueprint](#).
- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

**Note**

If the update fails, the next blueprint run uses the latest version of the blueprint that was successfully registered or updated.

### To update a blueprint (AWS CLI)

1. Enter the following command.

```
aws glue update-blueprint --name <blueprint-name> [--description <description>] --  
blueprint-location s3://<s3-path>/<archive-filename>
```

2. Enter the following command to check the blueprint status. Repeat the command until the status goes to ACTIVE or FAILED.

```
aws glue get-blueprint --name <blueprint-name>
```

If the status is FAILED and the error message is "Unable to access object at location..." or "Access denied on object at location...", review the following requirements:

- The user that you are signed in as must have read permission on the blueprint ZIP archive in Amazon S3.
- The Amazon S3 bucket containing the ZIP archive must have a bucket policy that grants read permission on the object to your AWS account ID. For more information, see [Publishing a blueprint](#).
- The Amazon S3 bucket that you're using must be in the same Region as the Region that you're signed into on the console.

- [Overview of blueprints in AWS Glue](#)

## Creating a workflow from a blueprint in AWS Glue

You can create an AWS Glue workflow manually, adding one component at a time, or you can create a workflow from an AWS Glue [blueprint](#). AWS Glue includes blueprints for common use cases. Your AWS Glue developers can create additional blueprints.

**⚠ Important**

Limit the total number of jobs, crawlers, and triggers within a workflow to 100 or less. If you include more than 100, you might get errors when trying to resume or stop workflow runs.

When you use a blueprint, you can quickly generate a workflow for a specific use case based on the generalized use case defined by the blueprint. You define the specific use case by providing values for the blueprint parameters. For example, a blueprint that partitions a dataset could have the Amazon S3 source and target paths as parameters.

AWS Glue creates a workflow from a blueprint by *running* the blueprint. The blueprint run saves the parameter values that you supplied, and is used to track the progress and outcome of the creation of the workflow and its components. When troubleshooting a workflow, you can view the blueprint run to determine the blueprint parameter values that were used to create a workflow.

To create and view workflows, you require certain IAM permissions. For a suggested IAM policy, see [Data analyst permissions for blueprints](#).

You can create a workflow from a blueprint by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

### To create a workflow from a blueprint (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.

Sign in as a user that has permissions to create a workflow.

2. In the navigation pane, choose **blueprints**.
3. Select a blueprint, and on the **Actions** menu, choose **Create workflow**.
4. On the **Create a workflow from <blueprint-name>** page, enter the following information:

### Blueprint parameters

These vary depending on the blueprint design. For questions about the parameters, see the developer. blueprints typically include a parameter for the workflow name.

### IAM role

The role that AWS Glue assumes to create the workflow and its components. The role must have permissions to create and delete workflows, jobs, crawlers, and triggers. For a suggested policy for the role, see [Permissions for blueprint roles](#).

5. Choose **Submit**.

The **Blueprint Details** page appears, showing a list of blueprint runs at the bottom.

6. In the blueprint runs list, check the topmost blueprint run for workflow creation status.

The initial status is RUNNING. Choose the refresh button until the status goes to SUCCEEDED or FAILED.

7. Do one of the following:
  - If the completion status is SUCCEEDED, you can go to the **Workflows** page, select the newly created workflow, and run it. Before running the workflow, you can review the design graph.
  - If the completion status is FAILED, select the blueprint run, and on the **Actions** menu, choose **View** to see the error message.

For more information on workflows and blueprints, see the following topics.

- [Overview of workflows in AWS Glue](#)
- [Updating a blueprint in AWS Glue](#)
- [Creating and building out a workflow manually in AWS Glue](#)

## Viewing blueprint runs in AWS Glue

View a blueprint run to see the following information:

- Name of the workflow that was created.
- blueprint parameter values that were used to create the workflow.
- Status of the workflow creation operation.

You can view a blueprint run by using the AWS Glue console, AWS Glue API, or AWS Command Line Interface (AWS CLI).

### To view a blueprint run (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane, choose **blueprints**.
3. On the **blueprints** page, select a blueprint. Then on the **Actions** menu, choose **View**.
4. At the bottom of the **Blueprint Details** page, select a blueprint run, and on the **Actions** menu, choose **View**.

### To view a blueprint run (AWS CLI)

- Enter the following command. Replace *<blueprint-name>* with the name of the blueprint. Replace *<blueprint-run-id>* with the blueprint run ID.

```
aws glue get-blueprint-run --blueprint-name <blueprint-name> --run-id <blueprint-run-id>
```

# AWS CloudFormation for AWS Glue

AWS CloudFormation is a service that can create many AWS resources. AWS Glue provides API operations to create objects in the AWS Glue Data Catalog. However, it might be more convenient to define and create AWS Glue objects and other related AWS resource objects in an AWS CloudFormation template file. Then you can automate the process of creating the objects.

AWS CloudFormation provides a simplified syntax—either JSON (JavaScript Object Notation) or YAML (YAML Ain't Markup Language)—to express the creation of AWS resources. You can use AWS CloudFormation templates to define Data Catalog objects such as databases, tables, partitions, crawlers, classifiers, and connections. You can also define ETL objects such as jobs, triggers, and development endpoints. You create a template that describes all the AWS resources you want, and AWS CloudFormation takes care of provisioning and configuring those resources for you.

For more information, see [What Is AWS CloudFormation?](#) and [Working with AWS CloudFormation Templates](#) in the *AWS CloudFormation User Guide*.

If you plan to use AWS CloudFormation templates that are compatible with AWS Glue, as an administrator, you must grant access to AWS CloudFormation and to the AWS services and actions on which it depends. To grant permissions to create AWS CloudFormation resources, attach the following policy to users that work with AWS CloudFormation:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:*"
      ],
      "Resource": "*"
    }
  ]
}
```

The following table contains the actions that an AWS CloudFormation template can perform on your behalf. It includes links to information about the AWS resource types and their property types that you can add to an AWS CloudFormation template.

<b>AWS Glue resource</b>	<b>AWS CloudFormation template</b>	<b>AWS Glue samples</b>
Classifier	<a href="#">AWS::Glue::Classifier</a>	<a href="#">Grok classifier</a> , <a href="#">JSON classifier</a> , <a href="#">XML classifier</a>
Connection	<a href="#">AWS::Glue::Connection</a>	<a href="#">MySQL connection</a>
Crawler	<a href="#">AWS::Glue::Crawler</a>	<a href="#">Amazon S3 crawler</a> , <a href="#">MySQL crawler</a>
Database	<a href="#">AWS::Glue::Database</a>	<a href="#">Empty database</a> , <a href="#">Database with tables</a>
Development endpoint	<a href="#">AWS::Glue::DevEndpoint</a>	<a href="#">Development endpoint</a>
Job	<a href="#">AWS::Glue::Job</a>	<a href="#">Amazon S3 job</a> , <a href="#">JDBC job</a>

Partition	<a href="#">AWS::Glue::Partition</a>	<a href="#">Partitions of a table</a>
Table	<a href="#">AWS::Glue::Table</a>	<a href="#">Table in a database</a>
Trigger	<a href="#">AWS::Glue::Trigger</a>	<a href="#">On-demand trigger</a> , <a href="#">Scheduled trigger</a> , <a href="#">Conditional trigger</a>

To get started, use the following sample templates and customize them with your own metadata. Then use the AWS CloudFormation console to create an AWS CloudFormation stack to add objects to AWS Glue and any associated services. Many fields in an AWS Glue object are optional. These templates illustrate the fields that are required or are necessary for a working and functional AWS Glue object.

An AWS CloudFormation template can be in either JSON or YAML format. In these examples, YAML is used for easier readability. The examples contain comments (#) to describe the values that are defined in the templates.

AWS CloudFormation templates can include a `Parameters` section. This section can be changed in the sample text or when the YAML file is submitted to the AWS CloudFormation console to create a stack. The `Resources` section of the template contains the definition of AWS Glue and related objects. AWS CloudFormation template syntax definitions might contain properties that include more detailed property syntax. Not all properties might be required to create an AWS Glue object. These samples show example values for common properties to create an AWS Glue object.

## Sample AWS CloudFormation template for an AWS Glue database

An AWS Glue database in the Data Catalog contains metadata tables. The database consists of very few properties and can be created in the Data Catalog with an AWS CloudFormation template. The following sample template is provided to get you started and to illustrate the use of AWS CloudFormation stacks with AWS Glue. The only resource created by the sample template is a database named `cfn-mysampledatabase`. You can change it by editing the text of the sample or changing the value on the AWS CloudFormation console when you submit the YAML.

The following shows example values for common properties to create an AWS Glue database. For more information about the AWS CloudFormation database template for AWS Glue, see [AWS::Glue::Database](#).

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CloudFormation template in YAML to demonstrate creating a database named
# mysampledatabase
# The metadata created in the Data Catalog points to the flights public S3 bucket
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
  CFNDatabaseName:
    Type: String
    Default: cfn-mysampledatabse

# Resources section defines metadata for the Data Catalog
```

```
Resources:
# Create an AWS Glue database
CFNDatabaseFlights:
  Type: AWS::Glue::Database
  Properties:
    # The database is created in the Data Catalog for your account
    CatalogId: !Ref AWS::AccountId
    DatabaseInput:
      # The name of the database is defined in the Parameters section above
      Name: !Ref CFNDatabaseName
      Description: Database to hold tables for flights data
      LocationUri: s3://crawler-public-us-east-1/flight/2016/csv/
      #Parameters: Leave AWS database parameters blank
```

## Sample AWS CloudFormation template for an AWS Glue database, table, and partition

An AWS Glue table contains the metadata that defines the structure and location of data that you want to process with your ETL scripts. Within a table, you can define partitions to parallelize the processing of your data. A partition is a chunk of data that you defined with a key. For example, using month as a key, all the data for January is contained in the same partition. In AWS Glue, databases can contain tables, and tables can contain partitions.

The following sample shows how to populate a database, a table, and partitions using an AWS CloudFormation template. The base data format is csv and delimited by a comma (,). Because a database must exist before it can contain a table, and a table must exist before partitions can be created, the template uses the `DependsOn` statement to define the dependency of these objects when they are created.

The values in this sample define a table that contains flight data from a publicly available Amazon S3 bucket. For illustration, only a few columns of the data and one partitioning key are defined. Four partitions are also defined in the Data Catalog. Some fields to describe the storage of the base data are also shown in the `StorageDescriptor` fields.

```

```

## Sample AWS CloudFormation template for an AWS Glue grok classifier

An AWS Glue classifier determines the schema of your data. One type of custom classifier uses a grok pattern to match your data. If the pattern matches, then the custom classifier is used to create your table's schema and set the classification to the value set in the classifier definition.

This sample creates a classifier that creates a schema with one column named message and sets the classification to greedy.

```

---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
CFNClassifierName:

```

```

    Type: String
    Default: cfn-classifier-grok-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses grok pattern to put all data in one column and classifies
it as "greedy".
CFNClassifierFlights:
  Type: AWS::Glue::Classifier
  Properties:
    GrokClassifier:
      #Grok classifier that puts all data in one column
      Name: !Ref CFNClassifierName
      Classification: greedy

      GrokPattern: "%{GREEDYDATA:message}"
      #CustomPatterns: none

```

## Sample AWS CloudFormation template for an AWS Glue JSON classifier

An AWS Glue classifier determines the schema of your data. One type of custom classifier uses a `JsonPath` string defining the JSON data for the classifier to classify. AWS Glue supports a subset of the operators for `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

If the pattern matches, then the custom classifier is used to create your table's schema.

This sample creates a classifier that creates a schema with each record in the `Records3` array in an object.

```

---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a JSON classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created

```

```

CFNClassifierName:
  Type: String
  Default: cfn-classifier-json-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses a JSON pattern.
CFNClassifierFlights:
  Type: AWS::Glue::Classifier
  Properties:
    JSONClassifier:
      #JSON classifier
      Name: !Ref CFNClassifierName
      JsonPath: $.Records3[*]

```

## Sample AWS CloudFormation template for an AWS Glue XML classifier

An AWS Glue classifier determines the schema of your data. One type of custom classifier specifies an XML tag to designate the element that contains each record in an XML document that is being parsed. If the pattern matches, then the custom classifier is used to create your table's schema and set the classification to the value set in the classifier definition.

This sample creates a classifier that creates a schema with each record in the Record tag and sets the classification to XML.

```

---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating an XML classifier
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the classifier to be created
CFNClassifierName:
  Type: String

```

```

Default: cfn-classifier-xml-one-column-1

#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create classifier that uses the XML pattern and classifies it as "XML".
CFNClassifierFlights:
  Type: AWS::Glue::Classifier
  Properties:
    XMLClassifier:
      #XML classifier
      Name: !Ref CFNClassifierName
      Classification: XML
      RowTag: <Records>

```

## Sample AWS CloudFormation template for an AWS Glue crawler for Amazon S3

An AWS Glue crawler creates metadata tables in your Data Catalog that correspond to your data. You can then use these table definitions as sources and targets in your ETL jobs.

This sample creates a crawler, the required IAM role, and an AWS Glue database in the Data Catalog. When this crawler is run, it assumes the IAM role and creates a table in the database for the public flights data. The table is created with the prefix "cfn\_sample\_1\_". The IAM role created by this template allows global permissions; you might want to create a custom role. No custom classifiers are defined by this classifier. AWS Glue built-in classifiers are used by default.

When you submit this sample to the AWS CloudFormation console, you must confirm that you want to create the IAM role.

```

---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a crawler
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the crawler to be created

```

```

CFNCrawlerName:
  Type: String
  Default: cfn-crawler-flights-1
CFNDatabaseName:
  Type: String
  Default: cfn-database-flights-1
CFNTablePrefixName:
  Type: String
  Default: cfn_sample_1_
#
#

```

## Sample AWS CloudFormation template for an AWS Glue job for Amazon S3 to Amazon S3

An AWS Glue job in the Data Catalog contains the parameter values that are required to run a script in AWS Glue.

This sample creates a job that reads flight data from an Amazon S3 bucket in csv format and writes it to an Amazon S3 Parquet file. The script that is run by this job must already exist. You can generate an ETL script for your environment with the AWS Glue console. When this job is run, an IAM role with the correct permissions must also be supplied.

Common parameter values are shown in the template. For example, `AllocatedCapacity` (DPUs) defaults to 5.

```

# Sample CFN YAML to demonstrate creating a job using the public flights S3 table in a
public bucket
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the job to be created
CFNJobName:
  Type: String
  Default: cfn-job-S3-to-S3-2
# The name of the IAM role that the job assumes. It must have access to data, script,
temporary directory
CFNIAMRoleName:
  Type: String
  Default: AWSGlueServiceRoleGA
# The S3 path where the script for this job is located
CFNScriptLocation:
  Type: String
  Default: s3://aws-glue-scripts-123456789012-us-east-1/myid/sal-job-test2
#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create job to run script which accesses flightscsv table and write to S3 file as
parquet.
# The script already exists and is called by this job
CFNJobFlights:
  Type: AWS::Glue::Job
  Properties:
    Role: !Ref CFNIAMRoleName
    #DefaultArguments: JSON object
    # If script written in Scala, then set DefaultArguments={'--job-language';
'scala', '--class': 'your scala class'}
    #Connections: No connection needed for S3 to S3 job
    # ConnectionsList
    #MaxRetries: Double
    Description: Job created with CloudFormation
    #LogUri: String
    Command:
      Name: glueetl
      ScriptLocation: !Ref CFNScriptLocation
      # for access to directories use proper IAM role with permission to buckets
and folders that begin with "aws-glue-"

```

```
    # script uses temp directory from job definition if required (temp
directory not used S3 to S3)
    # script defines target for output as s3://aws-glue-target/sal
AllocatedCapacity: 5
ExecutionProperty:
  MaxConcurrentRuns: 1
Name: !Ref CFNJobName
```

## Sample AWS CloudFormation template for an AWS Glue job for JDBC to Amazon S3

An AWS Glue job in the Data Catalog contains the parameter values that are required to run a script in AWS Glue.

This sample creates a job that reads flight data from a MySQL JDBC database as defined by the connection named `cfn-connection-mysql-flights-1` and writes it to an Amazon S3 Parquet file. The script that is run by this job must already exist. You can generate an ETL script for your environment with the AWS Glue console. When this job is run, an IAM role with the correct permissions must also be supplied.

Common parameter values are shown in the template. For example, `AllocatedCapacity` (DPUs) defaults to 5.

```

# Sample CFN YAML to demonstrate creating a job using a MySQL JDBC DB with the flights
data to an S3 file
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the job to be created
CFNJobName:
  Type: String
  Default: cfn-job-JDBC-to-S3-1
# The name of the IAM role that the job assumes. It must have access to data, script,
temporary directory
CFNIAMRoleName:
  Type: String
```

```

    Default: AWSGlueServiceRoleGA
# The S3 path where the script for this job is located
CFNScriptLocation:
  Type: String
  Default: s3://aws-glue-scripts-123456789012-us-east-1/myid/sal-job-dec4a
# The name of the connection used for JDBC data source
CFNConnectionName:
  Type: String
  Default: cfn-connection-mysql-flights-1
#
#
# Resources section defines metadata for the Data Catalog
Resources:
# Create job to run script which accesses JDBC flights table via a connection and write
to S3 file as parquet.
# The script already exists and is called by this job
CFNJobFlights:
  Type: AWS::Glue::Job
  Properties:
    Role: !Ref CFNIAMRoleName
    #DefaultArguments: JSON object
    # For example, if required by script, set temporary directory as
DefaultArguments={'--TempDir'; 's3://aws-glue-temporary-xyc/sal'}
    Connections:
      Connections:
        - !Ref CFNConnectionName
    #MaxRetries: Double
    Description: Job created with CloudFormation using existing script
    #LogUri: String
    Command:
      Name: glueetl
      ScriptLocation: !Ref CFNScriptLocation
        # for access to directories use proper IAM role with permission to buckets
and folders that begin with "aws-glue-"
        # if required, script defines temp directory as argument TempDir and used
in script like redshift_tmp_dir = args["TempDir"]
        # script defines target for output as s3://aws-glue-target/sal
    AllocatedCapacity: 5
    ExecutionProperty:
      MaxConcurrentRuns: 1
    Name: !Ref CFNJobName

```

# Sample AWS CloudFormation template for an AWS Glue on-demand trigger

An AWS Glue trigger in the Data Catalog contains the parameter values that are required to start a job run when the trigger fires. An on-demand trigger fires when you enable it.

This sample creates an on-demand trigger that starts one job named `cfn-job-S3-to-S3-1`.

```

          # Arguments: JSON object
      #Schedule:
      #Predicate:
```

# Sample AWS CloudFormation template for an AWS Glue scheduled trigger

An AWS Glue trigger in the Data Catalog contains the parameter values that are required to start a job run when the trigger fires. A scheduled trigger fires when it is enabled and the cron timer pops.

This sample creates a scheduled trigger that starts one job named `cfn-job-S3-to-S3-1`. The timer is a cron expression to run the job every 10 minutes on weekdays.
