# Sample CFN YAML to demonstrate creating a scheduled trigger for a job
#
Resources:
# Create trigger to run an existing job (CFNJobName) on a cron schedule.
  TriggerSample1CFN:
    Type: AWS::Glue::Trigger
    Properties:
      Name:
        Ref: CFNTriggerName
      Description: Trigger created with CloudFormation
      Type: SCHEDULED
      Actions:
        - JobName: !Ref CFNJobName
          # Arguments: JSON object
    # # Run the trigger every 10 minutes on Monday to Friday
```

```
Schedule: cron(0/10 * ? * MON-FRI *)
#Predicate:
```

## Sample AWS CloudFormation template for an AWS Glue conditional trigger

An AWS Glue trigger in the Data Catalog contains the parameter values that are required to start a job run when the trigger fires. A conditional trigger fires when it is enabled and its conditions are met, such as a job completing successfully.

This sample creates a conditional trigger that starts one job named `cfn-job-S3-to-S3-1`. This job starts when the job named `cfn-job-S3-to-S3-2` completes successfully.

```
---
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a conditional trigger for a job, which starts
  when another job completes
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:
  # The existing job to be started by this trigger
  CFNJobName:
    Type: String
    Default: cfn-job-S3-to-S3-1
  # The existing job that when it finishes causes trigger to fire
  CFNJobName2:
    Type: String
    Default: cfn-job-S3-to-S3-2
  # The name of the trigger to be created
  CFNTriggerName:
    Type: String
    Default: cfn-trigger-conditional-1
#
Resources:
# Create trigger to run an existing job (CFNJobName) when another job completes
(CFNJobName2).
  CFNTriggerSample:
    Type: AWS::Glue::Trigger
    Properties:
```

```

Name:
  Ref: CFNTriggerName
Description: Trigger created with CloudFormation
Type: CONDITIONAL
Actions:
  - JobName: !Ref CFNJobName
  # Arguments: JSON object
#Schedule: none
Predicate:
  #Value for Logical is required if more than 1 job listed in Conditions
  Logical: AND
Conditions:
  - LogicalOperator: EQUALS
    JobName: !Ref CFNJobName2
    State: SUCCEEDED

```

## Sample AWS CloudFormation template for an AWS Glue development endpoint

An AWS Glue machine learning transform is a custom transform to cleanse your data. There is currently one available transform named FindMatches. The FindMatches transform enables you to identify duplicate or matching records in your dataset, even when the records do not have a common unique identifier and no fields match exactly.

This sample creates a machine learning transform. For more information about the parameters that you need to create a machine learning transform, see [Record matching with AWS Lake Formation FindMatches](#).

## Sample AWS CloudFormation template for an AWS Glue Data Quality ruleset

An AWS Glue Data Quality ruleset contains rules that can be evaluated on a table within the Data Catalog. Once the ruleset is placed on your targeted table you can go into the Data Catalog and run an evaluation which runs your data against those rules within the ruleset. These rules can vary from evaluating the row count to evaluating referential integrity on your data.

The following sample is a CloudFormation template which creates a ruleset with a variety of rules on the specified target table.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a DataQualityRuleset
#
```

```
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the ruleset to be created
RulesetName:
  Type: String
  Default: "CFNRulesetName"
RulesetDescription:
  Type: String
  Default: "CFN DataQualityRuleset"
# Rules that will be associated with this ruleset
Rules:
  Type: String
  Default: 'Rules = [
    RowCount > 100,
    IsUnique "id",
    IsComplete "nametype"
  ]'
# Name of database and table within Data Catalog which the ruleset will
# be applied too
DatabaseName:
  Type: String
  Default: "ExampleDatabaseName"
TableName:
  Type: String
  Default: "ExampleTableName"

# Resources section defines metadata for the Data Catalog
Resources:
# Creates a Data Quality ruleset under specified rules
DQRuleset:
  Type: AWS::Glue::DataQualityRuleset
  Properties:
    Name: !Ref RulesetName
    Description: !Ref RulesetDescription
    # The String within rules must be formatted in DQDL, a language
    # used specifically to make rules
    Ruleset: !Ref Rules
    # The targeted table must exist within Data Catalog alongside
    # the correct database
    TargetTable:
      DatabaseName: !Ref DatabaseName
```

```
TableName: !Ref TableName
```

## Sample AWS CloudFormation template for an AWS Glue Data Quality ruleset with EventBridge scheduler

An AWS Glue Data Quality ruleset contains rules that can be evaluated on a table within the Data Catalog. Once the ruleset is placed on your targeted table you can go into the Data Catalog and run an evaluation which runs your data against those rules within the ruleset. Instead of having to manually go into the Data Catalog to evaluate the ruleset, you can also add an EventBridge Scheduler within our CloudFormation template to schedule these ruleset evaluations for you on a timed interval.

The following sample is a CloudFormation template which creates a Data Quality ruleset and a EventBridge Scheduler to evaluate the aforementioned ruleset every five minutes.

```
AWSTemplateFormatVersion: '2010-09-09'
# Sample CFN YAML to demonstrate creating a DataQualityRuleset
#
# Parameters section contains names that are substituted in the Resources section
# These parameters are the names the resources created in the Data Catalog
Parameters:

# The name of the ruleset to be created
RulesetName:
  Type: String
  Default: "CFNRulesetName"
# Rules that will be associated with this Ruleset
Rules:
  Type: String
  Default: 'Rules = [
    RowCount > 100,
    IsUnique "id",
    IsComplete "nametype"
  ]'
# The name of the Schedule to be created
ScheduleName:
  Type: String
  Default: "ScheduleDQRulsetEvaluation"
# This expression determines the rate at which the Schedule will evaluate
# your data using the above ruleset
ScheduleRate:
```

```

Type: String
Default: "rate(5 minutes)"
# The Request that being sent must match the details of the Data Quality Ruleset
ScheduleRequest:
Type: String
Default: '
  { "DataSource": { "GlueTable": { "DatabaseName": "ExampleDatabaseName",
    "TableName": "ExampleTableName" } },
    "Role": "role/AWSGlueServiceRoleDefault",
    "RulesetNames": [ "CFNRulesetName" ] }
  ,

# Resources section defines metadata for the Data Catalog
Resources:
# Creates a Data Quality ruleset under specified rules
DQRuleset:
Type: AWS::Glue::DataQualityRuleset
Properties:
Name: !Ref RulesetName
Description: "CFN DataQualityRuleset"
# The String within rules must be formatted in DQDL, a language
# used specifically to make rules
Ruleset: !Ref Rules
# The targeted table must exist within Data Catalog alongside
# the correct database
TargetTable:
  DatabaseName: "ExampleDatabaseName"
  TableName: "ExampleTableName"
# Create a Scheduler to schedule evaluation runs on the above ruleset

  "Role": "role/AWSGlueServiceRoleDefault",
  "RulesetNames": [ "TestCFN" ] }
'
```

## Sample AWS CloudFormation template for an AWS Glue development endpoint

An AWS Glue development endpoint is an environment that you can use to develop and test your AWS Glue scripts.

This sample creates a development endpoint with the minimal network parameter values required to successfully create it. For more information about the parameters that you need to set up a development endpoint, see [Setting up networking for development for AWS Glue](#).

You provide an existing IAM role ARN (Amazon Resource Name) to create the development endpoint. Supply a valid RSA public key and keep the corresponding private key available if you plan to create a notebook server on the development endpoint.

### Note

For any notebook server that you create that is associated with a development endpoint, you manage it. Therefore, if you delete the development endpoint, to delete the notebook server, you must delete the AWS CloudFormation stack on the AWS CloudFormation console.

```

```

# AWS Glue programming guide

A script contains the code that extracts data from sources, transforms it, and loads it into targets. AWS Glue runs a script when it starts a job.

AWS Glue ETL scripts are coded in Python or Scala. While all job types can be written in Python, AWS Glue for Spark jobs can be written in Scala as well. When you automatically generate the source code logic for your job in AWS Glue Studio, a script is created. You can edit this script, or you can provide your own script to process your ETL work.

## Providing your own custom scripts

Scripts perform the extract, transform, and load (ETL) work in AWS Glue. A script is created when you automatically generate the source code logic for a job. You can either edit this generated script, or you can provide your own custom script.

**To provide your own custom script in AWS Glue, follow these general steps:**

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose the **ETL Jobs** tab, and then view the **Create job** section. Choose a **script editor** option.
3. Under **This job runs**, choose one of the following:
  - **Create a new script with boilerplate code**
  - **Upload and edit an existing script**
4. On the **Job details** page, choose the **IAM role** that is required for your custom script to run. For more information, see [Identity and access management for AWS Glue](#).
5. Choose any connections that your script references. These objects are needed to connect to the necessary JDBC data stores.

An elastic network interface is a virtual network interface that you can attach to an instance in a virtual private cloud (VPC). Choose the elastic network interface that is required to connect to the data store that's used in the script.

6. Provide additional configuration, including parameters, specific to your job type. For more information about configuration for your job type, see the [Building visual ETL jobs with AWS Glue Studio](#) section.

7. On the **Script** tab, paste or write your custom script.

Use the content in this section to guide the process of writing your custom script.

For more information about adding jobs in AWS Glue, see [Building visual ETL jobs with AWS Glue Studio](#).

For step-by-step guidance, see the **Add job** tutorial in the AWS Glue console.

## Programming Spark scripts

AWS Glue makes it easy to write or autogenerate extract, transform, and load (ETL) scripts, in addition to testing and running them. This section describes the extensions to Apache Spark that AWS Glue has introduced, and provides examples of how to code and run ETL scripts in Python and Scala.

### Important

Different versions of AWS Glue support different versions of Apache Spark. Your custom script must be compatible with the supported Apache Spark version. For information about AWS Glue versions, see the [Glue version job property](#).

### Topics

- [Tutorial: Writing an AWS Glue for Spark script](#)
- [Program AWS Glue ETL scripts in PySpark](#)
- [Programming AWS Glue ETL scripts in Scala](#)
- [Features and optimizations for programming AWS Glue for Spark ETL scripts](#)

## Tutorial: Writing an AWS Glue for Spark script

This tutorial introduces you to the process of writing AWS Glue scripts. You can run scripts on a schedule with jobs, or interactively with interactive sessions. For more information about jobs, see [Building visual ETL jobs with AWS Glue Studio](#). For more information about interactive sessions, see [the section called "Overview of AWS Glue interactive sessions"](#).

The AWS Glue Studio visual editor offers a graphical, no-code interface for building AWS Glue jobs. AWS Glue scripts back visual jobs. They give you access to the expanded set of tools available to work with Apache Spark programs. You can access native Spark APIs, as well as AWS Glue libraries that facilitate extract, transform, and load (ETL) workflows from within an AWS Glue script.

In this tutorial, you extract, transform, and load a dataset of parking tickets. The script that does this work is identical in form and function to the one generated in [Making ETL easier with AWS Glue Studio](#) on the AWS Big Data Blog, which introduces the AWS Glue Studio visual editor. By running this script in a job, you can compare it to visual jobs and see how AWS Glue ETL scripts work. This prepares you to use additional functionalities that aren't yet available in visual jobs.

You use the Python language and libraries in this tutorial. Similar functionality is available in Scala. After going through this tutorial, you should be able to generate and inspect a sample Scala script to understand how to perform the Scala AWS Glue ETL script writing process.

## Prerequisites

This tutorial has the following prerequisites:

- The same prerequisites as the AWS Glue Studio blog post, which instructs you to run a AWS CloudFormation template.

This template uses the AWS Glue Data Catalog to manage the parking ticket dataset available in `s3://aws-bigdata-blog/artifacts/gluestudio/`. It creates the following resources which will be referenced:

- **AWS Glue StudioRole** – IAM role to run AWS Gluejobs
- **AWS Glue StudioAmazon S3Bucket** – Name of the Amazon S3 bucket to store blog-related files
- **AWS Glue StudioTicketsYYZDB** – AWS Glue Data Catalog database
- **AWS Glue StudioTableTickets** – Data Catalog table to use as a source
- **AWS Glue StudioTableTrials** – Data Catalog table to use as a source
- **AWS Glue StudioParkingTicketCount** – Data Catalog table to use as the destination
- The script generated in the AWS Glue Studio blog post. If the blog post changes, the script is also available in the following text.

## Generate a sample script

You can use the AWS Glue Studio visual editor as a powerful code generation tool to create a scaffold for the script you want to write. You will use this tool to create a sample script.

If you want to skip these steps, the script is provided.

## Tutorial sample script

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args["JOB_NAME"], args)

# Script generated for node S3 bucket
S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(
    database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"
)

# Script generated for node ApplyMapping
ApplyMapping_node2 = ApplyMapping.apply(
    frame=S3bucket_node1,
    mappings=[
        ("tag_number_masked", "string", "tag_number_masked", "string"),
        ("date_of_infraction", "string", "date_of_infraction", "string"),
        ("ticket_date", "string", "ticket_date", "string"),
        ("ticket_number", "decimal", "ticket_number", "float"),
        ("officer", "decimal", "officer_name", "decimal"),
        ("infraction_code", "decimal", "infraction_code", "decimal"),
        ("infraction_description", "string", "infraction_description", "string"),
        ("set_fine_amount", "decimal", "set_fine_amount", "float"),
        ("time_of_infraction", "decimal", "time_of_infraction", "decimal"),
    ],
    transformation_ctx="ApplyMapping_node2",
)

# Script generated for node S3 bucket
S3bucket_node3 = glueContext.write_dynamic_frame.from_options(
    frame=ApplyMapping_node2,
    connection_type="s3",
```

```

format="glueparquet",
connection_options={"path": "s3://DOC-EXAMPLE-BUCKET", "partitionKeys": []},
format_options={"compression": "gzip"},
transformation_ctx="S3bucket_node3",
)

job.commit()

```

## To generate a sample script

1. Complete the AWS Glue Studio tutorial. To complete this tutorial, see [Creating a job in AWS Glue Studio from an example job](#).
2. Navigate to the **Script** tab on the job page, as shown in the following screenshot:

The screenshot shows the AWS Glue Studio interface. At the top, there's a navigation bar with 'Visual', 'Script', 'Job details', 'Runs', and 'Schedules' tabs. The 'Script' tab is selected. Below the tabs, there's a header for the script, 'Tutorial: Getting started with AWS Glue Studio', with a 'Save' button, a 'Delete' button, an 'Actions' dropdown, and a 'Run' button. The script content is displayed in a code editor. The code is as follows:

```

1 import sys
2 from aws glue.transforms import *
3 from aws glue.utils import getResolvedOptions
4 from pyspark.context import SparkContext
5 from aws glue.context import GlueContext
6 from aws glue.job import Job
7
8 args = getResolvedOptions(sys.argv, ["JOB_NAME"])
9 sc = SparkContext()
10 glueContext = GlueContext(sc)
11 spark = glueContext.spark_session
12 job = Job(glueContext)
13 job.init(args["JOB_NAME"], args)
14
15 # Script generated for node S3 bucket
16 S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(
17     database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"
18 )
19
20 # Script generated for node ApplyMapping
21 ApplyMapping_node2 = ApplyMapping.apply(
22     frame=S3bucket_node1,
23     mappings=[
24         ("tag_number_masked", "string", "tag_number_masked", "string"),
25         ("date_of_infraction", "string", "date_of_infraction", "string"),
26         ("ticket_date", "string", "ticket_date", "string"),
27         ("ticket_number", "decimal", "ticket_number", "float"),
28         ("officer", "decimal", "officer_name", "decimal"),

```

3. Copy the complete contents of the **Script** tab. By setting the script language in **Job details**, you can switch back and forth between generating Python or Scala code.

## Step 1. Create a job and paste your script

In this step, you create an AWS Glue job in the AWS Management Console. This sets up a configuration that allows AWS Glue to run your script. It also creates a place for you to store and edit your script.

### To create a job

1. In the AWS Management Console, navigate to the AWS Glue landing page.
2. In the side navigation pane, choose **Jobs**.
3. Choose **Spark script editor in Create job**, and then choose **Create**.
4. **Optional** - Paste the full text of your script into the **Script** pane. Alternatively, you can follow along with the tutorial.

## Step 2. Import AWS Glue libraries

You need to set your script up to interact with code and configuration that are defined outside of the script. This work is done behind the scenes in AWS Glue Studio.

In this step, you perform the following actions.

- Import and initialize a `GlueContext` object. This is the most important import, from the script writing perspective. This exposes standard methods for defining source and target datasets, which is the starting point for any ETL script. To learn more about the `GlueContext` class, see [GlueContext class](#).
- Initialize a `SparkContext` and `SparkSession`. These allow you to configure the Spark engine available inside the AWS Glue job. You won't need to use them directly within introductory AWS Glue scripts.
- Call `getResolvedOptions` to prepare your job arguments for use within the script. For more information about resolving job parameters, see [the section called "getResolvedOptions"](#).
- Initialize a `Job`. The `Job` object sets configuration and tracks the state of various optional AWS Glue features. Your script can run without a `Job` object, but the best practice is to initialize it so that you don't encounter confusion if those features are later integrated.

One of these features is job bookmarks, which you can optionally configure in this tutorial. You can learn about job bookmarks in the following section, [the section called "Optional - Enable job bookmarks"](#).

In this procedure, you write the following code. This code is a portion of the generated sample script.

```
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args["JOB_NAME"], args)
```

### To import AWS Glue libraries

- Copy this section of code and paste it into the **Script** editor.

#### Note

You might consider copying code to be a bad engineering practice. In this tutorial, we suggest this to encourage you to consistently name your core variables across all AWS Glue ETL scripts.

### Step 3. Extract data from a source

In any ETL process, you first need to define a source dataset that you want to change. In the AWS Glue Studio visual editor, you provide this information by creating a **Source** node.

In this step, you provide the `create_dynamic_frame.from_catalog` method a database and `table_name` to extract data from a source configured in the AWS Glue Data Catalog.

In the previous step, you initialized a `GlueContext` object. You use this object to find methods that are used to configure sources, such as `create_dynamic_frame.from_catalog`.

In this procedure, you write the following code using `create_dynamic_frame.from_catalog`. This code is a portion of the generated sample script.

```
S3bucket_node1 = glueContext.create_dynamic_frame.from_catalog(  
    database="yyz-tickets", table_name="tickets", transformation_ctx="S3bucket_node1"  
)
```

## To extract data from a source

1. Examine the documentation to find a method on `GlueContext` to extract data from a source defined in the AWS Glue Data Catalog. These methods are documented in [the section called "GlueContext"](#). Choose the [create\\_dynamic\\_frame.from\\_catalog](#) method. Call this method on `glueContext`.
2. Examine the documentation for `create_dynamic_frame.from_catalog`. This method requires `database` and `table_name` parameters. Provide the necessary parameters to `create_dynamic_frame.from_catalog`.

The AWS Glue Data Catalog stores information about the location and format of your source data, and was set up in the prerequisite section. You don't have to directly provide your script with that information.

3. **Optional** – Provide the `transformation_ctx` parameter to the method in order to support job bookmarks. You can learn about job bookmarks in the following section, [the section called "Optional - Enable job bookmarks"](#).

### Note

#### Common methods for extracting data

[the section called "create\\_dynamic\\_frame\\_from\\_catalog"](#) is used to connect to tables in the AWS Glue Data Catalog.

If you need to directly provide your job with configuration that describes the structure and location of your source, see the [the section called "create\\_dynamic\\_frame\\_from\\_options"](#) method. You will need to provide more detailed parameters describing your data than when using `create_dynamic_frame.from_catalog`.

Refer to the supplemental documentation about `format_options` and `connection_parameters` to identify your required parameters. For an explanation of how to provide your script information about your source data format, see [the section called "Data format options"](#). For an explanation of how to provide your script information about your source data location, see [the section called "Connection parameters"](#).

If you're reading information from a streaming source, you provide your job with source information through the [the section called "create\\_data\\_frame\\_from\\_catalog"](#) or [the section called "create\\_data\\_frame\\_from\\_options"](#) methods. Note that these methods return Apache Spark DataFrames.

Our generated code calls `create_dynamic_frame.from_catalog` while the reference documentation refers to `create_dynamic_frame_from_catalog`. These methods ultimately call the same code, and are included so you can write cleaner code. You can verify this by viewing the source for our Python wrapper, available at [aws-glue-libs](#).

## Step 4. Transform data with AWS Glue

After extracting source data in an ETL process, you need to describe how you want to change your data. You provide this information by creating a **Transform** node in the AWS Glue Studio visual editor.

In this step, you provide the `ApplyMapping` method with a map of current and desired field names and types to transform your `DynamicFrame`.

You perform the following transformations.

- Drop the four `location` and `province` keys.
- Change the name of `officer` to `officer_name`.
- Change the type of `ticket_number` and `set_fine_amount` to `float`.

`create_dynamic_frame.from_catalog` provides you with a `DynamicFrame` object. A `DynamicFrame` represents a dataset in AWS Glue. AWS Glue transforms are operations that change `DynamicFrames`.

### Note

What is a `DynamicFrame`?

A `DynamicFrame` is an abstraction that allows you to connect a dataset with a description of the names and types of entries in the data. In Apache Spark, a similar abstraction exists called a `DataFrame`. For an explanation of `DataFrames`, see [Spark SQL Guide](#).

With `DynamicFrames`, you can describe dataset schemas dynamically. Consider a dataset with a `price` column, where some entries store price as a string, and others store price as

a double. AWS Glue computes a schema on-the-fly—it creates a self-describing record for each row.

Inconsistent fields (like price) are explicitly represented with a type (`ChoiceType`) in the schema for the frame. You can address your inconsistent fields by dropping them with `DropFields` or resolving them with `ResolveChoice`. These are transforms that are available on the `DynamicFrame`. You can then write your data back to your data lake with `writeDynamicFrame`.

You can call many of the same transforms from methods on the `DynamicFrame` class, which can lead to more readable scripts. For more information about `DynamicFrame`, see [the section called “DynamicFrame”](#).

In this procedure, you write the following code using `ApplyMapping`. This code is a portion of the generated sample script.

```
ApplyMapping_node2 = ApplyMapping.apply(  
    frame=S3bucket_node1,  
    mappings=[  
        ("tag_number_masked", "string", "tag_number_masked", "string"),  
        ("date_of_infraction", "string", "date_of_infraction", "string"),  
        ("ticket_date", "string", "ticket_date", "string"),  
        ("ticket_number", "decimal", "ticket_number", "float"),  
        ("officer", "decimal", "officer_name", "decimal"),  
        ("infraction_code", "decimal", "infraction_code", "decimal"),  
        ("infraction_description", "string", "infraction_description", "string"),  
        ("set_fine_amount", "decimal", "set_fine_amount", "float"),  
        ("time_of_infraction", "decimal", "time_of_infraction", "decimal"),  
    ],  
    transformation_ctx="ApplyMapping_node2",  
)
```

## To transform data with AWS Glue

1. Examine the documentation to identify a transform to change and drop fields. For details, see [the section called “GlueTransform”](#). Choose the `ApplyMapping` transform. For more information about `ApplyMapping`, see [the section called “ApplyMapping”](#). Call `apply` on the `ApplyMapping` transform object.

**Note**

What is ApplyMapping?

ApplyMapping takes a DynamicFrame and transforms it. It takes a list of tuples that represent transformations on fields—a "mapping". The first two tuple elements, a field name and type, are used to identify a field in the frame. The second two parameters are also a field name and type.

ApplyMapping converts the source field to the target name and type in a new DynamicFrame, which it returns. Fields that aren't provided are dropped in the return value.

Rather than calling apply, you can call the same transform with the apply\_mapping method on the DynamicFrame to create more fluent, readable code. For more information, see [the section called "apply\\_mapping"](#).

2. Examine the documentation for ApplyMapping to identify required parameters. See [the section called "ApplyMapping"](#). You will find that this method requires frame and mappings parameters. Provide the necessary parameters to ApplyMapping.
3. **Optional** – Provide transformation\_ctx to the method to support job bookmarks. You can learn about job bookmarks in the following section, [the section called "Optional - Enable job bookmarks"](#).

**Note****Apache Spark functionality**

We provide transforms to streamline ETL workflows within your job. You also have access to the libraries that are available in a Spark program in your job, built for more general purposes. In order to use them, you convert between DynamicFrame and DataFrame. You can create a DataFrame with [the section called "toDF"](#). Then, you can use methods available on the DataFrame to transform your dataset. For more information on these methods, see [DataFrame](#). You can then convert backwards with [the section called "fromDF"](#) to use AWS Glue operations for loading your frame to a target.

## Step 5. Load data into a target

After you transform your data, you typically store the transformed data in a different place from the source. You perform this operation by creating a **target** node in the AWS Glue Studio visual editor.

In this step, you provide the `write_dynamic_frame.from_options` method a `connection_type`, `connection_options`, `format`, and `format_options` to load data into a target bucket in Amazon S3.

In Step 1, you initialized a `GlueContext` object. In AWS Glue, this is where you will find methods that are used to configure targets, much like sources.

In this procedure, you write the following code using `write_dynamic_frame.from_options`. This code is a portion of the generated sample script.

```
S3bucket_node3 = glueContext.write_dynamic_frame.from_options(  
    frame=ApplyMapping_node2,  
    connection_type="s3",  
    format="glueparquet",  
    connection_options={"path": "s3://DOC-EXAMPLE-BUCKET", "partitionKeys": []},  
    format_options={"compression": "gzip"},  
    transformation_ctx="S3bucket_node3",  
)
```

### To load data into a target

1. Examine the documentation to find a method to load data into a target Amazon S3 bucket. These methods are documented in [the section called “GlueContext”](#). Choose the [the section called “write\\_dynamic\\_frame\\_from\\_options”](#) method. Call this method on `glueContext`.

#### Note

##### Common methods for loading data

`write_dynamic_frame.from_options` is the most common method used to load data. It supports all targets that are available in AWS Glue.

If you're writing to a JDBC target defined in an AWS Glue connection, use the [the section called “write\\_dynamic\\_frame\\_from\\_jdbc\\_conf”](#) method. AWS Glue connections store information about how to connect to a data source. This removes the need to

provide that information in `connection_options`. However, you still need to use `connection_options` to provide `dbtable`.  
`write_dynamic_frame.from_catalog` is not a common method for loading data. This method updates the AWS Glue Data Catalog without updating the underlying dataset, and is used in combination with other processes that change the underlying dataset. For more information, see [the section called “Updating the schema and adding new partitions”](#).

2. Examine the documentation for [the section called “write\\_dynamic\\_frame\\_from\\_options”](#). This method requires `frame`, `connection_type`, `format`, `connection_options`, and `format_options`. Call this method on `glueContext`.
  - a. Refer to the supplemental documentation about `format_options` and `format` to identify the parameters you need. For an explanation of data formats, see [the section called “Data format options”](#).
  - b. Refer to the supplemental documentation about `connection_type` and `connection_options` to identify the parameters you need. For an explanation of connections, see [the section called “Connection parameters”](#).
  - c. Provide the necessary parameters to `write_dynamic_frame.from_options`. This method has a similar configuration to `create_dynamic_frame.from_options`.
3. **Optional** – Provide `transformation_ctx` to `write_dynamic_frame.from_options` to support job bookmarks. You can learn about job bookmarks in the following section, [the section called “Optional - Enable job bookmarks”](#).

## Step 6. Commit the Job object

You initialized a Job object in Step 1. You need to manually conclude its lifecycle at the end of your script. Certain optional features need this to function properly. This work is done behind the scenes in AWS Glue Studio.

In this step, call the `commit` method on the Job object.

In this procedure, you write the following code. This code is a portion of the generated sample script.

```
job.commit()
```

## To commit the Job object

1. If you have not yet done this, perform the optional steps outlined in previous sections to include `transformation_ctx`.
2. Call `commit`.

## Optional - Enable job bookmarks

In every prior step, you have been instructed to set `transformation_ctx` parameters. This is related to a feature called job bookmarks.

With job bookmarks, you can save time and money with jobs that run on a recurring basis, against datasets where previous work can easily be tracked. Job bookmarks track the progress of an AWS Glue transform across a dataset from previous runs. By tracking where previous runs ended, AWS Glue can limit its work to rows it hasn't processed before. For more information about job bookmarks, see [the section called "Tracking processed data using job bookmarks"](#).

To enable job bookmarks, first add the `transformation_ctx` statements into our provided functions, as described in the previous examples. Job bookmark state is persisted across runs. `transformation_ctx` parameters are keys used to access that state. On their own, these statements will do nothing. You also need to activate the feature in the configuration for your job.

In this procedure, you enable job bookmarks using the AWS Management Console.

### To enable job bookmarks

1. Navigate to the **Job details** section of your corresponding job.
2. Set **Job bookmark** to **Enable**.

## Step 7. Run your code as a job

In this step, you run your job to verify that you successfully completed this tutorial. This is done with the click of a button, as in the AWS Glue Studio visual editor.

### To run your code as a job

1. Choose **Untitled job** on the title bar to edit and set your job name.

2. Navigate to the **Job details** tab. Assign your job an **IAM Role**. You can use the one created by the AWS CloudFormation template in the prerequisites for the AWS Glue Studio tutorial. If you have completed that tutorial, it should be available as `AWS Glue StudioRole`.
3. Choose **Save** to save your script.
4. Choose **Run** to run your job.
5. Navigate to the **Runs** tab to verify that your job completes.
6. Navigate to `DOC-EXAMPLE-BUCKET`, the target for `write_dynamic_frame.from_options`. Confirm that the output matches your expectations.

For more information about configuring and managing jobs, see [the section called “Providing your own custom scripts”](#).

## More information

Apache Spark libraries and methods are available in AWS Glue scripts. You can look at the Spark documentation to understand what you can do with those included libraries. For more information, see the [examples section of the Spark source repository](#).

AWS Glue 2.0+ includes several common Python libraries by default. There are also mechanisms for loading your own dependencies into an AWS Glue job in a Scala or Python environment. For information about Python dependencies, see [the section called “Python libraries”](#).

For more examples of how to use AWS Glue features in Python, see [the section called “Python samples”](#). Scala and Python jobs have feature parity, so our Python examples should give you some thoughts about how to perform similar work in Scala.

## Program AWS Glue ETL scripts in PySpark

You can find Python code examples and utilities for AWS Glue in the [AWS Glue samples repository](#) on the GitHub website.

## Using Python with AWS Glue

AWS Glue supports an extension of the PySpark Python dialect for scripting extract, transform, and load (ETL) jobs. This section describes how to use Python in ETL scripts and with the AWS Glue API.

- [Setting up to use Python with AWS Glue](#)

- [Calling AWS Glue APIs in Python](#)
- [Using Python libraries with AWS Glue](#)
- [AWS Glue Python code samples](#)

## AWS Glue PySpark extensions

AWS Glue has created the following extensions to the PySpark Python dialect.

- [Accessing parameters using `getResolvedOptions`](#)
- [PySpark extension types](#)
- [DynamicFrame class](#)
- [DynamicFrameCollection class](#)
- [DynamicFrameWriter class](#)
- [DynamicFrameReader class](#)
- [GlueContext class](#)

## AWS Glue PySpark transforms

AWS Glue has created the following transform Classes to use in PySpark ETL operations.

- [GlueTransform base class](#)
- [ApplyMapping class](#)
- [DropFields class](#)
- [DropNullFields class](#)
- [ErrorsAsDynamicFrame class](#)
- [FillMissingValues class](#)
- [Filter class](#)
- [FindIncrementalMatches class](#)
- [FindMatches class](#)
- [FlatMap class](#)
- [Join class](#)
- [Map class](#)

- [MapToCollection class](#)
- [mergeDynamicFrame](#)
- [Relationalize class](#)
- [RenameField class](#)
- [ResolveChoice class](#)
- [SelectFields class](#)
- [SelectFromCollection class](#)
- [Spigot class](#)
- [SplitFields class](#)
- [SplitRows class](#)
- [Unbox class](#)
- [UnnestFrame class](#)

## Setting up to use Python with AWS Glue

Use Python to develop your ETL scripts for Spark jobs. The supported Python versions for ETL jobs depend on the AWS Glue version of the job. For more information on AWS Glue versions, see the [Glue version job property](#).

### To set up your system for using Python with AWS Glue

Follow these steps to install Python and to be able to invoke the AWS Glue APIs.

1. If you don't already have Python installed, download and install it from the [Python.org download page](#).
2. Install the AWS Command Line Interface (AWS CLI) as documented in the [AWS CLI documentation](#).

The AWS CLI is not directly necessary for using Python. However, installing and configuring it is a convenient way to set up AWS with your account credentials and verify that they work.

3. Install the AWS SDK for Python (Boto 3), as documented in the [Boto3 Quickstart](#) .

Boto 3 resource APIs are not yet available for AWS Glue. Currently, only the Boto 3 client APIs can be used.

For more information about Boto 3, see [AWS SDK for Python \(Boto3\) Getting Started](#).

You can find Python code examples and utilities for AWS Glue in the [AWS Glue samples repository](#) on the GitHub website.

## Calling AWS Glue APIs in Python

Note that Boto 3 resource APIs are not yet available for AWS Glue. Currently, only the Boto 3 client APIs can be used.

### AWS Glue API names in Python

AWS Glue API names in Java and other programming languages are generally CamelCased. However, when called from Python, these generic names are changed to lowercase, with the parts of the name separated by underscore characters to make them more "Pythonic". In the [AWS Glue API](#) reference documentation, these Pythonic names are listed in parentheses after the generic CamelCased names.

However, although the AWS Glue API names themselves are transformed to lowercase, their parameter names remain capitalized. It is important to remember this, because parameters should be passed by name when calling AWS Glue APIs, as described in the following section.

### Passing and accessing Python parameters in AWS Glue

In Python calls to AWS Glue APIs, it's best to pass parameters explicitly by name. For example:

```
job = glue.create_job(Name='sample', Role='Glue_DefaultRole',
                     Command={'Name': 'glueetl',
                              'ScriptLocation': 's3://my_script_bucket/scripts/
my_etl_script.py'})
```

It is helpful to understand that Python creates a dictionary of the name/value tuples that you specify as arguments to an ETL script in a [Job structure](#) or [JobRun structure](#). Boto 3 then passes them to AWS Glue in JSON format by way of a REST API call. This means that you cannot rely on the order of the arguments when you access them in your script.

For example, suppose that you're starting a JobRun in a Python Lambda handler function, and you want to specify several parameters. Your code might look something like the following:

```
from datetime import datetime, timedelta
```

```

client = boto3.client('glue')

def lambda_handler(event, context):
    last_hour_date_time = datetime.now() - timedelta(hours = 1)
    day_partition_value = last_hour_date_time.strftime("%Y-%m-%d")
    hour_partition_value = last_hour_date_time.strftime("%-H")

    response = client.start_job_run(
        JobName = 'my_test_job',
        Arguments = {
            '--day_partition_key': 'partition_0',
            '--hour_partition_key': 'partition_1',
            '--day_partition_value': day_partition_value,
            '--hour_partition_value': hour_partition_value } )

```

To access these parameters reliably in your ETL script, specify them by name using AWS Glue's `getResolvedOptions` function and then access them from the resulting dictionary:

```

import sys
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv,
                          ['JOB_NAME',
                           'day_partition_key',
                           'hour_partition_key',
                           'day_partition_value',
                           'hour_partition_value'])
print "The day partition key is: ", args['day_partition_key']
print "and the day partition value is: ", args['day_partition_value']

```

If you want to pass an argument that is a nested JSON string, to preserve the parameter value as it gets passed to your AWS Glue ETL job, you must encode the parameter string before starting the job run, and then decode the parameter string before referencing it your job script. For example, consider the following argument string:

```

glue_client.start_job_run(JobName = "gluejobname", Arguments={
"--my_curly_braces_string": '{"a": {"b": {"c": [{"d": {"e": 42}]}}}'
})

```

To pass this parameter correctly, you should encode the argument as a Base64 encoded string.

```

import base64
...
sample_string='{"a": {"b": {"c": [{"d": {"e": 42}}]}}}'
sample_string_bytes = sample_string.encode("ascii")

base64_bytes = base64.b64encode(sample_string_bytes)
base64_string = base64_bytes.decode("ascii")
...
glue_client.start_job_run(JobName = "gluejobname", Arguments={
"--my_curly_braces_string": base64_bytes})
...
sample_string_bytes = base64.b64decode(base64_bytes)
sample_string = sample_string_bytes.decode("ascii")
print(f"Decoded string: {sample_string}")
...

```

### Example: Create and run a job

The following example shows how call the AWS Glue APIs using Python, to create and run an ETL job.

#### To create and run a job

1. Create an instance of the AWS Glue client:

```

import boto3
glue = boto3.client(service_name='glue', region_name='us-east-1',
                    endpoint_url='https://glue.us-east-1.amazonaws.com')

```

2. Create a job. You must use `glueetl` as the name for the ETL command, as shown in the following code:

```

myJob = glue.create_job(Name='sample', Role='Glue_DefaultRole',
                        Command={'Name': 'glueetl',
                                'ScriptLocation': 's3://my_script_bucket/
scripts/my_etl_script.py'})

```

3. Start a new run of the job that you created in the previous step:

```

myNewJobRun = glue.start_job_run(JobName=myJob['Name'])

```

4. Get the job status:

```
status = glue.get_job_run(JobName=myJob['Name'], RunId=myNewJobRun['JobRunId'])
```

5. Print the current state of the job run:

```
print(status['JobRun']['JobRunState'])
```

## Using Python libraries with AWS Glue

AWS Glue lets you install additional Python modules and libraries for use with AWS Glue ETL.

### Topics

- [Installing additional Python modules with pip in AWS Glue 2.0+](#)
- [Including Python files with PySpark native features](#)
- [Programming scripts that use visual transforms](#)
- [Python modules already provided in AWS Glue](#)
- [Zipping libraries for inclusion](#)
- [Loading Python libraries in a development endpoint](#)
- [Using Python libraries in a job or JobRun](#)

### Installing additional Python modules with pip in AWS Glue 2.0+

AWS Glue uses the Python Package Installer (pip3) to install additional modules to be used by AWS Glue ETL. You can use the `--additional-python-modules` parameter with a list of comma-separated Python modules to add a new module or change the version of an existing module. You can install custom distributions of a library by uploading the distribution to Amazon S3, then include the path to the Amazon S3 object in your list of modules.

You can pass additional options to pip3 with the `--python-modules-installer-option` parameter. For example, you could pass `--upgrade` to upgrade the packages specified by `--additional-python-modules`. For more examples, see [Building Python modules from a wheel for Spark ETL workloads using AWS Glue 2.0](#).

If your Python dependencies transitively depend on native, compiled code, you may run against the following limitation: AWS Glue does not support compiling native code in the job environment. However, AWS Glue jobs run within an Amazon Linux 2 environment. You may be able to provide your native dependencies in a compiled form through a Wheel distributable.

For example to update or to add a new `scikit-learn` module use the following key/value: `--additional-python-modules", "scikit-learn==0.21.3"`.

Also, within the `--additional-python-modules` option you can specify an Amazon S3 path to a Python wheel module. For example:

```
--additional-python-modules s3://aws-glue-native-spark/tests/j4.2/ephem-3.7.7.1-cp37-cp37m-linux_x86_64.whl,s3://aws-glue-native-spark/tests/j4.2/fbprophet-0.6-py3-none-any.whl,scikit-learn==0.21.3
```

You specify the `--additional-python-modules` in the **Job parameters** field of the AWS Glue console or by altering the job arguments in the AWS SDK. For more information about setting job parameters, see [the section called “Job parameters”](#).

### Including Python files with PySpark native features

AWS Glue uses PySpark to include Python files in AWS Glue ETL jobs. You will want to use `--additional-python-modules` to manage your dependencies when available. You can use the `--extra-py-files` job parameter to include Python files. Dependencies must be hosted in Amazon S3 and the argument value should be a comma delimited list of Amazon S3 paths with no spaces. This functionality behaves like the Python dependency management you would use with Spark. For more information on Python dependency management in Spark, see [Using PySpark Native Features](#) page in Apache Spark documentation. `--extra-py-files` is useful in cases where your additional code is not packaged, or when you are migrating a Spark program with an existing toolchain for managing dependencies. For your dependency tooling to be maintainable, you will have to bundle your dependencies before submitting.

### Programming scripts that use visual transforms

When you create a AWS Glue job using the AWS Glue Studio visual interface, you can transform your data with managed data transform nodes and custom visual transforms. For more information about managed data transform nodes, see [the section called “Editing AWS Glue managed data transform nodes”](#). For more information about custom visual transforms, see [the section called “Custom visual transforms”](#). Scripts using visual transforms can only be generated when when your job **Language** is set to use Python.

When generating a AWS Glue job using visual transforms, AWS Glue Studio will include these transforms in the runtime environment using the `--extra-py-files` parameter in the job configuration. For more information about job parameters, see [the section called “Job parameters”](#).

When making changes to a generated script or runtime environment, you will need to preserve this job configuration for your script to run successfully.

## Python modules already provided in AWS Glue

To change the version of these provided modules, provide new versions with the `--additional-python-modules` job parameter.

### AWS Glue version 2.0

AWS Glue version 2.0 includes the following Python modules out of the box:

- `avro-python3==1.10.0`
- `awscli==1.27.60`
- `boto3==1.12.4`
- `botocore==1.15.4`
- `certifi==2019.11.28`
- `chardet==3.0.4`
- `click==8.1.3`
- `colorama==0.4.4`
- `cycler==0.10.0`
- `Cython==0.29.15`
- `docutils==0.15.2`
- `enum34==1.1.9`
- `fsspec==0.6.2`
- `idna==2.9`
- `importlib-metadata==6.0.0`
- `jmespath==0.9.4`
- `joblib==0.14.1`
- `kiwisolver==1.1.0`
- `matplotlib==3.1.3`
- `mpmath==1.1.0`

- nltk==3.5
- numpy==1.18.1
- pandas==1.0.1
- patsy==0.5.1
- pmdarima==1.5.3
- ptvsd==4.3.2
- pyarrow==0.16.0
- pyasn1==0.4.8
- pydevd==1.9.0
- pyhocon==0.3.54
- PyMySQL==0.9.3
- pyparsing==2.4.6
- python-dateutil==2.8.1
- pytz==2019.3
- PyYAML==5.3.1
- regex==2022.10.31
- requests==2.23.0
- rsa==4.7.2
- s3fs==0.4.0
- s3transfer==0.3.3
- scikit-learn==0.22.1
- scipy==1.4.1
- setuptools==45.2.0
- six==1.14.0
- Spark==1.0
- statsmodels==0.11.1
- subprocess32==3.5.4
- sympy==1.5.1
- tbats==1.0.9

- tqdm==4.64.1
- typing-extensions==4.4.0
- urllib3==1.25.8
- wheel==0.35.1
- zipp==3.12.0

## AWS Glue version 3.0

AWS Glue version 3.0 includes the following Python modules out of the box,

- aiobotocore==1.4.2
- aiohttp==3.8.3
- aioitertools==0.11.0
- aiosignal==1.3.1
- async-timeout==4.0.2
- asyncctest==0.13.0
- attrs==22.2.0
- avro-python3==1.10.2
- boto3==1.18.50
- botocore==1.21.50
- certifi==2021.5.30
- chardet==3.0.4
- charset-normalizer==2.1.1
- click==8.1.3
- cycler==0.10.0
- Cython==0.29.4
- docutils==0.17.1
- enum34==1.1.10
- frozenlist==1.3.3
- fsspec==2021.8.1

- idna==2.10
- importlib-metadata==6.0.0
- jmespath==0.10.0
- joblib==1.0.1
- kiwisolver==1.3.2
- matplotlib==3.4.3
- mpmath==1.2.1
- multidict==6.0.4
- nltk==3.6.3
- numpy==1.19.5
- packaging==23.0
- pandas==1.3.2
- patsy==0.5.1
- Pillow==9.4.0
- pip==23.0
- pmdarima==1.8.2
- ptvsd==4.3.2
- pyarrow==5.0.0
- pydevd==2.5.0
- pyhocon==0.3.58
- PyMySQL==1.0.2
- pyparsing==2.4.7
- python-dateutil==2.8.2
- pytz==2021.1
- PyYAML==5.4.1
- regex==2022.10.31
- requests==2.23.0
- s3fs==2021.8.1
- s3transfer==0.5.0

- scikit-learn==0.24.2
- scipy==1.7.1
- six==1.16.0
- Spark==1.0
- statsmodels==0.12.2
- subprocess32==3.5.4
- sympy==1.8
- tbats==1.1.0
- threadpoolctl==3.1.0
- tqdm==4.64.1
- typing\_extensions==4.4.0
- urllib3==1.25.11
- wheel==0.37.0
- wrapt==1.14.1
- yarl==1.8.2
- zipp==3.12.0

## AWS Glue version 4.0

AWS Glue version 4.0 includes the following Python modules out of the box:

- aiobotocore==2.4.1
- aiohttp==3.8.3
- aioitertools==0.11.0
- aiosignal==1.3.1
- async-timeout==4.0.2
- asynctest==0.13.0
- attrs==22.2.0
- avro-python3==1.10.2
- boto3==1.24.70

- `botocore==1.27.59`
- `certifi==2021.5.30`
- `chardet==3.0.4`
- `charset-normalizer==2.1.1`
- `click==8.1.3`
- `cycler==0.10.0`
- `Cython==0.29.32`
- `docutils==0.17.1`
- `enum34==1.1.10`
- `frozenset==1.3.3`
- `fsspec==2021.8.1`
- `idna==2.10`
- `importlib-metadata==5.0.0`
- `jmespath==0.10.0`
- `joblib==1.0.1`
- `kaleido==0.2.1`
- `kiwisolver==1.4.4`
- `matplotlib==3.4.3`
- `mpmath==1.2.1`
- `multidict==6.0.4`
- `nltk==3.7`
- `numpy==1.23.5`
- `packaging==23.0`
- `pandas==1.5.1`
- `patsy==0.5.1`
- `Pillow==9.4.0`
- `pip==23.0.1`
- `plotly==5.16.0`
- `pmdarima==2.0.1`

- ptvsd==4.3.2
- pyarrow==10.0.0
- pydevd==2.5.0
- pyhocon==0.3.58
- PyMySQL==1.0.2
- pyparsing==2.4.7
- python-dateutil==2.8.2

## Zippping libraries for inclusion

Unless a library is contained in a single `.py` file, it should be packaged in a `.zip` archive. The package directory should be at the root of the archive, and must contain an `__init__.py` file for the package. Python will then be able to import the package in the normal way.

If your library only consists of a single Python module in one `.py` file, you do not need to place it in a `.zip` file.

## Loading Python libraries in a development endpoint

If you are using different library sets for different ETL scripts, you can either set up a separate development endpoint for each set, or you can overwrite the library `.zip` file(s) that your development endpoint loads every time you switch scripts.

You can use the console to specify one or more library `.zip` files for a development endpoint when you create it. After assigning a name and an IAM role, choose **Script Libraries and job parameters (optional)** and enter the full Amazon S3 path to your library `.zip` file in the **Python library path** box. For example:

```
s3://bucket/prefix/site-packages.zip
```

If you want, you can specify multiple full paths to files, separating them with commas but no spaces, like this:

```
s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/lib_X.zip
```

If you update these `.zip` files later, you can use the console to re-import them into your development endpoint. Navigate to the developer endpoint in question, check the box beside it, and choose **Update ETL libraries** from the **Action** menu.

In a similar way, you can specify library files using the AWS Glue APIs. When you create a development endpoint by calling [CreateDevEndpoint action \(Python: create\\_dev\\_endpoint\)](#), you can specify one or more full paths to libraries in the `ExtraPythonLibsS3Path` parameter, in a call that looks this:

```
dep = glue.create_dev_endpoint(  
    EndpointName="testDevEndpoint",  
    RoleArn="arn:aws:iam::123456789012",
```

```
SecurityGroupIds="sg-7f5ad1ff",
SubnetId="subnet-c12fdb4",
PublicKey="ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAQCTp04H/y...",
NumberOfNodes=3,
ExtraPythonLibsS3Path="s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/
lib_X.zip")
```

When you update a development endpoint, you can also update the libraries it loads using a [DevEndpointCustomLibraries](#) object and setting the `UpdateEtlLibraries` parameter to `True` when calling [UpdateDevEndpoint \(update\\_dev\\_endpoint\)](#).

## Using Python libraries in a job or JobRun

When you are creating a new Job on the console, you can specify one or more library .zip files by choosing **Script Libraries and job parameters (optional)** and entering the full Amazon S3 library path(s) in the same way you would when creating a development endpoint:

```
s3://bucket/prefix/lib_A.zip,s3://bucket_B/prefix/lib_X.zip
```

If you are calling [CreateJob \(create\\_job\)](#), you can specify one or more full paths to default libraries using the `--extra-py-files` default parameter, like this:

```
job = glue.create_job(Name='sampleJob',
                      Role='Glue_DefaultRole',
                      Command={'Name': 'glueetl',
                                'ScriptLocation': 's3://my_script_bucket/scripts/
my_etl_script.py'},
                      DefaultArguments={'--extra-py-files': 's3://bucket/prefix/
lib_A.zip,s3://bucket_B/prefix/lib_X.zip'})
```

Then when you are starting a JobRun, you can override the default library setting with a different one:

```
runId = glue.start_job_run(JobName='sampleJob',
                           Arguments={'--extra-py-files': 's3://bucket/prefix/
lib_B.zip'})
```

## AWS Glue Python code samples

- [Code example: Joining and relationalizing data](#)

- [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#)

### Code example: Joining and relationalizing data

This example uses a dataset that was downloaded from <http://everypolitician.org/> to the sample-dataset bucket in Amazon Simple Storage Service (Amazon S3): `s3://awsglue-datasets/examples/us-legislators/all`. The dataset contains data in JSON format about United States legislators and the seats that they have held in the US House of Representatives and Senate, and has been modified slightly and made available in a public Amazon S3 bucket for purposes of this tutorial.

You can find the source code for this example in the `join_and_relationalize.py` file in the [AWS Glue samples repository](#) on the GitHub website.

Using this data, this tutorial shows you how to do the following:

- Use an AWS Glue crawler to classify objects that are stored in a public Amazon S3 bucket and save their schemas into the AWS Glue Data Catalog.
- Examine the table metadata and schemas that result from the crawl.
- Write a Python extract, transfer, and load (ETL) script that uses the metadata in the Data Catalog to do the following:
  - Join the data in the different source files together into a single data table (that is, denormalize the data).
  - Filter the joined table into separate tables by type of legislator.
  - Write out the resulting data to separate Apache Parquet files for later analysis.

The preferred way to debug Python or PySpark scripts while running on AWS is to use [Notebooks on AWS Glue Studio](#).

### Step 1: Crawl the data in the Amazon S3 bucket

1. Sign in to the AWS Management Console, and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Following the steps in [Configuring a crawler](#), create a new crawler that can crawl the `s3://awsglue-datasets/examples/us-legislators/all` dataset into a database named `legislators` in the AWS Glue Data Catalog. The example data is already in this public Amazon S3 bucket.

### 3. Run the new crawler, and then check the legislators database.

The crawler creates the following metadata tables:

- persons\_json
- memberships\_json
- organizations\_json
- events\_json
- areas\_json
- countries\_r\_json

This is a semi-normalized collection of tables containing legislators and their histories.

## Step 2: Add boilerplate script to the development endpoint notebook

Paste the following boilerplate script into the development endpoint notebook to import the AWS Glue libraries that you need, and set up a single GlueContext:

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

glueContext = GlueContext(SparkContext.getOrCreate())
```

## Step 3: Examine the schemas from the data in the Data Catalog

Next, you can easily create examine a DynamicFrame from the AWS Glue Data Catalog, and examine the schemas of the data. For example, to see the schema of the persons\_json table, add the following in your notebook:

```
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators",
    table_name="persons_json")
print "Count: ", persons.count()
```

```
persons.printSchema()
```

Here's the output from the print calls:

```
Count: 1961
root
 |-- family_name: string
 |-- name: string
 |-- links: array
 |   |-- element: struct
 |   |   |-- note: string
 |   |   |-- url: string
 |-- gender: string
 |-- image: string
 |-- identifiers: array
 |   |-- element: struct
 |   |   |-- scheme: string
 |   |   |-- identifier: string
 |-- other_names: array
 |   |-- element: struct
 |   |   |-- note: string
 |   |   |-- name: string
 |   |   |-- lang: string
 |-- sort_name: string
 |-- images: array
 |   |-- element: struct
 |   |   |-- url: string
 |-- given_name: string
 |-- birth_date: string
 |-- id: string
 |-- contact_details: array
 |   |-- element: struct
 |   |   |-- type: string
 |   |   |-- value: string
 |-- death_date: string
```

Each person in the table is a member of some US congressional body.

To view the schema of the `memberships_json` table, type the following:

```
memberships = glueContext.create_dynamic_frame.from_catalog(
```

```
        database="legislators",
        table_name="memberships_json")
print "Count: ", memberships.count()
memberships.printSchema()
```

The output is as follows:

```
Count: 10439
root
|-- area_id: string
|-- on_behalf_of_id: string
|-- organization_id: string
|-- role: string
|-- person_id: string
|-- legislative_period_id: string
|-- start_date: string
|-- end_date: string
```

The organizations are parties and the two chambers of Congress, the Senate and House of Representatives. To view the schema of the `organizations_json` table, type the following:

```
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators",
    table_name="organizations_json")
print "Count: ", orgs.count()
orgs.printSchema()
```

The output is as follows:

```
Count: 13
root
|-- classification: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
```

```

|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- id: string
|-- name: string
|-- seats: int
|-- type: string

```

#### Step 4: Filter the data

Next, keep only the fields that you want, and rename `id` to `org_id`. The dataset is small enough that you can view the whole thing.

The `toDF()` converts a `DynamicFrame` to an Apache Spark `DataFrame`, so you can apply the transforms that already exist in Apache Spark SQL:

```

orgs = orgs.drop_fields(['other_names',
                        'identifiers']).rename_field(
    'id', 'org_id').rename_field(
    'name', 'org_name')

orgs.toDF().show()

```

The following shows the output:

```

+-----+-----+-----+-----+-----+
+-----+-----+
|classification|          org_id|          org_name|          links|seats|
|      type|          image|
+-----+-----+-----+-----+
+-----+-----+
|      party|      party/al|          AL|          null| null|
|      null|          null|
|      party|      party/democrat|      Democrat|[[website,http://...| null|
|      null|https://upload.wi...|
|      party|party/democrat-li...|      Democrat-Liberal|[[website,http://...| null|
|      null|          null|

```

```

| legislature|d56acebe-8fdc-47b...|House of Represen...| null| 435|
lower house| null|
| party| party/independent| Independent| null| null|
null| null|
| party|party/new_progres...| New Progressive|[[website,http://...| null|
null|https://upload.wi...|
| party|party/popular_dem...| Popular Democrat|[[website,http://...| null|
null| null|
| party| party/republican| Republican|[[website,http://...| null|
null|https://upload.wi...|
| party|party/republican-...|Republican-Conser...|[[website,http://...| null|
null| null|
| party| party/democrat| Democrat|[[website,http://...| null|
null|https://upload.wi...|
| party| party/independent| Independent| null| null|
null| null|
| party| party/republican| Republican|[[website,http://...| null|
null|https://upload.wi...|
| legislature|8fa6c3d2-71dc-478...| Senate| null| 100|
upper house| null|
+-----+-----+-----+-----+-----+
+-----+

```

Type the following to view the organizations that appear in memberships:

```
memberships.select_fields(['organization_id']).toDF().distinct().show()
```

The following shows the output:

```

+-----+
| organization_id|
+-----+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+-----+

```

## Step 5: Put it all together

Now, use AWS Glue to join these relational tables and create one full history table of legislator memberships and their corresponding organizations.

1. First, join persons and memberships on id and person\_id.
2. Next, join the result with orgs on org\_id and organization\_id.
3. Then, drop the redundant fields, person\_id and org\_id.

You can do all these operations in one (extended) line of code:

```
l_history = Join.apply(orgs,
                      Join.apply(persons, memberships, 'id', 'person_id'),
                      'org_id', 'organization_id').drop_fields(['person_id',
                                                                'org_id'])
print "Count: ", l_history.count()
l_history.printSchema()
```

The output is as follows:

```
Count: 10439
root
|-- role: string
|-- seats: int
|-- org_name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- type: string
|-- sort_name: string
|-- area_id: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- on_behalf_of_id: string
|-- other_names: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- name: string
|   |   |-- lang: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
```

```

|    |    |-- value: string
|-- name: string
|-- birth_date: string
|-- organization_id: string
|-- gender: string
|-- classification: string
|-- death_date: string
|-- legislative_period_id: string
|-- identifiers: array
|    |-- element: struct
|    |    |-- scheme: string
|    |    |-- identifier: string
|-- image: string
|-- given_name: string
|-- family_name: string
|-- id: string
|-- start_date: string
|-- end_date: string

```

You now have the final table that you can use for analysis. You can write it out in a compact, efficient format for analytics—namely Parquet—that you can run SQL over in AWS Glue, Amazon Athena, or Amazon Redshift Spectrum.

The following call writes the table across multiple files to support fast parallel reads when doing analysis later:

```

glueContext.write_dynamic_frame.from_options(frame = l_history,
      connection_type = "s3",
      connection_options = {"path": "s3://glue-sample-target/output-dir/
legislator_history"},
      format = "parquet")

```

To put all the history data into a single file, you must convert it to a data frame, repartition it, and write it out:

```

s_history = l_history.toDF().repartition(1)
s_history.write.parquet('s3://glue-sample-target/output-dir/legislator_single')

```

Or, if you want to separate it by the Senate and the House:

```
l_history.toDF().write.parquet('s3://glue-sample-target/output-dir/legislator_part',
                              partitionBy=['org_name'])
```

## Step 6: Transform the data for relational databases

AWS Glue makes it easy to write the data to relational databases like Amazon Redshift, even with semi-structured data. It offers a transform `relationalize`, which flattens `DynamicFrames` no matter how complex the objects in the frame might be.

Using the `l_history` `DynamicFrame` in this example, pass in the name of a root table (`hist_root`) and a temporary working path to `relationalize`. This returns a `DynamicFrameCollection`. You can then list the names of the `DynamicFrames` in that collection:

```
dfc = l_history.relationalize("hist_root", "s3://glue-sample-target/temp-dir/")
dfc.keys()
```

The following is the output of the keys call:

```
[u'hist_root', u'hist_root_contact_details', u'hist_root_links',
 u'hist_root_other_names', u'hist_root_images', u'hist_root_identifiers']
```

`Relationalize` broke the history table out into six new tables: a root table that contains a record for each object in the `DynamicFrame`, and auxiliary tables for the arrays. Array handling in relational databases is often suboptimal, especially as those arrays become large. Separating the arrays into different tables makes the queries go much faster.

Next, look at the separation by examining `contact_details`:

```
l_history.select_fields('contact_details').printSchema()
dfc.select('hist_root_contact_details').toDF().where("id = 10 or id =
75").orderBy(['id', 'index']).show()
```

The following is the output of the show call:

```

root
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
+-----+-----+-----+-----+
| id|index|contact_details.val.type|contact_details.val.value|
+-----+-----+-----+-----+
| 10|  0|          fax|          |
| 10|  1|          |      202-225-1314|
| 10|  2|        phone|          |
| 10|  3|          |      202-225-3772|
| 10|  4|       twitter|          |
| 10|  5|          |  MikeRossUpdates|
| 75|  0|          fax|          |
| 75|  1|          |      202-225-7856|
| 75|  2|        phone|          |
| 75|  3|          |      202-225-2711|
| 75|  4|       twitter|          |
| 75|  5|          |      SenCapito|
+-----+-----+-----+-----+

```

The `contact_details` field was an array of structs in the original `DynamicFrame`. Each element of those arrays is a separate row in the auxiliary table, indexed by `index`. The `id` here is a foreign key into the `hist_root` table with the key `contact_details`:

```

dfc.select('hist_root').toDF().where(
    "contact_details = 10 or contact_details = 75").select(
    ['id', 'given_name', 'family_name', 'contact_details']).show()

```

The following is the output:

```

+-----+-----+-----+-----+
|          id|given_name|family_name|contact_details|
+-----+-----+-----+-----+
|f4fc30ee-7b42-432...|    Mike|    Ross|    10|
|e3c60f34-7d1b-4c0...|  Shelley|  Capito|    75|
+-----+-----+-----+-----+

```

Notice in these commands that `toDF()` and then a `where` expression are used to filter for the rows that you want to see.

So, joining the `hist_root` table with the auxiliary tables lets you do the following:

- Load data into databases without array support.
- Query each individual item in an array using SQL.

Safely store and access your Amazon Redshift credentials with a AWS Glue connection. For information about how to create your own connection, see [Connecting to data](#).

You are now ready to write your data to a connection by cycling through the `DynamicFrames` one at a time:

```
for df_name in dfc.keys():
    m_df = dfc.select(df_name)
    print "Writing to table: ", df_name
    glueContext.write_dynamic_frame.from_jdbc_conf(frame = m_df, connection settings here)
```

Your connection settings will differ based on your type of relational database:

- For instructions on writing to Amazon Redshift consult [the section called "Redshift connections"](#).
- For other databases, consult [Connection types and options for ETL in AWS Glue for Spark](#).

## Conclusion

Overall, AWS Glue is very flexible. It lets you accomplish, in a few lines of code, what normally would take days to write. You can find the entire source-to-target ETL scripts in the Python file `join_and_relationalize.py` in the [AWS Glue samples](#) on GitHub.

## Code example: Data preparation using `ResolveChoice`, `Lambda`, and `ApplyMapping`

The dataset that is used in this example consists of Medicare Provider payment data that was downloaded from two [Data.CMS.gov](#) data sets: "Inpatient Prospective Payment System Provider Summary for the Top 100 Diagnosis-Related Groups - FY2011" and "Inpatient Charge Data FY 2011". After downloading the data, we modified the dataset to introduce a couple of erroneous

records at the end of the file. This modified file is located in a public Amazon S3 bucket at `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv`.

You can find the source code for this example in the `data_cleaning_and_lambda.py` file in the [AWS Glue examples](#) GitHub repository.

The preferred way to debug Python or PySpark scripts while running on AWS is to use [Notebooks on AWS Glue Studio](#).

### Step 1: Crawl the data in the Amazon S3 bucket

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Following the process described in [Configuring a crawler](#), create a new crawler that can crawl the `s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv` file, and can place the resulting metadata into a database named `payments` in the AWS Glue Data Catalog.
3. Run the new crawler, and then check the `payments` database. You should find that the crawler has created a metadata table named `medicare` in the database after reading the beginning of the file to determine its format and delimiter.

The schema of the new `medicare` table is as follows:

Column name	Data type
=====	
<code>drg definition</code>	<code>string</code>
<code>provider id</code>	<code>bigint</code>
<code>provider name</code>	<code>string</code>
<code>provider street address</code>	<code>string</code>
<code>provider city</code>	<code>string</code>
<code>provider state</code>	<code>string</code>
<code>provider zip code</code>	<code>bigint</code>
<code>hospital referral region description</code>	<code>string</code>
<code>total discharges</code>	<code>bigint</code>
<code>average covered charges</code>	<code>string</code>
<code>average total payments</code>	<code>string</code>
<code>average medicare payments</code>	<code>string</code>

## Step 2: Add boilerplate script to the development endpoint notebook

Paste the following boilerplate script into the development endpoint notebook to import the AWS Glue libraries that you need, and set up a single GlueContext:

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

glueContext = GlueContext(SparkContext.getOrCreate())
```

## Step 3: Compare different schema parsings

Next, you can see if the schema that was recognized by an Apache Spark DataFrame is the same as the one that your AWS Glue crawler recorded. Run this code:

```
medicare = spark.read.format(
    "com.databricks.spark.csv").option(
    "header", "true").option(
    "inferSchema", "true").load(
    's3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv')
medicare.printSchema()
```

Here's the output from the printSchema call:

```
root
 |-- DRG Definition: string (nullable = true)
 |-- Provider Id: string (nullable = true)
 |-- Provider Name: string (nullable = true)
 |-- Provider Street Address: string (nullable = true)
 |-- Provider City: string (nullable = true)
 |-- Provider State: string (nullable = true)
 |-- Provider Zip Code: integer (nullable = true)
 |-- Hospital Referral Region Description: string (nullable = true)
 |-- Total Discharges : integer (nullable = true)
 |-- Average Covered Charges : string (nullable = true)
 |-- Average Total Payments : string (nullable = true)
```

```
|-- Average Medicare Payments: string (nullable = true)
```

Next, look at the schema that an AWS Glue `DynamicFrame` generates:

```
medicare_dynamicframe = glueContext.create_dynamic_frame.from_catalog(  
    database = "payments",  
    table_name = "medicare")  
medicare_dynamicframe.printSchema()
```

The output from `printSchema` is as follows:

```
root  
|-- drg definition: string  
|-- provider id: choice  
|   |-- long  
|   |-- string  
|-- provider name: string  
|-- provider street address: string  
|-- provider city: string  
|-- provider state: string  
|-- provider zip code: long  
|-- hospital referral region description: string  
|-- total discharges: long  
|-- average covered charges: string  
|-- average total payments: string  
|-- average medicare payments: string
```

The `DynamicFrame` generates a schema in which `provider id` could be either a `long` or a `string` type. The `DataFrame` schema lists `Provider Id` as being a `string` type, and the `Data Catalog` lists `provider id` as being a `bigint` type.

Which one is correct? There are two records at the end of the file (out of 160,000 records) with `string` values in that column. These are the erroneous records that were introduced to illustrate a problem.

To address this kind of problem, the AWS Glue `DynamicFrame` introduces the concept of a *choice* type. In this case, the `DynamicFrame` shows that both `long` and `string` values can appear in that column. The AWS Glue crawler missed the `string` values because it considered only a 2 MB prefix of the data. The Apache Spark `DataFrame` considered the whole dataset, but it was forced

to assign the most general type to the column, namely `string`. In fact, Spark often resorts to the most general case when there are complex types or variations with which it is unfamiliar.

To query the provider `id` column, resolve the choice type first. You can use the `resolveChoice` transform method in your `DynamicFrame` to convert those `string` values to `long` values with a `cast:long` option:

```
medicare_res = medicare_dynamicframe.resolveChoice(specs = [('provider
id', 'cast:long']))
medicare_res.printSchema()
```

The `printSchema` output is now:

```
root
 |-- drg definition: string
 |-- provider id: long
 |-- provider name: string
 |-- provider street address: string
 |-- provider city: string
 |-- provider state: string
 |-- provider zip code: long
 |-- hospital referral region description: string
 |-- total discharges: long
 |-- average covered charges: string
 |-- average total payments: string
 |-- average medicare payments: string
```

Where the value was a `string` that could not be cast, AWS Glue inserted a `null`.

Another option is to convert the choice type to a `struct`, which keeps values of both types.

Next, look at the rows that were anomalous:

```
medicare_res.toDF().where("'provider id' is NULL").show()
```

You see the following:

```

+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
|   drg definition|provider id|  provider name|provider street address|provider
city|provider state|provider zip code|hospital referral region description|total
discharges|average covered charges|average total payments|average medicare payments|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
|948 - SIGNS & SYM...|      null|          INC|      1050 DIVISION ST|
MAUSTON|          WI|      53948|          WI - Madison|
   12|      $11961.41|          $4619.00|          $3775.33|
|948 - SIGNS & SYM...|      null| INC- ST JOSEPH|      5000 W CHAMBERS ST|
MILWAUKEE|          WI|      53210|          WI - Milwaukee|
   14|      $10514.28|          $5562.50|          $4522.78|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+

```

Now remove the two malformed records, as follows:

```

medicare_dataframe = medicare_res.toDF()
medicare_dataframe = medicare_dataframe.where("'provider id' is NOT NULL")

```

#### Step 4: Map the data and use Apache Spark Lambda functions

AWS Glue does not yet directly support Lambda functions, also known as user-defined functions. But you can always convert a `DynamicFrame` to and from an Apache Spark `DataFrame` to take advantage of Spark functionality in addition to the special features of `DynamicFrames`.

Next, turn the payment information into numbers, so analytic engines like Amazon Redshift or Amazon Athena can do their number crunching faster:

```

from pyspark.sql.functions import udf
from pyspark.sql.types import StringType

chop_f = udf(lambda x: x[1:], StringType())
medicare_dataframe = medicare_dataframe.withColumn(
    "ACC", chop_f(
        medicare_dataframe["average covered charges"])).withColumn(
    "ATP", chop_f(
        medicare_dataframe["average total payments"])).withColumn(
    "AMP", chop_f(

```

```
medicare_dataframe["average medicare payments"]))
medicare_dataframe.select(['ACC', 'ATP', 'AMP']).show()
```

The output from the show call is as follows:

```
+-----+-----+-----+
|   ACC|   ATP|   AMP|
+-----+-----+-----+
|32963.07|5777.24|4763.73|
|15131.85|5787.57|4976.71|
|37560.37|5434.95|4453.79|
|13998.28|5417.56|4129.16|
|31633.27|5658.33|4851.44|
|16920.79|6653.80|5374.14|
|11977.13|5834.74|4761.41|
|35841.09|8031.12|5858.50|
|28523.39|6113.38|5228.40|
|75233.38|5541.05|4386.94|
|67327.92|5461.57|4493.57|
|39607.28|5356.28|4408.20|
|22862.23|5374.65|4186.02|
|31110.85|5366.23|4376.23|
|25411.33|5282.93|4383.73|
| 9234.51|5676.55|4509.11|
|15895.85|5930.11|3972.85|
|19721.16|6192.54|5179.38|
|10710.88|4968.00|3898.88|
|51343.75|5996.00|4962.45|
+-----+-----+-----+
only showing top 20 rows
```

These are all still strings in the data. We can use the powerful `apply_mapping` transform method to drop, rename, cast, and nest the data so that other data programming languages and systems can easily access it:

```
from awsglue.dynamicframe import DynamicFrame
medicare_tmp_dyf = DynamicFrame.fromDF(medicare_dataframe, glueContext, "nested")
medicare_nest_dyf = medicare_tmp_dyf.apply_mapping([('drg definition', 'string', 'drg',
'provider id', 'long', 'provider.id', 'long'),
('provider name', 'string', 'provider.name', 'string'),
('provider city', 'string', 'provider.city', 'string'),
```

```

        ('provider state', 'string', 'provider.state', 'string'),
        ('provider zip code', 'long', 'provider.zip', 'long'),
        ('hospital referral region description', 'string', 'rr', 'string'),
        ('ACC', 'string', 'charges.covered', 'double'),
        ('ATP', 'string', 'charges.total_pay', 'double'),
        ('AMP', 'string', 'charges.medicare_pay', 'double']]
medicare_nest_dyf.printSchema()

```

The `printSchema` output is as follows:

```

root
 |-- drg: string
 |-- provider: struct
 |   |-- id: long
 |   |-- name: string
 |   |-- city: string
 |   |-- state: string
 |   |-- zip: long
 |-- rr: string
 |-- charges: struct
 |   |-- covered: double
 |   |-- total_pay: double
 |   |-- medicare_pay: double

```

Turning the data back into a Spark `DataFrame`, you can show what it looks like now:

```
medicare_nest_dyf.toDF().show()
```

The output is as follows:

```

+-----+-----+-----+-----+
|          drg|          provider|          rr|          charges|
+-----+-----+-----+-----+

only showing top 20 rows
```

## Step 5: Write the data to Apache Parquet

AWS Glue makes it easy to write the data in a format such as Apache Parquet that relational databases can effectively consume:

```
glueContext.write_dynamic_frame.from_options(
    frame = medicare_nest_dyf,
    connection_type = "s3",
    connection_options = {"path": "s3://glue-sample-target/output-dir/
medicare_parquet"},
    format = "parquet")
```

## AWS Glue PySpark extensions reference

AWS Glue has created the following extensions to the PySpark Python dialect.

- [Accessing parameters using getResolvedOptions](#)
- [PySpark extension types](#)
- [DynamicFrame class](#)
- [DynamicFrameCollection class](#)
- [DynamicFrameWriter class](#)
- [DynamicFrameReader class](#)
- [GlueContext class](#)

## Accessing parameters using getResolvedOptions

The AWS Glue `getResolvedOptions(args, options)` utility function gives you access to the arguments that are passed to your script when you run a job. To use this function, start by importing it from the AWS Glue `utils` module, along with the `sys` module:

```
import sys
from awsglue.utils import getResolvedOptions
```

### getResolvedOptions(args, options)

- `args` – The list of arguments contained in `sys.argv`.
- `options` – A Python array of the argument names that you want to retrieve.

### Example Retrieving arguments passed to a JobRun

Suppose that you created a `JobRun` in a script, perhaps within a Lambda function:

```
response = client.start_job_run(
    JobName = 'my_test_job',
    Arguments = {
        '--day_partition_key': 'partition_0',
        '--hour_partition_key': 'partition_1',
        '--day_partition_value': day_partition_value,
        '--hour_partition_value': hour_partition_value } )
```

To retrieve the arguments that are passed, you can use the `getResolvedOptions` function as follows:

```
import sys
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv,
                          ['JOB_NAME',
                           'day_partition_key',
                           'hour_partition_key',
                           'day_partition_value',
                           'hour_partition_value'])

print "The day-partition key is: ", args['day_partition_key']
print "and the day-partition value is: ", args['day_partition_value']
```

Note that each of the arguments are defined as beginning with two hyphens, then referenced in the script without the hyphens. The arguments use only underscores, not hyphens. Your arguments need to follow this convention to be resolved.

## PySpark extension types

The types that are used by the AWS Glue PySpark extensions.

### **DataType**

The base class for the other AWS Glue types.

#### **`__init__(properties={})`**

- `properties` – Properties of the data type (optional).

#### **`typeName(cls)`**

Returns the type of the AWS Glue type class (that is, the class name with "Type" removed from the end).

- `cls` – An AWS Glue class instance derived from `DataType`.

#### **`jsonValue( )`**

Returns a JSON object that contains the data type and properties of the class:

```
{
  "dataType": typeName,
  "properties": properties
}
```

## **AtomicType and simple derivatives**

Inherits from and extends the [DataType](#) class, and serves as the base class for all the AWS Glue atomic data types.

#### **`fromJsonValue(cls, json_value)`**

Initializes a class instance with values from a JSON object.

- `cls` – An AWS Glue type class instance to initialize.
- `json_value` – The JSON object to load key-value pairs from.

The following types are simple derivatives of the [AtomicType](#) class:

- `BinaryType` – Binary data.
- `BooleanType` – Boolean values.
- `ByteType` – A byte value.
- `DateType` – A datetime value.
- `DoubleType` – A floating-point double value.
- `IntegerType` – An integer value.
- `LongType` – A long integer value.
- `NullType` – A null value.
- `ShortType` – A short integer value.
- `StringType` – A text string.
- `TimestampType` – A timestamp value (typically in seconds from 1/1/1970).
- `UnknownType` – A value of unidentified type.

### **DecimalType(AtomicType)**

Inherits from and extends the [AtomicType](#) class to represent a decimal number (a number expressed in decimal digits, as opposed to binary base-2 numbers).

**`__init__(precision=10, scale=2, properties={})`**

- `precision` – The number of digits in the decimal number (optional; the default is 10).
- `scale` – The number of digits to the right of the decimal point (optional; the default is 2).
- `properties` – The properties of the decimal number (optional).

### **EnumType(AtomicType)**

Inherits from and extends the [AtomicType](#) class to represent an enumeration of valid options.

## **`__init__(options)`**

- `options` – A list of the options being enumerated.

### **collection types**

- [ArrayType\(DataType\)](#)
- [ChoiceType\(DataType\)](#)
- [MapType\(DataType\)](#)
- [Field\(Object\)](#)
- [StructType\(DataType\)](#)
- [EntityType\(DataType\)](#)

### **ArrayType(DataType)**

#### **`__init__(elementType=UnknownType(), properties={})`**

- `elementType` – The type of elements in the array (optional; the default is `UnknownType`).
- `properties` – Properties of the array (optional).

### **ChoiceType(DataType)**

#### **`__init__(choices=[], properties={})`**

- `choices` – A list of possible choices (optional).
- `properties` – Properties of these choices (optional).

### **add(new\_choice)**

Adds a new choice to the list of possible choices.

- `new_choice` – The choice to add to the list of possible choices.

### **merge(new\_choices)**

Merges a list of new choices with the existing list of choices.

- `new_choices` – A list of new choices to merge with existing choices.

### **MapType(DataType)**

**`__init__(valueType=UnknownType, properties={})`**

- `valueType` – The type of values in the map (optional; the default is `UnknownType`).
- `properties` – Properties of the map (optional).

### **Field(Object)**

Creates a field object out of an object that derives from [DataType](#).

**`__init__(name, dataType, properties={})`**

- `name` – The name to be assigned to the field.
- `dataType` – The object to create a field from.
- `properties` – Properties of the field (optional).

### **StructType(DataType)**

Defines a data structure (`struct`).

**`__init__(fields=[], properties={})`**

- `fields` – A list of the fields (of type `Field`) to include in the structure (optional).
- `properties` – Properties of the structure (optional).

### **add(field)**

- `field` – An object of type `Field` to add to the structure.

### **hasField(field)**

Returns `True` if this structure has a field of the same name, or `False` if not.

- `field` – A field name, or an object of type `Field` whose name is used.

### **getField(field)**

- `field` – A field name or an object of type `Field` whose name is used. If the structure has a field of the same name, it is returned.

### **EntityType(DataType)**

`__init__(entity, base_type, properties)`

This class is not yet implemented.

#### **other types**

- [DataSource\(object\)](#)
- [DataSink\(object\)](#)

### **DataSource(object)**

`__init__(j_source, sql_ctx, name)`

- `j_source` – The data source.
- `sql_ctx` – The SQL context.
- `name` – The data-source name.

### **setFormat(format, \*\*options)**

- `format` – The format to set for the data source.
- `options` – A collection of options to set for the data source. For more information about format options, see [the section called “Data format options”](#).

`getFrame()`

Returns a `DynamicFrame` for the data source.

## DataSink(object)

### `__init__(j_sink, sql_ctx)`

- `j_sink` – The sink to create.
- `sql_ctx` – The SQL context for the data sink.

### `setFormat(format, **options)`

- `format` – The format to set for the data sink.
- `options` – A collection of options to set for the data sink. For more information about format options, see [the section called “Data format options”](#).

### `setAccumulableSize(size)`

- `size` – The accumulable size to set, in bytes.

### `writeFrame(dynamic_frame, info="")`

- `dynamic_frame` – The `DynamicFrame` to write.
- `info` – Information about the `DynamicFrame` (optional).

### `write(dynamic_frame_or_dfc, info="")`

Writes a `DynamicFrame` or a `DynamicFrameCollection`.

- `dynamic_frame_or_dfc` – Either a `DynamicFrame` object or a `DynamicFrameCollection` object to be written.
- `info` – Information about the `DynamicFrame` or `DynamicFrames` to be written (optional).

## DynamicFrame class

One of the major abstractions in Apache Spark is the SparkSQL `DataFrame`, which is similar to the `DataFrame` construct found in R and Pandas. A `DataFrame` is similar to a table and

supports functional-style (map/reduce/filter/etc.) operations and SQL operations (select, project, aggregate).

`DataFrame`s are powerful and widely used, but they have limitations with respect to extract, transform, and load (ETL) operations. Most significantly, they require a schema to be specified before any data is loaded. SparkSQL addresses this by making two passes over the data—the first to infer the schema, and the second to load the data. However, this inference is limited and doesn't address the realities of messy data. For example, the same field might be of a different type in different records. Apache Spark often gives up and reports the type as `string` using the original field text. This might not be correct, and you might want finer control over how schema discrepancies are resolved. And for large datasets, an additional pass over the source data might be prohibitively expensive.

To address these limitations, AWS Glue introduces the `DynamicFrame`. A `DynamicFrame` is similar to a `DataFrame`, except that each record is self-describing, so no schema is required initially. Instead, AWS Glue computes a schema on-the-fly when required, and explicitly encodes schema inconsistencies using a choice (or union) type. You can resolve these inconsistencies to make your datasets compatible with data stores that require a fixed schema.

Similarly, a `DynamicRecord` represents a logical record within a `DynamicFrame`. It is like a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does not conform to a fixed schema. When using AWS Glue with PySpark, you do not typically manipulate independent `DynamicRecords`. Rather, you will transform the dataset together through its `DynamicFrame`.

You can convert `DynamicFrames` to and from `DataFrames` after you resolve any schema inconsistencies.

#### — construction —

- [\\_\\_init\\_\\_](#)
- [fromDF](#)
- [toDF](#)

#### `__init__`

`__init__(jdf, glue_ctx, name)`

- `jdf` – A reference to the data frame in the Java Virtual Machine (JVM).

- `glue_ctx` – A [GlueContext class](#) object.
- `name` – An optional name string, empty by default.

## fromDF

### `fromDF(dataframe, glue_ctx, name)`

Converts a `DataFrame` to a `DynamicFrame` by converting `DataFrame` fields to `DynamicRecord` fields. Returns the new `DynamicFrame`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It is similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does not conform to a fixed schema.

This function expects columns with duplicated names in your `DataFrame` to have already been resolved.

- `dataframe` – The Apache Spark SQL `DataFrame` to convert (required).
- `glue_ctx` – The [GlueContext class](#) object that specifies the context for this transform (required).
- `name` – The name of the resulting `DynamicFrame` (optional since AWS Glue 3.0).

## toDF

### `toDF(options)`

Converts a `DynamicFrame` to an Apache Spark `DataFrame` by converting `DynamicRecords` into `DataFrame` fields. Returns the new `DataFrame`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It is similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that does not conform to a fixed schema.

- `options` – A list of options. Specify the target type if you choose the `Project` and `Cast` action type. Examples include the following.

```
>>>toDF([ResolveOption("a.b.c", "KeepAsStruct")])
>>>toDF([ResolveOption("a.b.c", "Project", DoubleType())])
```

---

**— information —**

- [count](#)
- [schema](#)
- [printSchema](#)
- [show](#)
- [repartition](#)
- [coalesce](#)

**count**

`count( )` – Returns the number of rows in the underlying DataFrame.

**schema**

`schema( )` – Returns the schema of this `DynamicFrame`, or if that is not available, the schema of the underlying DataFrame.

For more information about the `DynamicFrame` types that make up this schema, see [the section called “Types”](#).

**printSchema**

`printSchema( )` – Prints the schema of the underlying DataFrame.

**show**

`show(num_rows)` – Prints a specified number of rows from the underlying DataFrame.

**repartition**

`repartition(numPartitions)` – Returns a new `DynamicFrame` with `numPartitions` partitions.

**coalesce**

`coalesce(numPartitions)` – Returns a new `DynamicFrame` with `numPartitions` partitions.

**— transforms —**

- [apply\\_mapping](#)

- [drop\\_fields](#)
- [filter](#)
- [join](#)

## apply\_mapping

**apply\_mapping(mappings, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Applies a declarative mapping to a `DynamicFrame` and returns a new `DynamicFrame` with those mappings applied to the fields that you specify. Unspecified fields are omitted from the new `DynamicFrame`.

- `mappings` – A list of mapping tuples (required). Each consists of: (source column, source type, target column, target type).

If the source column has a dot "." in the name, you must place backticks "`" around it. For example, to map `this.old.name` (string) to `thisNewName`, you would use the following tuple:

```
("`this.old.name`", "string", "thisNewName", "string")
```

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use `apply_mapping` to rename fields and change field types

The following code example shows how to use the `apply_mapping` method to rename selected fields and change field types.

#### Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use apply_mapping to reshape source data into
# the desired column names and types as a new DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Select and rename fields, change field type
```

```
print("Schema for the persons_mapped DynamicFrame, created with apply_mapping:")
persons_mapped = persons.apply_mapping(
    [
        ("family_name", "String", "last_name", "String"),
        ("name", "String", "first_name", "String"),
        ("birth_date", "String", "date_of_birth", "Date"),
    ]
)
persons_mapped.printSchema()
```

## Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct

```

```
|-- death_date: string
```

Schema for the `persons_mapped` `DynamicFrame`, created with `apply_mapping`:

```
root
```

```
|-- last_name: string
```

```
|-- first_name: string
```

```
|-- date_of_birth: date
```

## drop\_fields

**drop\_fields(paths, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Calls the [FlatMap class](#) transform to remove fields from a `DynamicFrame`. Returns a new `DynamicFrame` with the specified fields dropped.

- `paths` – A list of strings. Each contains the full path to a field node that you want to drop. You can use dot notation to specify nested fields. For example, if field `first` is a child of field `name` in the tree, you specify `"name.first"` for the path.

If a field node has a literal `.` in the name, you must enclose the name in backticks (```).

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use `drop_fields` to remove fields from a `DynamicFrame`

This code example uses the `drop_fields` method to remove selected top-level and nested fields from a `DynamicFrame`.

### Example dataset

The example uses the following dataset that is represented by the `EXAMPLE-FRIENDS-DATA` table in the code:

```
{"name": "Sally", "age": 23, "location": {"state": "WY", "county": "Fremont"},  
  "friends": []}  
{"name": "Varun", "age": 34, "location": {"state": "NE", "county": "Douglas"},  
  "friends": [{"name": "Arjun", "age": 3}]}  
{"name": "George", "age": 52, "location": {"state": "NY"}, "friends": [{"name":  
  "Fred"}, {"name": "Amy", "age": 15}]}  
{"name": "Haruki", "age": 21, "location": {"state": "AK", "county": "Denali"}}  
{"name": "Sheila", "age": 63, "friends": [{"name": "Nancy", "age": 22}]}
```

## Example code

```
# Example: Use drop_fields to remove top-level and nested fields from a DynamicFrame.  
# Replace MY-EXAMPLE-DATABASE with your Glue Data Catalog database name.  
# Replace EXAMPLE-FRIENDS-DATA with your table name.  
  
from pyspark.context import SparkContext  
from awsglue.context import GlueContext  
  
# Create GlueContext  
sc = SparkContext.getOrCreate()  
glueContext = GlueContext(sc)  
  
# Create a DynamicFrame from Glue Data Catalog  
glue_source_database = "MY-EXAMPLE-DATABASE"  
glue_source_table = "EXAMPLE-FRIENDS-DATA"  
  
friends = glueContext.create_dynamic_frame.from_catalog(  
    database=glue_source_database, table_name=glue_source_table  
)  
print("Schema for friends DynamicFrame before calling drop_fields:")  
friends.printSchema()  
  
# Remove location.county, remove friends.age, remove age  
friends = friends.drop_fields(paths=["age", "location.county", "friends.age"])  
print("Schema for friends DynamicFrame after removing age, county, and friend age:")  
friends.printSchema()
```

## Output

Schema for friends DynamicFrame before calling drop\_fields:

```
root
|-- name: string
|-- age: int
|-- location: struct
|   |-- state: string
|   |-- county: string
|-- friends: array
|   |-- element: struct
|   |   |-- name: string
|   |   |-- age: int
```

Schema for friends DynamicFrame after removing age, county, and friend age:

```
root
|-- name: string
|-- location: struct
|   |-- state: string
|-- friends: array
|   |-- element: struct
|   |   |-- name: string
```

## filter

**filter(f, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Returns a new DynamicFrame that contains all DynamicRecords within the input DynamicFrame that satisfy the specified predicate function f.

- **f** – The predicate function to apply to the DynamicFrame. The function must take a DynamicRecord as an argument and return True if the DynamicRecord meets the filter requirements, or False if not (required).

A DynamicRecord represents a logical record in a DynamicFrame. It's similar to a row in a Spark DataFrame, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- **transformation\_ctx** – A unique string that is used to identify state information (optional).
- **info** – A string to be associated with error reporting for this transformation (optional).

- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use filter to get a filtered selection of fields

This example uses the `filter` method to create a new `DynamicFrame` that includes a filtered selection of another `DynamicFrame`'s fields.

Like the `map` method, `filter` takes a function as an argument that gets applied to each record in the original `DynamicFrame`. The function takes a record as an input and returns a Boolean value. If the return value is true, the record gets included in the resulting `DynamicFrame`. If it's false, the record is left out.

#### Note

To access the dataset that is used in this example, see [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use filter to create a new DynamicFrame
# with a filtered selection of records

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create DynamicFrame from Glue Data Catalog
medicare = glueContext.create_dynamic_frame.from_options(
    "s3",
    {
        "paths": [
            "s3://awsglue-datasets/examples/medicare/Medicare_Hospital_Provider.csv"
```

```
    ]
  },
  "csv",
  {"withHeader": True},
)

# Create filtered DynamicFrame with custom lambda
# to filter records by Provider State and Provider City
sac_or_mon = medicare.filter(
    f=lambda x: x["Provider State"] in ["CA", "AL"]
    and x["Provider City"] in ["SACRAMENTO", "MONTGOMERY"]
)

# Compare record counts
print("Unfiltered record count: ", medicare.count())
print("Filtered record count:  ", sac_or_mon.count())
```

## Output

```
Unfiltered record count: 163065
Filtered record count: 564
```

## join

**join(paths1, paths2, frame2, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Performs an equality join with another `DynamicFrame` and returns the resulting `DynamicFrame`.

- `paths1` – A list of the keys in this frame to join.
- `paths2` – A list of the keys in the other frame to join.
- `frame2` – The other `DynamicFrame` to join.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

## Example: Use join to combine DynamicFrames

This example uses the `join` method to perform a join on three `DynamicFrames`. AWS Glue performs the join based on the field keys that you provide. The resulting `DynamicFrame` contains rows from the two original frames where the specified keys match.

Note that the `join` transform keeps all fields intact. This means that the fields that you specify to match appear in the resulting `DynamicFrame`, even if they're redundant and contain the same keys. In this example, we use `drop_fields` to remove these redundant keys after the join.

### Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use join to combine data from three DynamicFrames

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load DynamicFrames from Glue Data Catalog
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
memberships = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="memberships_json"
)
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="organizations_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()
print("Schema for the memberships DynamicFrame:")
memberships.printSchema()
print("Schema for the orgs DynamicFrame:")
orgs.printSchema()
```

```
# Join persons and memberships by ID
persons_memberships = persons.join(
    paths1=["id"], paths2=["person_id"], frame2=memberships
)

# Rename and drop fields from orgs
# to prevent field name collisions with persons_memberships
orgs = (
    orgs.drop_fields(["other_names", "identifiers"])
    .rename_field("id", "org_id")
    .rename_field("name", "org_name")
)

# Create final join of all three DynamicFrames
legislators_combined = orgs.join(
    paths1=["org_id"], paths2=["organization_id"], frame2=persons_memberships
).drop_fields(["person_id", "org_id"])

# Inspect the schema for the joined data
print("Schema for the new legislators_combined DynamicFrame:")
legislators_combined.printSchema()
```

## Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string

|-- given_name: string
|-- start_date: string
|-- family_name: string
|-- id: string
|-- death_date: string
```

```
|-- end_date: string
```

## map

**map(f, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Returns a new `DynamicFrame` that results from applying the specified mapping function to all records in the original `DynamicFrame`.

- `f` – The mapping function to apply to all records in the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return a new `DynamicRecord` (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

### Example: Use map to apply a function to every record in a DynamicFrame

This example shows how to use the `map` method to apply a function to every record of a `DynamicFrame`. Specifically, this example applies a function called `MergeAddress` to each record in order to merge several address fields into a single `struct` type.

#### Note

To access the dataset that is used in this example, see [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use map to combine fields in all records  
# of a DynamicFrame
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
medicare = glueContext.create_dynamic_frame.from_options(
    "s3",
    {"paths": ["s3://awsglue-datasets/examples/medicare/
Medicare_Hospital_Provider.csv"]},
    "csv",
    {"withHeader": True})
print("Schema for medicare DynamicFrame:")
medicare.printSchema()

# Define a function to supply to the map transform
# that merges address fields into a single field
def MergeAddress(rec):
    rec["Address"] = {}
    rec["Address"]["Street"] = rec["Provider Street Address"]
    rec["Address"]["City"] = rec["Provider City"]
    rec["Address"]["State"] = rec["Provider State"]
    rec["Address"]["Zip.Code"] = rec["Provider Zip Code"]
    rec["Address"]["Array"] = [rec["Provider Street Address"], rec["Provider City"],
rec["Provider State"], rec["Provider Zip Code"]]
    del rec["Provider Street Address"]
    del rec["Provider City"]
    del rec["Provider State"]
    del rec["Provider Zip Code"]
    return rec

# Use map to apply MergeAddress to every record
mapped_medicare = medicare.map(f = MergeAddress)
print("Schema for mapped_medicare DynamicFrame:")
mapped_medicare.printSchema()
```

## Output

```
Schema for medicare DynamicFrame:
root
```

```

|-- DRG Definition: string
|-- Provider Id: string
|-- Provider Name: string
|-- Provider Street Address: string
|-- Provider City: string
|-- Provider State: string
|-- Provider Zip Code: string
|-- Hospital Referral Region Description: string
|-- Total Discharges: string
|-- Average Covered Charges: string
|-- Average Total Payments: string
|-- Average Medicare Payments: string

```

Schema for mapped\_medicare DynamicFrame:

```

root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address: struct
|   |-- Zip.Code: string
|   |-- City: string
|   |-- Array: array
|     |-- element: string
|   |-- State: string
|   |-- Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string

```

## mergeDynamicFrame

```

mergeDynamicFrame(stage_dynamic_frame, primary_keys, transformation_ctx =
"", options = {}, info = "", stageThreshold = 0, totalThreshold = 0)

```

Merges this DynamicFrame with a staging DynamicFrame based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not deduplicated. If there is no matching record in the staging frame, all records (including duplicates) are retained from the source. If the staging frame has matching records, the records from the staging frame overwrite the records in the source in AWS Glue.

- `stage_dynamic_frame` – The staging DynamicFrame to merge.

- `primary_keys` – The list of primary key fields to match records from the source and staging dynamic frames.
- `transformation_ctx` – A unique string that is used to retrieve metadata about the current transformation (optional).
- `options` – A string of JSON name-value pairs that provide additional information for this transformation. This argument is not currently used.
- `info` – A `String`. Any string to be associated with errors in this transformation.
- `stageThreshold` – A `Long`. The number of errors in the given transformation for which the processing needs to error out.
- `totalThreshold` – A `Long`. The total number of errors up to and including this transformation for which the processing needs to error out.

This method returns a new `DynamicFrame` that is obtained by merging this `DynamicFrame` with the staging `DynamicFrame`.

The returned `DynamicFrame` contains record A in these cases:

- If A exists in both the source frame and the staging frame, then A in the staging frame is returned.
- If A is in the source table and `A.primaryKeys` is not in the `stagingDynamicFrame`, A is not updated in the staging table.

The source frame and staging frame don't need to have the same schema.

### **Example: Use `mergeDynamicFrame` to merge two `DynamicFrames` based on a primary key**

The following code example shows how to use the `mergeDynamicFrame` method to merge a `DynamicFrame` with a "staging" `DynamicFrame`, based on the primary key `id`.

#### **Example dataset**

The example uses two `DynamicFrames` from a `DynamicFrameCollection` called `split_rows_collection`. The following is the list of keys in `split_rows_collection`.

```
dict_keys(['high', 'low'])
```

#### **Example code**

```
# Example: Use mergeDynamicFrame to merge DynamicFrames
# based on a set of specified primary keys

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import SelectFromCollection

# Inspect the original DynamicFrames
frame_low = SelectFromCollection.apply(dfc=split_rows_collection, key="low")
print("Inspect the DynamicFrame that contains rows where ID < 10")
frame_low.toDF().show()

frame_high = SelectFromCollection.apply(dfc=split_rows_collection, key="high")
print("Inspect the DynamicFrame that contains rows where ID > 10")
frame_high.toDF().show()

# Merge the DynamicFrames based on the "id" primary key
merged_high_low = frame_high.mergeDynamicFrame(
    stage_dynamic_frame=frame_low, primary_keys=["id"]
)

# View the results where the ID is 1 or 20
print("Inspect the merged DynamicFrame that contains the combined rows")
merged_high_low.toDF().where("id = 1 or id= 20").orderBy("id").show()
```

## Output

```
Inspect the DynamicFrame that contains rows where ID < 10

## relationalize

**relationalize(root\_table\_name, staging\_path, options, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Converts a `DynamicFrame` into a form that fits within a relational database. Relationalizing a `DynamicFrame` is especially useful when you want to move data from a NoSQL environment like DynamoDB into a relational database like MySQL.

The transform generates a list of frames by unnesting nested columns and pivoting array columns. You can join the pivoted array columns to the root table by using the join key that is generated during the unnest phase.

- `root_table_name` – The name for the root table.
- `staging_path` – The path where the method can store partitions of pivoted tables in CSV format (optional). Pivoted tables are read back from this path.
- `options` – A dictionary of optional parameters.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use `relationalize` to flatten a nested schema in a `DynamicFrame`

This code example uses the `relationalize` method to flatten a nested schema into a form that fits into a relational database.

### Example dataset

The example uses a DynamicFrame called `legislators_combined` with the following schema. `legislators_combined` has multiple nested fields such as `links`, `images`, and `contact_details`, which will be flattened by the `relationalize` transform.

```
root
|-- role: string
|-- seats: int
|-- org_name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- type: string
|-- sort_name: string
|-- area_id: string
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- on_behalf_of_id: string
|-- other_names: array
|   |-- element: struct
|   |   |-- note: string

## Example code

```
# Example: Use relationalize to flatten
# a nested schema into a format that fits
# into a relational database.
# Replace DOC-EXAMPLE-S3-BUCKET/tmpDir with your own location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Apply relationalize and inspect new tables
legislators_relationalized = legislators_combined.relationalize(
    "l_root", "s3://DOC-EXAMPLE-BUCKET/tmpDir"
)
legislators_relationalized.keys()

# Compare the schema of the contact_details
# nested field to the new relationalized table that
# represents it
legislators_combined.select_fields("contact_details").printSchema()
legislators_relationalized.select("l_root_contact_details").toDF().where(
    "id = 10 or id = 75"
).orderBy(["id", "index"]).show()
```

## Output

The following output lets you compare the schema of the nested field called `contact_details` to the table that the `relationalize` transform created. Notice that the table records link back to the main table using a foreign key called `id` and an `index` column that represents the positions of the array.

```
dict_keys(['l_root', 'l_root_images', 'l_root_links', 'l_root_other_names',
'l_root_contact_details', 'l_root_identifiers'])

root
```

```
 |-- contact_details: array
 |   |-- element: struct
 |     |-- type: string
 |     |-- value: string

+---+-----+-----+-----+-----+
| id|index|contact_details.val.type|contact_details.val.value|
+---+-----+-----+-----+-----+
| 10|  0|           fax|           202-225-4160|
| 10|  1|           phone|           202-225-3436|
| 75|  0|           fax|           202-225-6791|
| 75|  1|           phone|           202-225-2861|

+---+-----+-----+-----+-----+
```

## rename\_field

**rename\_field(oldName, newName, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Renames a field in this `DynamicFrame` and returns a new `DynamicFrame` with the field renamed.

- `oldName` – The full path to the node you want to rename.

If the old name has dots in it, `RenameField` doesn't work unless you place backticks around it (```). For example, to replace `this.old.name` with `thisNewName`, you would call `rename_field` as follows.

```
newDyF = oldDyF.rename_field("`this.old.name`", "thisNewName")
```

- `newName` – The new name, as a full path.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

## Example: Use `rename_field` to rename fields in a `DynamicFrame`

This code example uses the `rename_field` method to rename fields in a `DynamicFrame`. Notice that the example uses method chaining to rename multiple fields at the same time.

### Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

## Example code

```
# Example: Use rename_field to rename fields
# in a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Inspect the original orgs schema
orgs = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="organizations_json"
)
print("Original orgs schema: ")
orgs.printSchema()

# Rename fields and view the new schema
orgs = orgs.rename_field("id", "org_id").rename_field("name", "org_name")
print("New orgs schema with renamed fields: ")
orgs.printSchema()
```

## Output

```
Original orgs schema:
root
|-- identifiers: array
|   |-- element: struct
```

```
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- id: string
|-- classification: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- image: string
|-- seats: int
|-- type: string
```

New orgs schema with renamed fields:

```
root
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- classification: string
|-- org_id: string
|-- org_name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- image: string
|-- seats: int
|-- type: string
```

## resolveChoice

```
resolveChoice(specs = None, choice = "" , database = None , table_name =
None , transformation_ctx="", info="", stageThreshold=0, totalThreshold=0,
catalog_id = None)
```

Resolves a choice type within this `DynamicFrame` and returns the new `DynamicFrame`.

- `specs` – A list of specific ambiguities to resolve, each in the form of a tuple: (`field_path`, `action`).

There are two ways to use `resolveChoice`. The first is to use the `specs` argument to specify a sequence of specific fields and how to resolve them. The other mode for `resolveChoice` is to use the `choice` argument to specify a single resolution for all `ChoiceTypes`.

Values for `specs` are specified as tuples made up of (`field_path`, `action`) pairs. The `field_path` value identifies a specific ambiguous element, and the `action` value identifies the corresponding resolution. The following are the possible actions:

- `cast: type` – Attempts to cast all values to the specified type. For example: `cast:int`.
- `make_cols` – Converts each distinct type to a column with the name `columnName_type`. It resolves a potential ambiguity by flattening the data. For example, if `columnA` could be an `int` or a `string`, the resolution would be to produce two columns named `columnA_int` and `columnA_string` in the resulting `DynamicFrame`.
- `make_struct` – Resolves a potential ambiguity by using a `struct` to represent the data. For example, if data in a column could be an `int` or a `string`, the `make_struct` action produces a column of structures in the resulting `DynamicFrame`. Each structure contains both an `int` and a `string`.
- `project: type` – Resolves a potential ambiguity by projecting all the data to one of the possible data types. For example, if data in a column could be an `int` or a `string`, using a `project:string` action produces a column in the resulting `DynamicFrame` where all the `int` values have been converted to strings.

If the `field_path` identifies an array, place empty square brackets after the name of the array to avoid ambiguity. For example, suppose you are working with data structured as follows:

```
"myList": [
  { "price": 100.00 },
  { "price": "$100.00" }
```

```
]
```

You can select the numeric rather than the string version of the price by setting the `field_path` to `"myList[].price"`, and setting the action to `"cast:double"`.

### Note

You can only use one of the `specs` and `choice` parameters. If the `specs` parameter is not `None`, then the `choice` parameter must be an empty string. Conversely, if the `choice` is not an empty string, then the `specs` parameter must be `None`.

- `choice` – Specifies a single resolution for all `ChoiceTypes`. You can use this in cases where the complete list of `ChoiceTypes` is unknown before runtime. In addition to the actions listed previously for `specs`, this argument also supports the following action:
  - `match_catalog` – Attempts to cast each `ChoiceType` to the corresponding type in the specified Data Catalog table.
- `database` – The Data Catalog database to use with the `match_catalog` action.
- `table_name` – The Data Catalog table to use with the `match_catalog` action.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). When set to `None` (default value), it uses the catalog ID of the calling account.

### Example: Use `resolveChoice` to handle a column that contains multiple types

This code example uses the `resolveChoice` method to specify how to handle a `DynamicFrame` column that contains values of multiple types. The example demonstrates two common ways to handle a column with different types:

- Cast the column to a single data type.

- Retain all types in separate columns.

## Example dataset

### Note

To access the dataset that is used in this example, see [Code example: Data preparation using ResolveChoice, Lambda, and ApplyMapping](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

The example uses a DynamicFrame called `medicare` with the following schema:

```
root
|-- drg definition: string
|-- provider id: choice
|   |-- long
|   |-- string
|-- provider name: string
|-- provider street address: string
|-- provider city: string
|-- provider state: string
|-- provider zip code: long
|-- hospital referral region description: string
|-- total discharges: long
|-- average covered charges: string
|-- average total payments: string
|-- average medicare payments: string
```

## Example code

```
# Example: Use resolveChoice to handle
# a column that contains multiple types

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
```

```
# Load the input data and inspect the "provider id" column
medicare = glueContext.create_dynamic_frame.from_catalog(
    database="payments", table_name="medicare_hospital_provider_csv"
)
print("Inspect the provider id column:")
medicare.toDF().select("provider id").show()

# Cast provider id to type long
medicare_resolved_long = medicare.resolveChoice(specs=[("provider id", "cast:long")])
print("Schema after casting provider id to type long:")
medicare_resolved_long.printSchema()
medicare_resolved_long.toDF().select("provider id").show()

# Create separate columns
# for each provider id type
medicare_resolved_cols = medicare.resolveChoice(choice="make_cols")
print("Schema after creating separate columns for each type:")
medicare_resolved_cols.printSchema()
medicare_resolved_cols.toDF().select("provider id_long", "provider id_string").show()
```

## Output

```
Inspect the 'provider id' column:

## select\_fields

**select\_fields(paths, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Returns a new `DynamicFrame` that contains the selected fields.

- `paths` – A list of strings. Each string is a path to a top-level node that you want to select.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use `select_fields` to create a new `DynamicFrame` with chosen fields

The following code example shows how to use the `select_fields` method to create a new `DynamicFrame` with a chosen list of fields from an existing `DynamicFrame`.

#### Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use select_fields to select specific fields from a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
```

```

glueContext = GlueContext(sc)

# Create a DynamicFrame and view its schema
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Create a new DynamicFrame with chosen fields
names = persons.select_fields(paths=["family_name", "given_name"])
print("Schema for the names DynamicFrame, created with select_fields:")
names.printSchema()
names.toDF().show()

```

## Output

```

Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string

## simplify\_ddb\_json

### simplify\_ddb\_json(): DynamicFrame

Simplifies nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new simplified `DynamicFrame`. If there're multiple types or Map type

in a List type, the elements in the List will not be simplified. Note that this is a specific type of transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see [DynamoDB JSON](#).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```

root
|-- Item: struct
|   |-- parentMap: struct
|   |   |-- M: struct
|   |   |   |-- childMap: struct
|   |   |   |   |-- M: struct
|   |   |   |   |   |-- appName: struct
|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- packageName: struct
|   |   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |   |-- updatedAt: struct
|   |   |   |   |   |   |   |   |-- N: string
|   |   |-- strings: struct
|   |   |   |-- SS: array
|   |   |   |   |-- element: string
|   |   |-- numbers: struct
|   |   |   |-- NS: array
|   |   |   |   |-- element: string
|   |   |-- binaries: struct
|   |   |   |-- BS: array
|   |   |   |   |-- element: string
|   |   |-- isDDBJson: struct
|   |   |   |-- BOOL: boolean
|   |   |-- nullValue: struct
|   |   |   |-- NULL: boolean

```

The `simplify_ddb_json()` transform would convert this to:

```

root
|-- parentMap: struct
|   |-- childMap: struct
|   |   |-- appName: string
|   |   |-- packageName: string
|   |   |-- updatedAt: string
|-- strings: array

```

```
|   |-- element: string
|-- numbers: array
|   |-- element: string
|-- binaries: array
|   |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null
```

### Example: Use `simplify_ddb_json` to invoke a DynamoDB JSON simplify

This code example uses the `simplify_ddb_json` method to use the AWS Glue DynamoDB export connector, invoke a DynamoDB JSON simplify, and print the number of partitions.

### Example code

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type = "dynamodb",
    connection_options = {
        'dynamodb.export': 'ddb',
        'dynamodb.tableArn': '<table arn>',
        'dynamodb.s3.bucket': '<bucket name>',
        'dynamodb.s3.prefix': '<bucket prefix>',
        'dynamodb.s3.bucketOwner': '<account_id of bucket>'
    }
)
simplified = dynamicFrame.simplify_ddb_json()
print(simplified.getNumPartitions())
```

### spigot

#### `spigot(path, options={})`

Writes sample records to a specified destination to help you verify the transformations performed by your job.

- `path` – The path of the destination to write to (required).

- `options` – Key-value pairs that specify options (optional). The "topk" option specifies that the first k records should be written. The "prob" option specifies the probability (as a decimal) of choosing any given record. You can use it in selecting records to write.
- `transformation_ctx` – A unique string that is used to identify state information (optional).

### Example: Use `spigot` to write sample fields from a `DynamicFrame` to Amazon S3

This code example uses the `spigot` method to write sample records to an Amazon S3 bucket after applying the `select_fields` transform.

### Example dataset

#### Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

The example uses a `DynamicFrame` called `persons` with the following schema:

```
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
|-- images: array
```

```
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

## Example code

```
# Example: Use spigot to write sample records
# to a destination during a transformation
# from pyspark.context import SparkContext.
# Replace DOC-EXAMPLE-BUCKET with your own location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load table data into a DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)

# Perform the select_fields on the DynamicFrame
persons = persons.select_fields(paths=["family_name", "given_name", "birth_date"])

# Use spigot to write a sample of the transformed data
# (the first 10 records)
spigot_output = persons.spigot(
    path="s3://DOC-EXAMPLE-BUCKET", options={"topk": 10}
)
```

## Output

The following is an example of the data that spigot writes to Amazon S3. Because the example code specified `options={"topk": 10}`, the sample data contains the first 10 records.

```
{"family_name":"Collins","given_name":"Michael","birth_date":"1944-10-15"}
{"family_name":"Huizenga","given_name":"Bill","birth_date":"1969-01-31"}
{"family_name":"Clawson","given_name":"Curtis","birth_date":"1959-09-28"}
{"family_name":"Solomon","given_name":"Gerald","birth_date":"1930-08-14"}
{"family_name":"Rigell","given_name":"Edward","birth_date":"1960-05-28"}
{"family_name":"Crapo","given_name":"Michael","birth_date":"1951-05-20"}
{"family_name":"Hutto","given_name":"Earl","birth_date":"1926-05-12"}

## split\_fields

**split\_fields(paths, name1, name2, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Returns a new `DynamicFrameCollection` that contains two `DynamicFrames`. The first `DynamicFrame` contains all the nodes that have been split off, and the second contains the nodes that remain.

- `paths` – A list of strings, each of which is a full path to a node that you want to split into a new `DynamicFrame`.
- `name1` – A name string for the `DynamicFrame` that is split off.
- `name2` – A name string for the `DynamicFrame` that remains after the specified nodes have been split off.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

## Example: Use `split_fields` to split selected fields into a separate `DynamicFrame`

This code example uses the `split_fields` method to split a list of specified fields into a separate `DynamicFrame`.

### Example dataset

The example uses a `DynamicFrame` called `l_root_contact_details` that is from a collection named `legislators_relationalized`.

`l_root_contact_details` has the following schema and entries.

```
root
|-- id: long
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string
```

id	index	contact_details.val.type	contact_details.val.value
1	0	phone	202-225-5265
1	1	twitter	kathyhochul
2	0	phone	202-225-3252
2	1	twitter	repjackyrosen
3	0	fax	202-225-1314
3	1	phone	202-225-3772
...			

### Example code

```
# Example: Use split_fields to split selected
# fields into a separate DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Load the input DynamicFrame and inspect its schema
frame_to_split = legislators_relationalized.select("l_root_contact_details")
```

```
print("Inspect the input DynamicFrame schema:")
frame_to_split.printSchema()

# Split id and index fields into a separate DynamicFrame
split_fields_collection = frame_to_split.split_fields(["id", "index"], "left", "right")

# Inspect the resulting DynamicFrames
print("Inspect the schemas of the DynamicFrames created with split_fields:")
split_fields_collection.select("left").printSchema()
split_fields_collection.select("right").printSchema()
```

## Output

```
Inspect the input DynamicFrame's schema:
root
|-- id: long
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string

Inspect the schemas of the DynamicFrames created with split_fields:
root
|-- id: long
|-- index: int

root
|-- contact_details.val.type: string
|-- contact_details.val.value: string
```

## split\_rows

**split\_rows(comparison\_dict, name1, name2, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

Splits one or more rows in a `DynamicFrame` off into a new `DynamicFrame`.

The method returns a new `DynamicFrameCollection` that contains two `DynamicFrames`. The first `DynamicFrame` contains all the rows that have been split off, and the second contains the rows that remain.

- `comparison_dict` – A dictionary where the key is a path to a column, and the value is another dictionary for mapping comparators to values that the column values are compared to. For

example, `{"age": {">": 10, "<": 20}}` splits off all rows whose value in the age column is greater than 10 and less than 20.

- `name1` – A name string for the `DynamicFrame` that is split off.
- `name2` – A name string for the `DynamicFrame` that remains after the specified nodes have been split off.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use `split_rows` to split rows in a `DynamicFrame`

This code example uses the `split_rows` method to split rows in a `DynamicFrame` based on the `id` field value.

#### Example dataset

The example uses a `DynamicFrame` called `l_root_contact_details` that is selected from a collection named `legislators_relationalized`.

`l_root_contact_details` has the following schema and entries.

```
root
|-- id: long
|-- index: int
|-- contact_details.val.type: string
|-- contact_details.val.value: string

## unbox

**unbox(path, format, transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0, \*\*options)**

Unboxes (reformats) a string field in a `DynamicFrame` and returns a new `DynamicFrame` that contains the unboxed `DynamicRecords`.

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `path` – A full path to the string node you want to unbox.
- `format` – A format specification (optional). You use this for an Amazon S3 or AWS Glue connection that supports multiple formats. For the formats that are supported, see [Data format options for inputs and outputs in AWS Glue for Spark](#).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).
- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `options` – One or more of the following:

- `separator` – A string that contains the separator character.
- `escaper` – A string that contains the escape character.
- `skipFirst` – A Boolean value that indicates whether to skip the first instance.
- `withSchema` – A string containing a JSON representation of the node's schema. The format of a schema's JSON representation is defined by the output of `StructType.json()`.
- `withHeader` – A Boolean value that indicates whether a header is included.

### Example: Use `unbox` to unbox a string field into a struct

This code example uses the `unbox` method to *unbox*, or reformat, a string field in a `DynamicFrame` into a field of type struct.

#### Example dataset

The example uses a `DynamicFrame` called `mapped_with_string` with the following schema and entries.

Notice the field named `AddressString`. This is the field that the example unboxes into a struct.

```

root
|-- Average Total Payments: string
|-- AddressString: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address: struct
|   |-- Zip.Code: string
|   |-- City: string
|   |-- Array: array
|   |   |-- element: string
|   |-- State: string
|   |-- Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string

+-----+-----+-----+
+-----+-----+-----+
+-----+-----+-----+

```

```

## union

**`union(frame1, frame2, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Union two DynamicFrames. Returns DynamicFrame containing all records from both input DynamicFrames. This transform may return different results from the union of two DataFrames with equivalent data. If you need the Spark DataFrame union behavior, consider using `toDF`.

- `frame1` – First DynamicFrame to union.
- `frame2` – Second DynamicFrame to union.
- `transformation_ctx` – (optional) A unique string that is used to identify stats / state information
- `info` – (optional) Any string to be associated with errors in the transformation
- `stageThreshold` – (optional) Max number of errors in the transformation until processing will error out
- `totalThreshold` – (optional) Max number of errors total until processing will error out.

## unnest

**`unnest(transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`**

Unnests nested objects in a DynamicFrame, which makes them top-level objects, and returns a new unnested DynamicFrame.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).

- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional). The default is zero, which indicates that the process should not error out.

### Example: Use `unnest` to turn nested fields into top-level fields

This code example uses the `unnest` method to flatten all of the nested fields in a `DynamicFrame` into top-level fields.

#### Example dataset

The example uses a `DynamicFrame` called `mapped_medicare` with the following schema. Notice that the `Address` field is the only field that contains nested data.

```
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address: struct
|   |-- Zip.Code: string
|   |-- City: string
|   |-- Array: array
|     |-- element: string
|   |-- State: string
|   |-- Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string
```

#### Example code

```
# Example: Use unnest to unnest nested
# objects in a DynamicFrame

from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```
# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Unnest all nested fields
unnested = mapped_medicare.unnest()
unnested.printSchema()
```

## Output

```
root
|-- Average Total Payments: string
|-- Average Covered Charges: string
|-- DRG Definition: string
|-- Average Medicare Payments: string
|-- Hospital Referral Region Description: string
|-- Address.Zip.Code: string
|-- Address.City: string
|-- Address.Array: array
|   |-- element: string
|-- Address.State: string
|-- Address.Street: string
|-- Provider Id: string
|-- Total Discharges: string
|-- Provider Name: string
```

## unnest\_ddb\_json

Unnests nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new unnested `DynamicFrame`. Columns that are of an array of struct types will not be unnested. Note that this is a specific type of unnesting transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see [DynamoDB JSON](#).

**unnest\_ddb\_json(transformation\_ctx="", info="", stageThreshold=0, totalThreshold=0)**

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string to be associated with error reporting for this transformation (optional).

- `stageThreshold` – The number of errors encountered during this transformation at which the process should error out (optional: zero by default, indicating that the process should not error out).
- `totalThreshold` – The number of errors encountered up to and including this transformation at which the process should error out (optional: zero by default, indicating that the process should not error out).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```
root
|-- Item: struct
|   |-- ColA: struct
|   |   |-- S: string
|   |-- ColB: struct
|   |   |-- S: string
|   |-- ColC: struct
|   |   |-- N: string
|   |-- ColD: struct
|   |   |-- L: array
|   |   |   |-- element: null
```

The `unnest_ddb_json()` transform would convert this to:

```
root
|-- ColA: string
|-- ColB: string
|-- ColC: string
|-- ColD: array
|   |-- element: null
```

The following code example shows how to use the AWS Glue DynamoDB export connector, invoke a DynamoDB JSON unnest, and print the number of partitions:

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions
```

```
args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dynamicFrame = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": "<test_source>",
        "dynamodb.s3.bucket": "<bucket name>",
        "dynamodb.s3.prefix": "<bucket prefix>",
        "dynamodb.s3.bucketOwner": "<account_id>",
    }
)
unnested = dynamicFrame.unnest_ddb_json()
print(unnested.getNumPartitions())

job.commit()
```

## write

### **write(connection\_type, connection\_options, format, format\_options, accumulator\_size)**

Gets a [DataSink\(object\)](#) of the specified connection type from the [GlueContext class](#) of this DynamicFrame, and uses it to format and write the contents of this DynamicFrame. Returns the new DynamicFrame formatted and written as specified.

- **connection\_type** – The connection type to use. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- **connection\_options** – The connection option to use (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

**⚠ Warning**

Storing passwords in your script is not recommended. Consider using boto3 to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",  
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-  
  path"}
```

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `accumulator_size` – The accumulable size to use, in bytes (optional).

**— errors —**

- [assertErrorThreshold](#)
- [errorsAsDynamicFrame](#)
- [errorsCount](#)
- [stageErrorsCount](#)

**assertErrorThreshold**

`assertErrorThreshold( )` – An assert for errors in the transformations that created this `DynamicFrame`. Returns an `Exception` from the underlying `DataFrame`.

**errorsAsDynamicFrame**

`errorsAsDynamicFrame( )` – Returns a `DynamicFrame` that has error records nested inside.

**Example: Use errorsAsDynamicFrame to view error records**

The following code example shows how to use the `errorsAsDynamicFrame` method to view an error record for a `DynamicFrame`.

## Example dataset

The example uses the following dataset that you can upload to Amazon S3 as JSON. Notice that the second record is malformed. Malformed data typically breaks file parsing when you use SparkSQL. However, `DynamicFrame` recognizes malformation issues and turns malformed lines into error records that you can handle individually.

```
{"id": 1, "name": "george", "surname": "washington", "height": 178}
{"id": 2, "name": "benjamin", "surname": "franklin",
{"id": 3, "name": "alexander", "surname": "hamilton", "height": 171}
{"id": 4, "name": "john", "surname": "jay", "height": 190}
```

## Example code

```
# Example: Use errorsAsDynamicFrame to view error records.
# Replace s3://DOC-EXAMPLE-S3-BUCKET/error_data.json with your location.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Create errors DynamicFrame, view schema
errors = glueContext.create_dynamic_frame.from_options(
    "s3", {"paths": ["s3://DOC-EXAMPLE-S3-BUCKET/error_data.json"]}, "json"
)
print("Schema of errors DynamicFrame:")
errors.printSchema()

# Show that errors only contains valid entries from the dataset
print("errors contains only valid records from the input dataset (2 of 4 records)")
errors.toDF().show()

# View errors
print("Errors count:", str(errors.errorsCount()))
print("Errors:")
errors.errorsAsDynamicFrame().toDF().show()

# View error fields and error data
error_record = errors.errorsAsDynamicFrame().toDF().head()
```

```

error_fields = error_record["error"]
print("Error fields: ")
print(error_fields.asDict().keys())

print("\nError record data:")
for key in error_fields.asDict().keys():
    print("\n", key, ": ", str(error_fields[key]))

```

## Output

Schema of errors DynamicFrame:

```

root
|-- id: int
|-- name: string
|-- surname: string
|-- height: int

```

errors contains only valid records from the input dataset (2 of 4 records)

```

+---+-----+-----+-----+
| id|  name|  surname|height|
+---+-----+-----+-----+
|  1|george|washington|  178|
|  4|  john|      jay|  190|
+---+-----+-----+-----+

```

Errors count: 1

Errors:

```

+-----+
|          error|
+-----+
|[[  File "/tmp/20...|
+-----+

```

Error fields:

```

dict_keys(['callsite', 'msg', 'stackTrace', 'input', 'bytesread', 'source',
'dynamicRecord'])

```

Error record data:

```

callsite : Row(site='  File "/tmp/2060612586885849088", line 549, in <module>\n
sys.exit(main())\n  File "/tmp/2060612586885849088", line 523, in main\n    response

```

input :

bytesread : 252

source :

dynamicRecord : Row(id=2, name='benjamin', surname='franklin')

## errorsCount

`errorsCount()` – Returns the total number of errors in a `DynamicFrame`.

## stageErrorsCount

`stageErrorsCount` – Returns the number of errors that occurred in the process of generating this `DynamicFrame`.

## DynamicFrameCollection class

A `DynamicFrameCollection` is a dictionary of [DynamicFrame class](#) objects, in which the keys are the names of the `DynamicFrames` and the values are the `DynamicFrame` objects.

### `__init__`

#### `__init__(dynamic_frames, glue_ctx)`

- `dynamic_frames` – A dictionary of [DynamicFrame class](#) objects.
- `glue_ctx` – A [GlueContext class](#) object.

## Keys

`keys()` – Returns a list of the keys in this collection, which generally consists of the names of the corresponding `DynamicFrame` values.

## Values

`values(key)` – Returns a list of the `DynamicFrame` values in this collection.

## Select

### `select(key)`

Returns the `DynamicFrame` that corresponds to the specified key (which is generally the name of the `DynamicFrame`).

- `key` – A key in the `DynamicFrameCollection`, which usually represents the name of a `DynamicFrame`.

## Map

**map(callable, transformation\_ctx="")**

Uses a passed-in function to create and return a new `DynamicFrameCollection` based on the `DynamicFrames` in this collection.

- `callable` – A function that takes a `DynamicFrame` and the specified transformation context as parameters and returns a `DynamicFrame`.
- `transformation_ctx` – A transformation context to be used by the callable (optional).

## Flatmap

**flatmap(f, transformation\_ctx="")**

Uses a passed-in function to create and return a new `DynamicFrameCollection` based on the `DynamicFrames` in this collection.

- `f` – A function that takes a `DynamicFrame` as a parameter and returns a `DynamicFrame` or `DynamicFrameCollection`.
- `transformation_ctx` – A transformation context to be used by the function (optional).

## DynamicFrameWriter class

### methods

- [`\_\_init\_\_`](#)
- [`from\_options`](#)
- [`from\_catalog`](#)
- [`from\_jdbc\_conf`](#)

### `__init__`

**`__init__(glue_context)`**

- `glue_context` – The [`GlueContext` class](#) to use.

## from\_options

```
from_options(frame, connection_type, connection_options={}, format=None,
            format_options={}, transformation_ctx="")
```

Writes a `DynamicFrame` using the specified connection and format.

- `frame` – The `DynamicFrame` to write.
- `connection_type` – The connection type. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

### Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
                    "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.

- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

## `from_catalog`

```
from_catalog(frame, name_space, table_name, redshift_tmp_dir="", transformation_ctx="")
```

Writes a `DynamicFrame` using the specified catalog database and table name.

- `frame` – The `DynamicFrame` to write.
- `name_space` – The database to use.
- `table_name` – The `table_name` to use.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `additional_options` – Additional options provided to AWS Glue.

To write to Lake Formation governed tables, you can use these additional options:

- `transactionId` – (String) The transaction ID at which to do the write to the Governed table. This transaction can not be already committed or aborted, or the write will fail.
- `callDeleteObjectsOnCancel` – (Boolean, optional) If set to `true` (default), AWS Glue automatically calls the `DeleteObjectsOnCancel` API after the object is written to Amazon S3. For more information, see [DeleteObjectsOnCancel](#) in the *AWS Lake Formation Developer Guide*.

### **Example Example: Writing to a governed table in Lake Formation**

```
txId = glueContext.start_transaction(read_only=False)
glueContext.write_dynamic_frame.from_catalog(
    frame=dyf,
    database = db,
    table_name = tbl,
    transformation_ctx = "datasource0",
    additional_options={"transactionId":txId})
...
glueContext.commit_transaction(txId)
```

## from\_jdbc\_conf

```
from_jdbc_conf(frame, catalog_connection, connection_options={},
redshift_tmp_dir = "", transformation_ctx="")
```

Writes a `DynamicFrame` using the specified JDBC connection information.

- `frame` – The `DynamicFrame` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional).
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).

## Example for write\_dynamic\_frame

This example writes the output locally using a `connection_type` of `S3` with a POSIX path argument in `connection_options`, which allows writing to local storage.

```
glueContext.write_dynamic_frame.from_options(\
frame = dyf_splitFields,\
connection_options = {'path': '/home/glue/GlueLocalOutput/'},\
connection_type = 's3',\
format = 'json')
```

## DynamicFrameReader class

### — methods —

- [`\_\_init\_\_`](#)
- [`from\_rdd`](#)
- [`from\_options`](#)
- [`from\_catalog`](#)

### `__init__`

### `__init__(glue_context)`

- `glue_context` – The [GlueContext class](#) to use.

## from\_rdd

```
from_rdd(data, name, schema=None, sampleRatio=None)
```

Reads a `DynamicFrame` from a Resilient Distributed Dataset (RDD).

- `data` – The dataset to read from.
- `name` – The name to read from.
- `schema` – The schema to read (optional).
- `sampleRatio` – The sample ratio (optional).

## from\_options

```
from_options(connection_type, connection_options={}, format=None,  
format_options={}, transformation_ctx="")
```

Reads a `DynamicFrame` using the specified connection and format.

- `connection_type` – The connection type. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `dynamodb`, and `snowflake`.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see [Connection types and options for ETL in AWS Glue for Spark](#). For a `connection_type` of `s3`, Amazon S3 paths are defined in an array.

```
connection_options = {"paths": [ "s3://mybucket/object_a", "s3://mybucket/object_b" ]}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

### Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",  
"password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-  
path"}
```

For a JDBC connection that performs parallel reads, you can set the hashfield option. For example:

```
connection_options = {"url": "jdbc-url/database", "user": "username",  
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-  
path" , "hashfield": "month"}
```

For more information, see [Reading from JDBC tables in parallel](#).

- `format` – A format specification (optional). This is used for an Amazon Simple Storage Service (Amazon S3) or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-Filtering Using Pushdown Predicates](#).

## `from_catalog`

```
from_catalog(database, table_name, redshift_tmp_dir="",  
transformation_ctx="", push_down_predicate="", additional_options={})
```

Reads a `DynamicFrame` using the specified catalog namespace and table name.

- `database` – The database to read from.
- `table_name` – The name of the table to read from.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional if not reading data from Redshift).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).
- `additional_options` – Additional options provided to AWS Glue.
  - To use a JDBC connection that performs parallel reads, you can set the `hashfield`, `hashexpression`, or `hashpartitions` options. For example:

```
additional_options = {"hashfield": "month"}
```

For more information, see [Reading from JDBC tables in parallel](#).

- To pass a catalog expression to filter based on the index columns, you can see the `catalogPartitionPredicate` option.

`catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see [AWS Glue Partition Indexes](#). Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

For more information, see [Managing partitions for ETL output in AWS Glue](#).

- To read from Lake Formation governed tables, you can use these additional options:
  - `transactionId` – (String) The transaction ID at which to read the Governed table contents. If this transaction is not committed, the read will be treated as part of that transaction and will see its writes. If this transaction is committed, its writes will be visible in this read. If this transaction has aborted, an error will be returned. Cannot be specified along with `asOfTime`.

#### Note

Either `transactionId` or `asOfTime` must set to access the governed table.

- `asOfTime` – (TimeStamp: yyyy-[m]m-[d]d hh:mm:ss) The time as of when to read the table contents. Cannot be specified along with `transactionId`.
- `query` – (Optional) A PartiQL query statement used as an input to the Lake Formation planner service. If not set, the default setting is to select all data from the table. For more details about PartiQL, see [PartiQL Support in Row Filter Expressions](#) in the *AWS Lake Formation Developer Guide*.

### Example Example: Using a PartiQL query statement when reading from a governed table in Lake Formation

```
txId = glueContext.start_transaction(read_only=False)
datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = db,
```

```
    table_name = tbl,
    transformation_ctx = "datasource0",
    additional_options={
        "transactionId":txId,
        "query":"SELECT * from tblName WHERE partitionKey=value;"
    })
...
glueContext.commit_transaction(txId)
```

## GlueContext class

Wraps the Apache Spark [SparkContext](#) object, and thereby provides mechanisms for interacting with the Apache Spark platform.

### `__init__`

#### `__init__(sparkContext)`

- `sparkContext` – The Apache Spark context to use.

## Creating

- [\\_\\_init\\_\\_](#)
- [getSource](#)
- [create\\_dynamic\\_frame\\_from\\_rdd](#)
- [create\\_dynamic\\_frame\\_from\\_catalog](#)
- [create\\_dynamic\\_frame\\_from\\_options](#)
- [create\\_sample\\_dynamic\\_frame\\_from\\_catalog](#)
- [create\\_sample\\_dynamic\\_frame\\_from\\_options](#)
- [add\\_ingestion\\_time\\_columns](#)
- [create\\_data\\_frame\\_from\\_catalog](#)
- [create\\_data\\_frame\\_from\\_options](#)
- [forEachBatch](#)

## getSource

### **getSource(connection\_type, transformation\_ctx = "", \*\*options)**

Creates a DataSource object that can be used to read DynamicFrames from external sources.

- **connection\_type** – The connection type to use, such as Amazon Simple Storage Service (Amazon S3), Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- **transformation\_ctx** – The transformation context to use (optional).
- **options** – A collection of optional name-value pairs. For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).

The following is an example of using `getSource`.

```
>>> data_source = context.getSource("file", paths=["/in/path"])
>>> data_source.setFormat("json")
>>> myFrame = data_source.getFrame()
```

## create\_dynamic\_frame\_from\_rdd

### **create\_dynamic\_frame\_from\_rdd(data, name, schema=None, sample\_ratio=None, transformation\_ctx="")**

Returns a DynamicFrame that is created from an Apache Spark Resilient Distributed Dataset (RDD).

- **data** – The data source to use.
- **name** – The name of the data to use.
- **schema** – The schema to use (optional).
- **sample\_ratio** – The sample ratio to use (optional).
- **transformation\_ctx** – The transformation context to use (optional).

## `create_dynamic_frame_from_catalog`

```
create_dynamic_frame_from_catalog(database, table_name, redshift_tmp_dir,  
transformation_ctx = "", push_down_predicate= "", additional_options = {},  
catalog_id = None)
```

Returns a `DynamicFrame` that is created using a Data Catalog database and table name. When using this method, you provide `format_options` through table properties on the specified AWS Glue Data Catalog table and other options through the `additional_options` argument.

- `Database` – The database to read from.
- `table_name` – The name of the table to read from.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in AWS Glue for Spark](#) except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`. Another supported option is `catalogPartitionPredicate`:

`catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see [AWS Glue Partition Indexes](#). Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

## `create_dynamic_frame_from_options`

```
create_dynamic_frame_from_options(connection_type, connection_options={},  
format=None, format_options={}, transformation_ctx = "")
```

Returns a `DynamicFrame` created with the specified connection and format.

- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `connection_options` – Connection options, such as paths and database table (optional). For a `connection_type` of `s3`, a list of Amazon S3 paths is defined.

```
connection_options = {"paths": ["s3://aws-glue-target/temp"]}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

### Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
  "password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).

- `format` – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-Filtering Using Pushdown Predicates](#).

## create\_sample\_dynamic\_frame\_from\_catalog

```
create_sample_dynamic_frame_from_catalog(database, table_name, num,  
redshift_tmp_dir, transformation_ctx = "", push_down_predicate= "",  
additional_options = {}, sample_options = {}, catalog_id = None)
```

Returns a sample `DynamicFrame` that is created using a Data Catalog database and table name. The `DynamicFrame` only contains first `num` records from a datasource.

- `database` – The database to read from.
- `table_name` – The name of the table to read from.
- `num` – The maximum number of records in the returned sample dynamic frame.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in AWS Glue for Spark](#) except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`.
- `sample_options` – Parameters to control sampling behavior (optional). Current available parameters for Amazon S3 sources:
  - `maxSamplePartitions` – The maximum number of partitions the sampling will read. Default value is 10
  - `maxSampleFilesPerPartition` – The maximum number of files the sampling will read in one partition. Default value is 10.

These parameters help to reduce the time consumed by file listing. For example, suppose the dataset has 1000 partitions, and each partition has 10 files. If you set `maxSamplePartitions = 10`, and `maxSampleFilesPerPartition = 10`, instead of listing all 10,000 files, the sampling will only list and read the first 10 partitions with the first 10 files in each:  $10 * 10 = 100$  files in total.

- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.

## create\_sample\_dynamic\_frame\_from\_options

```
create_sample_dynamic_frame_from_options(connection_type,  
connection_options={}, num, sample_options={}, format=None,  
format_options={}, transformation_ctx = "")
```

Returns a sample `DynamicFrame` created with the specified connection and format. The `DynamicFrame` only contains first `num` records from a datasource.

- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, and `dynamodb`.
- `connection_options` – Connection options, such as paths and database table (optional). For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).
- `num` – The maximum number of records in the returned sample dynamic frame.
- `sample_options` – Parameters to control sampling behavior (optional). Current available parameters for Amazon S3 sources:
  - `maxSamplePartitions` – The maximum number of partitions the sampling will read. Default value is 10
  - `maxSampleFilesPerPartition` – The maximum number of files the sampling will read in one partition. Default value is 10.

These parameters help to reduce the time consumed by file listing. For example, suppose the dataset has 1000 partitions, and each partition has 10 files. If you set `maxSamplePartitions = 10`, and `maxSampleFilesPerPartition = 10`, instead of listing all 10,000 files, the sampling will only list and read the first 10 partitions with the first 10 files in each:  $10 \times 10 = 100$  files in total.

- `format` – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – The transformation context to use (optional).
- `push_down_predicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).

## add\_ingestion\_time\_columns

```
add_ingestion_time_columns(dataFrame, timeGranularity = "")
```

Appends ingestion time columns like `ingest_year`, `ingest_month`, `ingest_day`, `ingest_hour`, `ingest_minute` to the input `DataFrame`. This function is automatically generated in the script generated by the AWS Glue when you specify a Data Catalog table with Amazon S3 as the target. This function automatically updates the partition with ingestion time columns on the output table. This allows the output data to be automatically partitioned on ingestion time without requiring explicit ingestion time columns in the input data.

- `dataFrame` – The `dataFrame` to append the ingestion time columns to.
- `timeGranularity` – The granularity of the time columns. Valid values are "day", "hour" and "minute". For example, if "hour" is passed in to the function, the original `dataFrame` will have "ingest\_year", "ingest\_month", "ingest\_day", and "ingest\_hour" time columns appended.

Returns the data frame after appending the time granularity columns.

Example:

```
dynamic_frame = DynamicFrame.fromDF(glueContext.add_ingestion_time_columns(dataFrame, "hour"))
```

## create\_data\_frame\_from\_catalog

```
create_data_frame_from_catalog(database, table_name, transformation_ctx = "", additional_options = {})
```

Returns a `DataFrame` that is created using information from a Data Catalog table.

- `database` – The Data Catalog database to read from.
- `table_name` – The name of the Data Catalog table to read from.
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in AWS Glue for Spark](#) for streaming sources, such as `startingPosition`, `maxFetchTimeInMs`, and `startingOffsets`.

- `useSparkDataSource` – When set to true, forces AWS Glue to use the native Spark Data Source API to read the table. The Spark Data Source API supports the following formats: AVRO, binary, CSV, JSON, ORC, Parquet, and text. In a Data Catalog table, you specify the format using the `classification` property. To learn more about the Spark Data Source API, see the official [Apache Spark documentation](#).

Using `create_data_frame_from_catalog` with `useSparkDataSource` has the following benefits:

- Directly returns a `DataFrame` and provides an alternative to `create_dynamic_frame_from_catalog().toDF()`.
- Supports AWS Lake Formation table-level permission control for native formats.
- Supports reading data lake formats without AWS Lake Formation table-level permission control. For more information, see [Using data lake frameworks with AWS Glue ETL jobs](#).

When you enable `useSparkDataSource`, you can also add any of the [Spark Data Source options](#) in `additional_options` as needed. AWS Glue passes these options directly to the Spark reader.

- `useCatalogSchema` – When set to true, AWS Glue applies the Data Catalog schema to the resulting `DataFrame`. Otherwise, the reader infers the schema from the data. When you enable `useCatalogSchema`, you must also set `useSparkDataSource` to true.

## Limitations

Consider the following limitations when you use the `useSparkDataSource` option:

- When you use `useSparkDataSource`, AWS Glue creates a new `DataFrame` in a separate Spark session that is different from the original Spark session.
- Spark `DataFrame` partition filtering doesn't work with the following AWS Glue features.
  - [Job bookmarks](#)
  - [Excluding Amazon S3 storage classes](#)
  - [Catalog partition predicates](#)

To use partition filtering with these features, you can use the AWS Glue pushdown predicate. For more information, see [Pre-filtering using pushdown predicates](#). Filtering on non-partitioned columns is not affected.

The following example script demonstrates the incorrect way to perform partition filtering with the `excludeStorageClasses` option.

```
// Incorrect partition filtering using Spark filter with excludeStorageClasses
read_df = glueContext.create_data_frame.from_catalog(
    database=database_name,
    table_name=table_name,
    additional_options = {
        "useSparkDataSource": True,
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)

// Suppose year and month are partition keys.
// Filtering on year and month won't work, the filtered_df will still
// contain data with other year/month values.
filtered_df = read_df.filter("year == '2017 and month == '04' and 'state == 'CA'")
```

The following example script demonstrates the correct way to use a pushdown predicate in order to perform partition filtering with the `excludeStorageClasses` option.

```
// Correct partition filtering using the AWS Glue pushdown predicate
// with excludeStorageClasses
read_df = glueContext.create_data_frame.from_catalog(
    database=database_name,
    table_name=table_name,
    // Use AWS Glue pushdown predicate to perform partition filtering
    push_down_predicate = "(year=='2017' and month=='04')",
    additional_options = {
        "useSparkDataSource": True,
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]
    }
)

// Use Spark filter only on non-partitioned columns
filtered_df = read_df.filter("state == 'CA'")
```

### Example: Creating a CSV table using the Spark data source reader

```
// Read a CSV table with '\t' as separator
```

```
read_df = glueContext.create_data_frame.from_catalog(  
    database=<database_name>,  
    table_name=<table_name>,  
    additional_options = {"useSparkDataSource": True, "sep": '\t'}  
)
```

## create\_data\_frame\_from\_options

```
create_data_frame_from_options(connection_type, connection_options={},  
format=None, format_options={}, transformation_ctx = "")
```

This API is now deprecated. Instead use the `getSource()` API. Returns a `DataFrame` created with the specified connection and format. Use this function only with AWS Glue streaming sources.

- `connection_type` – The streaming connection type. Valid values include `kinesis` and `kafka`.
- `connection_options` – Connection options, which are different for Kinesis and Kafka. You can find the list of all connection options for each streaming data source at [Connection types and options for ETL in AWS Glue for Spark](#). Note the following differences in streaming connection options:
  - Kinesis streaming sources require `streamARN`, `startingPosition`, `inferSchema`, and `classification`.
  - Kafka streaming sources require `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- `format` – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. For information about the supported formats, see [Data format options for inputs and outputs in AWS Glue for Spark](#).
- `format_options` – Format options for the specified format. For information about the supported format options, see [Data format options for inputs and outputs in AWS Glue for Spark](#).
- `transformation_ctx` – The transformation context to use (optional).

Example for Amazon Kinesis streaming source:

```
kinesis_options =  
{ "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",  
  "startingPosition": "TRIM_HORIZON",  
  "inferSchema": "true",  
  "classification": "json"
```

```
    }  
    data_frame_datasource0 =  
    glueContext.create_data_frame.from_options(connection_type="kinesis",  
    connection_options=kinesis_options)
```

Example for Kafka streaming source:

```
kafka_options =  
    { "connectionName": "ConfluentKafka",  
      "topicName": "kafka-auth-topic",  
      "startingOffsets": "earliest",  
      "inferSchema": "true",  
      "classification": "json"  
    }  
data_frame_datasource0 =  
    glueContext.create_data_frame.from_options(connection_type="kafka",  
    connection_options=kafka_options)
```

## forEachBatch

### forEachBatch(frame, batch\_function, options)

Applies the `batch_function` passed in to every micro batch that is read from the Streaming source.

- `frame` – The DataFrame containing the current micro batch.
- `batch_function` – A function that will be applied for every micro batch.
- `options` – A collection of key-value pairs that holds information about how to process micro batches. The following options are required:
  - `windowSize` – The amount of time to spend processing each batch.
  - `checkpointLocation` – The location where checkpoints are stored for the streaming ETL job.
  - `batchMaxRetries` – The maximum number of times to retry the batch if it fails. The default value is 3. This option is only configurable for Glue version 2.0 and above.

### Example:

```
glueContext.forEachBatch(  
    frame = data_frame_datasource0,  
    batch_function = processBatch,
```

```

options = {
    "windowSize": "100 seconds",
    "checkpointLocation": "s3://kafka-auth-dataplane/confluent-test/output/
checkpoint/"
}
)

def processBatch(data_frame, batchId):
    if (data_frame.count() > 0):
        datasource0 = DynamicFrame.fromDF(
            glueContext.add_ingestion_time_columns(data_frame, "hour"),
            glueContext, "from_data_frame"
        )
        additionalOptions_datasink1 = {"enableUpdateCatalog": True}
        additionalOptions_datasink1["partitionKeys"] = ["ingest_yr", "ingest_mo",
"ingest_day"]
        datasink1 = glueContext.write_dynamic_frame.from_catalog(
            frame = datasource0,
            database = "tempdb",
            table_name = "kafka-auth-table-output",
            transformation_ctx = "datasink1",
            additional_options = additionalOptions_datasink1
        )

```

## Working with datasets in Amazon S3

- [purge\\_table](#)
- [purge\\_s3\\_path](#)
- [transition\\_table](#)
- [transition\\_s3\\_path](#)

### purge\_table

```
purge_table(catalog_id=None, database="", table_name="", options={},
transformation_ctx="")
```

Deletes files from Amazon S3 for the specified catalog's database and table. If all files in a partition are deleted, that partition is also deleted from the catalog.

If you want to be able to recover deleted objects, you can turn on [object versioning](#) on the Amazon S3 bucket. When an object is deleted from a bucket that doesn't have object versioning enabled,

the object can't be recovered. For more information about how to recover deleted objects in a version-enabled bucket, see [How can I retrieve an Amazon S3 object that was deleted?](#) in the AWS Support Knowledge Center.

- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.
- `database` – The database to use.
- `table_name` – The name of the table to use.
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `partitionPredicate` – Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to `""` – empty by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not deleted. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully purged are recorded in `Success.csv`, and those that failed in `Failed.csv`
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

## Example

```
glueContext.purge_table("database", "table", {"partitionPredicate": "(month=='march')",
"retentionPeriod": 1, "excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath":
"s3://bucketmanifest/"})
```

## purge\_s3\_path

**purge\_s3\_path(s3\_path, options={}, transformation\_ctx="")**

Deletes files from the specified Amazon S3 path recursively.

If you want to be able to recover deleted objects, you can turn on [object versioning](#) on the Amazon S3 bucket. When an object is deleted from a bucket that doesn't have object versioning turned on, the object can't be recovered. For more information about how to recover deleted objects in a

bucket with versioning, see [How can I retrieve an Amazon S3 object that was deleted?](#) in the AWS Support Knowledge Center.

- `s3_path` – The path in Amazon S3 of the files to be deleted in the format `s3://<bucket>/<prefix>/`
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not deleted. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully purged are recorded in `Success.csv`, and those that failed in `Failed.csv`
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

## Example

```
glueContext.purge_s3_path("s3://bucket/path/", {"retentionPeriod": 1,
"excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath": "s3://bucketmanifest/"})
```

## transition\_table

```
transition_table(database, table_name, transition_to, options={},
transformation_ctx="", catalog_id=None)
```

Transitions the storage class of the files stored on Amazon S3 for the specified catalog's database and table.

You can transition between any two storage classes. For the GLACIER and DEEP\_ARCHIVE storage classes, you can transition to these classes. However, you would use an S3 RESTORE to transition from GLACIER and DEEP\_ARCHIVE storage classes.

If you're running AWS Glue ETL jobs that read files or partitions from Amazon S3, you can exclude some Amazon S3 storage class types. For more information, see [Excluding Amazon S3 Storage Classes](#).

- `database` – The database to use.
- `table_name` – The name of the table to use.

- `transition_to` – The [Amazon S3 storage class](#) to transition to.
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `partitionPredicate` – Partitions satisfying this predicate are transitioned. Files within the retention period in these partitions are not transitioned. Set to "" – empty by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not transitioned. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully transitioned are recorded in `Success.csv`, and those that failed in `Failed.csv`
  - `accountId` – The Amazon Web Services account ID to run the transition transform. Mandatory for this transform.
  - `roleArn` – The AWS role to run the transition transform. Mandatory for this transform.
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.
- `catalog_id` – The catalog ID of the Data Catalog being accessed (the account ID of the Data Catalog). Set to `None` by default. `None` defaults to the catalog ID of the calling account in the service.

## Example

```
glueContext.transition_table("database", "table", "STANDARD_IA", {"retentionPeriod": 1,
"excludeStorageClasses": ["STANDARD_IA"], "manifestFilePath": "s3://bucketmanifest/",
"accountId": "12345678901", "roleArn": "arn:aws:iam:123456789012:user/example-username"})
```

## `transition_s3_path`

```
transition_s3_path(s3_path, transition_to, options={},
transformation_ctx="")
```

Transitions the storage class of the files in the specified Amazon S3 path recursively.

You can transition between any two storage classes. For the `GLACIER` and `DEEP_ARCHIVE` storage classes, you can transition to these classes. However, you would use an `S3 RESTORE` to transition from `GLACIER` and `DEEP_ARCHIVE` storage classes.

If you're running AWS Glue ETL jobs that read files or partitions from Amazon S3, you can exclude some Amazon S3 storage class types. For more information, see [Excluding Amazon S3 Storage Classes](#).

- `s3_path` – The path in Amazon S3 of the files to be transitioned in the format `s3://<bucket>/<prefix>/`
- `transition_to` – The [Amazon S3 storage class](#) to transition to.
- `options` – Options to filter files to be deleted and for manifest file generation.
  - `retentionPeriod` – Specifies a period in number of hours to retain files. Files newer than the retention period are retained. Set to 168 hours (7 days) by default.
  - `partitionPredicate` – Partitions satisfying this predicate are transitioned. Files within the retention period in these partitions are not transitioned. Set to "" – empty by default.
  - `excludeStorageClasses` – Files with storage class in the `excludeStorageClasses` set are not transitioned. The default is `Set()` – an empty set.
  - `manifestFilePath` – An optional path for manifest file generation. All files that were successfully transitioned are recorded in `Success.csv`, and those that failed in `Failed.csv`
  - `accountId` – The Amazon Web Services account ID to run the transition transform. Mandatory for this transform.
  - `roleArn` – The AWS role to run the transition transform. Mandatory for this transform.
- `transformation_ctx` – The transformation context to use (optional). Used in the manifest file path.

## Example

```
glueContext.transition_s3_path("s3://bucket/prefix/", "STANDARD_IA",
    {"retentionPeriod": 1, "excludeStorageClasses": ["STANDARD_IA"],
    "manifestFilePath": "s3://bucketmanifest/", "accountId": "12345678901", "roleArn":
    "arn:aws:iam::123456789012:user/example-username"})
```

## Extracting

- [extract\\_jdbc\\_conf](#)

## extract\_jdbc\_conf

### extract\_jdbc\_conf(connection\_name, catalog\_id = None)

Returns a dict with keys with the configuration properties from the AWS Glue connection object in the Data Catalog.

- `user` – The database user name.
- `password` – The database password.
- `vendor` – Specifies a vendor (`mysql`, `postgresql`, `oracle`, `sqlserver`, etc.).
- `enforceSSL` – A boolean string indicating if a secure connection is required.
- `customJDBCCert` – Use a specific client certificate from the Amazon S3 path indicated.
- `skipCustomJDBCCertValidation` – A boolean string indicating if the `customJDBCCert` must be validated by a CA.
- `customJDBCCertString` – Additional information about the custom certificate, specific for the driver type.
- `url` – (Deprecated) JDBC URL with only protocol, server and port.
- `fullUrl` – JDBC URL as entered when the connection was created (Available in AWS Glue version 3.0 or later).

Example retrieving JDBC configurations:

```
jdbc_conf = glueContext.extract_jdbc_conf(connection_name="your_glue_connection_name")
print(jdbc_conf)
>>> {'enforceSSL': 'false', 'skipCustomJDBCCertValidation': 'false', 'url':
'jdbc:mysql://myserver:3306', 'fullUrl': 'jdbc:mysql://myserver:3306/mydb',
'customJDBCCertString': '', 'user': 'admin', 'customJDBCCert': '', 'password': '1234',
'vendor': 'mysql'}
```

## Transactions

- [start\\_transaction](#)
- [commit\\_transaction](#)
- [cancel\\_transaction](#)

## **start\_transaction**

### **start\_transaction(read\_only)**

Start a new transaction. Internally calls the Lake Formation [startTransaction](#) API.

- `read_only` – (Boolean) Indicates whether this transaction should be read only or read and write. Writes made using a read-only transaction ID will be rejected. Read-only transactions do not need to be committed.

Returns the transaction ID.

## **commit\_transaction**

### **commit\_transaction(transaction\_id, wait\_for\_commit = True)**

Attempts to commit the specified transaction. `commit_transaction` may return before the transaction has finished committing. Internally calls the Lake Formation [commitTransaction](#) API.

- `transaction_id` – (String) The transaction to commit.
- `wait_for_commit` – (Boolean) Determines whether the `commit_transaction` returns immediately. The default value is true. If false, `commit_transaction` polls and waits until the transaction is committed. The amount of wait time is restricted to 1 minute using exponential backoff with a maximum of 6 retry attempts.

Returns a Boolean to indicate whether the commit is done or not.

## **cancel\_transaction**

### **cancel\_transaction(transaction\_id)**

Attempts to cancel the specified transaction. Returns a `TransactionCommittedException` exception if the transaction was previously committed. Internally calls the Lake Formation [CancelTransaction](#) API.

- `transaction_id` – (String) The transaction to cancel.

## **Writing**

- [getSink](#)

- [write\\_dynamic\\_frame\\_from\\_options](#)
- [write\\_from\\_options](#)
- [write\\_dynamic\\_frame\\_from\\_catalog](#)
- [write\\_data\\_frame\\_from\\_catalog](#)
- [write\\_dynamic\\_frame\\_from\\_jdbc\\_conf](#)
- [write\\_from\\_jdbc\\_conf](#)

## getSink

**getSink(connection\_type, format = None, transformation\_ctx = "", \*\*options)**

Gets a DataSink object that can be used to write DynamicFrames to external sources. Check the SparkSQL format first to be sure to get the expected sink.

- `connection_type` – The connection type to use, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `kinesis`, and `kafka`.
- `format` – The SparkSQL format to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `options` – A collection of name-value pairs used to specify the connection options. Some of the possible values are:
  - `user` and `password`: For authorization
  - `url`: The endpoint for the data store
  - `dbtable`: The name of the target table
  - `bulkSize`: Degree of parallelism for insert operations

The options that you can specify depends on the connection type. See [Connection types and options for ETL in AWS Glue for Spark](#) for additional values and examples.

### Example:

```
>>> data_sink = context.getSink("s3")
>>> data_sink.setFormat("json"),
>>> data_sink.writeFrame(myFrame)
```

## write\_dynamic\_frame\_from\_options

```
write_dynamic_frame_from_options(frame, connection_type,
connection_options={}, format=None, format_options={}, transformation_ctx =
"")
```

Writes and returns a `DynamicFrame` using the specified connection and format.

- `frame` – The `DynamicFrame` to write.
- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, `oracle`, `kinesis`, and `kafka`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

### Warning

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
"password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-
path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).

- `format` – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.

- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

### `write_from_options`

```
write_from_options(frame_or_dfc, connection_type, connection_options={},
format={}, format_options={}, transformation_ctx = "")
```

Writes and returns a `DynamicFrame` or `DynamicFrameCollection` that is created with the specified connection and format information.

- `frame_or_dfc` – The `DynamicFrame` or `DynamicFrameCollection` to write.
- `connection_type` – The connection type, such as Amazon S3, Amazon Redshift, and JDBC. Valid values include `s3`, `mysql`, `postgresql`, `redshift`, `sqlserver`, and `oracle`.
- `connection_options` – Connection options, such as path and database table (optional). For a `connection_type` of `s3`, an Amazon S3 path is defined.

```
connection_options = {"path": "s3://aws-glue-target/temp"}
```

For JDBC connections, several properties must be defined. Note that the database name must be part of the URL. It can optionally be included in the connection options.

#### **Warning**

Storing passwords in your script is not recommended. Consider using `boto3` to retrieve them from AWS Secrets Manager or the AWS Glue Data Catalog.

```
connection_options = {"url": "jdbc-url/database", "user": "username",
"password": passwordVariable, "dbtable": "table-name", "redshiftTmpDir": "s3-tempdir-path"}
```

The `dbtable` property is the name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.

For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).

- `format` – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `format_options` – Format options for the specified format. See [Data format options for inputs and outputs in AWS Glue for Spark](#) for the formats that are supported.
- `transformation_ctx` – A transformation context to use (optional).

### **write\_dynamic\_frame\_from\_catalog**

```
write_dynamic_frame_from_catalog(frame, database, table_name,  
redshift_tmp_dir, transformation_ctx = "", additional_options = {},  
catalog_id = None)
```

Writes and returns a `DynamicFrame` using information from a Data Catalog database and table.

- `frame` – The `DynamicFrame` to write.
- `Database` – The Data Catalog database that contains the table.
- `table_name` – The name of the Data Catalog table associated with the target.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs.
- `catalog_id` – The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

### **write\_data\_frame\_from\_catalog**

```
write_data_frame_from_catalog(frame, database, table_name,  
redshift_tmp_dir, transformation_ctx = "", additional_options = {},  
catalog_id = None)
```

Writes and returns a `DataFrame` using information from a Data Catalog database and table. This method supports writing to data lake formats (Hudi, Iceberg, and Delta Lake). For more information, see [Using data lake frameworks with AWS Glue ETL jobs](#).

- `frame` – The DataFrame to write.
- `Database` – The Data Catalog database that contains the table.
- `table_name` – The name of the Data Catalog table that is associated with the target.
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – The transformation context to use (optional).
- `additional_options` – A collection of optional name-value pairs.
  - `useSparkDataSink` – When set to true, forces AWS Glue to use the native Spark Data Sink API to write to the table. When you enable this option, you can add any [Spark Data Source options](#) to `additional_options` as needed. AWS Glue passes these options directly to the Spark writer.
- `catalog_id` – The catalog ID (account ID) of the Data Catalog being accessed. When you don't specify a value, the default account ID of the caller is used.

## Limitations

Consider the following limitations when you use the `useSparkDataSink` option:

- The [enableUpdateCatalog](#) option isn't supported when you use the `useSparkDataSink` option.

## Example: Writing to a Hudi table using the Spark Data Source writer

```
hudi_options = {
    'useSparkDataSink': True,
    'hoodie.table.name': <table_name>,
    'hoodie.datasource.write.storage.type': 'COPY_ON_WRITE',
    'hoodie.datasource.write.recordkey.field': 'product_id',
    'hoodie.datasource.write.table.name': <table_name>,
    'hoodie.datasource.write.operation': 'upsert',
    'hoodie.datasource.write.precombine.field': 'updated_at',
    'hoodie.datasource.write.hive_style_partitioning': 'true',
    'hoodie.upsert.shuffle.parallelism': 2,
    'hoodie.insert.shuffle.parallelism': 2,
    'hoodie.datasource.hive_sync.enable': 'true',
    'hoodie.datasource.hive_sync.database': <database_name>,
    'hoodie.datasource.hive_sync.table': <table_name>,
    'hoodie.datasource.hive_sync.use_jdbc': 'false',
    'hoodie.datasource.hive_sync.mode': 'hms'}
```

```
glueContext.write_data_frame.from_catalog(  
    frame = <df_product_inserts>,  
    database = <database_name>,  
    table_name = <table_name>,  
    additional_options = hudi_options  
)
```

### **write\_dynamic\_frame\_from\_jdbc\_conf**

```
write_dynamic_frame_from_jdbc_conf(frame, catalog_connection,  
connection_options={}, redshift_tmp_dir = "", transformation_ctx = "",  
catalog_id = None)
```

Writes and returns a `DynamicFrame` using the specified JDBC connection information.

- `frame` – The `DynamicFrame` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).
- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `catalog_id` – The catalog ID (account ID) of the Data Catalog being accessed. When `None`, the default account ID of the caller is used.

### **write\_from\_jdbc\_conf**

```
write_from_jdbc_conf(frame_or_dfc, catalog_connection,  
connection_options={}, redshift_tmp_dir = "", transformation_ctx = "",  
catalog_id = None)
```

Writes and returns a `DynamicFrame` or `DynamicFrameCollection` using the specified JDBC connection information.

- `frame_or_dfc` – The `DynamicFrame` or `DynamicFrameCollection` to write.
- `catalog_connection` – A catalog connection to use.
- `connection_options` – Connection options, such as path and database table (optional). For more information, see [Connection types and options for ETL in AWS Glue for Spark](#).

- `redshift_tmp_dir` – An Amazon Redshift temporary directory to use (optional).
- `transformation_ctx` – A transformation context to use (optional).
- `catalog_id` — The catalog ID (account ID) of the Data Catalog being accessed. When None, the default account ID of the caller is used.

## AWS Glue PySpark transforms reference

AWS Glue provides the following built-in transforms that you can use in PySpark ETL operations. Your data passes from transform to transform in a data structure called a *DynamicFrame*, which is an extension to an Apache Spark SQL DataFrame. The *DynamicFrame* contains your data, and you reference its schema to process your data.

Most of these transforms also exist as methods of the *DynamicFrame* class. For more information, see [DynamicFrame transforms](#).

- [GlueTransform base class](#)
- [ApplyMapping class](#)
- [DropFields class](#)
- [DropNullFields class](#)
- [ErrorsAsDynamicFrame class](#)

- [UnnestFrame class](#)

## GlueTransform base class

The base class that all the `aws glue . transforms` classes inherit from.

The classes all define a `__call__` method. They either override the `GlueTransform` class methods listed in the following sections, or they are called using the class name by default.

## Methods

- [apply\(cls, \\*args, \\*\\*kwargs\)](#)
- [name\(cls\)](#)
- [describeArgs\(cls\)](#)
- [describeReturn\(cls\)](#)
- [describeTransform\(cls\)](#)
- [describeErrors\(cls\)](#)
- [describe\(cls\)](#)

### **apply(cls, \*args, \*\*kwargs)**

Applies the transform by calling the transform class, and returns the result.

- `cls` – The `self` class object.

### **name(cls)**

Returns the name of the derived transform class.

- `cls` – The self class object.

### **describeArgs(cls)**

- `cls` – The self class object.

Returns a list of dictionaries, each corresponding to a named argument, in the following format:

```
[
  {
    "name": "(name of argument)",
    "type": "(type of argument)",
    "description": "(description of argument)",
    "optional": "(Boolean, True if the argument is optional)",
    "defaultValue": "(Default value string, or None)(String; the default value, or None)"
  },
  ...
]
```

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

### **describeReturn(cls)**

- `cls` – The self class object.

Returns a dictionary with information about the return type, in the following format:

```
{
  "type": "(return type)",
  "description": "(description of output)"
}
```

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

### **describeTransform(cls)**

Returns a string describing the transform.

- `cls` – The self class object.

Raises a `NotImplementedError` exception when called in a derived transform where it is not implemented.

### **describeErrors(cls)**

- `cls` – The self class object.

Returns a list of dictionaries, each describing a possible exception thrown by this transform, in the following format:

```
[
  {
    "type": "(type of error)",
    "description": "(description of error)"
  },
  ...
]
```

### **describe(cls)**

- `cls` – The self class object.

Returns an object with the following format:

```
{
  "transform" : {
    "name" : cls.name( ),
    "args" : cls.describeArgs( ),
    "returns" : cls.describeReturn( ),
    "raises" : cls.describeErrors( ),
    "location" : "internal"
  }
}
```

## **ApplyMapping class**

Applies a mapping in a `DynamicFrame`.

## Example

We recommend that you use the [DynamicFrame.apply\\_mapping\(\)](#) method to apply a mapping in a DynamicFrame. To view a code example, see [Example: Use apply\\_mapping to rename fields and change field types](#).

## Methods

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(frame, mappings, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Applies a declarative mapping to a specified DynamicFrame.

- `frame` – The DynamicFrame to apply the mapping to (required).
- `mappings` – A list of mapping tuples (required). Each consists of: (source column, source type, target column, target type).

If the source column has a dot "." in the name, you must place back-ticks "`" around it. For example, to map `this.old.name` (string) to `thisNewName`, you would use the following tuple:

```
("`this.old.name`", "string", "thisNewName", "string")
```

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns only the fields of the `DynamicFrame` that are specified in the "mapping" tuples.

### **apply(cls, \*args, \*\*kwargs)**

Inherited from `GlueTransform` [apply](#).

### **name(cls)**

Inherited from `GlueTransform` [name](#).

### **describeArgs(cls)**

Inherited from `GlueTransform` [describeArgs](#).

### **describeReturn(cls)**

Inherited from `GlueTransform` [describeReturn](#).

### **describeTransform(cls)**

Inherited from `GlueTransform` [describeTransform](#).

### **describeErrors(cls)**

Inherited from `GlueTransform` [describeErrors](#).

### **describe(cls)**

Inherited from `GlueTransform` [describe](#).

## **DropFields class**

Drops fields within a `DynamicFrame`.

## **Example**

We recommend that you use the [`DynamicFrame.drop\_fields\(\)`](#) method to drop fields from a `DynamicFrame`. To view a code example, see [Example: Use `drop\_fields` to remove fields from a `DynamicFrame`](#).

## **Methods**

- [\\_\\_call\\_\\_](#)
- [apply](#)

- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(frame, paths, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Drops nodes within a `DynamicFrame`.

- `frame` – The `DynamicFrame` to drop the nodes in (required).
- `paths` – A list of full paths to the nodes to drop (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` without the specified fields.

**`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [apply](#).

**`name(cls)`**

Inherited from `GlueTransform` [name](#).

**`describeArgs(cls)`**

Inherited from `GlueTransform` [describeArgs](#).

**`describeReturn(cls)`**

Inherited from `GlueTransform` [describeReturn](#).

## describeTransform(cls)

Inherited from GlueTransform [describeTransform](#).

## describeErrors(cls)

Inherited from GlueTransform [describeErrors](#).

## describe(cls)

Inherited from GlueTransform [describe](#).

## DropNullFields class

Drops all null fields in a `DynamicFrame` whose type is `NullType`. These are fields with missing or null values in every record in the `DynamicFrame` dataset.

## Example

This example uses `DropNullFields` to create a new `DynamicFrame` where fields of type `NullType` have been dropped. In order to demonstrate `DropNullFields`, we add a new column named `empty_column` with type `null` to the already-loaded `persons` dataset.

### Note

To access the dataset that is used in this example, see [Code example: Joining and relationalizing data](#) and follow the instructions in [Step 1: Crawl the data in the Amazon S3 bucket](#).

```
# Example: Use DropNullFields to create a new DynamicFrame without NullType fields

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from pyspark.sql.functions import lit
from pyspark.sql.types import NullType
from awsglue.dynamicframe import DynamicFrame
from awsglue.transforms import DropNullFields

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
```

```
# Create DynamicFrame
persons = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="persons_json"
)
print("Schema for the persons DynamicFrame:")
persons.printSchema()

# Add new column "empty_column" with NullType
persons_with_nulls = persons.toDF().withColumn("empty_column",
    lit(None).cast(NullType()))
persons_with_nulls_dyf = DynamicFrame.fromDF(persons_with_nulls, glueContext,
    "persons_with_nulls")
print("Schema for the persons_with_nulls_dyf DynamicFrame:")
persons_with_nulls_dyf.printSchema()

# Remove the NullType field
persons_no_nulls = DropNullFields.apply(persons_with_nulls_dyf)
print("Schema for the persons_no_nulls DynamicFrame:")
persons_no_nulls.printSchema()
```

## Output

```
Schema for the persons DynamicFrame:
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string
|-- identifiers: array
|   |-- element: struct
|   |   |-- scheme: string
|   |   |-- identifier: string
|-- other_names: array
|   |-- element: struct
|   |   |-- lang: string
|   |   |-- note: string
|   |   |-- name: string
|-- sort_name: string
```

```
|-- images: array
|   |-- element: struct
|   |   |-- url: string
|-- given_name: string
|-- birth_date: string
|-- id: string
|-- contact_details: array
|   |-- element: struct
|   |   |-- type: string
|   |   |-- value: string
|-- death_date: string
```

Schema for the persons\_with\_nulls\_dyf DynamicFrame:

```
root
|-- family_name: string
|-- name: string
|-- links: array
|   |-- element: struct
|   |   |-- note: string
|   |   |-- url: string
|-- gender: string
|-- image: string

|   |   |-- value: string
|-- death_date: string
```

## Methods

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)

- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(frame, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Drops all null fields in a `DynamicFrame` whose type is `NullType`. These are fields with missing or null values in every record in the `DynamicFrame` dataset.

- `frame` – The `DynamicFrame` to drop null fields in (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` with no null fields.

**`apply(cls, *args, **kwargs)`**

- `cls` – `cls`

**`name(cls)`**

- `cls` – `cls`

**`describeArgs(cls)`**

- `cls` – `cls`

**`describeReturn(cls)`**

- `cls` – `cls`

## **describeTransform(cls)**

- `cls - cls`

## **describeErrors(cls)**

- `cls - cls`

## **describe(cls)**

- `cls - cls`

## **ErrorsAsDynamicFrame class**

Returns a `DynamicFrame` that contains nested records for errors that occurred while the source `DynamicFrame` was created.

### **Example**

We recommend that you use the [`DynamicFrame.errorsAsDynamicFrame\(\)`](#) method to retrieve and view error records. To view a code example, see [Example: Use errorsAsDynamicFrame to view error records](#).

### **Methods**

- [`\_\_call\_\_`](#)
- [`apply`](#)
- [`name`](#)
- [`describeArgs`](#)
- [`describeReturn`](#)
- [`describeTransform`](#)
- [`describeErrors`](#)
- [`Describe`](#)

**\_\_call\_\_(frame)**

Returns a `DynamicFrame` that contains nested error records that relate to the source `DynamicFrame`.

- `frame` – The source `DynamicFrame` (required).

**apply(cls, \*args, \*\*kwargs)**

- `cls` – `cls`

**name(cls)**

- `cls` – `cls`

**describeArgs(cls)**

- `cls` – `cls`

**describeReturn(cls)**

- `cls` – `cls`

**describeTransform(cls)**

- `cls` – `cls`

**describeErrors(cls)**

- `cls` – `cls`

**describe(cls)**

- `cls` – `cls`

## EvaluateDataQuality class

Evaluates a data quality ruleset against a `DynamicFrame` and returns a new `DynamicFrame` with results of the evaluation.

### Example

The following example code demonstrates how to evaluate data quality for a `DynamicFrame` and then view the data quality results.

```
from awsglue.transforms import *
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsgluedq.transforms import EvaluateDataQuality

#Create Glue context
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Define DynamicFrame
legislatorsAreas = glueContext.create_dynamic_frame.from_catalog(
    database="legislators", table_name="areas_json")

# Create data quality ruleset
ruleset = """"Rules = [ColumnExists "id", IsComplete "id"]""""

# Evaluate data quality
dqResults = EvaluateDataQuality.apply(
    frame=legislatorsAreas,
    ruleset=ruleset,
    publishing_options={
        "dataQualityEvaluationContext": "legislatorsAreas",
        "enableDataQualityCloudWatchMetrics": True,
        "enableDataQualityResultsPublishing": True,
        "resultsS3Prefix": "DOC-EXAMPLE-BUCKET1",
    },
)

# Inspect data quality results
dqResults.printSchema()
dqResults.toDF().show()
```

## Output

```

root
|-- Rule: string
|-- Outcome: string
|-- FailureReason: string
|-- EvaluatedMetrics: map
|   |-- keyType: string
|   |-- valueType: double

```

```

+-----+-----+-----+-----+
|Rule          |Outcome|FailureReason|EvaluatedMetrics|
+-----+-----+-----+-----+
|ColumnExists "id"  |Passed |null         |{}               |
|IsComplete "id"   |Passed |null         |{Column.first_name.Completeness -> 1.0}|
+-----+-----+-----+-----+

```

## Methods

- [\\_\\_call\\_\\_](#)

- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

### **`__call__(frame, ruleset, publishing_options = {})`**

- `frame` – The `DynamicFrame` that you want evaluate the data quality of.
- `ruleset` – A Data Quality Definition Language (DQDL) ruleset in string format. To learn more about DQDL, see the [Data Quality Definition Language \(DQDL\) reference](#) guide.
- `publishing_options` – A dictionary that specifies the following options for publishing evaluation results and metrics:

- `dataQualityEvaluationContext` – A string that specifies the namespace under which AWS Glue should publish Amazon CloudWatch metrics and the data quality results. The aggregated metrics appear in CloudWatch, while the full results appear in the AWS Glue Studio interface.
  - Required: No
  - Default value: `default_context`
- `enableDataQualityCloudWatchMetrics` – Specifies whether the results of the data quality evaluation should be published to CloudWatch. You specify a namespace for the metrics using the `dataQualityEvaluationContext` option.
  - Required: No
  - Default value: `False`
- `enableDataQualityResultsPublishing` – Specifies whether the data quality results should be visible on the **Data Quality** tab in the AWS Glue Studio interface.
  - Required: No
  - Default value: `True`
- `resultsS3Prefix` – Specifies the Amazon S3 location where AWS Glue can write the data quality evaluation results.
  - Required: No
  - Default value: `""` (empty string)

## describe(cls)

Inherited from `GlueTransform` [describe](#).

## FillMissingValues class

The `FillMissingValues` class locates null values and empty strings in a specified `DynamicFrame` and uses machine learning methods, such as linear regression and random forest, to predict the missing values. The ETL job uses the values in the input dataset to train the machine learning model, which then predicts what the missing values should be.

### Tip

If you use incremental data sets, then each incremental set is used as the training data for the machine learning model, so the results might not be as accurate.

To import:

```
from awsglueml.transforms import FillMissingValues
```

## Methods

- [Apply](#)

**`apply(frame, missing_values_column, output_column = "", transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Fills a dynamic frame's missing values in a specified column and returns a new frame with estimates in a new column. For rows without missing values, the specified column's value is duplicated to the new column.

- `frame` – The `DynamicFrame` in which to fill missing values. Required.
- `missing_values_column` – The column containing missing values (null values and empty strings). Required.

- `output_column` – The name of the new column that will contain estimated values for all rows whose value was missing. Optional; the default is the name of `missing_values_column` suffixed by `"_filled"`.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional; the default is zero).
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional; the default is zero).

Returns a new `DynamicFrame` with one additional column that contains estimations for rows with missing values and the present value for other rows.

## Filter class

Builds a new `DynamicFrame` that contains records from the input `DynamicFrame` that satisfy a specified predicate function.

## Example

We recommend that you use the [`DynamicFrame.filter\(\)`](#) method to filter records in a `DynamicFrame`. To view a code example, see [Example: Use filter to get a filtered selection of fields](#).

## Methods

- [`\_\_call\_\_`](#)
- [`apply`](#)
- [`name`](#)
- [`describeArgs`](#)
- [`describeReturn`](#)
- [`describeTransform`](#)
- [`describeErrors`](#)
- [`describe`](#)

**`__call__(frame, f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`**

Returns a new `DynamicFrame` that is built by selecting records from the input `DynamicFrame` that satisfy a specified predicate function.

- `frame` – The source `DynamicFrame` to apply the specified filter function to (required).
- `f` – The predicate function to apply to each `DynamicRecord` in the `DynamicFrame`. The function must take a `DynamicRecord` as its argument and return `True` if the `DynamicRecord` meets the filter requirements, or `False` if it doesn't (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in a Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

**`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [apply](#).

**`name(cls)`**

Inherited from `GlueTransform` [name](#).

**`describeArgs(cls)`**

Inherited from `GlueTransform` [describeArgs](#).

**`describeReturn(cls)`**

**`describeTransform(cls)`**

Inherited from `GlueTransform` [describeTransform](#).

## **describeErrors(cls)**

Inherited from `GlueTransform` [describeErrors](#).

## **describe(cls)**

Inherited from `GlueTransform` [describe](#).

## **FindIncrementalMatches class**

Identifies matching records in the existing and incremental `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

To import:

```
from awsglueml.transforms import FindIncrementalMatches
```

## **Methods**

- [Apply](#)

**apply(existingFrame, incrementalFrame, transformId, transformation\_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0, enforcedMatches = none, computeMatchConfidenceScores = 0)**

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

- `existingFrame` – The existing and pre-matched `DynamicFrame` to apply the `FindIncrementalMatches` transform. Required.
- `incrementalFrame` – The incremental `DynamicFrame` to apply the `FindIncrementalMatches` transform to match against the `existingFrame`. Required.
- `transformId` – The unique ID associated with the `FindIncrementalMatches` transform to apply on records in the `DynamicFrames`. Required.
- `transformation_ctx` – A unique string that is used to identify stats/state information. Optional.
- `info` – A string to be associated with errors in the transformation. Optional.
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out. Optional. The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out. Optional. The default is zero.
- `enforcedMatches` – The `DynamicFrame` used to enforce matches. Optional. The default is `None`.
- `computeMatchConfidenceScores` – A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

## FindMatches class

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

To import:

```
from awsglueml.transforms import FindMatches
```

## Methods

- [Apply](#)

**`apply(frame, transformId, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0, enforcedMatches = none, computeMatchConfidenceScores = 0)`**

Identifies matching records in the input `DynamicFrame` and creates a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

- `frame` – The `DynamicFrame` to apply the `FindMatches` transform. Required.
- `transformId` – The unique ID associated with the `FindMatches` transform to apply on records in the `DynamicFrame`. Required.
- `transformation_ctx` – A unique string that is used to identify stats/state information. Optional.
- `info` – A string to be associated with errors in the transformation. Optional.
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out. Optional. The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out. Optional. The default is zero.
- `enforcedMatches` – The `DynamicFrame` used to enforce matches. Optional. The default is `None`.
- `computeMatchConfidenceScores` – A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new `DynamicFrame` with a unique identifier assigned to each group of matching records.

## FlatMap class

Applies a transform to each `DynamicFrame` in a collection. Results are not flattened into a single `DynamicFrame`, but preserved as a collection.

## Examples for FlatMap

The following example snippet demonstrates how to use the `ResolveChoice` transform on a collection of dynamic frames when applied to a `FlatMap`. The data used for input is in the JSON located at the placeholder Amazon S3 address `s3://bucket/path-for-data/sample.json` and contains the following data.

## Example JSON data

```
[{
  "firstname": "Arnav",
  "lastname": "Desai",
  "address": {
    "street": "6 Anyroad Avenue",
    "city": "London",
    "state": "England",
    "country": "UK"
  },
  "phone": 17235550101,
  "affiliations": [
    "General Anonymous Example Products",
    "Example Independent Research",
    "Government Department of Examples"
  ]
},
{
  "firstname": "Mary",
```

```

    "lastname": "Major",
    "address": {
      "street": "7821 Spot Place",
      "city": "Centerville",
      "state": "OK",
      "country": "US"
    },
    "phone": 19185550023,
    "affiliations": [
      "Example Dot Com",
      "Example Independent Research",
      "Example.io"
    ]
  },
  {
    "firstname": "Paulo",
    "lastname": "Santos",
    "address": {
      "street": "123 Maple Street",
      "city": "London",
      "state": "Ontario",
      "country": "CA"
    },
    "phone": 12175550181,
    "affiliations": [
      "General Anonymous Example Products",
      "Example Dot Com"
    ]
  }
]}

```

### Example Apply ResolveChoice to a DynamicFrameCollection and show output.

```

#Read DynamicFrame
datasource = glueContext.create_dynamic_frame_from_options("s3", connection_options =
  {"paths":["s3://bucket/path/to/file/mysamplejson.json"]}, format="json")
datasource.printSchema()
datasource.show()

## Split to create a DynamicFrameCollection
split_frame=datasource.split_fields(["firstname","lastname","address"],"personal_info","business")
split_frame.keys()
print("---")

```

```
## Use FlatMap to run ResolveChoice
kwargs = {"choice": "cast:string"}
flat = FlatMap.apply(split_frame, ResolveChoice, frame_name="frame",
  transformation_ctx='tcx', **kwargs)
flat.keys()

##Select one of the DynamicFrames
personal_info = flat.select("personal_info")
personal_info.printSchema()
personal_info.show()
print("---")

business_info = flat.select("business_info")
business_info.printSchema()
business_info.show()
```

### Important

When calling `FlatMap.apply`, the `frame_name` parameter **must** be `"frame"`. No other value is currently accepted.

## Example output

```
root
|-- firstname: string
|-- lastname: string
|-- address: struct
|   |-- street: string
|   |-- city: string
|   |-- state: string
|   |-- country: string
|-- phone: long
|-- affiliations: array
|   |-- element: string
---
{
  "firstname": "Mary",
  "lastname": "Major",
  "address": {
    "street": "7821 Spot Place",
    "city": "Centerville",
```

```
    "state": "OK",
    "country": "US"
  },

- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(dfc, BaseTransform, frame_name, transformation_ctx = "", **base_kwargs)`**

Applies a transform to each `DynamicFrame` in a collection and flattens the results.

- `dfc` – The `DynamicFrameCollection` over which to flatmap (required).
- `BaseTransform` – A transform derived from `GlueTransform` to apply to each member of the collection (required).
- `frame_name` – The argument name to pass the elements of the collection to (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `base_kwargs` – Arguments to pass to the base transform (required).

Returns a new `DynamicFrameCollection` created by applying the transform to each `DynamicFrame` in the source `DynamicFrameCollection`.

**`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [apply](#).

**`name(cls)`**

## **Join class**

Performs an equality join on two DynamicFrames.

## **Example**

We recommend that you use the [DynamicFrame.join\(\)](#) method to join DynamicFrames. To view a code example, see [Example: Use join to combine DynamicFrames](#).

## **Methods**

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(frame1, frame2, keys1, keys2, transformation_ctx = "")`**

Performs an equality join on two DynamicFrames.

- `frame1` – The first DynamicFrame to join (required).
- `frame2` – The second DynamicFrame to join (required).
- `keys1` – The keys to join on for the first frame (required).
- `keys2` – The keys to join on for the second frame (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).

Returns a new `DynamicFrame` that is created by joining the two `DynamicFrames`.

### **`apply(cls, *args, **kwargs)`**

## **Map class**

Builds a new `DynamicFrame` by applying a function to all records in the input `DynamicFrame`.

## **Example**

We recommend that you use the [`DynamicFrame.map\(\)`](#) method to apply a function to all records in a `DynamicFrame`. To view a code example, see [Example: Use map to apply a function to every record in a DynamicFrame](#).

## **Methods**

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)

- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(frame, f, transformation_ctx="", info="", stageThreshold=0, totalThreshold=0)`**

Returns a new `DynamicFrame` that results from applying the specified function to all `DynamicRecords` in the original `DynamicFrame`.

- `frame` – The original `DynamicFrame` to apply the mapping function to (required).
- `f` – The function to apply to all `DynamicRecords` in the `DynamicFrame`. The function must take a `DynamicRecord` as an argument and return a new `DynamicRecord` that is produced by the mapping (required).

A `DynamicRecord` represents a logical record in a `DynamicFrame`. It's similar to a row in an Apache Spark `DataFrame`, except that it is self-describing and can be used for data that doesn't conform to a fixed schema.

- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` that results from applying the specified function to all `DynamicRecords` in the original `DynamicFrame`.

Inherited from `GlueTransform` [describeErrors](#).

**describe(cls)**

Inherited from `GlueTransform` [describe](#).

**MapToCollection class**

Applies a transform to each `DynamicFrame` in the specified `DynamicFrameCollection`.

**Methods**

- [\\_\\_call\\_\\_](#)
- [Apply](#)
- [Name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(dfc, BaseTransform, frame_name, transformation_ctx = "", **base_kwargs)`**

Applies a transform function to each `DynamicFrame` in the specified `DynamicFrameCollection`.

- `dfc` – The `DynamicFrameCollection` over which to apply the transform function (required).
- `callable` – A callable transform function to apply to each member of the collection (required).

- `transformation_ctx` – A unique string that is used to identify state information (optional).

Returns a new `DynamicFrameCollection` created by applying the transform to each `DynamicFrame` in the source `DynamicFrameCollection`.

## **Relationalize class**

Flattens a nested schema in a `DynamicFrame` and pivots out array columns from the flattened frame.

## **Example**

We recommend that you use the [`DynamicFrame.relationalize\(\)`](#) method to relationalize a `DynamicFrame`. To view a code example, see [Example: Use relationalize to flatten a nested schema in a `DynamicFrame`](#).

## Methods

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(frame, staging_path=None, name='roottable', options=None, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Relationalizes a `DynamicFrame` and produces a list of frames that are generated by unnesting nested columns and pivoting array columns. You can join a pivoted array column to the root table by using the join key that is generated in the unnest phase.

- `frame` – The `DynamicFrame` to relationalize (required).
- `staging_path` – The path where the method can store partitions of pivoted tables in CSV format (optional). Pivoted tables are read back from this path.
- `name` – The name of the root table (optional).
- `options` – A dictionary of optional parameters. Currently unused.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

**`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [apply](#).

**name(cls)**

Inherited from `GlueTransform` [name](#).

**describeArgs(cls)**

**describeReturn(cls)**

Inherited from `GlueTransform` [describeReturn](#).

**describeTransform(cls)**

Inherited from `GlueTransform` [describeTransform](#).

**describeErrors(cls)**

Inherited from `GlueTransform` [describeErrors](#).

**describe(cls)**

Inherited from `GlueTransform` [describe](#).

**RenameField class**

Renames a node within a `DynamicFrame`.

**Example**

We recommend that you use the [DynamicFrame.rename\\_field\(\)](#) method to rename a field in a `DynamicFrame`. To view a code example, see [Example: Use rename\\_field to rename fields in a DynamicFrame](#).

**Methods**

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)

- [describe](#)

**\_\_call\_\_(frame, old\_name, new\_name, transformation\_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)**

Renames a node within a DynamicFrame.

- `frame` – The DynamicFrame in which to rename a node (required).
- `old_name` – The full path to the node to rename (required).

If the old name has dots in it, `RenameField` will not work unless you place backticks around it (```). For example, to replace `this.old.name` with `thisNewName`, you would call `RenameField` as follows:

```
newDyF = RenameField(oldDyF, "`this.old.name`", "thisNewName")
```

- `new_name` – The new name, including full path (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

**apply(cls, \*args, \*\*kwargs)**

Inherited from `GlueTransform` [apply](#).

**name(cls)**

Inherited from `GlueTransform` [name](#).

**describeArgs(cls)**

Inherited from `GlueTransform` [describeArgs](#).

**describeReturn(cls)**

Inherited from `GlueTransform` [describeReturn](#).

## **describeTransform(cls)**

Inherited from `GlueTransform` [describeTransform](#).

## **describeErrors(cls)**

Inherited from `GlueTransform` [describeErrors](#).

## **describe(cls)**

Inherited from `GlueTransform` [describe](#).

## **ResolveChoice class**

Resolves a choice type within a `DynamicFrame`.

## **Example**

We recommend that you use the [`DynamicFrame.resolveChoice\(\)`](#) method to handle fields that contain multiple types in a `DynamicFrame`. To view a code example, see [Example: Use `resolveChoice` to handle a column that contains multiple types](#).

## **Methods**

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(frame, specs = none, choice = "", transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Provides information for resolving ambiguous types within a `DynamicFrame`. It returns the resulting `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to resolve the choice type (required).
- `specs` – A list of specific ambiguities to resolve, each in the form of a tuple: (`path`, `action`). The `path` value identifies a specific ambiguous element, and the `action` value identifies the corresponding resolution.

You can only use one of the `spec` and `choice` parameters. If the `spec` parameter is not `None`, then the `choice` parameter must be an empty string. Conversely, if the `choice` is not an empty string, then the `spec` parameter must be `None`. If neither parameter is provided, AWS Glue tries to parse the schema and use it to resolve ambiguities.

You can specify one of the following resolution strategies in the `action` portion of a `specs` tuple:

- `cast` – Allows you to specify a type to cast to (for example, `cast:int`).
- `make_cols` – Resolves a potential ambiguity by flattening the data. For example, if `columnA` could be an `int` or a `string`, the resolution is to produce two columns named `columnA_int` and `columnA_string` in the resulting `DynamicFrame`.
- `make_struct` – Resolves a potential ambiguity by using a struct to represent the data. For example, if data in a column could be an `int` or a `string`, using the `make_struct` action produces a column of structures in the resulting `DynamicFrame` with each containing both an `int` and a `string`.
- `project` – Resolves a potential ambiguity by retaining only values of a specified type in the resulting `DynamicFrame`. For example, if data in a `ChoiceType` column could be an `int` or a `string`, specifying a `project:string` action drops values from the resulting `DynamicFrame` that are not `string`.

If the `path` identifies an array, place empty square brackets after the name of the array to avoid ambiguity. For example, suppose you are working with data structured as follows:

```
"myList": [  
  { "price": 100.00 },  
  { "price": "$100.00" }  
]
```

You can select the numeric rather than the string version of the price by setting the `path` to `"myList[].price"`, and setting the `action` to `"cast:double"`.

- `choice` – The default resolution action if the `specs` parameter is `None`. If the `specs` parameter is not `None`, then this must not be set to anything but an empty string.

In addition to the specs actions previously described, this argument also supports the following action:

- `MATCH_CATALOG` – Attempts to cast each `ChoiceType` to the corresponding type in the specified Data Catalog table.
- `database` – The AWS Glue Data Catalog database to use with the `MATCH_CATALOG` choice (required for `MATCH_CATALOG` ).
- `table_name` – The AWS Glue Data Catalog table name to use with the `MATCH_CATALOG` action (required for `MATCH_CATALOG` ).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

### SelectFields class

The `SelectFields` class creates a new `DynamicFrame` from an existing `DynamicFrame`, and keeps only the fields that you specify. `SelectFields` provides similar functionality to a SQL `SELECT` statement.

### Example

We recommend that you use the [DynamicFrame.select\\_fields\(\)](#) method to select fields from a `DynamicFrame`. To view a code example, see [Example: Use select\\_fields to create a new DynamicFrame with chosen fields](#).

### Methods

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [Describe](#)

**`__call__(frame, paths, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Gets fields (nodes) in a `DynamicFrame`.

- `frame` – The `DynamicFrame` to select fields in (required).
- `paths` – A list of full paths to the fields to select (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string that is associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

Returns a new `DynamicFrame` that contains only the specified fields.

## **SelectFromCollection class**

Selects one `DynamicFrame` in a `DynamicFrameCollection`.

### **Example**

This example uses `SelectFromCollection` to select a `DynamicFrame` from a `DynamicFrameCollection`.

### **Example dataset**

The example selects two DynamicFrames from a DynamicFrameCollection called `split_rows_collection`. The following is the list of keys in `split_rows_collection`.

```
dict_keys(['high', 'low'])
```

## Example code

```
# Example: Use SelectFromCollection to select
# DynamicFrames from a DynamicFrameCollection

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import SelectFromCollection

# Create GlueContext
sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

# Select frames and inspect entries
frame_low = SelectFromCollection.apply(dfc=split_rows_collection, key="low")
frame_low.toDF().show()

frame_high = SelectFromCollection.apply(dfc=split_rows_collection, key="high")
frame_high.toDF().show()
```

## Output

- [apply](#)
- [name](#)

- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(dfc, key, transformation_ctx = "")`**

Gets one `DynamicFrame` from a `DynamicFrameCollection`.

- `dfc` – The `DynamicFrameCollection` that the `DynamicFrame` should be selected from (required).
- `key` – The key of the `DynamicFrame` to select (required).
- `transformation_ctx` – A unique string that is used to identify state information (optional).

**`apply(cls, *args, **kwargs)`**

## describe(cls)

Inherited from `GlueTransform` [describe](#).

## Simplify\_ddb\_json class

Simplifies nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new simplified `DynamicFrame`.

### Example

We recommend that you use the `DynamicFrame.simplify_ddb_json()` method to simplify nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure. To view a code example, see [Example: Use simplify\\_ddb\\_json to invoke a DynamoDB JSON simplify](#).

## Spigot class

Writes sample records to a specified destination to help you verify the transformations performed by your AWS Glue job.

### Example

We recommend that you use the [DynamicFrame.spigot\(\)](#) method to write a subset of records from a `DynamicFrame` to a specified destination. To view a code example, see [Example: Use spigot to write sample fields from a DynamicFrame to Amazon S3](#).

## Methods

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(frame, path, options, transformation_ctx = "")`**

Writes sample records to a specified destination during a transformation.

- `frame` – The `DynamicFrame` to spigot (required).
- `path` – The path of the destination to write to (required).
- `options` – JSON key-value pairs that specify options (optional). The "topk" option specifies that the first *k* records should be written. The "prob" option specifies the probability (as a decimal) of picking any given record. You use this in selecting records to write.
- `transformation_ctx` – A unique string that is used to identify state information (optional).

### **`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [describe](#)

### **`SplitFields` class**

Splits a `DynamicFrame` into two new ones, by specified fields.

## Example

We recommend that you use the `DynamicFrame.split_fields()` method to split fields in a `DynamicFrame`. To view a code example, see [Example: Use `split\_fields` to split selected fields into a separate `DynamicFrame`](#).

## Methods

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(frame, paths, name1 = none, name2 = none, transformation_ctx = "", info = "", stageThreshold = 0, totalThreshold = 0)`**

Splits one or more fields in a `DynamicFrame` off into a new `DynamicFrame`, and creates another new `DynamicFrame` that contains the fields that remain.

- `frame` – The source `DynamicFrame` to split into two new ones (required).
- `paths` – A list of full paths to the fields to be split (required).
- `name1` – The name to assign to the `DynamicFrame` that will contain the fields to be split off (optional). If no name is supplied, the name of the source frame is used with "1" appended.
- `name2` – The name to assign to the `DynamicFrame` that will contain the fields that remain after the specified fields are split off (optional). If no name is provided, the name of the source frame is used with "2" appended.
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.

- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

### **`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [describe](#).

## **SplitRows class**

Creates a `DynamicFrameCollection` that contains two `DynamicFrames`. One `DynamicFrame` contains only the specified rows to be split, and the other contains all remaining rows.

## **Example**

We recommend that you use the `DynamicFrame.split_rows()` method to split rows in a `DynamicFrame`. To view a code example, see [Example: Use split\\_rows to split rows in a DynamicFrame](#).

## **Methods**

- [\\_\\_call\\_\\_](#)

- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)
- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(frame, comparison_dict, name1="frame1", name2="frame2", transformation_ctx = "", info = none, stageThreshold = 0, totalThreshold = 0)`**

Splits one or more rows in a `DynamicFrame` off into a new `DynamicFrame`.

- `frame` – The source `DynamicFrame` to split into two new ones (required).
- `comparison_dict` – A dictionary where the key is the full path to a column, and the value is another dictionary for mapping comparators to values that the column values are compared to. For example, `{"age": {">": 10, "<": 20}}` splits rows where the value of "age" is between 10 and 20, exclusive, from rows where "age" is outside that range (required).
- `name1` – The name to assign to the `DynamicFrame` that will contain the rows to be split off (optional).
- `name2` – The name to assign to the `DynamicFrame` that will contain the rows that remain after the specified rows are split off (optional).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.

**describe(cls)**

Inherited from `GlueTransform` [describe](#).

**Unbox class**

Unboxes (reformats) a string field in a `DynamicFrame`.

**Example**

We recommend that you use the [`DynamicFrame.unbox\(\)`](#) method to unbox a field in a `DynamicFrame`. To view a code example, see [Example: Use unbox to unbox a string field into a struct](#).

**Methods**

- [\\_\\_call\\_\\_](#)
- [apply](#)
- [name](#)
- [describeArgs](#)
- [describeReturn](#)

- [describeTransform](#)
- [describeErrors](#)
- [describe](#)

**`__call__(frame, path, format, transformation_ctx = "", info="", stageThreshold=0, totalThreshold=0, **options)`**

Unboxes a string field in a `DynamicFrame`.

- `frame` – The `DynamicFrame` in which to unbox a field. (required).
- `path` – The full path to the `StringNode` to unbox (required).
- `format` – A format specification (optional). This is used for an Amazon S3 or AWS Glue connection that supports multiple formats. For the formats that are supported, see [Data format options for inputs and outputs in AWS Glue for Spark](#).
- `transformation_ctx` – A unique string that is used to identify state information (optional).
- `info` – A string associated with errors in the transformation (optional).
- `stageThreshold` – The maximum number of errors that can occur in the transformation before it errors out (optional). The default is zero.
- `totalThreshold` – The maximum number of errors that can occur overall before processing errors out (optional). The default is zero.
- `separator` – A separator token (optional).
- `escaper` – An escape token (optional).
- `skipFirst` – True if the first line of data should be skipped, or False if it should not be skipped (optional).
- `withSchema` – A string that contains a schema for the data to be unboxed (optional). This should always be created using `StructType.json`.
- `withHeader` – True if the data being unpacked includes a header, or False if not (optional).

**`apply(cls, *args, **kwargs)`**

Inherited from `GlueTransform` [apply](#).

**`name(cls)`**

## Using Scala to program AWS Glue ETL scripts

You can automatically generate a Scala extract, transform, and load (ETL) program using the AWS Glue console, and modify it as needed before assigning it to a job. Or, you can write your own program from scratch. For more information, see [Configuring job properties for Spark jobs in AWS Glue](#). AWS Glue then compiles your Scala program on the server before running the associated job.

To ensure that your program compiles without errors and runs as expected, it's important that you load it on a development endpoint in a REPL (Read-Eval-Print Loop) or a Jupyter Notebook and test it there before running it in a job. Because the compile process occurs on the server, you will not have good visibility into any problems that happen there.

### Testing a Scala ETL program in a Jupyter notebook on a development endpoint

To test a Scala program on an AWS Glue development endpoint, set up the development endpoint [as described in Adding a development endpoint](#).

Next, connect it to a Jupyter Notebook that is either running locally on your machine or remotely on an Amazon EC2 notebook server. To install a local version of a Jupyter Notebook, follow the instructions in [Tutorial: Jupyter notebook in JupyterLab](#).

The only difference between running Scala code and running PySpark code on your Notebook is that you should start each paragraph on the Notebook with the the following:

```
%spark
```

This prevents the Notebook server from defaulting to the PySpark flavor of the Spark interpreter.

### Testing a Scala ETL program in a Scala REPL

You can test a Scala program on a development endpoint using the AWS GlueScala REPL. Follow the instructions in [Tutorial: Use a SageMaker notebook](#), except at the end of the SSH-to-REPL command, replace `-t gluepyspark` with `-t glue-spark-shell`. This invokes the AWS Glue Scala REPL.

To close the REPL when you are finished, type `sys.exit`.

### Scala script example - streaming ETL

#### Example

The following example script connects to Amazon Kinesis Data Streams, uses a schema from the Data Catalog to parse a data stream, joins the stream to a static dataset on Amazon S3, and outputs the joined results to Amazon S3 in parquet format.

```
// This script connects to an Amazon Kinesis stream, uses a schema from the data
// catalog to parse the stream,
// joins the stream to a static dataset on Amazon S3, and outputs the joined results to
// Amazon S3 in parquet format.
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import java.util.Calendar
import org.apache.spark.SparkContext
import org.apache.spark.sql.Dataset
import org.apache.spark.sql.Row
import org.apache.spark.sql.SaveMode
import org.apache.spark.sql.Session
import org.apache.spark.sql.functions.from_json
```

```
import org.apache.spark.sql.streaming.Trigger
import scala.collection.JavaConverters._

object streamJoiner {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val sparkSession: SparkSession = glueContext.getSparkSession
    import sparkSession.implicits._
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val staticData = sparkSession.read          // read() returns type DataFrameReader
      .format("csv")
      .option("header", "true")
      .load("s3://awsexamplebucket-streaming-demo2/inputs/productsStatic.csv") //
    load() returns a DataFrame

    val datasource0 = sparkSession.readStream // readstream() returns type
    DataStreamReader
      .format("kinesis")
      .option("streamName", "stream-join-demo")
      .option("endpointUrl", "https://kinesis.us-east-1.amazonaws.com")
      .option("startingPosition", "TRIM_HORIZON")
      .load // load() returns a DataFrame

    val selectfields1 = datasource0.select(from_json($"data".cast("string"),
    glueContext.getCatalogSchemaAsSparkSchema("stream-demos", "stream-join-demo2")) as
    "data").select("data.*")

    val datasink2 = selectfields1.writeStream.foreachBatch { (dataFrame: Dataset[Row],
    batchId: Long) => { //foreachBatch() returns type DataStreamWriter
      val joined = dataFrame.join(staticData, "product_id")
      val year: Int = Calendar.getInstance().get(Calendar.YEAR)
      val month :Int = Calendar.getInstance().get(Calendar.MONTH) + 1
      val day: Int = Calendar.getInstance().get(Calendar.DATE)
      val hour: Int = Calendar.getInstance().get(Calendar.HOUR_OF_DAY)

      if (dataFrame.count() > 0) {
        joined.write // joined.write returns type
        DataFrameWriter
          .mode(SaveMode.Append)
          .format("parquet")
      }
    }
  }
}
```

```
        .option("quote", " ")
        .save("s3://awsexamplebucket-streaming-demo2/output/" + "/year=" +
"%04d".format(year) + "/month=" + "%02d".format(month) + "/day=" + "%02d".format(day)
+ "/hour=" + "%02d".format(hour) + "/")
    }
}
} // end foreachBatch()
.trigger(Trigger.ProcessingTime("100 seconds"))
.option("checkpointLocation", "s3://awsexamplebucket-streaming-demo2/
checkpoint/")
.start().awaitTermination() // start() returns type StreamingQuery
Job.commit()
}
}
```

## APIs in the AWS Glue Scala library

AWS Glue supports an extension of the PySpark Scala dialect for scripting extract, transform, and load (ETL) jobs. The following sections describe the APIs in the AWS Glue Scala library.

### **com.amazonaws.services.glue**

The **com.amazonaws.services.glue** package in the AWS Glue Scala library contains the following APIs:

- [ChoiceOption](#)
- [DataSink](#)
- [DataSource trait](#)
- [DynamicFrame](#)
- [DynamicRecord](#)
- [GlueContext](#)
- [MappingSpec](#)
- [ResolveSpec](#)

### **com.amazonaws.services.glue.ml**

The **com.amazonaws.services.glue.ml** package in the AWS Glue Scala library contains the following APIs:

- [FillMissingValues](#)
- [FindIncrementalMatches](#)
- [FindMatches](#)

### **com.amazonaws.services.glue.dq**

The **com.amazonaws.services.glue.dq** package in the AWS Glue Scala library contains the following APIs:

- [EvaluateDataQuality](#)

### **com.amazonaws.services.glue.types**

The **com.amazonaws.services.glue.types** package in the AWS Glue Scala library contains the following APIs:

- [ArrayNode](#)
- [BinaryNode](#)
- [BooleanNode](#)
- [ByteNode](#)
- [DateNode](#)
- [DecimalNode](#)
- [DoubleNode](#)
- [DynamicNode](#)
- [FloatNode](#)
- [IntegerNode](#)
- [LongNode](#)
- [MapLikeNode](#)
- [MapNode](#)
- [NullNode](#)
- [ObjectNode](#)
- [ScalarNode](#)
- [ShortNode](#)

- [StringNode](#)
- [TimestampNode](#)

## **com.amazonaws.services.glue.util**

The **com.amazonaws.services.glue.util** package in the AWS Glue Scala library contains the following APIs:

- [GlueArgParser](#)
- [Job](#)

## **AWS Glue Scala ChoiceOption APIs**

### **Topics**

- [ChoiceOption trait](#)
- [ChoiceOption object](#)
- [Case class ChoiceOptionWithResolver](#)
- [Case class MatchCatalogSchemaChoiceOption](#)

**Package:** `com.amazonaws.services.glue`

### **ChoiceOption trait**

```
trait ChoiceOption extends Serializable
```

### **ChoiceOption object**

### **ChoiceOption**

```
object ChoiceOption
```

A general strategy to resolve choice applicable to all ChoiceType nodes in a DynamicFrame.

- `val CAST`
- `val MAKE_COLS`
- `val MAKE_STRUCT`

- val MATCH\_CATALOG
- val PROJECT

## Def apply

```
def apply(choice: String): ChoiceOption
```

## Case class ChoiceOptionWithResolver

```
case class ChoiceOptionWithResolver(name: String, choiceResolver: ChoiceResolver)  
  extends ChoiceOption {}
```

## Case class MatchCatalogSchemaChoiceOption

```
case class MatchCatalogSchemaChoiceOption() extends ChoiceOption {}
```

## Abstract DataSink class

### Topics

- [Def writeDynamicFrame](#)
- [Def pyWriteDynamicFrame](#)
- [Def writeDataFrame](#)
- [Def pyWriteDataFrame](#)
- [Def setCatalogInfo](#)
- [Def supportsFormat](#)
- [Def setFormat](#)
- [Def withFormat](#)
- [Def setAccumulableSize](#)
- [Def getOutputErrorRecordsAccumulable](#)
- [Def errorsAsDynamicFrame](#)
- [DataSink object](#)

**Package: com.amazonaws.services.glue**

```
abstract class DataSink
```

The writer analog to a `DataSource`. `DataSink` encapsulates a destination and a format that a `DynamicFrame` can be written to.

**Def writeDynamicFrame**

```
def writeDynamicFrame( frame : DynamicFrame,  
                      callSite : CallSite = CallSite("Not provided", "")  
                      ) : DynamicFrame
```

**Def pyWriteDynamicFrame**

```
def pyWriteDynamicFrame( frame : DynamicFrame,  
                        site : String = "Not provided",  
                        info : String = "" )
```

**Def writeDataFrame**

```
def writeDataFrame(frame: DataFrame,  
                  glueContext: GlueContext,  
                  callSite: CallSite = CallSite("Not provided", ""))  
  ): DataFrame
```

**Def pyWriteDataFrame**

```
def pyWriteDataFrame(frame: DataFrame,  
                    glueContext: GlueContext,  
                    site: String = "Not provided",  
                    info: String = ""  
                    ): DataFrame
```

**Def setCatalogInfo**

```
def setCatalogInfo(catalogDatabase: String,
```

```
catalogTableName : String,  
catalogId : String = "")
```

## Def supportsFormat

```
def supportsFormat( format : String ) : Boolean
```

## Def setFormat

```
def setFormat( format : String,  
              options : JsonOptions  
              ) : Unit
```

## Def withFormat

```
def withFormat( format : String,  
               options : JsonOptions = JsonOptions.empty  
               ) : DataSink
```

## Def setAccumulableSize

```
def setAccumulableSize( size : Int ) : Unit
```

## Def getOutputErrorRecordsAccumulable

```
def getOutputErrorRecordsAccumulable : Accumulable[List[OutputError], OutputError]
```

## Def errorsAsDynamicFrame

```
def errorsAsDynamicFrame : DynamicFrame
```

## DataSink object

```
object DataSink
```

## Def recordMetrics

```
def recordMetrics( frame : DynamicFrame,
                  ctxt : String
                  ) : DynamicFrame
```

## AWS Glue Scala DataSource trait

### Package: com.amazonaws.services.glue

A high-level interface for producing a DynamicFrame.

```
trait DataSource {

  def getDynamicFrame : DynamicFrame

  def getDynamicFrame( minPartitions : Int,
                      targetPartitions : Int
                      ) : DynamicFrame

  def getDataFrame : DataFrame

  /** @param num: the number of records for sampling.
    * @param options: optional parameters to control sampling behavior. Current
    available parameter for Amazon S3 sources in options:
    * 1. maxSamplePartitions: the maximum number of partitions the sampling will
    read.
    * 2. maxSampleFilesPerPartition: the maximum number of files the sampling will
    read in one partition.
    */
  def getSampleDynamicFrame(num:Int, options: JsonOptions = JsonOptions.empty):
  DynamicFrame

  def glueContext : GlueContext

  def setFormat( format : String,
                options : String
                ) : Unit

  def setFormat( format : String,
                options : JsonOptions
                ) : Unit
```

```
def supportsFormat( format : String ) : Boolean

def withFormat( format : String,
                options : JsonOptions = JsonOptions.empty
                ) : DataSource
}
```

## AWS Glue Scala DynamicFrame class

**Package:** `com.amazonaws.services.glue`

```
class DynamicFrame extends Serializable with Logging {  
  val glueContext : GlueContext,
```

```
_records : RDD[DynamicRecord],
val name : String = s"",
val transformationContext : String = DynamicFrame.UNDEFINED,
callSite : CallSite = CallSite("Not provided", ""),
stageThreshold : Long = 0,
totalThreshold : Long = 0,
prevErrors : => Long = 0,
errorExpr : => Unit = {} )
```

A `DynamicFrame` is a distributed collection of self-describing [DynamicRecord](#) objects.

`DynamicFrames` are designed to provide a flexible data model for ETL (extract, transform, and load) operations. They don't require a schema to create, and you can use them to read and transform data that contains messy or inconsistent values and types. A schema can be computed on demand for those operations that need one.

`DynamicFrames` provide a range of transformations for data cleaning and ETL. They also support conversion to and from SparkSQL `DataFrames` to integrate with existing code and the many analytics operations that `DataFrames` provide.

The following parameters are shared across many of the AWS Glue transformations that construct `DynamicFrames`:

- `transformationContext` — The identifier for this `DynamicFrame`. The `transformationContext` is used as a key for job bookmark state that is persisted across runs.
- `callSite` — Provides context information for error reporting. These values are automatically set when calling from Python.
- `stageThreshold` — The maximum number of error records that are allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records that are present in the previous `DynamicFrame`.
- `totalThreshold` — The maximum number of total error records before an exception is thrown, including those from previous frames.

### Val errorsCount

```
val errorsCount
```

The number of error records in this `DynamicFrame`. This includes errors from previous operations.

## Def applyMapping

```
def applyMapping( mappings : Seq[Product4[String, String, String, String]],
                  caseSensitive : Boolean = true,
                  transformationContext : String = "",
                  callSite : CallSite = CallSite("Not provided", ""),
                  stageThreshold : Long = 0,
                  totalThreshold : Long = 0
                ) : DynamicFrame
```

- **mappings** — A sequence of mappings to construct a new `DynamicFrame`.
- **caseSensitive** — Whether to treat source columns as case sensitive. Setting this to false might help when integrating with case-insensitive stores like the AWS Glue Data Catalog.

Selects, projects, and casts columns based on a sequence of mappings.

Each mapping is made up of a source column and type and a target column and type. Mappings can be specified as either a four-tuple (`source_path`, `source_type`, `target_path`, `target_type`) or a [MappingSpec](#) object containing the same information.

In addition to using mappings for simple projections and casting, you can use them to nest or unnest fields by separating components of the path with '.' (period).

For example, suppose that you have a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |   |-- state: string
  |   |-- zip: int
  }}}}
```

You can make the following call to unnest the state and zip fields.

```
{{{
  df.applyMapping(
    Seq(("name", "string", "name", "string"),
        ("age", "int", "age", "int"),
```

```

    ("address.state", "string", "state", "string"),
    ("address.zip", "int", "zip", "int")))
  }}}

```

The resulting schema is as follows.

```

{{{
  root
  |-- name: string
  |-- age: int
  |-- state: string
  |-- zip: int
  }}}

```

You can also use `applyMapping` to re-nest columns. For example, the following inverts the previous transformation and creates a struct named `address` in the target.

```

{{{
  df.applyMapping(
    Seq(("name", "string", "name", "string"),
        ("age", "int", "age", "int"),
        ("state", "string", "address.state", "string"),
        ("zip", "int", "address.zip", "int")))
  }}}

```

Field names that contain '.' (period) characters can be quoted by using backticks (` `).

### Note

Currently, you can't use the `applyMapping` method to map columns that are nested under arrays.

## Def `assertErrorThreshold`

```
def assertErrorThreshold : Unit
```

An action that forces computation and verifies that the number of error records falls below `stageThreshold` and `totalThreshold`. Throws an exception if either condition fails.

## Def count

```
lazy
def count
```

Returns the number of elements in this `DynamicFrame`.

## Def dropField

```
def dropField( path : String,
               transformationContext : String = "",
               callSite : CallSite = CallSite("Not provided", ""),
               stageThreshold : Long = 0,
               totalThreshold : Long = 0
               ) : DynamicFrame
```

Returns a new `DynamicFrame` with the specified column removed.

## Def dropFields

```
def dropFields( fieldNames : Seq[String], // The column names to drop.
               transformationContext : String = "",
               callSite : CallSite = CallSite("Not provided", ""),
               stageThreshold : Long = 0,
               totalThreshold : Long = 0
               ) : DynamicFrame
```

Returns a new `DynamicFrame` with the specified columns removed.

You can use this method to delete nested columns, including those inside of arrays, but not to drop specific array elements.

## Def dropNulls

```
def dropNulls( transformationContext : String = "",
               callSite : CallSite = CallSite("Not provided", ""),
               stageThreshold : Long = 0,
               totalThreshold : Long = 0 )
```

Returns a new `DynamicFrame` with all null columns removed.

**Note**

This only removes columns of type `NullType`. Individual null values in other columns are not removed or modified.

**Def errorsAsDynamicFrame**

```
def errorsAsDynamicFrame
```

Returns a new `DynamicFrame` containing the error records from this `DynamicFrame`.

**Def filter**

```
def filter( f : DynamicRecord => Boolean,  
           errorMsg : String = "",  
           transformationContext : String = "",  
           callSite : CallSite = CallSite("Not provided"),  
           stageThreshold : Long = 0,  
           totalThreshold : Long = 0  
         ) : DynamicFrame
```

Constructs a new `DynamicFrame` containing only those records for which the function 'f' returns `true`. The filter function 'f' should not mutate the input record.

**Def getName**

```
def getName : String
```

Returns the name of this `DynamicFrame`.

**Def getNumPartitions**

```
def getNumPartitions
```

Returns the number of partitions in this `DynamicFrame`.

**Def getSchemaIfComputed**

```
def getSchemaIfComputed : Option[Schema]
```

Returns the schema if it has already been computed. Does not scan the data if the schema has not already been computed.

### Def `isSchemaComputed`

```
def isSchemaComputed : Boolean
```

Returns `true` if the schema has been computed for this `DynamicFrame`, or `false` if not. If this method returns `false`, then calling the `schema` method requires another pass over the records in this `DynamicFrame`.

### Def `javaToPython`

```
def javaToPython : JavaRDD[Array[Byte]]
```

### Def `join`

```
def join( keys1 : Seq[String],
          keys2 : Seq[String],
          frame2 : DynamicFrame,
          transformationContext : String = "",
          callSite : CallSite = CallSite("Not provided", ""),
          stageThreshold : Long = 0,
          totalThreshold : Long = 0
        ) : DynamicFrame
```

- `keys1` — The columns in this `DynamicFrame` to use for the join.
- `keys2` — The columns in `frame2` to use for the join. Must be the same length as `keys1`.
- `frame2` — The `DynamicFrame` to join against.

Returns the result of performing an equijoin with `frame2` using the specified keys.

### Def `map`

```
def map( f : DynamicRecord => DynamicRecord,
         errorMsg : String = "",
         transformationContext : String = "",
```

```
callSite : CallSite = CallSite("Not provided", ""),
stageThreshold : Long = 0,
totalThreshold : Long = 0
) : DynamicFrame
```

Returns a new `DynamicFrame` constructed by applying the specified function 'f' to each record in this `DynamicFrame`.

This method copies each record before applying the specified function, so it is safe to mutate the records. If the mapping function throws an exception on a given record, that record is marked as an error, and the stack trace is saved as a column in the error record.

### Def mergeDynamicFrames

```
def mergeDynamicFrames( stageDynamicFrame: DynamicFrame, primaryKeys: Seq[String],
  transformationContext: String = "",
                        options: JsonOptions = JsonOptions.empty, callSite: CallSite =
  CallSite("Not provided"),
                        stageThreshold: Long = 0, totalThreshold: Long = 0):
  DynamicFrame
```

- `stageDynamicFrame` — The staging `DynamicFrame` to merge.
- `primaryKeys` — The list of primary key fields to match records from the source and staging `DynamicFrames`.
- `transformationContext` — A unique string that is used to retrieve metadata about the current transformation (optional).
- `options` — A string of JSON name-value pairs that provide additional information for this transformation.
- `callSite` — Used to provide context information for error reporting.
- `stageThreshold` — A `Long`. The number of errors in the given transformation for which the processing needs to error out.
- `totalThreshold` — A `Long`. The total number of errors up to and including in this transformation for which the processing needs to error out.

Merges this `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated. If there is no matching record in the staging frame, all records (including duplicates) are retained

from the source. If the staging frame has matching records, the records from the staging frame overwrite the records in the source in AWS Glue.

The returned `DynamicFrame` contains record A in the following cases:

1. If A exists in both the source frame and the staging frame, then A in the staging frame is returned.
2. If A is in the source table and `A.primaryKeys` is not in the `stagingDynamicFrame` (that means A is not updated in the staging table).

The source frame and staging frame do not need to have the same schema.

### Example

```
val mergedFrame: DynamicFrame = srcFrame.mergeDynamicFrames(stageFrame, Seq("id1",
  "id2"))
```

### Def printSchema

```
def printSchema : Unit
```

Prints the schema of this `DynamicFrame` to `stdout` in a human-readable format.

### Def recomputeSchema

```
def recomputeSchema : Schema
```

Forces a schema recomputation. This requires a scan over the data, but it might "tighten" the schema if there are some fields in the current schema that are not present in the data.

Returns the recomputed schema.

### Def relationalize

```
def relationalize( rootTableName : String,
  stagingPath : String,
  options : JsonOptions = JsonOptions.empty,
  transformationContext : String = "",
```

```

        callSite : CallSite = CallSite("Not provided"),
        stageThreshold : Long = 0,
        totalThreshold : Long = 0
    ) : Seq[DynamicFrame]

```

- `rootTableName` — The name to use for the base `DynamicFrame` in the output. `DynamicFrames` that are created by pivoting arrays start with this as a prefix.
- `stagingPath` — The Amazon Simple Storage Service (Amazon S3) path for writing intermediate data.
- `options` — Relationalize options and configuration. Currently unused.

Flattens all nested structures and pivots arrays into separate tables.

You can use this operation to prepare deeply nested data for ingestion into a relational database. Nested structs are flattened in the same manner as the [Unnest](#) transform. Additionally, arrays are pivoted into separate tables with each array element becoming a row. For example, suppose that you have a `DynamicFrame` with the following data.

```

{"name": "Nancy", "age": 47, "friends": ["Fred", "Lakshmi"]}
{"name": "Stephanie", "age": 28, "friends": ["Yao", "Phil", "Alvin"]}
{"name": "Nathan", "age": 54, "friends": ["Nicolai", "Karen"]}

```

Run the following code.

```

{{{
  df.relationalize("people", "s3:/my_bucket/my_path", JsonOptions.empty)
}}}

```

This produces two tables. The first table is named "people" and contains the following.

```

{{{
  {"name": "Nancy", "age": 47, "friends": 1}
  {"name": "Stephanie", "age": 28, "friends": 2}
  {"name": "Nathan", "age": 54, "friends": 3}
}}}

```

Here, the `friends` array has been replaced with an auto-generated join key. A separate table named `people.friends` is created with the following content.

```
{{
  {"id": 1, "index": 0, "val": "Fred"}
  {"id": 1, "index": 1, "val": "Lakshmi"}
  {"id": 2, "index": 0, "val": "Yao"}
  {"id": 2, "index": 1, "val": "Phil"}
  {"id": 2, "index": 2, "val": "Alvin"}
  {"id": 3, "index": 0, "val": "Nicolai"}
  {"id": 3, "index": 1, "val": "Karen"}
}}
```

In this table, 'id' is a join key that identifies which record the array element came from, 'index' refers to the position in the original array, and 'val' is the actual array entry.

The `relationalize` method returns the sequence of `DynamicFrames` created by applying this process recursively to all arrays.

#### Note

The AWS Glue library automatically generates join keys for new tables. To ensure that join keys are unique across job runs, you must enable job bookmarks.

## Def `renameField`

```
def renameField( oldName : String,
                 newName : String,
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
                 ) : DynamicFrame
```

- `oldName` — The original name of the column.
- `newName` — The new name of the column.

Returns a new `DynamicFrame` with the specified field renamed.

You can use this method to rename nested fields. For example, the following code would rename `state` to `state_code` inside the `address` struct.

```
{{  
  df.renameField("address.state", "address.state_code")  
}}
```

## Def repartition

```
def repartition( numPartitions : Int,  
                transformationContext : String = "",  
                callSite : CallSite = CallSite("Not provided", ""),  
                stageThreshold : Long = 0,  
                totalThreshold : Long = 0  
                ) : DynamicFrame
```

Returns a new `DynamicFrame` with `numPartitions` partitions.

## Def resolveChoice

```
def resolveChoice( specs : Seq[Product2[String, String]] = Seq.empty[ResolveSpec],  
                 choiceOption : Option[ChoiceOption] = None,  
                 database : Option[String] = None,  
                 tableName : Option[String] = None,  
                 transformationContext : String = "",  
                 callSite : CallSite = CallSite("Not provided", ""),  
                 stageThreshold : Long = 0,  
                 totalThreshold : Long = 0  
                 ) : DynamicFrame
```

- `choiceOption` — An action to apply to all `ChoiceType` columns not listed in the specs sequence.
- `database` — The Data Catalog database to use with the `match_catalog` action.
- `tableName` — The Data Catalog table to use with the `match_catalog` action.

Returns a new `DynamicFrame` by replacing one or more `ChoiceTypes` with a more specific type.

There are two ways to use `resolveChoice`. The first is to specify a sequence of specific columns and how to resolve them. These are specified as tuples made up of (column, action) pairs.

The following are the possible actions:

- `cast : type` — Attempts to cast all values to the specified type.

- `make_cols` — Converts each distinct type to a column with the name `columnName_type`.
- `make_struct` — Converts a column to a struct with keys for each distinct type.
- `project:type` — Retains only values of the specified type.

The other mode for `resolveChoice` is to specify a single resolution for all `ChoiceTypes`. You can use this in cases where the complete list of `ChoiceTypes` is unknown before execution. In addition to the actions listed preceding, this mode also supports the following action:

- `match_catalog` — Attempts to cast each `ChoiceType` to the corresponding type in the specified catalog table.

### Examples:

Resolve the `user.id` column by casting to an `int`, and make the `address` field retain only structs.

```
{{{
  df.resolveChoice(specs = Seq(("user.id", "cast:int"), ("address", "project:struct")))
}}}
```

Resolve all `ChoiceTypes` by converting each choice to a separate column.

```
{{{
  df.resolveChoice(choiceOption = Some(ChoiceOption("make_cols")))
}}}
```

Resolve all `ChoiceTypes` by casting to the types in the specified catalog table.

```
{{{
  df.resolveChoice(choiceOption = Some(ChoiceOption("match_catalog")),
                  database = Some("my_database"),
                  tableName = Some("my_table"))
}}}
```

### Def schema

```
def schema : Schema
```

Returns the schema of this `DynamicFrame`.

The returned schema is guaranteed to contain every field that is present in a record in this `DynamicFrame`. But in a small number of cases, it might also contain additional fields. You can use the [Unnest](#) method to "tighten" the schema based on the records in this `DynamicFrame`.

### Def selectField

```
def selectField( fieldName : String,
                transformationContext : String = "",
                callSite : CallSite = CallSite("Not provided", ""),
                stageThreshold : Long = 0,
                totalThreshold : Long = 0
                ) : DynamicFrame
```

Returns a single field as a `DynamicFrame`.

### Def selectFields

```
def selectFields( paths : Seq[String],
                 transformationContext : String = "",
                 callSite : CallSite = CallSite("Not provided", ""),
                 stageThreshold : Long = 0,
                 totalThreshold : Long = 0
                 ) : DynamicFrame
```

- `paths` — The sequence of column names to select.

Returns a new `DynamicFrame` containing the specified columns.

#### Note

You can only use the `selectFields` method to select top-level columns. You can use the [applyMapping](#) method to select nested columns.

### Def show

```
def show( numRows : Int = 20 ) : Unit
```

- `numRows` — The number of rows to print.

Prints rows from this `DynamicFrame` in JSON format.

## Def `simplifyDDBJson`

DynamoDB exports with the AWS Glue DynamoDB export connector results in JSON files of specific nested structures. For more information, see [Data objects](#). `simplifyDDBJson` Simplifies nested columns in a `DynamicFrame` of this type of data, and returns a new simplified `DynamicFrame`. If there are multiple types or a Map type contained in a List type, the elements in the List will not be simplified. This method only supports data in the DynamoDB export JSON format. Consider `unnest` to perform similar changes on other kinds of data.

```
def simplifyDDBJson() : DynamicFrame
```

This method does not take any parameters.

## Example input

Consider the following schema generated by a DynamoDB export:

```
root
|-- Item: struct
|   |-- parentMap: struct
|   |   |-- M: struct
|   |   |   |-- childMap: struct
|   |   |   |   |-- M: struct
|   |   |   |   |   |-- appName: struct
|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- packageName: struct
|   |   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |   |-- updatedAt: struct
|   |   |   |   |   |   |   |   |-- N: string
|   |   |-- strings: struct
|   |   |   |-- SS: array
|   |   |   |   |-- element: string
|   |-- numbers: struct
|   |   |-- NS: array
|   |   |   |-- element: string
|   |-- binaries: struct
|   |   |-- BS: array
|   |   |   |-- element: string
|   |-- isDDBJson: struct
|   |   |-- BOOL: boolean
```

```
|      |-- nullValue: struct
|      |      |-- NULL: boolean
```

## Example code

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContextimport scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> "ddbTableARN",
        "dynamodb.s3.bucket" -> "exportBucketLocation",
        "dynamodb.s3.prefix" -> "exportBucketPrefix",
        "dynamodb.s3.bucketOwner" -> "exportBucketAccountID",
      ))
    ).getDynamicFrame()

    val simplified = dynamicFrame.simplifyDDBJson()
    simplified.printSchema()

    Job.commit()
  }
}
```

## Example output

The `simplifyDDBJson` transform will simplify this to:

```
root
```

```

|-- parentMap: struct
|   |-- childMap: struct
|   |   |-- appName: string
|   |   |-- packageName: string
|   |   |-- updatedAt: string
|-- strings: array
|   |-- element: string
|-- numbers: array
|   |-- element: string
|-- binaries: array
|   |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null

```

## Def spigot

```

def spigot( path : String,
            options : JsonObject = new JsonObject("{}"),
            transformationContext : String = "",
            callSite : CallSite = CallSite("Not provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
            ) : DynamicFrame

```

Passthrough transformation that returns the same records but writes out a subset of records as a side effect.

- `path` — The path in Amazon S3 to write output to, in the form `s3://bucket//path`.
- `options` — An optional `JsonObject` map describing the sampling behavior.

Returns a `DynamicFrame` that contains the same records as this one.

By default, writes 100 arbitrary records to the location specified by `path`. You can customize this behavior by using the `options` map. Valid keys include the following:

- `topk` — Specifies the total number of records written out. The default is 100.
- `prob` — Specifies the probability (as a decimal) that an individual record is included. Default is 1.

For example, the following call would sample the dataset by selecting each record with a 20 percent probability and stopping after 200 records have been written.

```

{{{
  df.spigot("s3://my_bucket/my_path", JsonOptions(Map("topk" -> 200, "prob" ->
    0.2)))
}}}
```

## Def splitFields

```

def splitFields( paths : Seq[String],
                transformationContext : String = "",
                callSite : CallSite = CallSite("Not provided", ""),
                stageThreshold : Long = 0,
                totalThreshold : Long = 0
                ) : Seq[DynamicFrame]
```

- `paths` — The paths to include in the first `DynamicFrame`.

Returns a sequence of two `DynamicFrames`. The first `DynamicFrame` contains the specified paths, and the second contains all other columns.

## Example

This example takes a `DynamicFrame` created from the `persons` table in the `legislators` database in the AWS Glue Data Catalog and splits the `DynamicFrame` into two, with the specified fields going into the first `DynamicFrame` and the remaining fields going into a second `DynamicFrame`. The example then chooses the first `DynamicFrame` from the result.

```

val InputFrame = glueContext.getCatalogSource(database="legislators",
  tableName="persons",
  transformationContext="InputFrame").getDynamicFrame()

val SplitField_collection = InputFrame.splitFields(paths=Seq("family_name", "name",
  "links.note",
  "links.url", "gender", "image", "identifiers.scheme", "identifiers.identifier",
  "other_names.lang",
  "other_names.note", "other_names.name"), transformationContext="SplitField_collection")

val ResultFrame = SplitField_collection(0)
```

## Def splitRows

```
def splitRows( paths : Seq[String],
              values : Seq[Any],
              operators : Seq[String],
              transformationContext : String,
              callSite : CallSite,
              stageThreshold : Long,
              totalThreshold : Long
            ) : Seq[DynamicFrame]
```

Splits rows based on predicates that compare columns to constants.

- `paths` — The columns to use for comparison.
- `values` — The constant values to use for comparison.
- `operators` — The operators to use for comparison.

Returns a sequence of two `DynamicFrames`. The first contains rows for which the predicate is true and the second contains those for which it is false.

Predicates are specified using three sequences: `paths` contains the (possibly nested) column names, `values` contains the constant values to compare to, and `operators` contains the operators to use for comparison. All three sequences must be the same length: The `n`th operator is used to compare the `n`th column with the `n`th value.

Each operator must be one of `"!="`, `"="`, `"<="`, `"<"`, `">="`, or `">"`.

As an example, the following call would split a `DynamicFrame` so that the first output frame would contain records of people over 65 from the United States, and the second would contain all other records.

```
{{{
  df.splitRows(Seq("age", "address.country"), Seq(65, "USA"), Seq(">=", "="))
}}}
```

## Def stageErrorsCount

```
def stageErrorsCount
```

Returns the number of error records created while computing this `DynamicFrame`. This excludes errors from previous operations that were passed into this `DynamicFrame` as input.

### Def toDF

```
def toDF( specs : Seq[ResolveSpec] = Seq.empty[ResolveSpec] ) : DataFrame
```

Converts this `DynamicFrame` to an Apache Spark SQL `DataFrame` with the same schema and records.

#### Note

Because `DataFrames` don't support `ChoiceTypes`, this method automatically converts `ChoiceType` columns into `StructTypes`. For more information and options for resolving choice, see [resolveChoice](#).

### Def unbox

```
def unbox( path : String,
          format : String,
          optionString : String = "{}",
          transformationContext : String = "",
          callSite : CallSite = CallSite("Not provided"),
          stageThreshold : Long = 0,
          totalThreshold : Long = 0
        ) : DynamicFrame
```

- `path` — The column to parse. Must be a string or binary.
- `format` — The format to use for parsing.
- `optionString` — Options to pass to the format, such as the CSV separator.

Parses an embedded string or binary column according to the specified format. Parsed columns are nested under a struct with the original column name.

For example, suppose that you have a CSV file with an embedded JSON column.

```
name, age, address
Sally, 36, {"state": "NE", "city": "Omaha"}
```

```
...
```

After an initial parse, you would get a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: string
}}}
```

You can call `unbox` on the `address` column to parse the specific components.

```
{{{
  df.unbox("address", "json")
}}}
```

This gives us a `DynamicFrame` with the following schema.

```
{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |   |-- state: string
  |   |-- city: string
}}}
```

## Def unnest

```
def unnest( transformationContext : String = "",
            callSite : CallSite = CallSite("Not Provided"),
            stageThreshold : Long = 0,
            totalThreshold : Long = 0
            ) : DynamicFrame
```

Returns a new `DynamicFrame` with all nested structures flattened. Names are constructed using the '.' (period) character.

For example, suppose that you have a `DynamicFrame` with the following schema.

```

{{{
  root
  |-- name: string
  |-- age: int
  |-- address: struct
  |     |-- state: string
  |     |-- city: string
  }}}

```

The following call unnests the address struct.

```

{{{
  df.unnest()
  }}}

```

The resulting schema is as follows.

```

{{{
  root
  |-- name: string
  |-- age: int
  |-- address.state: string
  |-- address.city: string
  }}}

```

This method also unnests nested structs inside of arrays. But for historical reasons, the names of such fields are prepended with the name of the enclosing array and ".val".

### Def unnestDDBJson

```

unnestDDBJson(transformationContext : String = "",
              callSite : CallSite = CallSite("Not Provided"),
              stageThreshold : Long = 0,
              totalThreshold : Long = 0): DynamicFrame

```

Unnests nested columns in a `DynamicFrame` that are specifically in the DynamoDB JSON structure, and returns a new unnested `DynamicFrame`. Columns that are of an array of struct types will not be unnested. Note that this is a specific type of unnesting transform that behaves differently from the regular `unnest` transform and requires the data to already be in the DynamoDB JSON structure. For more information, see [DynamoDB JSON](#).

For example, the schema of a reading an export with the DynamoDB JSON structure might look like the following:

```

root
|-- Item: struct
|   |-- ColA: struct
|   |   |-- S: string
|   |-- ColB: struct
|   |   |-- S: string
|   |-- ColC: struct
|   |   |-- N: string
|   |-- ColD: struct
|   |   |-- L: array
|   |   |   |-- element: null

```

The `unnestDDBJson()` transform would convert this to:

```

root
|-- ColA: string
|-- ColB: string
|-- ColC: string
|-- ColD: array
|   |-- element: null

```

The following code example shows how to use the AWS Glue DynamoDB export connector, invoke a DynamoDB JSON unnest, and print the number of partitions:

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
  }
}

```

```
val dynamicFrame = glueContext.getSourceWithFormat(
  connectionType = "dynamodb",
  options = JsonOptions(Map(
    "dynamodb.export" -> "ddb",
    "dynamodb.tableArn" -> "<test_source>",
    "dynamodb.s3.bucket" -> "<bucket name>",
    "dynamodb.s3.prefix" -> "<bucket prefix>",
    "dynamodb.s3.bucketOwner" -> "<account_id of bucket>",
  ))
).getDynamicFrame()

val unnested = dynamicFrame.unnestDDBJson()
print(unnested.getNumPartitions())

Job.commit()
}
```

## Def withFrameSchema

```
def withFrameSchema( getSchema : () => Schema ) : DynamicFrame
```

- `getSchema` — A function that returns the schema to use. Specified as a zero-parameter function to defer potentially expensive computation.

Sets the schema of this `DynamicFrame` to the specified value. This is primarily used internally to avoid costly schema recomputation. The passed-in schema must contain all columns present in the data.

## Def withName

```
def withName( name : String ) : DynamicFrame
```

- `name` — The new name to use.

Returns a copy of this `DynamicFrame` with a new name.

## Def withTransformationContext

```
def withTransformationContext( ctx : String ) : DynamicFrame
```

Returns a copy of this `DynamicFrame` with the specified transformation context.

## The `DynamicFrame` object

**Package:** `com.amazonaws.services.glue`

```
object DynamicFrame
```

## Def apply

```
def apply( df : DataFrame,  
          glueContext : GlueContext  
          ) : DynamicFrame
```

## Def emptyDynamicFrame

```
def emptyDynamicFrame( glueContext : GlueContext ) : DynamicFrame
```

## Def fromPythonRDD

```
def fromPythonRDD( rdd : JavaRDD[Array[Byte]],  
                  glueContext : GlueContext  
                  ) : DynamicFrame
```

## Def ignoreErrors

```
def ignoreErrors( fn : DynamicRecord => DynamicRecord ) : DynamicRecord
```

## Def inlineErrors

```
def inlineErrors( msg : String,  
                 callSite : CallSite  
                 ) : (DynamicRecord => DynamicRecord)
```

## Def newFrameWithErrors

```
def newFrameWithErrors( prevFrame : DynamicFrame,
                        rdd : RDD[DynamicRecord],
                        name : String = "",
                        transformationContext : String = "",
                        callSite : CallSite,
                        stageThreshold : Long,
                        totalThreshold : Long
                        ) : DynamicFrame
```

## AWS Glue Scala DynamicRecord class

### Topics

- [Def addField](#)

- [Def setError](#)
- [Def isError](#)
- [Def getError](#)
- [Def clearError](#)
- [Def write](#)
- [Def readFields](#)
- [Def clone](#)
- [Def schema](#)
- [Def getRoot](#)
- [Def toJson](#)
- [Def getFieldNode](#)
- [Def getField](#)
- [Def hashCode](#)
- [Def equals](#)
- [DynamicRecord object](#)
- [RecordTraverser trait](#)

## Package: `com.amazonaws.services.glue`

```
class DynamicRecord extends Serializable with Writable with Cloneable
```

A `DynamicRecord` is a self-describing data structure that represents a row of data in the dataset that is being processed. It is self-describing in the sense that you can get the schema of the row that is represented by the `DynamicRecord` by inspecting the record itself. A `DynamicRecord` is similar to a `Row` in Apache Spark.

### Def `addField`

```
def addField( path : String,  
             dynamicNode : DynamicNode  
             ) : Unit
```

Adds a [DynamicNode](#) to the specified path.

- `path` — The path for the field to be added.
- `dynamicNode` — The [DynamicNode](#) to be added at the specified path.

### Def `dropField`

```
def dropField(path: String, underRename: Boolean = false): Option[DynamicNode]
```

Drops a [DynamicNode](#) from the specified path and returns the dropped node if there is not an array in the specified path.

- `path` — The path to the field to drop.
- `underRename` — True if `dropField` is called as part of a rename transform, or false otherwise (false by default).

Returns a `scala.Option Option` ([DynamicNode](#)).

### Def `setError`

```
def setError( error : Error )
```

Sets this record as an error record, as specified by the `error` parameter.

Returns a `DynamicRecord`.

### Def `isError`

```
def isError
```

Checks whether this record is an error record.

### Def `getError`

```
def getError
```

Gets the `Error` if the record is an error record. Returns `scala.Some Some (Error)` if this record is an error record, or otherwise `scala.None`.

### Def `clearError`

```
def clearError
```

Set the `Error` to `scala.None.None`.

### Def `write`

```
override def write( out : DataOutput ) : Unit
```

### Def `readFields`

```
override def readFields( in : DataInput ) : Unit
```

### Def `clone`

```
override def clone : DynamicRecord
```

Clones this record to a new `DynamicRecord` and returns it.

### Def `schema`

```
def schema
```

Gets the Schema by inspecting the record.

### Def getRoot

```
def getRoot : ObjectNode
```

Gets the root ObjectNode for the record.

### Def toJson

```
def toJson : String
```

Gets the JSON string for the record.

### Def getFieldNode

```
def getFieldNode( path : String ) : Option[DynamicNode]
```

Gets the field's value at the specified path as an option of DynamicNode.

Returns `scala.Some` `Some` ([DynamicNode](#)) if the field exists, or otherwise `scala.None` `None` .

### Def getField

```
def getField( path : String ) : Option[Any]
```

Gets the field's value at the specified path as an option of DynamicNode.

Returns `scala.Some` `Some` (value).

### Def hashCode

```
override def hashCode : Int
```

### Def equals

```
override def equals( other : Any )
```

## DynamicRecord object

```
object DynamicRecord
```

## Def apply

```
def apply( row : Row,  
          schema : SparkStructType )
```

Apply method to convert an Apache Spark SQL Row to a [DynamicRecord](#).

- row — A Spark SQL Row.
- schema — The Schema of that row.

Returns a DynamicRecord.

## RecordTraverser trait

```
trait RecordTraverser {  
  def nullValue(): Unit  
  def byteValue(value: Byte): Unit  
  def binaryValue(value: Array[Byte]): Unit  
  def booleanValue(value: Boolean): Unit  
  def shortValue(value: Short) : Unit  
  def intValue(value: Int) : Unit  
  def longValue(value: Long) : Unit  
  def floatValue(value: Float): Unit  
  def doubleValue(value: Double): Unit  
  def decimalValue(value: BigDecimal): Unit  
  def stringValue(value: String): Unit  
  def dateValue(value: Date): Unit  
  def timestampValue(value: Timestamp): Unit  
  def objectStart(length: Int): Unit  
  def objectKey(key: String): Unit  
  def objectEnd(): Unit  
  def mapStart(length: Int): Unit  
  def mapKey(key: String): Unit  
  def mapEnd(): Unit  
  def arrayStart(length: Int): Unit  
  def arrayEnd(): Unit
```

```
}
```

## AWS Glue Scala GlueContext APIs

### Package: `com.amazonaws.services.glue`

```
class GlueContext extends SQLContext(sc) (  
    @transient val sc : SparkContext,  
    val defaultSourcePartitioner : PartitioningStrategy )
```

`GlueContext` is the entry point for reading and writing a [DynamicFrame](#) from and to Amazon Simple Storage Service (Amazon S3), the AWS Glue Data Catalog, JDBC, and so on. This class provides utility functions to create [DataSource trait](#) and [DataSink](#) objects that can in turn be used to read and write `DynamicFrames`.

You can also use `GlueContext` to set a target number of partitions (default 20) in the `DynamicFrame` if the number of partitions created from the source is less than a minimum threshold for partitions (default 10).

### `def addIngestionTimeColumns`

```
def addIngestionTimeColumns(  
    df : DataFrame,  
    timeGranularity : String = "" ) : DataFrame
```

Appends ingestion time columns like `ingest_year`, `ingest_month`, `ingest_day`, `ingest_hour`, `ingest_minute` to the input `DataFrame`. This function is automatically generated in the script generated by the AWS Glue when you specify a Data Catalog table with Amazon S3 as the target. This function automatically updates the partition with ingestion time columns on the output table. This allows the output data to be automatically partitioned on ingestion time without requiring explicit ingestion time columns in the input data.

- `dataFrame` – The `dataFrame` to append the ingestion time columns to.
- `timeGranularity` – The granularity of the time columns. Valid values are "day", "hour" and "minute". For example, if "hour" is passed in to the function, the original `dataFrame` will have "ingest\_year", "ingest\_month", "ingest\_day", and "ingest\_hour" time columns appended.

Returns the data frame after appending the time granularity columns.

**Example:**

```
glueContext.addIngestionTimeColumns(dataFrame, "hour")
```

**def createDataFrameFromOptions**

```
def createDataFrameFromOptions( connectionType : String,  
                                connectionOptions : JsonOptions,  
                                transformationContext : String = "",  
                                format : String = null,  
                                formatOptions : JsonOptions = JsonOptions.empty  
                                ) : DataSource
```

Returns a DataFrame created with the specified connection and format. Use this function only with AWS Glue streaming sources.

- **connectionType** – The streaming connection type. Valid values include `kinesis` and `kafka`.
- **connectionOptions** – Connection options, which are different for Kinesis and Kafka. You can find the list of all connection options for each streaming data source at [Connection types and options for ETL in AWS Glue for Spark](#). Note the following differences in streaming connection options:
  - Kinesis streaming sources require `streamARN`, `startingPosition`, `inferSchema`, and `classification`.
  - Kafka streaming sources require `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.
- **transformationContext** – The transformation context to use (optional).
- **format** – A format specification (optional). This is used for an Amazon S3 or an AWS Glue connection that supports multiple formats. For information about the supported formats, see [Data format options for inputs and outputs in AWS Glue for Spark](#)
- **formatOptions** – Format options for the specified format. For information about the supported format options, see [Data format options](#).

**Example for Amazon Kinesis streaming source:**

```
val data_frame_datasource0 =  
glueContext.createDataFrameFromOptions(transformationContext = "datasource0",  
                                        connectionType = "kinesis",
```

```
connectionOptions = JsonOptions("""{"streamName": "example_stream", "startingPosition":
  "TRIM_HORIZON", "inferSchema": "true", "classification": "json"}"""))
```

Example for Kafka streaming source:

```
val data_frame_datasource0 =
glueContext.createDataFrameFromOptions(transformationContext = "datasource0",
  connectionType = "kafka",
  connectionOptions = JsonOptions("""{"connectionName": "example_connection",
  "topicName": "example_topic", "startingPosition": "earliest", "inferSchema": "false",
  "classification": "json", "schema":"`column1` STRING, `column2` STRING"}"""))
```

## forEachBatch

### forEachBatch(frame, batch\_function, options)

Applies the `batch_function` passed in to every micro batch that is read from the Streaming source.

- `frame` – The `DataFrame` containing the current micro batch.
- `batch_function` – A function that will be applied for every micro batch.
- `options` – A collection of key-value pairs that holds information about how to process micro batches. The following options are required:
  - `windowSize` – The amount of time to spend processing each batch.
  - `checkpointLocation` – The location where checkpoints are stored for the streaming ETL job.
  - `batchMaxRetries` – The maximum number of times to retry the batch if it fails. The default value is 3. This option is only configurable for Glue version 2.0 and above.

### Example:

```
glueContext.forEachBatch(data_frame_datasource0, (dataFrame: Dataset[Row], batchId:
  Long) =>
  {
    if (dataFrame.count() > 0)
      {
        val datasource0 = DynamicFrame(glueContext.addIngestionTimeColumns(dataFrame,
  "hour"), glueContext)
        // @type: DataSink
```

```

    // @args: [database = "tempdb", table_name = "fromoptionsoutput",
stream_batch_time = "100 seconds",
    //      stream_checkpoint_location = "s3://from-options-testing-eu-central-1/
fromOptionsOutput/checkpoint/",
    //      transformation_ctx = "datasink1"]
    // @return: datasink1
    // @inputs: [frame = datasource0]
    val options_datasink1 = JsonOptions(
        Map("partitionKeys" -> Seq("ingest_year", "ingest_month","ingest_day",
"ingest_hour"),
        "enableUpdateCatalog" -> true))
    val datasink1 = glueContext.getCatalogSink(
        database = "tempdb",
        tableName = "fromoptionsoutput",
        redshiftTmpDir = "",
        transformationContext = "datasink1",
        additionalOptions = options_datasink1).writeDynamicFrame(datasource0)
    }
}, JsonOptions("""{"windowSize" : "100 seconds",
    "checkpointLocation" : "s3://from-options-testing-eu-central-1/
fromOptionsOutput/checkpoint/"}"""))

```

## def getCatalogSink

```

def getCatalogSink( database : String,
    tableName : String,
    redshiftTmpDir : String = "",
    transformationContext : String = ""
    additionalOptions: JsonOptions = JsonOptions.empty,
    catalogId: String = null
) : DataSink

```

Creates a [DataSink](#) that writes to a location specified in a table that is defined in the Data Catalog.

- `database` — The database name in the Data Catalog.
- `tableName` — The table name in the Data Catalog.
- `redshiftTmpDir` — The temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `additionalOptions` – Additional options provided to AWS Glue.

- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Returns the `DataSink`.

### def `getCatalogSource`

```
def getCatalogSource( database : String,
                      tableName : String,
                      redshiftTmpDir : String = "",
                      transformationContext : String = ""
                      pushDownPredicate : String = " "
                      additionalOptions: JsonOptions = JsonOptions.empty,
                      catalogId: String = null
                      ) : DataSource
```

Creates a [DataSource trait](#) that reads data from a table definition in the Data Catalog.

- `database` — The database name in the Data Catalog.
- `tableName` — The table name in the Data Catalog.
- `redshiftTmpDir` — The temporary staging directory to be used with certain data sinks. Set to empty by default.
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `pushDownPredicate` – Filters partitions without having to list and read all the files in your dataset. For more information, see [Pre-filtering using pushdown predicates](#).
- `additionalOptions` – A collection of optional name-value pairs. The possible options include those listed in [Connection types and options for ETL in AWS Glue for Spark](#) except for `endpointUrl`, `streamName`, `bootstrap.servers`, `security.protocol`, `topicName`, `classification`, and `delimiter`. Another supported option is `catalogPartitionPredicate`:

`catalogPartitionPredicate` — You can pass a catalog expression to filter based on the index columns. This pushes down the filtering to the server side. For more information, see [AWS Glue Partition Indexes](#). Note that `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

- `catalogId` — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Returns the `DataSource`.

### Example for streaming source

```
val data_frame_datasource0 = glueContext.getCatalogSource(
  database = "tempdb",
  tableName = "test-stream-input",
  redshiftTmpDir = "",
  transformationContext = "datasource0",
  additionalOptions = JsonOptions("""{
    "startingPosition": "TRIM_HORIZON", "inferSchema": "false"}""")
).getDataFrame()
```

### def getJDBCSink

```
def getJDBCSink( catalogConnection : String,
  options : JsonOptions,
  redshiftTmpDir : String = "",
  transformationContext : String = "",
  catalogId: String = null
) : DataSink
```

Creates a [DataSink](#) that writes to a JDBC database that is specified in a `Connection` object in the Data Catalog. The `Connection` object has information to connect to a JDBC sink, including the URL, user name, password, VPC, subnet, and security groups.

- `catalogConnection` — The name of the connection in the Data Catalog that contains the JDBC URL to write to.
- `options` — A string of JSON name-value pairs that provide additional information that is required to write to a JDBC data store. This includes:
  - `dbtable` (required) — The name of the JDBC table. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used. The following example shows an `options` parameter that points to a schema named `test` and a table named `test_table` in database `test_db`.

```
options = JsonOptions("""{"dbtable": "test.test_table", "database": "test_db"}""")
```

- *database* (required) — The name of the JDBC database.
- Any additional options passed directly to the SparkSQL JDBC writer. For more information, see [Redshift data source for Spark](#).
- *redshiftTmpDir* — A temporary staging directory to be used with certain data sinks. Set to empty by default.
- *transformationContext* — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- *catalogId* — The catalog ID (account ID) of the Data Catalog being accessed. When null, the default account ID of the caller is used.

Example code:

```
getJDBCSink(catalogConnection = "my-connection-name", options =
  JsonOptions("""{"dbtable": "my-jdbc-table", "database": "my-jdbc-db"}"""),
  redshiftTmpDir = "", transformationContext = "datasink4")
```

Returns the `DataSink`.

### def getSink

```
def getSink( connectionType : String,
             connectionOptions : JsonOptions,
             transformationContext : String = ""
           ) : DataSink
```

Creates a [DataSink](#) that writes data to a destination like Amazon Simple Storage Service (Amazon S3), JDBC, or the AWS Glue Data Catalog, or an Apache Kafka or Amazon Kinesis data stream.

- *connectionType* — The type of the connection. See [the section called "Connection parameters"](#).
- *connectionOptions* — A string of JSON name-value pairs that provide additional information to establish the connection with the data sink. See [the section called "Connection parameters"](#).
- *transformationContext* — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.

Returns the `DataSink`.

## def getSinkWithFormat

```
def getSinkWithFormat( connectionType : String,
                       options : JsonOptions,
                       transformationContext : String = "",
                       format : String = null,
                       formatOptions : JsonOptions = JsonOptions.empty
                       ) : DataSink
```

Creates a [DataSink](#) that writes data to a destination like Amazon S3, JDBC, or the Data Catalog, or an Apache Kafka or Amazon Kinesis data stream. Also sets the format for the data to be written out to the destination.

- `connectionType` — The type of the connection. See [the section called “Connection parameters”](#).
- `options` — A string of JSON name-value pairs that provide additional information to establish a connection with the data sink. See [the section called “Connection parameters”](#).
- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `format` — The format of the data to be written out to the destination.
- `formatOptions` — A string of JSON name-value pairs that provide additional options for formatting data at the destination. See [Data format options](#).

Returns the `DataSink`.

## def getSource

```
def getSource( connectionType : String,
               connectionOptions : JsonOptions,
               transformationContext : String = ""
               pushDownPredicate
               ) : DataSource
```

Creates a [DataSource trait](#) that reads data from a source like Amazon S3, JDBC, or the AWS Glue Data Catalog. Also supports Kafka and Kinesis streaming data sources.

- `connectionType` — The type of the data source. See [the section called “Connection parameters”](#).

- `connectionOptions` — A string of JSON name-value pairs that provide additional information for establishing a connection with the data source. For more information, see [the section called “Connection parameters”](#).

A Kinesis streaming source requires the following connection options: `streamARN`, `startingPosition`, `inferSchema`, and `classification`.

A Kafka streaming source requires the following connection options: `connectionName`, `topicName`, `startingOffsets`, `inferSchema`, and `classification`.

- `transformationContext` — The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `pushDownPredicate` — Predicate on partition columns.

Returns the `DataSource`.

Example for Amazon Kinesis streaming source:

```
val kinesisOptions = jsonOptions()
data_frame_datasource0 = glueContext.getSource("kinesis",
  kinesisOptions).getDataFrame()

private def jsonOptions(): JsonOptions = {
  new JsonOptions(
    s"""{"streamARN": "arn:aws:kinesis:eu-central-1:123456789012:stream/
fromOptionsStream",
      |"startingPosition": "TRIM_HORIZON",
      |"inferSchema": "true",
      |"classification": "json"}""").stripMargin)
}
```

Example for Kafka streaming source:

```
val kafkaOptions = jsonOptions()
val data_frame_datasource0 = glueContext.getSource("kafka",
  kafkaOptions).getDataFrame()

private def jsonOptions(): JsonOptions = {
  new JsonOptions(
    s"""{"connectionName": "ConfluentKafka",
      |"topicName": "kafka-auth-topic",
```

```
    |"startingOffsets": "earliest",  
    |"inferSchema": "true",  
    |"classification": "json"}""").stripMargin)  
}
```

## def getSourceWithFormat

```
def getSourceWithFormat( connectionType : String,  
                        options : JsonOptions,  
                        transformationContext : String = "",  
                        format : String = null,  
                        formatOptions : JsonOptions = JsonOptions.empty  
                        ) : DataSource
```

Creates a [DataSource trait](#) that reads data from a source like Amazon S3, JDBC, or the AWS Glue Data Catalog, and also sets the format of data stored in the source.

- `connectionType` – The type of the data source. See [the section called “Connection parameters”](#).
- `options` – A string of JSON name-value pairs that provide additional information for establishing a connection with the data source. See [the section called “Connection parameters”](#).
- `transformationContext` – The transformation context that is associated with the sink to be used by job bookmarks. Set to empty by default.
- `format` – The format of the data that is stored at the source. When the `connectionType` is `"s3"`, you can also specify `format`. Can be one of `"avro"`, `"csv"`, `"grokLog"`, `"ion"`, `"json"`, `"xml"`, `"parquet"`, or `"orc"`.
- `formatOptions` – A string of JSON name-value pairs that provide additional options for parsing data at the source. See [Data format options](#).

Returns the `DataSource`.

## Examples

Create a `DynamicFrame` from a data source that is a comma-separated values (CSV) file on Amazon S3:

```
val datasource0 = glueContext.getSourceWithFormat(  
    connectionType="s3",
```

```
options =JsonOptions(s""""{"paths": [ "s3://csv/nycflights.csv"]}""""),
transformationContext = "datasource0",
format = "csv",
formatOptions=JsonOptions(s""""{"withHeader":"true","separator": ","}""""))
).getDynamicFrame()
```

Create a DynamicFrame from a data source that is a PostgreSQL using a JDBC connection:

```
val datasource0 = glueContext.getSourceWithFormat(
  connectionType="postgresql",
  options =JsonOptions(s""""{
    "url":"jdbc:postgresql://databasePostgres-1.rds.amazonaws.com:5432/testdb",
    "dbtable": "public.company",
    "redshiftTmpDir":"","
    "user":"username",
    "password":"password123"
  }""""),
  transformationContext = "datasource0").getDynamicFrame()
```

Create a DynamicFrame from a data source that is a MySQL using a JDBC connection:

```
val datasource0 = glueContext.getSourceWithFormat(
  connectionType="mysql",
  options =JsonOptions(s""""{
    "url":"jdbc:mysql://databaseMySQL-1.rds.amazonaws.com:3306/testdb",
    "dbtable": "athenatest_nycflights13_csv",
    "redshiftTmpDir":"","
    "user":"username",
    "password":"password123"
  }""""),
  transformationContext = "datasource0").getDynamicFrame()
```

## def getSparkSession

```
def getSparkSession : SparkSession
```

Gets the SparkSession object associated with this GlueContext. Use this SparkSession object to register tables and UDFs for use with DataFrame created from DynamicFrames.

Returns the SparkSession.

## def startTransaction

```
def startTransaction(readOnly: Boolean):String
```

Start a new transaction. Internally calls the Lake Formation [startTransaction](#) API.

- `readOnly` – (Boolean) Indicates whether this transaction should be read only or read and write. Writes made using a read-only transaction ID will be rejected. Read-only transactions do not need to be committed.

Returns the transaction ID.

## def commitTransaction

```
def commitTransaction(transactionId: String, waitForCommit: Boolean): Boolean
```

Attempts to commit the specified transaction. `commitTransaction` may return before the transaction has finished committing. Internally calls the Lake Formation [commitTransaction](#) API.

- `transactionId` – (String) The transaction to commit.
- `waitForCommit` – (Boolean) Determines whether the `commitTransaction` returns immediately. The default value is true. If false, `commitTransaction` polls and waits until the transaction is committed. The amount of wait time is restricted to 1 minute using exponential backoff with a maximum of 6 retry attempts.

Returns a Boolean to indicate whether the commit is done or not.

## def cancelTransaction

```
def cancelTransaction(transactionId: String): Unit
```

Attempts to cancel the specified transaction. Internally calls the Lake Formation [CancelTransaction](#) API.

- `transactionId` – (String) The transaction to cancel.

Returns a `TransactionCommittedException` exception if the transaction was previously committed.

**def this**

```
def this( sc : SparkContext,  
         minPartitions : Int,  
         targetPartitions : Int )
```

Creates a `GlueContext` object using the specified `SparkContext`, minimum partitions, and target partitions.

- `sc` — The `SparkContext`.
- `minPartitions` — The minimum number of partitions.
- `targetPartitions` — The target number of partitions.

Returns the `GlueContext`.

**def this**

```
def this( sc : SparkContext )
```

Creates a `GlueContext` object with the provided `SparkContext`. Sets the minimum partitions to 10 and target partitions to 20.

- `sc` — The `SparkContext`.

Returns the `GlueContext`.

**def this**

```
def this( sparkContext : JavaSparkContext )
```

Creates a `GlueContext` object with the provided `JavaSparkContext`. Sets the minimum partitions to 10 and target partitions to 20.

- `sparkContext` — The `JavaSparkContext`.

Returns the `GlueContext`.

## MappingSpec

Package: `com.amazonaws.services.glue`

### MappingSpec case class

```
case class MappingSpec( sourcePath: SchemaPath,
                       sourceType: DataType,
                       targetPath: SchemaPath,
                       targetType: DataType
                       ) extends Product4[String, String, String, String] {
  override def _1: String = sourcePath.toString
  override def _2: String = ExtendedTypeName.fromDataType(sourceType)
  override def _3: String = targetPath.toString
  override def _4: String = ExtendedTypeName.fromDataType(targetType)
}
```

- `sourcePath` — The `SchemaPath` of the source field.
- `sourceType` — The `DataType` of the source field.
- `targetPath` — The `SchemaPath` of the target field.
- `targetType` — The `DataType` of the target field.

A `MappingSpec` specifies a mapping from a source path and a source data type to a target path and a target data type. The value at the source path in the source frame appears in the target frame at the target path. The source data type is cast to the target data type.

It extends from `Product4` so that you can handle any `Product4` in your `applyMapping` interface.

### MappingSpec object

```
object MappingSpec
```

The `MappingSpec` object has the following members:

### Val `orderingByTarget`

```
val orderingByTarget: Ordering[MappingSpec]
```

## Def apply

```
def apply( sourcePath : String,
           sourceType : DataType,
           targetPath : String,
           targetType : DataType
         ) : MappingSpec
```

Creates a MappingSpec.

- `sourcePath` — A string representation of the source path.
- `sourceType` — The source `DataType`.
- `targetPath` — A string representation of the target path.
- `targetType` — The target `DataType`.

Returns a MappingSpec.

## Def apply

```
def apply( sourcePath : String,
           sourceTypeString : String,
           targetPath : String,
           targetTypeString : String
         ) : MappingSpec
```

Creates a MappingSpec.

- `sourcePath` — A string representation of the source path.
- `sourceType` — A string representation of the source data type.
- `targetPath` — A string representation of the target path.
- `targetType` — A string representation of the target data type.

Returns a MappingSpec.

## Def apply

```
def apply( product : Product4[String, String, String, String] ) : MappingSpec
```

Creates a MappingSpec.

- `product` — The Product4 of the source path, source data type, target path, and target data type.

Returns a MappingSpec.

## AWS Glue Scala ResolveSpec APIs

### Topics

- [ResolveSpec object](#)
- [ResolveSpec case class](#)

Package: `com.amazonaws.services.glue`

### ResolveSpec object

#### ResolveSpec

```
object ResolveSpec
```

#### Def

```
def apply( path : String,  
          action : String  
          ) : ResolveSpec
```

Creates a ResolveSpec.

- `path` — A string representation of the choice field that needs to be resolved.
- `action` — A resolution action. The action can be one of the following: `Project`, `KeepAsStruct`, or `Cast`.

Returns the ResolveSpec.

#### Def

```
def apply( product : Product2[String, String] ) : ResolveSpec
```

Creates a `ResolveSpec`.

- `product` — `Product2` of: source path, resolution action.

Returns the `ResolveSpec`.

### **ResolveSpec case class**

```
case class ResolveSpec extends Product2[String, String] (  
    path : SchemaPath,  
    action : String )
```

Creates a `ResolveSpec`.

- `path` — The `SchemaPath` of the choice field that needs to be resolved.
- `action` — A resolution action. The action can be one of the following: `Project`, `KeepAsStruct`, or `Cast`.

### **ResolveSpec def methods**

```
def _1 : String
```

```
def _2 : String
```

## **AWS Glue Scala ArrayNode APIs**

**Package:** `com.amazonaws.services.glue.types`

### **ArrayNode case class**

#### **ArrayNode**

```
case class ArrayNode extends DynamicNode (  
    value : ArrayBuffer[DynamicNode] )
```

### **ArrayNode def methods**

```
def add( node : DynamicNode )
```

```
def clone
```

```
def equals( other : Any )
```

```
def get( index : Int ) : Option[DynamicNode]
```

```
def getValue
```

```
def hashCode : Int
```

```
def isEmpty : Boolean
```

```
def nodeType
```

```
def remove( index : Int )
```

```
def this
```

```
def toIterator : Iterator[DynamicNode]
```

```
def toJson : String
```

```
def update( index : Int,  
           node : DynamicNode )
```

## AWS Glue Scala BinaryNode APIs

**Package:** `com.amazonaws.services.glue.types`

### BinaryNode case class

#### BinaryNode

```
case class BinaryNode extends ScalarNode(value, TypeCode.BINARY) (  
    value : Array[Byte] )
```

## BinaryNode val fields

- ordering

## BinaryNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

## AWS Glue Scala BooleanNode APIs

**Package:** com.amazonaws.services.glue.types

### BooleanNode case class

#### BooleanNode

```
case class BooleanNode extends ScalarNode(value, TypeCode.BOOLEAN) (  
    value : Boolean )
```

## BooleanNode val fields

- ordering

## BooleanNode def methods

```
def equals( other : Any )
```

## AWS Glue Scala ByteNode APIs

**Package:** com.amazonaws.services.glue.types

### ByteNode case class

#### ByteNode

```
case class ByteNode extends ScalarNode(value, TypeCode.BYTE) (  
  value : Byte )
```

### ByteNode val fields

- ordering

### ByteNode def methods

```
def equals( other : Any )
```

## AWS Glue Scala DateNode APIs

**Package:** `com.amazonaws.services.glue.types`

### DateNode case class

#### DateNode

```
case class DateNode extends ScalarNode(value, TypeCode.DATE) (  
  value : Date )
```

### DateNode val fields

- ordering

### DateNode def methods

```
def equals( other : Any )
```

```
def this( value : Int )
```

## AWS Glue Scala DecimalNode APIs

**Package:** `com.amazonaws.services.glue.types`

### DecimalNode case class

#### DecimalNode

```
case class DecimalNode extends ScalarNode(value, TypeCode.DECIMAL) (  
    value : BigDecimal )
```

### DecimalNode val fields

- ordering

### DecimalNode def methods

```
def equals( other : Any )
```

```
def this( value : Decimal )
```

## AWS Glue Scala DoubleNode APIs

**Package:** `com.amazonaws.services.glue.types`

### DoubleNode case class

#### DoubleNode

```
case class DoubleNode extends ScalarNode(value, TypeCode.DOUBLE) (  
    value : Double )
```

### DoubleNode val fields

- ordering

### DoubleNode def methods

```
def equals( other : Any )
```

## AWS Glue Scala DynamicNode APIs

### Topics

- [DynamicNode class](#)
- [DynamicNode object](#)

## Package: com.amazonaws.services.glue.types

### DynamicNode class

#### DynamicNode

```
class DynamicNode extends Serializable with Cloneable
```

#### DynamicNode def methods

```
def getValue : Any
```

Get plain value and bind to the current record:

```
def nodeType : TypeCode
```

```
def toJson : String
```

Method for debug:

```
def toRow( schema : Schema,  
           options : Map[String, ResolveOption]  
           ) : Row
```

```
def typeName : String
```

#### DynamicNode object

#### DynamicNode

```
object DynamicNode
```

#### DynamicNode def methods

```
def quote( field : String,  
           useQuotes : Boolean  
           ) : String
```

```
def quote( node : DynamicNode,
```

```
        useQuotes : Boolean
    ) : String
```

## EvaluateDataQuality class

AWS Glue Data Quality is in preview release for AWS Glue and is subject to change.

### Package: `com.amazonaws.services.glue.dq`

```
object EvaluateDataQuality
```

### Def apply

```
def apply(frame: DynamicFrame,
          ruleset: String,
          publishingOptions: JsonOptions = JsonOptions.empty): DynamicFrame
```

Evaluates a data quality ruleset against a `DynamicFrame`, and returns a new `DynamicFrame` with results of the evaluation. To learn more about AWS Glue Data Quality, see [AWS Glue Data Quality](#).

- `frame` – The `DynamicFrame` that you want to evaluate the data quality of.
- `ruleset` – A Data Quality Definition Language (DQDL) ruleset in string format. To learn more about DQDL, see the [Data Quality Definition Language \(DQDL\) reference](#) guide.
- `publishingOptions` – A dictionary that specifies the following options for publishing evaluation results and metrics:
  - `dataQualityEvaluationContext` – A string that specifies the namespace under which AWS Glue should publish Amazon CloudWatch metrics and the data quality results. The aggregated metrics appear in CloudWatch, while the full results appear in the AWS Glue Studio interface.
    - Required: No
    - Default value: `default_context`
  - `enableDataQualityCloudWatchMetrics` – Specifies whether the results of the data quality evaluation should be published to CloudWatch. You specify a namespace for the metrics using the `dataQualityEvaluationContext` option.
    - Required: No
    - Default value: `False`

- `enableDataQualityResultsPublishing` – Specifies whether the data quality results should be visible on the **Data Quality** tab in the AWS Glue Studio interface.
  - Required: No
  - Default value: True
- `resultsS3Prefix` – Specifies the Amazon S3 location where AWS Glue can write the data quality evaluation results.
  - Required: No
  - Default value: "" (empty string)

## Example

The following example code demonstrates how to evaluate data quality for a `DynamicFrame` before performing a `SelectFields` transform. The script verifies that all data quality rules pass before it attempts the transform.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.dq.EvaluateDataQuality

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Create DynamicFrame with data
    val Legislators_Area = glueContext.getCatalogSource(database="legislators",
    tableName="areas_json", transformationContext="S3bucket_node1").getDynamicFrame()

    // Define data quality ruleset
    val DQ_Ruleset = ""
    Rules = [ColumnExists "id"]
  }
}
```

```
    ""

    // Evaluate data quality
    val DQ_Results = EvaluateDataQuality.apply(frame=Legislators_Area,
    ruleset=DQ_Ruleset, publishingOptions=JsonOptions("""{"dataQualityEvaluationContext":
    "Legislators_Area", "enableDataQualityMetrics": "true",
    "enableDataQualityResultsPublishing": "true"}""))
    assert(DQ_Results.filter(_.getField("Outcome").contains("Failed")).count == 0,
    "Failing DQ rules for Legislators_Area caused the job to fail.")

    // Script generated for node Select Fields
    val SelectFields_Results = Legislators_Area.selectFields(paths=Seq("id", "name"),
    transformationContext="Legislators_Area")

    Job.commit()
  }
}
```

## AWS Glue Scala FloatNode APIs

**Package:** `com.amazonaws.services.glue.types`

### FloatNode case class

#### FloatNode

```
case class FloatNode extends ScalarNode(value, TypeCode.FLOAT) (
    value : Float )
```

#### FloatNode val fields

- `ordering`

#### FloatNode def methods

```
def equals( other : Any )
```

### FillMissingValues class

**Package:** `com.amazonaws.services.glue.ml`

```
object FillMissingValues
```

## Def apply

```
def apply(frame: DynamicFrame,
          missingValuesColumn: String,
          outputColumn: String = "",
          transformationContext: String = "",
          callSite: CallSite = CallSite("Not provided", ""),
          stageThreshold: Long = 0,
          totalThreshold: Long = 0): DynamicFrame
```

Fills a dynamic frame's missing values in a specified column and returns a new frame with estimates in a new column. For rows without missing values, the specified column's value is duplicated to the new column.

- `frame` — The `DynamicFrame` in which to fill missing values. Required.
- `missingValuesColumn` — The column containing missing values (`null` values and empty strings). Required.
- `outputColumn` — The name of the new column that will contain estimated values for all rows whose value was missing. Optional; the default is the value of `missingValuesColumn` suffixed by `"_filled"`.
- `transformationContext` — A unique string that is used to identify state information (optional).
- `callSite` — Used to provide context information for error reporting. (optional).
- `stageThreshold` — The maximum number of errors that can occur in the transformation before it errors out (optional; the default is zero).
- `totalThreshold` — The maximum number of errors that can occur overall before processing errors out (optional; the default is zero).

Returns a new dynamic frame with one additional column that contains estimations for rows with missing values and the present value for other rows.

### FindMatches class

**Package:** `com.amazonaws.services.glue.ml`

```
object FindMatches
```

## Def apply

```
def apply(frame: DynamicFrame,
         transformId: String,
         transformationContext: String = "",
         callSite: CallSite = CallSite("Not provided", ""),
         stageThreshold: Long = 0,
         totalThreshold: Long = 0,
         enforcedMatches: DynamicFrame = null): DynamicFrame,
computeMatchConfidenceScores: Boolean
```

Find matches in an input frame and return a new frame with a new column containing a unique ID per match group.

- `frame` — The `DynamicFrame` in which to find matches. Required.
- `transformId` — A unique ID associated with the `FindMatches` transform to apply on the input frame. Required.
- `transformationContext` — Identifier for this `DynamicFrame`. The `transformationContext` is used as a key for the job bookmark state that is persisted across runs. Optional.
- `callSite` — Used to provide context information for error reporting. These values are automatically set when calling from Python. Optional.
- `stageThreshold` — The maximum number of error records allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records present in the previous `DynamicFrame`. Optional. The default is zero.
- `totalThreshold` — The maximum number of total errors records before an exception is thrown, including those from previous frames. Optional. The default is zero.
- `enforcedMatches` — The frame for enforced matches. Optional. The default is `null`.
- `computeMatchConfidenceScores` — A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new dynamic frame with a unique identifier assigned to each group of matching records.

### FindIncrementalMatches class

**Package:** `com.amazonaws.services.glue.ml`

```
object FindIncrementalMatches
```

## Def apply

```
apply(existingFrame: DynamicFrame,
       incrementalFrame: DynamicFrame,
       transformId: String,
       transformationContext: String = "",
       callSite: CallSite = CallSite("Not provided", ""),
       stageThreshold: Long = 0,
       totalThreshold: Long = 0,
       enforcedMatches: DynamicFrame = null): DynamicFrame,
computeMatchConfidenceScores: Boolean
```

Find matches across the existing and incremental frames and return a new frame with a column containing a unique ID per match group.

- `existingframe` — An existing frame which has been assigned a matching ID for each group. Required.
- `incrementalframe` — An incremental frame used to find matches against the existing frame. Required.
- `transformId` — A unique ID associated with the `FindIncrementalMatches` transform to apply on the input frames. Required.
- `transformationContext` — Identifier for this `DynamicFrame`. The `transformationContext` is used as a key for the job bookmark state that is persisted across runs. Optional.
- `callSite` — Used to provide context information for error reporting. These values are automatically set when calling from Python. Optional.
- `stageThreshold` — The maximum number of error records allowed from the computation of this `DynamicFrame` before throwing an exception, excluding records present in the previous `DynamicFrame`. Optional. The default is zero.
- `totalThreshold` — The maximum number of total errors records before an exception is thrown, including those from previous frames. Optional. The default is zero.
- `enforcedMatches` — The frame for enforced matches. Optional. The default is `null`.
- `computeMatchConfidenceScores` — A Boolean value indicating whether to compute a confidence score for each group of matching records. Optional. The default is `false`.

Returns a new dynamic frame with a unique identifier assigned to each group of matching records.

## AWS Glue Scala IntegerNode APIs

**Package:** `com.amazonaws.services.glue.types`

### IntegerNode case class

#### IntegerNode

```
case class IntegerNode extends ScalarNode(value, TypeCode.INT) (  
    value : Int )
```

#### IntegerNode val fields

- `ordering`

#### IntegerNode def methods

```
def equals( other : Any )
```

## AWS Glue Scala LongNode APIs

**Package:** `com.amazonaws.services.glue.types`

### LongNode case class

#### LongNode

```
case class LongNode extends ScalarNode(value, TypeCode.LONG) (  
    value : Long )
```

#### LongNode val fields

- `ordering`

#### LongNode def methods

```
def equals( other : Any )
```

## AWS Glue Scala MapLikeNode APIs

**Package:** `com.amazonaws.services.glue.types`

### MapLikeNode class

#### MapLikeNode

```
class MapLikeNode extends DynamicNode (
    value : mutable.Map[String, DynamicNode] )
```

#### MapLikeNode def methods

```
def clear : Unit
```

```
def get( name : String ) : Option[DynamicNode]
```

```
def getValue
```

```
def has( name : String ) : Boolean
```

```
def isEmpty : Boolean
```

```
def put( name : String,
        node : DynamicNode
        ) : Option[DynamicNode]
```

```
def remove( name : String ) : Option[DynamicNode]
```

```
def toIterator : Iterator[(String, DynamicNode)]
```

```
def toJson : String
```

```
def toJson( useQuotes : Boolean ) : String
```

**Example:** Given this JSON:

```
{"foo": "bar"}
```

If `useQuotes == true`, `toJson` yields `{"foo": "bar"}`. If `useQuotes == false`, `toJson` yields `{foo: bar}` @return.

## AWS Glue Scala MapNode APIs

**Package:** `com.amazonaws.services.glue.types`

### MapNode case class

#### MapNode

```
case class MapNode extends MapLikeNode(value) (  
    value : mutable.Map[String, DynamicNode] )
```

### MapNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

```
def nodeType
```

```
def this
```

## AWS Glue Scala NullNode APIs

```

### ObjectNode def methods

```
def apply( frameKeys : Set[String],  
          v1 : mutable.Map[String, DynamicNode],  
          v2 : mutable.Map[String, DynamicNode],  
          resolveWith : String  
        ) : ObjectNode
```

### ObjectNode case class

### ObjectNode

```
case class ObjectNode extends MapLikeNode(value) (
```

```
val value : mutable.Map[String, DynamicNode] )
```

## ObjectNode def methods

```
def clone
```

```
def equals( other : Any )
```

```
def hashCode : Int
```

```
def nodeType
```

```
def this
```

## AWS Glue Scala ScalarNode APIs

### Topics

- [ScalarNode class](#)
- [ScalarNode object](#)

**Package:** `com.amazonaws.services.glue.types`

### ScalarNode class

#### ScalarNode

```
class ScalarNode extends DynamicNode (
    value : Any,
    scalarType : TypeCode )
```

### ScalarNode def methods

```
def compare( other : Any,
            operator : String
            ) : Boolean
```

```
def getValue
```

```
def hashCode : Int
```

```
def nodeType
```

```
def toJson
```

## ScalarNode object

### ScalarNode

```
object ScalarNode
```

### ScalarNode def methods

```
def apply( v : Any ) : DynamicNode
```

```
def compare( tv : Ordered[T],  
            other : T,  
            operator : String  
            ) : Boolean
```

```
def compareAny( v : Any,  
               y : Any,  
               o : String )
```

```
def withEscapedSpecialCharacters( jsonToEscape : String ) : String
```

## AWS Glue Scala ShortNode APIs

### Package: com.amazonaws.services.glue.types

### ShortNode case class

### ShortNode

```
case class ShortNode extends ScalarNode(value, TypeCode.SHORT) (  
    value : Short )
```

## ShortNode val fields

- ordering

## ShortNode def methods

```
def equals( other : Any )
```

## AWS Glue Scala StringNode APIs

**Package:** com.amazonaws.services.glue.types

### StringNode case class

#### StringNode

```
case class StringNode extends ScalarNode(value, TypeCode.STRING) (  
    value : String )
```

## StringNode val fields

- ordering

## StringNode def methods

```
def equals( other : Any )
```

```
def this( value : UTF8String )
```

## AWS Glue Scala TimestampNode APIs

**Package:** com.amazonaws.services.glue.types

### TimestampNode case class

#### TimestampNode

```
case class TimestampNode extends ScalarNode(value, TypeCode.TIMESTAMP) (  
    value : Timestamp )
```

## TimestampNode val fields

- ordering

## TimestampNode def methods

```
def equals( other : Any )
```

```
def this( value : Long )
```

## AWS Glue Scala GlueArgParser APIs

**Package:** com.amazonaws.services.glue.util

### GlueArgParser object

#### GlueArgParser

```
object GlueArgParser
```

This is strictly consistent with the Python version of `utils.getResolvedOptions` in the `AWSGlueDataplanePython` package.

### GlueArgParser def methods

```
def getResolvedOptions( args : Array[String],  
                        options : Array[String]  
                        ) : Map[String, String]
```

```
def initParser( userOptionsSet : mutable.Set[String] ) : ArgumentParser
```

### Example Retrieving arguments passed to a job

To retrieve job arguments, you can use the `getResolvedOptions` method. Consider the following example, which retrieves a job argument named `aws_region`.

```
val args = GlueArgParser.getResolvedOptions(sysArgs,  
      Seq("JOB_NAME","aws_region").toArray)  
Job.init(args("JOB_NAME"), glueContext, args.asJava)  
val region = args("aws_region")
```

```
println(region)
```

## AWS Glue Scala job APIs

**Package:** `com.amazonaws.services.glue.util`

### Job object

#### Job

```
object Job
```

### Job def methods

```
def commit
```

```
def init( jobName : String,  
         glueContext : GlueContext,  
         args : java.util.Map[String, String] = Map[String, String]().asJava  
       ) : this.type
```

```
def init( jobName : String,  
         glueContext : GlueContext,  
         endpoint : String,  
         args : java.util.Map[String, String]  
       ) : this.type
```

```
def isInitialized
```

```
def reset
```

```
def runId
```

## Features and optimizations for programming AWS Glue for Spark ETL scripts

The following sections describe techniques and values that apply generally to AWS Glue for Spark ETL (extract, transform, and load) programming in any language.

## Topics

- [Connection types and options for ETL in AWS Glue for Spark](#)
- [Data format options for inputs and outputs in AWS Glue for Spark](#)
- [AWS Glue Data Catalog support for Spark SQL jobs](#)
- [Using job bookmarks](#)
- [Using Sensitive Data Detection outside AWS Glue Studio](#)
- [AWS Glue Visual Job API](#)

## Connection types and options for ETL in AWS Glue for Spark

In AWS Glue for Spark, various PySpark and Scala methods and transforms specify the connection type using a `connectionType` parameter. They specify connection options using a `connectionOptions` or `options` parameter.

The `connectionType` parameter can take the values shown in the following table. The associated `connectionOptions` (or `options`) parameter values for each type are documented in the following sections. Except where otherwise noted, the parameters apply when the connection is used as a source or sink.

For sample code that demonstrates setting and using connection options, see the homepage for each connection type.

<code>connectionType</code>	Connects to
<a href="#">dynamodb</a>	<a href="#">Amazon DynamoDB</a> database
<a href="#">kinesis</a>	<a href="#">Amazon Kinesis Data Streams</a>
<a href="#">s3</a>	<a href="#">Amazon S3</a>
<a href="#">documentdb</a>	<a href="#">Amazon DocumentDB (with MongoDB compatibility)</a> database
<a href="#">opensearch</a>	<a href="#">Amazon OpenSearch Service</a> .
<a href="#">redshift</a>	<a href="#">Amazon Redshift</a> database
<a href="#">kafka</a>	<a href="#">Kafka</a> or <a href="#">Amazon Managed Streaming for Apache Kafka</a>

<b>connectionType</b>	<b>Connects to</b>
<a href="#">azurecosmos</a>	Azure Cosmos for NoSQL.
<a href="#">azuresql</a>	Azure SQL.
<a href="#">bigquery</a>	Google BigQuery.
<a href="#">mongodb</a>	<a href="#">MongoDB</a> database, including MongoDB Atlas.
<a href="#">sqlserver</a>	Microsoft SQL Server database (see <a href="#">JDBC connections</a> )
<a href="#">mysql</a>	<a href="#">MySQL</a> database (see <a href="#">JDBC connections</a> )
<a href="#">oracle</a>	<a href="#">Oracle</a> database (see <a href="#">JDBC connections</a> )
<a href="#">postgresql</a>	<a href="#">PostgreSQL</a> database (see <a href="#">JDBC connections</a> )
<a href="#">saphana</a>	SAP HANA.
<a href="#">snowflake</a>	<a href="#">Snowflake</a> data lake
<a href="#">teradata</a>	Teradata Vantage.
<a href="#">vertica</a>	Vertica.
<a href="#">custom.*</a>	Spark, Athena, or JDBC data stores (see <a href="#">Custom and AWS Marketplace connectionType values</a> )

## DynamoDB connections

You can use AWS Glue for Spark to read from and write to tables in DynamoDB in AWS Glue. You connect to DynamoDB using IAM permissions attached to your AWS Glue job. AWS Glue supports writing data into another AWS account's DynamoDB table. For more information, see [the section called "Cross-account cross-Region access to DynamoDB tables"](#).

In addition to the AWS Glue DynamoDB ETL connector, you can read from DynamoDB using the DynamoDB export connector, that invokes a DynamoDB `ExportTableToPointInTime` request

and stores it in an Amazon S3 location you supply, in the format of [DynamoDB JSON](#). AWS Glue then creates a `DynamicFrame` object by reading the data from the Amazon S3 export location.

The DynamoDB writer is available in AWS Glue version 1.0 or later versions. The AWS Glue DynamoDB export connector is available in AWS Glue version 2.0 or later versions.

For more information about DynamoDB, consult [Amazon DynamoDB](#) documentation.

#### Note

The DynamoDB ETL reader does not support filters or pushdown predicates.

## Configuring DynamoDB connections

To connect to DynamoDB from AWS Glue, grant the IAM role associated with your AWS Glue job permission to interact with DynamoDB. For more information about permissions necessary to read or write from DynamoDB, consult [Actions, resources, and condition keys for DynamoDB](#) in the IAM documentation.

In the following situations, you may need additional configuration:

- When using the DynamoDB export connector, you will need to configure IAM so your job can request DynamoDB table exports. Additionally, you will need to identify an Amazon S3 bucket for the export and provide appropriate permissions in IAM for DynamoDB to write to it, and for your AWS Glue job to read from it. For more information, consult [Request a table export in DynamoDB](#).
- If your AWS Glue job has specific Amazon VPC connectivity requirements, use the NETWORK AWS Glue connection type to provide network options. Since access to DynamoDB is authorized by IAM, there is no need for a AWS Glue DynamoDB connection type.

## Reading from and writing to DynamoDB

The following code examples show how to read from (via the ETL connector) and write to DynamoDB tables. They demonstrate reading from one table and writing to another table.

Python

```
import sys
```

```

from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={"dynamodb.input.tableName": test_source,
        "dynamodb.throughput.read.percent": "1.0",
        "dynamodb.splits": "100"
    }
)
print(dyf.getNumPartitions())

glue_context.write_dynamic_frame_from_options(
    frame=dyf,
    connection_type="dynamodb",
    connection_options={"dynamodb.output.tableName": test_sink,
        "dynamodb.throughput.write.percent": "1.0"
    }
)

job.commit()

```

## Scala

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

    def main(sysArgs: Array[String]): Unit = {

```

```
val glueContext = new GlueContext(SparkContext.getOrCreate())
val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
Job.init(args("JOB_NAME"), glueContext, args.asJava)

val dynamicFrame = glueContext.getSourceWithFormat(
  connectionType = "dynamodb",
  options = JsonOptions(Map(
    "dynamodb.input.tableName" -> test_source,
    "dynamodb.throughput.read.percent" -> "1.0",
    "dynamodb.splits" -> "100"
  ))
).getDynamicFrame()

print(dynamicFrame.getNumPartitions())

val dynamoDbSink: DynamoDbDataSink = glueContext.getSinkWithFormat(
  connectionType = "dynamodb",
  options = JsonOptions(Map(
    "dynamodb.output.tableName" -> test_sink,
    "dynamodb.throughput.write.percent" -> "1.0"
  ))
).asInstanceOf[DynamoDbDataSink]

dynamoDbSink.writeDynamicFrame(dynamicFrame)

Job.commit()
}
```

## Using the DynamoDB export connector

The export connector performs better than the ETL connector when the DynamoDB table size is larger than 80 GB. In addition, given that the export request is conducted outside from the Spark processes in an AWS Glue job, you can enable [auto scaling of AWS Glue jobs](#) to save DPU usage during the export request. With the export connector, you also do not need to configure the number of splits for Spark executor parallelism or DynamoDB throughput read percentage.

**Note**

DynamoDB has specific requirements to invoke the `ExportTableToPointInTime` requests. For more information, see [Requesting a table export in DynamoDB](#). For example, Point-in-Time-Restore (PITR) needs to be enabled on the table to use this connector.

The DynamoDB connector also supports AWS KMS encryption for DynamoDB exports to Amazon S3. Supplying your security configuration in the AWS Glue job configuration enables AWS KMS encryption for a DynamoDB export. The KMS key must be in the same Region as the Amazon S3 bucket.

Note that additional charges for DynamoDB export and Amazon S3 storage costs apply. Exported data in Amazon S3 persists after a job run finishes so you can reuse it without additional DynamoDB exports. A requirement for using this connector is that point-in-time recovery (PITR) is enabled for the table.

The DynamoDB ETL connector or export connector do not support filters or pushdown predicates to be applied at the DynamoDB source.

The following code examples show how to read from (via the export connector) and print the number of partitions.

**Python**

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context = GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame.from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": test_source,
        "dynamodb.s3.bucket": bucket_name,
        "dynamodb.s3.prefix": bucket_prefix,
```

```
        "dynamodb.s3.bucketOwner": account_id_of_bucket,
    }
)
print(dyf.getNumPartitions())

job.commit()
```

## Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
    val glueContext = new GlueContext(SparkContext.getOrCreate())
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType = "dynamodb",
      options = JsonOptions(Map(
        "dynamodb.export" -> "ddb",
        "dynamodb.tableArn" -> test_source,
        "dynamodb.s3.bucket" -> bucket_name,
        "dynamodb.s3.prefix" -> bucket_prefix,
        "dynamodb.s3.bucketOwner" -> account_id_of_bucket,
      ))
    ).getDynamicFrame()

    print(dynamicFrame.getNumPartitions())

    Job.commit()
  }
}
```

These examples show how to do the read from (via the export connector) and print the number of partitions from an AWS Glue Data Catalog table that has a dynamodb classification:

## Python

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dynamicFrame = glue_context.create_dynamic_frame.from_catalog(
    database=catalog_database,
    table_name=catalog_table_name,
    additional_options={
        "dynamodb.export": "ddb",
        "dynamodb.s3.bucket": s3_bucket,
        "dynamodb.s3.prefix": s3_bucket_prefix
    }
)
print(dynamicFrame.getNumPartitions())

job.commit()
```

## Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamoDbDataSink
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {

  def main(sysArgs: Array[String]): Unit = {
```

```

val glueContext = new GlueContext(SparkContext.getOrCreate())
val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
Job.init(args("JOB_NAME"), glueContext, args.asJava)

val dynamicFrame = glueContext.getCatalogSource(
  database = catalog_database,
  tableName = catalog_table_name,
  additionalOptions = JsonOptions(Map(
    "dynamodb.export" -> "ddb",
    "dynamodb.s3.bucket" -> s3_bucket,
    "dynamodb.s3.prefix" -> s3_bucket_prefix
  ))
).getDynamicFrame()
print(dynamicFrame.getNumPartitions())
)

```

## Simplifying usage of DynamoDB export JSON

The DynamoDB exports with the AWS Glue DynamoDB export connector results in JSON files of specific nested structures. For more information, see [Data objects](#). AWS Glue supplies a `DynamicFrame` transformation, which can unnest such structures into an easier-to-use form for downstream applications.

The transform can be invoked in one of two ways. You can set the connection option `"dynamodb.simplifyDDBJson"` with the value `"true"` when calling a method to read from DynamoDB. You can also call the transform as a method independently available in the AWS Glue library.

Consider the following schema generated by a DynamoDB export:

```

root
|-- Item: struct
|   |-- parentMap: struct
|   |   |-- M: struct
|   |   |   |-- childMap: struct
|   |   |   |   |-- M: struct
|   |   |   |   |   |-- appName: struct
|   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |-- packageName: struct
|   |   |   |   |   |   |   |-- S: string
|   |   |   |   |   |   |   |-- updatedAt: struct
|   |   |   |   |   |   |   |   |-- N: string

```

```

|   |-- strings: struct
|   |   |-- SS: array
|   |   |   |-- element: string
|   |-- numbers: struct
|   |   |-- NS: array
|   |   |   |-- element: string
|   |-- binaries: struct
|   |   |-- BS: array
|   |   |   |-- element: string
|   |-- isDDBJson: struct
|   |   |-- BOOL: boolean
|   |-- nullValue: struct
|   |   |-- NULL: boolean

```

The `simplifyDDBJson` transform will simplify this to:

```

root
|-- parentMap: struct
|   |-- childMap: struct
|   |   |-- appName: string
|   |   |-- packageName: string
|   |   |-- updatedAt: string
|-- strings: array
|   |-- element: string
|-- numbers: array
|   |-- element: string
|-- binaries: array
|   |-- element: string
|-- isDDBJson: boolean
|-- nullValue: null

```

### Note

`simplifyDDBJson` is available in AWS Glue 3.0 and later versions. The `unnestDDBJson` transform is also available to simplify DynamoDB export JSON. We encourage users to transition to `simplifyDDBJson` from `unnestDDBJson`.

## Configuring parallelism in DynamoDB operations

To improve performance, you can tune certain parameters available for the DynamoDB connector. Your goal when tuning parallelism parameters is to maximize the use of the provisioned AWS

Glue workers. Then, if you need more performance, we recommend you to scale out your job by increasing the number of DPUs.

You can alter the parallelism in a DynamoDB read operation using the `dynamodb.splits` parameter when using the ETL connector. When reading with the export connector, you do not need to configure the number of splits for Spark executor parallelism. You can alter the parallelism in a DynamoDB write operation with `dynamodb.output.numParallelTasks`.

### Reading with the DynamoDB ETL connector

We recommend you to calculate `dynamodb.splits` based on the maximum number of workers set in your job configuration and the following `numSlots` calculation. If autoscaling, the actual number of workers available may change under that cap. For more information about setting the maximum number of workers, see **Number of workers** (`NumberOfWorkers`) in [the section called "Configuring Spark job properties"](#).

- `numExecutors = NumberOfWorkers - 1`

For context, one executor is reserved for the Spark driver; other executors are used to process data.

- `numSlotsPerExecutor =`

AWS Glue 3.0 and later versions

- 4 if `WorkerType` is G.1X
- 8 if `WorkerType` is G.2X
- 16 if `WorkerType` is G.4X
- 32 if `WorkerType` is G.8X

AWS Glue 2.0 and legacy versions

- 8 if `WorkerType` is G.1X
- 16 if `WorkerType` is G.2X

- `numSlots = numSlotsPerExecutor * numExecutors`

We recommend you set `dynamodb.splits` to the number of slots available, `numSlots`.

### Writing to DynamoDB

The `dynamodb.output.numParallelTasks` parameter is used to determine WCU per Spark task, using the following calculation:

$$\text{permittedWcuPerTask} = ( \text{TableWCU} * \text{dynamodb.throughput.write.percent} ) / \text{dynamodb.output.numParallelTasks}$$

The DynamoDB writer will function best if configuration accurately represents the number of Spark tasks writing to DynamoDB. In some cases, you may need to override the default calculation to improve write performance. If you do not specify this parameter, the permitted WCU per Spark task will be automatically calculated by the following formula:

- $\text{numPartitions} = \text{dynamicframe.getNumPartitions}()$
- $\text{numSlots}$  (as defined previously in this section)
- $\text{numParallelTasks} = \min(\text{numPartitions}, \text{numSlots})$
- Example 1. DPU=10, WorkerType=Standard. Input DynamicFrame has 100 RDD partitions.
  - $\text{numPartitions} = 100$
  - $\text{numExecutors} = (10 - 1) * 2 - 1 = 17$
  - $\text{numSlots} = 4 * 17 = 68$
  - $\text{numParallelTasks} = \min(100, 68) = 68$
- Example 2. DPU=10, WorkerType=Standard. Input DynamicFrame has 20 RDD partitions.
  - $\text{numPartitions} = 20$
  - $\text{numExecutors} = (10 - 1) * 2 - 1 = 17$
  - $\text{numSlots} = 4 * 17 = 68$
  - $\text{numParallelTasks} = \min(20, 68) = 20$

### Note

Jobs on legacy AWS Glue versions and those using Standard workers require different methods to calculate the number of slots. If you need to performance tune these jobs, we recommend you transition to supported AWS Glue versions.

## DynamoDB connection option reference

Designates a connection to Amazon DynamoDB.

Connection options differ for a source connection and a sink connection.

## "connectionType": "dynamodb" with the ETL connector as source

Use the following connection options with "connectionType": "dynamodb" as a source, when using the AWS Glue DynamoDB ETL connector:

- "dynamodb.input.tableName": (Required) The DynamoDB table to read from.
- "dynamodb.throughput.read.percent": (Optional) The percentage of read capacity units (RCU) to use. The default is set to "0.5". Acceptable values are from "0.1" to "1.5", inclusive.
  - 0.5 represents the default read rate, meaning that AWS Glue will attempt to consume half of the read capacity of the table. If you increase the value above 0.5, AWS Glue increases the request rate; decreasing the value below 0.5 decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)
- When the DynamoDB table is in on-demand mode, AWS Glue handles the read capacity of the table as 40000. For exporting a large table, we recommend switching your DynamoDB table to on-demand mode.
- "dynamodb.splits": (Optional) Defines how many splits we partition this DynamoDB table into while reading. The default is set to "1". Acceptable values are from "1" to "1,000,000", inclusive.

1 represents there is no parallelism. We highly recommend that you specify a larger value for better performance by using the below formula. For more information on appropriately setting a value, see [the section called "DynamoDB parallelism"](#).

- "dynamodb.sts.roleArn": (Optional) The IAM role ARN to be assumed for cross-account access. This parameter is available in AWS Glue 1.0 or later.
- "dynamodb.sts.roleSessionName": (Optional) STS session name. The default is set to "glue-dynamodb-read-sts-session". This parameter is available in AWS Glue 1.0 or later.

## "connectionType": "dynamodb" with the AWS Glue DynamoDB export connector as source

Use the following connection options with "connectionType": "dynamodb" as a source, when using the AWS Glue DynamoDB export connector, which is available only for AWS Glue version 2.0 onwards:

- "dynamodb.export": (Required) A string value:
  - If set to ddb enables the AWS Glue DynamoDB export connector where a new `ExportTableToPointInTimeRequest` will be invoked during the AWS Glue job. A

new export will be generated with the location passed from `dynamodb.s3.bucket` and `dynamodb.s3.prefix`.

- If set to `s3` enables the AWS Glue DynamoDB export connector but skips the creation of a new DynamoDB export and instead uses the `dynamodb.s3.bucket` and `dynamodb.s3.prefix` as the Amazon S3 location of a past export of that table.
- `"dynamodb.tableArn"`: (Required) The DynamoDB table to read from.
- `"dynamodb.unnestDDBJson"`: (Optional) Default: `false`. Valid values: `boolean`. If set to `true`, performs an `unnest` transformation of the DynamoDB JSON structure that is present in exports. It is an error to set `"dynamodb.unnestDDBJson"` and `"dynamodb.simplifyDDBJson"` to `true` at the same time. In AWS Glue 3.0 and later versions, we recommend you use `"dynamodb.simplifyDDBJson"` for better behavior when simplifying DynamoDB Map types. For more information, see [the section called "Simplifying usage of DynamoDB export JSON"](#).
- `"dynamodb.simplifyDDBJson"`: (Optional) Default: `false`. Valid values: `boolean`. If set to `true`, performs a transformation to simplify the schema of the DynamoDB JSON structure that is present in exports. This has the same purpose as the `"dynamodb.unnestDDBJson"` option but provides better support for DynamoDB Map types or even nested Map types in your DynamoDB table. This option is available in AWS Glue 3.0 and later versions. It is an error to set `"dynamodb.unnestDDBJson"` and `"dynamodb.simplifyDDBJson"` to `true` at the same time. For more information, see [the section called "Simplifying usage of DynamoDB export JSON"](#).
- `"dynamodb.s3.bucket"`: (Optional) Indicates the Amazon S3 bucket location in which the `DynamoDB ExportTableToPointInTime` process is to be conducted. The file format for the export is DynamoDB JSON.
  - `"dynamodb.s3.prefix"`: (Optional) Indicates the Amazon S3 prefix location inside the Amazon S3 bucket in which the `DynamoDB ExportTableToPointInTime` loads are to be stored. If neither `dynamodb.s3.prefix` nor `dynamodb.s3.bucket` are specified, these values will default to the Temporary Directory location specified in the AWS Glue job configuration. For more information, see [Special Parameters Used by AWS Glue](#).
  - `"dynamodb.s3.bucketOwner"`: Indicates the bucket owner needed for cross-account Amazon S3 access.
- `"dynamodb.sts.roleArn"`: (Optional) The IAM role ARN to be assumed for cross-account access and/or cross-Region access for the DynamoDB table. Note: The same IAM role ARN will be used to access the Amazon S3 location specified for the `ExportTableToPointInTime` request.
- `"dynamodb.sts.roleSessionName"`: (Optional) STS session name. The default is set to `"glue-dynamodb-read-sts-session"`.

- `"dynamodb.exportTime"` (Optional) Valid values: strings representing ISO-8601 instants. A point-in-time at which the export should be made.
- `"dynamodb.sts.region"`: (Required if making a cross-region call using a regional endpoint) The region hosting the DynamoDB table you want to read.

### **"connectionType": "dynamodb" with the ETL connector as sink**

Use the following connection options with `"connectionType": "dynamodb"` as a sink:

- `"dynamodb.output.tableName"`: (Required) The DynamoDB table to write to.
- `"dynamodb.throughput.write.percent"`: (Optional) The percentage of write capacity units (WCU) to use. The default is set to "0.5". Acceptable values are from "0.1" to "1.5", inclusive.
  - 0.5 represents the default write rate, meaning that AWS Glue will attempt to consume half of the write capacity of the table. If you increase the value above 0.5, AWS Glue increases the request rate; decreasing the value below 0.5 decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table).
- When the DynamoDB table is in on-demand mode, AWS Glue handles the write capacity of the table as 40000. For importing a large table, we recommend switching your DynamoDB table to on-demand mode.
- `"dynamodb.output.numParallelTasks"`: (Optional) Defines how many parallel tasks write into DynamoDB at the same time. Used to calculate permissive WCU per Spark task. In most cases, AWS Glue will calculate a reasonable default for this value. For more information, see [the section called "DynamoDB parallelism"](#).
- `"dynamodb.output.retry"`: (Optional) Defines how many retries we perform when there is a `ProvisionedThroughputExceededException` from DynamoDB. The default is set to "10".
- `"dynamodb.sts.roleArn"`: (Optional) The IAM role ARN to be assumed for cross-account access.
- `"dynamodb.sts.roleSessionName"`: (Optional) STS session name. The default is set to "glue-dynamodb-write-sts-session".

### **Cross-account cross-Region access to DynamoDB tables**

AWS Glue ETL jobs support both cross-region and cross-account access to DynamoDB tables.

AWS Glue ETL jobs support both reading data from another AWS Account's DynamoDB table, and

writing data into another AWS Account's DynamoDB table. AWS Glue also supports both reading from a DynamoDB table in another region, and writing into a DynamoDB table in another region. This section gives instructions on setting up the access, and provides an example script.

The procedures in this section reference an IAM tutorial for creating an IAM role and granting access to the role. The tutorial also discusses assuming a role, but here you will instead use a job script to assume the role in AWS Glue. This tutorial also contains information about general cross-account practices. For more information, see [Tutorial: Delegate Access Across AWS Accounts Using IAM Roles](#) in the *IAM User Guide*.

## Create a role

Follow [step 1 in the tutorial](#) to create an IAM role in account A. When defining the permissions of the role, you can choose to attach existing policies such as `AmazonDynamoDBReadOnlyAccess`, or `AmazonDynamoDBFullAccess` to allow the role to read/write DynamoDB. The following example shows creating a role named `DynamoDBCrossAccessRole`, with the permission policy `AmazonDynamoDBFullAccess`.

## Grant access to the role

Follow [step 2 in the tutorial](#) in the *IAM User Guide* to allow account B to switch to the newly-created role. The following example creates a new policy with the following statement:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "<DynamoDBCrossAccessRole's ARN>"
  }
}
```

Then, you can attach this policy to the group/role/user you would like to use to access DynamoDB.

## Assume the role in the AWS Glue job script

Now, you can log in to account B and create an AWS Glue job. To create a job, refer to the instructions at [Configuring job properties for Spark jobs in AWS Glue](#).

In the job script you need to use the `dynamodb.sts.roleArn` parameter to assume the `DynamoDBCrossAccessRole` role. Assuming this role allows you to get the temporary credentials, which need to be used to access DynamoDB in account B. Review these example scripts.

**For a cross-account read across regions (ETL connector):**

```

import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.region": "us-east-1",
        "dynamodb.input.tableName": "test_source",
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)
dyf.show()
job.commit()

```

**For a cross-account read across regions (ELT connector):**

```

import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME"])
glue_context= GlueContext(SparkContext.getOrCreate())
job = Job(glue_context)
job.init(args["JOB_NAME"], args)

dyf = glue_context.create_dynamic_frame_from_options(
    connection_type="dynamodb",
    connection_options={
        "dynamodb.export": "ddb",
        "dynamodb.tableArn": "<test_source ARN>",
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"
    }
)

```

```
    }  
  )  
  dyf.show()  
  job.commit()
```

For a read and cross-account write across regions:

```
import sys  
from pyspark.context import SparkContext  
from awsglue.context import GlueContext  
from awsglue.job import Job  
from awsglue.utils import getResolvedOptions  
  
args = getResolvedOptions(sys.argv, ["JOB_NAME"])  
glue_context= GlueContext(SparkContext.getOrCreate())  
job = Job(glue_context)  
job.init(args["JOB_NAME"], args)  
  
dyf = glue_context.create_dynamic_frame_from_options(  
    connection_type="dynamodb",  
    connection_options={  
        "dynamodb.region": "us-east-1",  
        "dynamodb.input.tableName": "test_source"  
    }  
)  
dyf.show()  
  
glue_context.write_dynamic_frame_from_options(  
    frame=dyf,  
    connection_type="dynamodb",  
    connection_options={  
        "dynamodb.region": "us-west-2",  
        "dynamodb.output.tableName": "test_sink",  
        "dynamodb.sts.roleArn": "<DynamoDBCrossAccessRole's ARN>"  
    }  
)  
  
job.commit()
```

## Kinesis connections

You can read and write to Amazon Kinesis data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information

from Kinesis into a Spark DataFrame, then convert it to a AWS Glue DynamicFrame. You can write DynamicFrames to Kinesis in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kinesis streaming source, the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kinesis streaming source. If you use `getSource`, `getSourceWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kinesis using the following arguments for the specified methods in the `GlueContext` class.

- Scala
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`
  - `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about Streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

## Configure Kinesis

To connect to a Kinesis data stream in an AWS Glue Spark job, you will need some prerequisites:

- If reading, the AWS Glue job must have Read access level IAM permissions to the Kinesis data stream.
- If writing, the AWS Glue job must have Write access level IAM permissions to the Kinesis data stream.

In certain cases, you will need to configure additional prerequisites:

- If your AWS Glue job is configured with **Additional network connections** (typically to connect to other datasets) and one of those connections provides Amazon VPC **Network options**, this will direct your job to communicate over Amazon VPC. In this case you will also need to configure your Kinesis data stream to communicate over Amazon VPC. You can do this by creating an interface VPC endpoint between your Amazon VPC and Kinesis data stream. For more information, see [Using Kinesis Data Streams with Interface VPC Endpoints](#).
- When specifying Amazon Kinesis Data Streams in another account, you must setup the roles and policies to allow cross-account access. For more information, see [Example: Read From a Kinesis Stream in a Different Account](#).

For more information about Streaming ETL job prerequisites, consult [the section called “Streaming ETL jobs”](#).

### Example: Reading from Kinesis streams

### Example: Reading from Kinesis streams

Used in conjunction with [the section called “forEachBatch”](#).

Example for Amazon Kinesis streaming source:

```
kinesis_options =
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",
    "startingPosition": "TRIM_HORIZON",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kinesis",
  connection_options=kinesis_options)
```

### Example: Writing to Kinesis streams

### Example: Reading from Kinesis streams

Used in conjunction with [the section called “forEachBatch”](#).

Example for Amazon Kinesis streaming source:

```
kinesis_options =  
  { "streamARN": "arn:aws:kinesis:us-east-2:777788889999:stream/fromOptionsStream",  
    "startingPosition": "TRIM_HORIZON",  
    "inferSchema": "true",  
    "classification": "json"  
  }  
data_frame_datasource0 =  
  glueContext.create_data_frame.from_options(connection_type="kinesis",  
  connection_options=kinesis_options)
```

## Kinesis connection option reference

Designates connection options for Amazon Kinesis Data Streams.

Use the following connection options for Kinesis streaming data sources:

- "streamARN" (Required) Used for Read/Write. The ARN of the Kinesis data stream.
- "classification" (Required for read) Used for Read. The file format used by the data in the record. Required unless provided through the Data Catalog.
- "streamName" – (Optional) Used for Read. The name of a Kinesis data stream to read from. Used with `endpointUrl`.
- "endpointUrl" – (Optional) Used for Read. Default: "https://kinesis.us-east-1.amazonaws.com". The AWS endpoint of the Kinesis stream. You do not need to change this unless you are connecting to a special region.
- "partitionKey" – (Optional) Used for Write. The Kinesis partition key used when producing records.
- "delimiter" (Optional) Used for Read. The value separator used when `classification` is CSV. Default is ",."
- "startingPosition": (Optional) Used for Read. The starting position in the Kinesis data stream to read data from. The possible values are "latest", "trim\_horizon", "earliest", or a Timestamp string in UTC format in the pattern yyyy-mm-ddTHH:MM:SSZ (where Z represents a UTC timezone offset with a +/-). For example "2023-04-04T08:00:00-04:00"). The default value is "latest". Note: the Timestamp string in UTC Format for "startingPosition" is supported only for AWS Glue version 4.0 or later.
- "failOnDataLoss": (Optional) Fail the job if any active shard is missing or expired. The default value is "false".

- `"awsSTSRoleARN"`: (Optional) Used for Read/Write. The Amazon Resource Name (ARN) of the role to assume using AWS Security Token Service (AWS STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with `"awsSTSSessionName"`.
- `"awsSTSSessionName"`: (Optional) Used for Read/Write. An identifier for the session assuming the role using AWS STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with `"awsSTSRoleARN"`.
- `"awsSTSEndpoint"`: (Optional) The AWS STS endpoint to use when connecting to Kinesis with an assumed role. This allows using the regional AWS STS endpoint in a VPC, which is not possible with the default global endpoint.
- `"maxFetchTimeInMs"`: (Optional) Used for Read. The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple `GetRecords` API calls may be made within this time. The default value is `1000`.
- `"maxFetchRecordsPerShard"`: (Optional) Used for Read. The maximum number of records to fetch per shard in the Kinesis data stream per microbatch. Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same `get-records` call). If `maxFetchRecordsPerShard` needs to be strict then it needs to be a multiple of `maxRecordPerRead`. The default value is `100000`.
- `"maxRecordPerRead"`: (Optional) Used for Read. The maximum number of records to fetch from the Kinesis data stream in each `getRecords` operation. The default value is `10000`.
- `"addIdleTimeBetweenReads"`: (Optional) Used for Read. Adds a time delay between two consecutive `getRecords` operations. The default value is `"False"`. This option is only configurable for Glue version 2.0 and above.
- `"idleTimeBetweenReadsInMs"`: (Optional) Used for Read. The minimum time delay between two consecutive `getRecords` operations, specified in ms. The default value is `1000`. This option is only configurable for Glue version 2.0 and above.
- `"describeShardInterval"`: (Optional) Used for Read. The minimum time interval between two `ListShards` API calls for your script to consider resharding. For more information, see [Strategies for Resharding](#) in *Amazon Kinesis Data Streams Developer Guide*. The default value is `1s`.
- `"numRetries"`: (Optional) Used for Read. The maximum number of retries for Kinesis Data Streams API requests. The default value is `3`.

- "retryIntervalMs": (Optional) Used for Read. The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is 1000.
- "maxRetryIntervalMs": (Optional) Used for Read. The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is 10000.
- "avoidEmptyBatches": (Optional) Used for Read. Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".
- "schema": (Required when inferSchema set to false) Used for Read. The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
`column1` INT, `column2` STRING , `column3` FLOAT
```

Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
        "name": "_id",
        "type": "string"
      },
      {
        "name": "index",
        "type":
        [
          "int",
          "string",
          "float"
        ]
      }
    ]
  }
}
```

```
    ]  
  }  
}
```

- `"inferSchema"`: (Optional) Used for Read. The default value is `'false'`. If set to `'true'`, the schema will be detected at runtime from the payload within `foreachbatch`.
- `"avroSchema"`: (Deprecated) Used for Read. Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- `"addRecordTimestamp"`: (Optional) Used for Read. When this option is set to `'true'`, the data output will contain an additional column named `"__src_timestamp"` that indicates the time when the corresponding record received by the stream. The default value is `'false'`. This option is supported in AWS Glue version 4.0 or later.
- `"emitConsumerLagMetrics"`: (Optional) Used for Read. When the option is set to `'true'`, for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in AWS Glue to CloudWatch. The metric's name is `"glue.driver.streaming.maxConsumerLagInMs"`. The default value is `'false'`. This option is supported in AWS Glue version 4.0 or later.
- `"fanoutConsumerARN"`: (Optional) Used for Read. The ARN of a Kinesis stream consumer for the stream specified in `streamARN`. Used to enable enhanced fan-out mode for your Kinesis connection. For more information on consuming a Kinesis stream with enhanced fan-out, see [the section called "Using enhanced fan-out in Kinesis streaming jobs"](#).
- `"recordMaxBufferedTime"` – (Optional) Used for Write. Default: 1000 (ms). Maximum time a record is buffered while waiting to be written.
- `"aggregationEnabled"` – (Optional) Used for Write. Default: `true`. Specifies if records should be aggregated before sending them to Kinesis.
- `"aggregationMaxSize"` – (Optional) Used for Write. Default: 51200 (bytes). If a record is larger than this limit, it will bypass the aggregator. Note Kinesis enforces a limit of 50KB on record size. If you set this beyond 50KB, oversized records will be rejected by Kinesis.
- `"aggregationMaxCount"` – (Optional) Used for Write. Default: 4294967295. Maximum number of items to pack into an aggregated record.
- `"producerRateLimit"` – (Optional) Used for Write. Default: 150 (%). Limits per-shard throughput sent from a single producer (such as your job), as a percentage of the backend limit.
- `"collectionMaxCount"` – (Optional) Used for Write. Default: 500. Maximum number of items to pack into an `PutRecords` request.

- "collectionMaxSize" – (Optional) Used for Write. Default: 5242880 (bytes). Maximum amount of data to send with a PutRecords request.

## Using enhanced fan-out in Kinesis streaming jobs

An enhanced fan-out consumer is able to receive records from a Kinesis stream with dedicated throughput that can be greater than typical consumers. This is done by optimizing the transfer protocol used to provide data to a Kinesis consumer, such as your job. For more information about Kinesis Enhanced Fan-Out, see [the Kinesis documentation](#).

In enhanced fan-out mode, the `maxRecordPerRead` and `idleTimeBetweenReadsInMs` connection options no longer apply, as those parameters are not configurable when using enhanced fan-out. The configuration options for retries perform as described.

Use the following procedures to enable and disable enhanced fan-out for your streaming job. You should register a stream consumer for each job that will consume data from your stream.

### To enable enhanced fan-out consumption on your job:

1. Register a stream consumer for your job using the Kinesis API. Follow the instructions to *register a consumer with enhanced fan-out using the Kinesis Data Streams API* in the [Kinesis documentation](#). You will only need to follow the first step - calling [RegisterStreamConsumer](#). Your request should return an ARN, *consumerARN*.
2. Set the connection option `fanoutConsumerARN` to *consumerARN* in your connection method arguments.
3. Restart your job.

### To disable enhanced fan-out consumption on your job:

1. Remove the `fanoutConsumerARN` connection option from your method call.
2. Restart your job.
3. Follow the instructions to *deregister a consumer* in the [Kinesis documentation](#). These instructions apply to the console, but can also be achieved through the Kinesis API. For more information about stream consumer deregistration through the Kinesis API, consult [DeregisterStreamConsumer](#) in the Kinesis documentation.

## Amazon S3 connections

You can use AWS Glue for Spark to read and write files in Amazon S3. AWS Glue for Spark supports many common data formats stored in Amazon S3 out of the box, including CSV, Avro, JSON, Orc and Parquet. For more information about supported data formats, see [the section called “Data format options”](#). Each data format may support a different set of AWS Glue features. Consult the page for your data format for the specifics of feature support. Additionally, you can read and write versioned files stored in the Hudi, Iceberg and Delta Lake data lake frameworks. For more information about data lake frameworks, see [the section called “Data lake frameworks”](#).

With AWS Glue you can partition your Amazon S3 objects into a folder structure while writing, then retrieve it by partition to improve performance using simple configuration. You can also set configuration to group small files together when transforming your data to improve performance. You can read and write bzip2 and gzip archives in Amazon S3.

- [Reading input files in larger groups](#)
- [Amazon VPC endpoints for Amazon S3](#)

### Configuring S3 connections

To connect to Amazon S3 in a AWS Glue with Spark job, you will need some prerequisites:

- The AWS Glue job must have IAM permissions for relevant Amazon S3 buckets.

In certain cases, you will need to configure additional prerequisites:

- When configuring cross-account access, appropriate access controls on the Amazon S3 bucket.
- For security reasons, you may choose to route your Amazon S3 requests through an Amazon VPC. This approach can introduce bandwidth and availability challenges. For more information, see [the section called “Amazon VPC endpoints for Amazon S3”](#).

## Amazon S3 connection option reference

Designates a connection to Amazon S3.

Since Amazon S3 manages files rather than tables, in addition to specifying the connection properties provided in this document, you will need to specify additional configuration about your file type. You specify this information through data format options. For more information about format options, see [the section called "Data format options"](#). You can also specify this information by integrating with the AWS Glue Data Catalog.

For an example of the distinction between connection options and format options, consider how the [the section called "create\\_dynamic\\_frame\\_from\\_options"](#) method takes `connection_type`, `connection_options`, `format` and `format_options`. This section specifically discusses parameters provided to `connection_options`.

Use the following connection options with `"connectionType": "s3"`:

- `"paths"`: (Required) A list of the Amazon S3 paths to read from.
- `"exclusions"`: (Optional) A string containing a JSON list of Unix-style glob patterns to exclude. For example, `"[\\\"** .pdf\\\"]"` excludes all PDF files. For more information about the glob syntax that AWS Glue supports, see [Include and Exclude Patterns](#).
- `"compressionType"`: or `"compression"`: (Optional) Specifies how the data is compressed. Use `"compressionType"` for Amazon S3 sources and `"compression"` for Amazon S3 targets. This is generally not necessary if the data has a standard file extension. Possible values are `"gzip"` and `"bzip2"`. Additional compression formats may be supported for specific formats. For the specifics of feature support, consult the data format page.
- `"groupFiles"`: (Optional) Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to `"inPartition"`. To disable grouping when there are more than 50,000 files, set this parameter to `"none"`.
- `"groupSize"`: (Optional) The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, `"groupFiles"` must be set to `"inPartition"` for this to take effect.
- `"recurse"`: (Optional) If set to true, recursively reads files in all subdirectories under the specified paths.
- `"maxBand"`: (Optional, advanced) This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the

last maxBand milliseconds are tracked specially when using JobBookmarks to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- "maxFilesInBand": (Optional, advanced) This option specifies the maximum number of files to save from the last maxBand seconds. If this number is exceeded, extra files are skipped and only processed in the next job run. Most users don't need to set this option.
- "isFailFast": (Optional) This option determines if an AWS Glue ETL job throws reader parsing exceptions. If set to true, jobs fail fast if four retries of the Spark task fail to parse the data correctly.
- "catalogPartitionPredicate": (Optional) Used for Read. The contents of a SQL WHERE clause. Used when reading from Data Catalog tables with a very large quantity of partitions. Retrieves matching partitions from Data Catalog indices. Used with push\_down\_predicate, an option on the [the section called "create\\_dynamic\\_frame\\_from\\_catalog"](#) method (and other similar methods). For more information, see [the section called "Catalog partition predicates"](#).
- "partitionKeys": (Optional) Used for Write. An array of column label strings. AWS Glue will partition your data as specified by this configuration. For more information, see [the section called "Writing partitions"](#).
- "excludeStorageClasses": (Optional) Used for Read. An array of strings specifying Amazon S3 storage classes. AWS Glue will exclude Amazon S3 objects based on this configuration. For more information, see [the section called "Excluding Amazon S3 storage classes"](#).

## Deprecated connection syntaxes for data formats

Certain data formats can be accessed using a specific connection type syntax. This syntax is deprecated. We recommend you specify your formats using the s3 connection type and the format options provided in [the section called "Data format options"](#) instead.

### "connectionType": "Orc"

Designates a connection to files stored in Amazon S3 in the [Apache Hive Optimized Row Columnar \(ORC\)](#) file format.

Use the following connection options with "connectionType": "orc":

- paths: (Required) A list of the Amazon S3 paths to read from.
- (Other option name/value pairs): Any additional options, including formatting options, are passed directly to the SparkSQL DataSource.

## "connectionType": "parquet"

Designates a connection to files stored in Amazon S3 in the [Apache Parquet](#) file format.

Use the following connection options with "connectionType": "parquet":

- `paths`: (Required) A list of the Amazon S3 paths to read from.
- *(Other option name/value pairs)*: Any additional options, including formatting options, are passed directly to the SparkSQL DataSource.

## Excluding Amazon S3 storage classes

If you're running AWS Glue ETL jobs that read files or partitions from Amazon Simple Storage Service (Amazon S3), you can exclude some Amazon S3 storage class types.

The following storage classes are available in Amazon S3:

- `STANDARD` — For general-purpose storage of frequently accessed data.
- `INTELLIGENT_TIERING` — For data with unknown or changing access patterns.
- `STANDARD_IA` and `ONEZONE_IA` — For long-lived, but less frequently accessed data.
- `GLACIER`, `DEEP_ARCHIVE`, and `REDUCED_REDUNDANCY` — For long-term archive and digital preservation.

For more information, see [Amazon S3 Storage Classes](#) in the *Amazon S3 Developer Guide*.

The examples in this section show how to exclude the `GLACIER` and `DEEP_ARCHIVE` storage classes. These classes allow you to list files, but they won't let you read the files unless they are restored. (For more information, see [Restoring Archived Objects](#) in the *Amazon S3 Developer Guide*.)

By using storage class exclusions, you can ensure that your AWS Glue jobs will work on tables that have partitions across these storage class tiers. Without exclusions, jobs that read data from these tiers fail with the following error: `AmazonS3Exception: The operation is not valid for the object's storage class.`

There are different ways that you can filter Amazon S3 storage classes in AWS Glue.

## Topics

- [Excluding Amazon S3 storage classes when creating a Dynamic Frame](#)

- [Excluding Amazon S3 storage classes on a Data Catalog table](#)

## Excluding Amazon S3 storage classes when creating a Dynamic Frame

To exclude Amazon S3 storage classes while creating a dynamic frame, use `excludeStorageClasses` in `additionalOptions`. AWS Glue automatically uses its own Amazon S3 Lister implementation to list and exclude files corresponding to the specified storage classes.

The following Python and Scala examples show how to exclude the GLACIER and DEEP\_ARCHIVE storage classes when creating a dynamic frame.

Python example:

```
glueContext.create_dynamic_frame.from_catalog(  
    database = "my_database",  
    tableName = "my_table_name",  
    redshift_tmp_dir = "",  
    transformation_ctx = "my_transformation_context",  
    additional_options = {  
        "excludeStorageClasses" : ["GLACIER", "DEEP_ARCHIVE"]  
    }  
)
```

Scala example:

```
val* *df = glueContext.getCatalogSource(  
    nameSpace, tableName, "", "my_transformation_context",  
    additionalOptions = JsonOptions(  
        Map("excludeStorageClasses" -> List("GLACIER", "DEEP_ARCHIVE"))  
    )  
)  
.getDynamicFrame()
```

## Excluding Amazon S3 storage classes on a Data Catalog table

You can specify storage class exclusions to be used by an AWS Glue ETL job as a table parameter in the AWS Glue Data Catalog. You can include this parameter in the `CreateTable` operation using the AWS Command Line Interface (AWS CLI) or programmatically using the API. For more information, see [Table Structure](#) and [CreateTable](#).

You can also specify excluded storage classes on the AWS Glue console.

## To exclude Amazon S3 storage classes (console)

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. In the navigation pane on the left, choose **Tables**.
3. Choose the table name in the list, and then choose **Edit table**.
4. In **Table properties**, add `excludeStorageClasses` as a key and `["GLACIER", "DEEP_ARCHIVE"]` as a value.
5. Choose **Apply**.

## Managing partitions for ETL output in AWS Glue

Partitioning is an important technique for organizing datasets so they can be queried efficiently. It organizes data in a hierarchical directory structure based on the distinct values of one or more columns.

For example, you might decide to partition your application logs in Amazon Simple Storage Service (Amazon S3) by date, broken down by year, month, and day. Files that correspond to a single day's worth of data are then placed under a prefix such as `s3://my_bucket/logs/year=2018/month=01/day=23/`. Systems like Amazon Athena, Amazon Redshift Spectrum, and now AWS Glue can use these partitions to filter data by partition value without having to read all the underlying data from Amazon S3.

Crawlers not only infer file types and schemas, they also automatically identify the partition structure of your dataset when they populate the AWS Glue Data Catalog. The resulting partition columns are available for querying in AWS Glue ETL jobs or query engines like Amazon Athena.

After you crawl a table, you can view the partitions that the crawler created. In the AWS Glue console, choose **Tables** in the left navigation pane. Choose the table created by the crawler, and then choose **View Partitions**.

For Apache Hive-style partitioned paths in `key=val` style, crawlers automatically populate the column name using the key name. Otherwise, it uses default names like `partition_0`, `partition_1`, and so on. You can change the default names on the console. To do so, navigate to the table. Check if indexes exist under the **Indexes** tab. If that's the case, you need to delete them to proceed (you can recreate them using the new column names afterwards). Then, choose **Edit Schema**, and modify the names of the partition columns there.

In your ETL scripts, you can then filter on the partition columns. Because the partition information is stored in the Data Catalog, use the `from_catalog` API calls to include the partition columns in the `DynamicFrame`. For example, use `create_dynamic_frame.from_catalog` instead of `create_dynamic_frame.from_options`.

Partitioning is an optimization technique that reduces data scan. For more information about the process of identifying when this technique is appropriate, consult [Reduce the amount of data scan](#) in the *Best practices for performance tuning AWS Glue for Apache Spark jobs* guide on AWS Prescriptive Guidance.

### Pre-filtering using pushdown predicates

In many cases, you can use a pushdown predicate to filter on partitions without having to list and read all the files in your dataset. Instead of reading the entire dataset and then filtering in a `DynamicFrame`, you can apply the filter directly on the partition metadata in the Data Catalog. Then you only list and read what you actually need into a `DynamicFrame`.

For example, in Python, you could write the following.

```
glue_context.create_dynamic_frame.from_catalog(  
    database = "my_S3_data_set",  
    table_name = "catalog_data_table",  
    push_down_predicate = my_partition_predicate)
```

This creates a `DynamicFrame` that loads only the partitions in the Data Catalog that satisfy the predicate expression. Depending on how small a subset of your data you are loading, this can save a great deal of processing time.

The predicate expression can be any Boolean expression supported by Spark SQL. Anything you could put in a `WHERE` clause in a Spark SQL query will work. For example, the predicate expression `pushDownPredicate = "(year=='2017' and month=='04')"` loads only the partitions in the Data Catalog that have both year equal to 2017 and month equal to 04. For more information, see the [Apache Spark SQL documentation](#), and in particular, the [Scala SQL functions reference](#).

### Server-side filtering using catalog partition predicates

The `push_down_predicate` option is applied after listing all the partitions from the catalog and before listing files from Amazon S3 for those partitions. If you have a lot of partitions

for a table, catalog partition listing can still incur additional time overhead. To address this overhead, you can use server-side partition pruning with the `catalogPartitionPredicate` option that uses [partition indexes](#) in the AWS Glue Data Catalog. This makes partition filtering much faster when you have millions of partitions in one table. You can use both `push_down_predicate` and `catalogPartitionPredicate` in `additional_options` together if your `catalogPartitionPredicate` requires predicate syntax that is not yet supported with the catalog partition indexes.

Python:

```
dynamic_frame = glueContext.create_dynamic_frame.from_catalog(  
    database=dbname,  
    table_name=tablename,  
    transformation_ctx="datasource0",  
    push_down_predicate="day>=10 and customer_id like '10%'",  
    additional_options={"catalogPartitionPredicate":"year='2021' and month='06'"}  
)
```

Scala:

```
val dynamicFrame = glueContext.getCatalogSource(  
    database = dbname,  
    tableName = tablename,  
    transformationContext = "datasource0",  
    pushDownPredicate="day>=10 and customer_id like '10%'",  
    additionalOptions = JsonOptions("""{  
        "catalogPartitionPredicate": "year='2021' and month='06'"}""")  
).getDynamicFrame()
```

### Note

The `push_down_predicate` and `catalogPartitionPredicate` use different syntaxes. The former one uses Spark SQL standard syntax and the later one uses JSQL parser.

## Writing partitions

By default, a `DynamicFrame` is not partitioned when it is written. All of the output files are written at the top level of the specified output path. Until recently, the only way to write a `DynamicFrame` into partitions was to convert it to a Spark SQL `DataFrame` before writing.

However, DynamicFrames now support native partitioning using a sequence of keys, using the `partitionKeys` option when you create a sink. For example, the following Python code writes out a dataset to Amazon S3 in the Parquet format, into directories partitioned by the type field. From there, you can process these partitions using other systems, such as Amazon Athena.

```
glue_context.write_dynamic_frame.from_options(  
    frame = projectedEvents,  
    connection_type = "s3",  
    connection_options = {"path": "$outpath", "partitionKeys": ["type"]},  
    format = "parquet")
```

## Reading input files in larger groups

You can set properties of your tables to enable an AWS Glue ETL job to group files when they are read from an Amazon S3 data store. These properties enable each ETL task to read a group of input files into a single in-memory partition, this is especially useful when there is a large number of small files in your Amazon S3 data store. When you set certain properties, you instruct AWS Glue to group files within an Amazon S3 data partition and set the size of the groups to be read. You can also set these options when reading from an Amazon S3 data store with the `create_dynamic_frame.from_options` method.

To enable grouping files for a table, you set key-value pairs in the `parameters` field of your table structure. Use JSON notation to set a value for the parameter field of your table. For more information about editing the properties of a table, see [Viewing and editing table details](#).

You can use this method to enable grouping for tables in the Data Catalog with Amazon S3 data stores.

### groupFiles

Set **groupFiles** to `inPartition` to enable the grouping of files within an Amazon S3 data partition. AWS Glue automatically enables grouping if there are more than 50,000 input files, as in the following example.

```
'groupFiles': 'inPartition'
```

## groupSize

Set **groupSize** to the target size of groups in bytes. The **groupSize** property is optional, if not provided, AWS Glue calculates a size to use all the CPU cores in the cluster while still reducing the overall number of ETL tasks and in-memory partitions.

For example, the following sets the group size to 1 MB.

```
'groupSize': '1048576'
```

Note that the groupsize should be set with the result of a calculation. For example  $1024 * 1024 = 1048576$ .

## recurse

Set **recurse** to `True` to recursively read files in all subdirectories when specifying paths as an array of paths. You do not need to set **recurse** if paths is an array of object keys in Amazon S3, or if the input format is parquet/orc, as in the following example.

```
'recurse': True
```

If you are reading from Amazon S3 directly using the `create_dynamic_frame.from_options` method, add these connection options. For example, the following attempts to group files into 1 MB groups.

```
df = glueContext.create_dynamic_frame.from_options("s3", {'paths': ["s3://s3path/"],  
'recurse': True, 'groupFiles': 'inPartition', 'groupSize': '1048576'}, format="json")
```

### Note

`groupFiles` is supported for DynamicFrames created from the following data formats: csv, ion, grokLog, json, and xml. This option is not supported for avro, parquet, and orc.

## Amazon VPC endpoints for Amazon S3

For security reasons, many AWS customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a virtual private cloud, which is logically isolated from other networks—including the public internet. With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

### Note

If you created your AWS account after 2013-12-04, you already have a default VPC in each AWS Region. You can immediately start using your default VPC without any additional configuration.

For more information, see [Your Default VPC and Subnets](#) in the Amazon VPC User Guide.

Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. Customers can address these concerns by using a virtual private network (VPN) to route all Amazon S3 network traffic through their own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for Amazon S3 can alleviate these challenges. A VPC endpoint for Amazon S3 enables AWS Glue to use private IP addresses to access Amazon S3 with no exposure to the public internet. AWS Glue does not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to Amazon S3. Traffic between your VPC and the AWS service does not leave the Amazon network.

When you create a VPC endpoint for Amazon S3, any requests to an Amazon S3 endpoint within the Region (for example, *s3.us-west-2.amazonaws.com*) are routed to a private Amazon S3 endpoint within the Amazon network. You don't need to modify your applications running on Amazon EC2 instances in your VPC—the endpoint name remains the same, but the route to Amazon S3 stays entirely within the Amazon network, and does not access the public internet.

For more information about VPC endpoints, see [VPC Endpoints](#) in the Amazon VPC User Guide.

The following diagram shows how AWS Glue can use a VPC endpoint to access Amazon S3.

### To set up access for Amazon S3

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Choose **Create Endpoint**, and follow the steps to create an Amazon S3 VPC endpoint of type Gateway.

### Amazon DocumentDB connections

You can use AWS Glue for Spark to read from and write to tables in Amazon DocumentDB. You can connect to Amazon DocumentDB using credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Amazon DocumentDB, consult the [Amazon DocumentDB documentation](#).

**Note**

Amazon DocumentDB elastic clusters are not currently supported when using the AWS Glue connector. For more information about elastic clusters, see [Using Amazon DocumentDB elastic clusters](#).

## Reading and writing to Amazon DocumentDB collections

**Note**

When you create an ETL job that connects to Amazon DocumentDB, for the `Connections` job property, you must designate a connection object that specifies the virtual private cloud (VPC) in which Amazon DocumentDB is running. For the connection object, the connection type must be JDBC, and the JDBC URL must be `mongo://<DocumentDB_host>:27017`.

**Note**

These code samples were developed for AWS Glue 3.0. To migrate to AWS Glue 4.0, consult [the section called "MongoDB"](#). The `uri` parameter has changed.

**Note**

When using Amazon DocumentDB, `retryWrites` must be set to `false` in certain situations, such as when the document written specifies `_id`. For more information, consult [Functional Differences with MongoDB](#) in the Amazon DocumentDB documentation.

The following Python script demonstrates using connection types and connection options for reading and writing to Amazon DocumentDB.

```
import sys
```

```
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'], args)

output_path = "s3://some_bucket/output/" + str(time.time()) + "/"
documentdb_uri = "mongodb://<mongo-instanced-ip-address>:27017"
documentdb_write_uri = "mongodb://<mongo-instanced-ip-address>:27017"

read_docdb_options = {
    "uri": documentdb_uri,
    "database": "test",
    "collection": "coll",
    "username": "username",
    "password": "1234567890",
    "ssl": "true",
    "ssl.domain_match": "false",
    "partitioner": "MongoSamplePartitioner",
    "partitionerOptions.partitionSizeMB": "10",
    "partitionerOptions.partitionKey": "_id"
}

write_documentdb_options = {
    "retryWrites": "false",
    "uri": documentdb_write_uri,
    "database": "test",
    "collection": "coll",
    "username": "username",
    "password": "pwd"
}

# Get DynamicFrame from DocumentDB
```

```
dynamic_frame2 =
  glueContext.create_dynamic_frame.from_options(connection_type="documentdb",
  connection_options=read_docdb_options)

# Write DynamicFrame to MongoDB and DocumentDB
glueContext.write_dynamic_frame.from_options(dynamic_frame2,
  connection_type="documentdb",

  connection_options=write_documentdb_options)

job.commit()
```

The following Scala script demonstrates using connection types and connection options for reading and writing to Amazon DocumentDB.

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamicFrame
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  val DOC_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  val DOC_WRITE_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  lazy val documentDBJsonOption = jsonOptions(DOC_URI)
  lazy val writeDocumentDBJsonOption = jsonOptions(DOC_WRITE_URI)
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Get DynamicFrame from DocumentDB
    val resultFrame2: DynamicFrame = glueContext.getSource("documentdb",
    documentDBJsonOption).getDynamicFrame()

    // Write DynamicFrame to DocumentDB
    glueContext.getSink("documentdb", writeJsonOption).writeDynamicFrame(resultFrame2)
```

```
    Job.commit()
  }

private def jsonOptions(uri: String): JsonOptions = {
  new JsonOptions(
    s""""{"uri": "${uri}",
      |"database":"test",
      |"collection":"coll",
      |"username": "username",
      |"password": "pwd",
      |"ssl":"true",
      |"ssl.domain_match":"false",
      |"partitioner": "MongoSamplePartitioner",
      |"partitionerOptions.partitionSizeMB": "10",
      |"partitionerOptions.partitionKey": "_id"}"""".stripMargin)
  }
}
```

## Amazon DocumentDB connection option reference

Designates a connection to Amazon DocumentDB (with MongoDB compatibility).

Connection options differ for a source connection and a sink connection.

### "connectionType": "Documentdb" as source

Use the following connection options with "connectionType": "documentdb" as a source:

- "uri": (Required) The Amazon DocumentDB host to read from, formatted as `mongodb://<host>:<port>`.
- "database": (Required) The Amazon DocumentDB database to read from.
- "collection": (Required) The Amazon DocumentDB collection to read from.
- "username": (Required) The Amazon DocumentDB user name.
- "password": (Required) The Amazon DocumentDB password.
- "ssl": (Required if using SSL) If your connection uses SSL, then you must include this option with the value "true".
- "ssl.domain\_match": (Required if using SSL) If your connection uses SSL, then you must include this option with the value "false".

- "batchSize": (Optional): The number of documents to return per batch, used within the cursor of internal batches.
- "partitioner": (Optional): The class name of the partitioner for reading input data from Amazon DocumentDB. The connector provides the following partitioners:
  - MongoDefaultPartitioner (default) (Not supported in AWS Glue 4.0)
  - MongoSamplePartitioner (Not supported in AWS Glue 4.0)
  - MongoShardedPartitioner
  - MongoSplitVectorPartitioner
  - MongoPaginateByCountPartitioner
  - MongoPaginateBySizePartitioner (Not supported in AWS Glue 4.0)
- "partitionerOptions" (Optional): Options for the designated partitioner. The following options are supported for each partitioner:
  - MongoSamplePartitioner: partitionKey, partitionSizeMB, samplesPerPartition
  - MongoShardedPartitioner: shardkey
  - MongoSplitVectorPartitioner: partitionKey, partitionSizeMB
  - MongoPaginateByCountPartitioner: partitionKey, numberOfPartitions
  - MongoPaginateBySizePartitioner: partitionKey, partitionSizeMB

For more information about these options, see [Partitioner Configuration](#) in the MongoDB documentation.

### "connectionType": "Documentdb" as sink

Use the following connection options with "connectionType": "documentdb" as a sink:

- "uri": (Required) The Amazon DocumentDB host to write to, formatted as `mongodb://<host>:<port>`.
- "database": (Required) The Amazon DocumentDB database to write to.
- "collection": (Required) The Amazon DocumentDB collection to write to.
- "username": (Required) The Amazon DocumentDB user name.
- "password": (Required) The Amazon DocumentDB password.
- "extendedBsonTypes": (Optional) If `true`, allows extended BSON types when writing data to Amazon DocumentDB. The default is `true`.

- "replaceDocument": (Optional) If `true`, replaces the whole document when saving datasets that contain an `_id` field. If `false`, only fields in the document that match the fields in the dataset are updated. The default is `true`.
- "maxBatchSize": (Optional): The maximum batch size for bulk operations when saving data. The default is 512.
- "retryWrites": (Optional): Automatically retry certain write operations a single time if AWS Glue encounters a network error.

## OpenSearch Service connections

You can use AWS Glue for Spark to read from and write to tables in OpenSearch Service in AWS Glue 4.0 and later versions. You can define what to read from OpenSearch Service with an OpenSearch query. You connect to OpenSearch Service using HTTP basic authentication credentials stored in AWS Secrets Manager through a AWS Glue connection. This feature is not compatible with OpenSearch Service serverless.

For more information about Amazon OpenSearch Service, see the [Amazon OpenSearch Service documentation](#).

## Configuring OpenSearch Service connections

To connect to OpenSearch Service from AWS Glue, you will need to create and store your OpenSearch Service credentials in a AWS Secrets Manager secret, then associate that secret with a OpenSearch Service AWS Glue connection.

### Prerequisites:

- Identify the domain endpoint, *aosEndpoint* and port, *aosPort* you would like to read from, or create the resource by following instructions in the Amazon OpenSearch Service documentation. For more information on creating a domain, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

An Amazon OpenSearch Service domain endpoint will have the following default form, `https://search-domainName-unstructuredIdContent.region.es.amazonaws.com`. For more information on identifying your domain endpoint, see [Creating and managing Amazon OpenSearch Service domains](#) in the Amazon OpenSearch Service documentation.

Identify or generate HTTP basic authentication credentials, *aosUser* and *aosPassword* for your domain.

## To configure a connection to OpenSearch Service:

1. In AWS Secrets Manager, create a secret using your OpenSearch Service credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `opensearch.net.http.auth.user` with the value *aosUser*.
  - When selecting **Key/value pairs**, create a pair for the key `opensearch.net.http.auth.pass` with the value *aosPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select OpenSearch Service.
  - When selecting a Domain endpoint, provide *aosEndpoint*.
  - When selecting a port, provide *aosPort*.
  - When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue OpenSearch Service connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Reading from OpenSearch Service indexes

### Prerequisites:

- A OpenSearch Service index you would like to read from, *aosIndex*.
- A AWS Glue OpenSearch Service connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to OpenSearch Service*. You will need the name of the AWS Glue connection, *connectionName*.

This example reads an index from Amazon OpenSearch Service. You will need to provide the pushdown parameter.

For example:

```
opensearch_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="opensearch",  
    connection_options={  
        "connectionName": "connectionName",  
        "opensearch.resource": "aosIndex",  
        "pushdown": "true",  
    }  
)
```

You can also provide a query string to filter the results returned in your DynamicFrame. You will need to configure `opensearch.query`.

`opensearch.query` can take a URL query parameter string *queryString* or a query DSL JSON object *queryObject*. For more information about the query DSL, see [Query DSL](#) in the OpenSearch documentation. To provide a URL query parameter string, prepend `?q=` to your query, as you would in a fully qualified URL. To provide a query DSL object, string escape the JSON object before providing it.

For example:

```
    queryObject = "{ \"query\": { \"multi_match\": { \"query\": \"Sample\", \"fields\":  
[ \"sample\" ] } } }"  
    queryString = "?q=queryString"  
  
    opensearch_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="opensearch",  
    connection_options={  
        "connectionName": "connectionName",  
        "opensearch.resource": "aosIndex",  
        "opensearch.query": queryString,  
        "pushdown": "true",  
    }  
)
```

For more information about how to build a query outside of its specific syntax, see [Query string syntax](#) in the OpenSearch documentation.

When reading from OpenSearch collections that contain array type data, you must specify which fields are array type in your method call using the `opensearch.read.field.as.array.include` parameter.

For example, when reading the following document, you will encounter the `genre` and `actor` array fields:

```
{
  "_index": "movies",
  "_id": "2",
  "_version": 1,
  "_seq_no": 0,
  "_primary_term": 1,
  "found": true,
  "_source": {
    "director": "Frankenheimer, John",
    "genre": [
      "Drama",
      "Mystery",
      "Thriller",
      "Crime"
    ],
    "year": 1962,
    "actor": [
      "Lansbury, Angela",
      "Sinatra, Frank",
      "Leigh, Janet",
      "Harvey, Laurence",
      "Silva, Henry",
      "Frees, Paul",
      "Gregory, James",
      "Bissell, Whit",
      "McGiver, John",
      "Parrish, Leslie",
      "Edwards, James",
      "Flowers, Bess",
      "Dhiegh, Khigh",
      "Payne, Julie",
      "Kleeb, Helen",
      "Gray, Joe",
      "Nalder, Reggie",
      "Stevens, Bert",
      "Masters, Michael",
    ]
  }
}
```

```
        "Lowell, Tom"
      ],
      "title": "The Manchurian Candidate"
    }
  }
}
```

In this case, you would include those field names in your method call. For example:

```
"opensearch.read.field.as.array.include": "genre,actor"
```

If your array field is nested inside of your document structure, refer to it using dot notation: "genre,actor,foo.bar.baz". This would specify an array baz included in your source document through the embedded document foo containing the embedded document bar.

## Writing to OpenSearch Service tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to OpenSearch Service. If the index already has information, AWS Glue will append data from your DynamicFrame. You will need to provide the pushdown parameter.

### Prerequisites:

- A OpenSearch Service table you would like to write to. You will need identification information for the table. Let's call this *tableName*.
- A AWS Glue OpenSearch Service connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to OpenSearch Service*. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
glueContext.write_dynamic_frame.from_options(  
    frame=dynamicFrame,  
    connection_type="opensearch",  
    connection_options={  
        "connectionName": "connectionName",  
        "opensearch.resource": "aosIndex",  
    },  
)
```

## OpenSearch Service connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue OpenSearch Service connection configured to provide auth and network location information to your connection method.
- `opensearch.resource` — Required. Used for Read/Write. Valid Values: OpenSearch index names. The name of the index your connection method will interact with.
- `opensearch.query` — Used for Read. Valid Values: String escaped JSON or, when this string begins with `?`, the search part of a URL. An OpenSearch query that filters what should be retrieved when reading. For more information on using this parameter, consult the previous section [the section called “Read from OpenSearch Service”](#).
- `pushdown` — Required if. Used for Read. Valid Values: boolean. Instructs Spark to pass read queries down to OpenSearch so the database only returns relevant documents.
- `opensearch.read.field.as.array.include` — Required if reading array type data. Used for Read. Valid Values: comma separated lists of field names. Specifies fields to read as arrays from OpenSearch documents. For more information on using this parameter, consult the previous section [the section called “Read from OpenSearch Service”](#).

## Redshift connections

You can use AWS Glue for Spark to read from and write to tables in Amazon Redshift databases. When connecting to Amazon Redshift databases, AWS Glue moves data through Amazon S3 to achieve maximum throughput, using the Amazon Redshift SQL COPY and UNLOAD commands. In AWS Glue 4.0 and later, you can use the [Amazon Redshift integration for Apache Spark](#) to read and write with optimizations and features specific to Amazon Redshift beyond those available when connecting through previous versions.

Learn about how AWS Glue is making it easier than ever for Amazon Redshift users to migrate to AWS Glue for serverless data integration and ETL.

## Configuring Redshift connections

To use Amazon Redshift clusters in AWS Glue, you will need some prerequisites:

- An Amazon S3 directory to use for temporary storage when reading from and writing to the database.
- An Amazon VPC enabling communication between your Amazon Redshift cluster, your AWS Glue job and your Amazon S3 directory.

- Appropriate IAM permissions on the AWS Glue job and Amazon Redshift cluster.

## Configuring IAM roles

### Set up the role for the Amazon Redshift cluster

Your Amazon Redshift cluster needs to be able to read and write to Amazon S3 in order to integrate with AWS Glue jobs. To allow this, you can associate IAM roles with the Amazon Redshift cluster you want to connect to. Your role should have a policy allowing read from and write to your Amazon S3 temporary directory. Your role should have a trust relationship allowing the `redshift.amazonaws.com` service to `AssumeRole`.

### To associate an IAM role with Amazon Redshift

1. **Prerequisites:** An Amazon S3 bucket or directory used for the temporary storage of files.
2. Identify which Amazon S3 permissions your Amazon Redshift cluster will need. When moving data to and from an Amazon Redshift cluster, AWS Glue jobs issue `COPY` and `UNLOAD` statements against Amazon Redshift. If your job modifies a table in Amazon Redshift, AWS Glue will also issue `CREATE LIBRARY` statements. For information on specific Amazon S3 permissions required for Amazon Redshift to execute these statements, refer to the Amazon Redshift documentation: [Amazon Redshift: Permissions to access other AWS Resources](#).
3. In the IAM console, create an IAM policy with the necessary permissions. For more information about creating a policy [Creating IAM policies](#).
4. In the IAM console, create a role and trust relationship allowing Amazon Redshift to assume the role. Follow the instructions in the IAM documentation [To create a role for an AWS service \(console\)](#)
  - When asked to choose an AWS service use case, choose "Redshift - Customizable".
  - When asked to attach a policy, choose the policy you previously defined.

#### Note

For more information about configuring roles for Amazon Redshift, see [Authorizing Amazon Redshift to access other AWS services on your behalf](#) in the Amazon Redshift documentation.

- In the Amazon Redshift console, associate the role with your Amazon Redshift cluster. Follow the instructions in [the Amazon Redshift documentation](#).

Select the highlighted option in the Amazon Redshift console to configure this setting:

The screenshot shows the Amazon Redshift console interface for a cluster named 'flight-2016'. The breadcrumb navigation at the top reads 'Amazon Redshift > Clusters > flight-2016'. The cluster title 'flight-2016' is prominently displayed. Below the title, there are several buttons: 'Actions' (with an upward arrow), 'Edit', 'Add partner integration', and 'Query data' (with a downward arrow). The 'Actions' dropdown menu is open, showing a list of options: 'Manage cluster', 'Resize', 'Reboot', 'Pause', 'Delete', 'Defer maintenance', 'Modify publicly accessible setting', 'Backup and disaster recovery', 'Restore table', 'Create snapshot', 'Configure cross-region snapshot', 'Relocate', 'Permissions', 'Manage IAM roles' (highlighted with a red box), 'Change admin user password', and 'Manage tags'. The 'General information' section on the left includes fields for 'Cluster identifier' (flight-2016), 'Cluster namespace' (redacted), 'Cluster configuration' (Production), 'Status' (Available with a green checkmark), 'Date created' (redacted), 'Storage used' (0.25% of 160 GB), and 'Multi-AZ' (No). The right side of the console shows fields for 'Endpoint', 'JDBC URL', and 'ODBC URL' (with a driver name partially visible).

### **Note**

By default, AWS Glue jobs pass Amazon Redshift temporary credentials that are created using the role that you specified to run the job. We do not recommend using these credentials. For security purposes, these credentials expire after 1 hour.

## Set up the role for the AWS Glue job

The AWS Glue job needs a role to access the Amazon S3 bucket. You do not need IAM permissions for the Amazon Redshift cluster, your access is controlled by connectivity in Amazon VPC and your database credentials.

## Set up Amazon VPC

### To set up access for Amazon Redshift data stores

1. Sign in to the AWS Management Console and open the Amazon Redshift console at <https://console.aws.amazon.com/redshiftv2/>.
2. In the left navigation pane, choose **Clusters**.
3. Choose the cluster name that you want to access from AWS Glue.
4. In the **Cluster Properties** section, choose a security group in **VPC security groups** to allow AWS Glue to use. Record the name of the security group that you chose for future reference. Choosing the security group opens the Amazon EC2 console **Security Groups** list.
5. Choose the security group to modify and navigate to the **Inbound** tab.
6. Add a self-referencing rule to allow AWS Glue components to communicate. Specifically, add or confirm that there is a rule of **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Source** is the same security group name as the **Group ID**.

The inbound rule looks similar to the following:

Type	Protocol	Port range	Source
All TCP	TCP	0–65535	<i>database-security-group</i>

For example:

7. Add a rule for outbound traffic also. Either open outbound traffic to all ports, for example:

Type	Protocol	Port range	Destination
All Traffic	ALL	ALL	0.0.0.0/0

Or create a self-referencing rule where **Type** All TCP, **Protocol** is TCP, **Port Range** includes all ports, and whose **Destination** is the same security group name as the **Group ID**. If using an Amazon S3 VPC endpoint, also add an HTTPS rule for Amazon S3 access. The *s3-prefix-*

*list-id* is required in the security group rule to allow traffic from the VPC to the Amazon S3 VPC endpoint.

For example:

Type	Protocol	Port range	Destination
All TCP	TCP	0–65535	<i>security-group</i>
HTTPS	TCP	443	<i>s3-prefix-list-id</i>

## Set up AWS Glue

You will need to create an AWS Glue Data Catalog connection that provides Amazon VPC connection information.

### To configure Amazon Redshift Amazon VPC connectivity to AWS Glue in the console

1. Create a Data Catalog connection by following the steps in: [the section called “Adding an AWS Glue connection”](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select **Amazon Redshift**.
  - When selecting a **Redshift cluster**, select your cluster by name.
  - Provide default connection information for a Amazon Redshift user on your cluster.
  - Your Amazon VPC settings will be automatically configured.

#### Note

You will need to manually provide `PhysicalConnectionRequirements` for your Amazon VPC when creating an **Amazon Redshift** connection through the AWS SDK.

2. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Example: Reading from Amazon Redshift tables

You can read from Amazon Redshift clusters and Amazon Redshift serverless environments.

**Prerequisites:** An Amazon Redshift table you would like to read from. Follow the steps in the previous section [the section called “Configure Redshift”](#) after which you should have the Amazon S3 URI for a temporary directory, *temp-s3-dir* and an IAM role, *rs-role-name*, (in account *role-account-id*).

### Using the Data Catalog

**Additional Prerequisites:** A Data Catalog Database and Table for the Amazon Redshift table you would like to read from. For more information about Data Catalog, see [Data discovery and cataloging](#). After creating a entry for your Amazon Redshift table you will identify your connection with a *redshift-dc-database-name* and *redshift-table-name*.

**Configuration:** In your function options you will identify your Data Catalog Table with the database and table\_name parameters. You will identify your Amazon S3 temporary directory with redshift\_tmp\_dir. You will also provide *rs-role-name* using the aws\_iam\_role key in the additional\_options parameter.

```
glueContext.create_dynamic_frame.from_catalog(  
    database = "redshift-dc-database-name",  
    table_name = "redshift-table-name",  
    redshift_tmp_dir = args["temp-s3-dir"],  
    additional_options = {"aws_iam_role": "arn:aws:iam::role-account-id:role/rs-  
role-name"})
```

### Connecting directly

**Additional Prerequisites:** You will need the name of your Amazon Redshift table (*redshift-table-name*). You will need the JDBC connection information for the Amazon Redshift cluster storing that table. You will supply your connection information with *host*, *port*, *redshift-database-name*, *username* and *password*.

You can retrieve your connection information from the Amazon Redshift console when working with Amazon Redshift clusters. When using Amazon Redshift serverless, consult [Connecting to Amazon Redshift Serverless](#) in the Amazon Redshift documentation.

**Configuration:** In your function options you will identify your connection parameters with `url`, `dbtable`, `user` and `password`. You will identify your Amazon S3 temporary directory with `redshift_tmp_dir`. You can specify your IAM role using `aws_iam_role` when you use `from_options`. The syntax is similar to connecting through the Data Catalog, but you put the parameters in the `connection_options` map.

It is bad practice to hardcode passwords into AWS Glue scripts. Consider storing your passwords in AWS Secrets Manager and retrieving them in your script with SDK for Python (Boto3).

```
my_conn_options = {
    "url": "jdbc:redshift://host:port/redshift-database-name",
    "dbtable": "redshift-table-name",
    "user": "username",
    "password": "password",
    "redshiftTmpDir": args["temp-s3-dir"],
    "aws_iam_role": "arn:aws:iam::account id:role/rs-role-name"
}

df = glueContext.create_dynamic_frame.from_options("redshift", my_conn_options)
```

### Example: Writing to Amazon Redshift tables

You can write to Amazon Redshift clusters and Amazon Redshift serverless environments.

**Prerequisites:** An Amazon Redshift cluster and follow the steps in the previous section [the section called "Configure Redshift"](#) after which you should have the Amazon S3 URI for a temporary directory, *temp-s3-dir* and an IAM role, *rs-role-name*, (in account *role-account-id*). You will also need a `DynamicFrame` whose contents you would like to write to the database.

### Using the Data Catalog

**Additional Prerequisites** A Data Catalog Database for the Amazon Redshift cluster and table you would like to write to. For more information about Data Catalog, see [Data discovery and cataloging](#). You will identify your connection with *redshift-dc-database-name* and the target table with *redshift-table-name*.

**Configuration:** In your function options you will identify your Data Catalog Database with the database parameter, then provide table with `table_name`. You will identify your Amazon S3

temporary directory with `redshift_tmp_dir`. You will also provide *rs-role-name* using the `aws_iam_role` key in the `additional_options` parameter.

```
glueContext.write_dynamic_frame.from_catalog(  
    frame = input dynamic frame,  
    database = "redshift-dc-database-name",  
    table_name = "redshift-table-name",  
    redshift_tmp_dir = args["temp-s3-dir"],  
    additional_options = {"aws_iam_role": "arn:aws:iam::account-id:role/rs-role-  
name"})
```

## Connecting through a AWS Glue connection

You can connect to Amazon Redshift directly using the `write_dynamic_frame.from_options` method. However, rather than insert your connection details directly into your script, you can reference connection details stored in a Data Catalog connection with the `from_jdbc_conf` method. You can do this without crawling or creating Data Catalog tables for your database. For more information about Data Catalog connections, see [Connecting to data](#).

**Additional Prerequisites:** A Data Catalog connection for your database, a Amazon Redshift table you would like to read from

**Configuration:** you will identify your Data Catalog connection with *dc-connection-name*. You will identify your Amazon Redshift database and table with *redshift-table-name* and *redshift-database-name*. You will provide your Data Catalog connection information with `catalog_connection` and your Amazon Redshift information with `dbtable` and `database`. The syntax is similar to connecting through the Data Catalog, but you put the parameters in the `connection_options` map.

```
my_conn_options = {  
    "dbtable": "redshift-table-name",  
    "database": "redshift-database-name",  
    "aws_iam_role": "arn:aws:iam::role-account-id:role/rs-role-name"  
}  
  
glueContext.write_dynamic_frame.from_jdbc_conf(  
    frame = input dynamic frame,
```

```
catalog_connection = "dc-connection-name",
connection_options = my_conn_options,
redshift_tmp_dir = args["temp-s3-dir"])
```

## Amazon Redshift connection option reference

The basic connection options used for all AWS Glue JDBC connections to set up information like `url`, `user` and `password` are consistent across all JDBC types. For more information about standard JDBC parameters, see [the section called "JDBC connection parameters"](#).

The Amazon Redshift connection type takes some additional connection options:

- `"redshiftTmpDir"`: (Required) The Amazon S3 path where temporary data can be staged when copying out of the database.
- `"aws_iam_role"`: (Optional) ARN for an IAM role. The AWS Glue job will pass this role to the Amazon Redshift cluster to grant the cluster permissions needed to complete instructions from the job.

## Additional connection options available in AWS Glue 4.0+

You can also pass options for the new Amazon Redshift connector through AWS Glue connection options. For a complete list of supported connector options, see the *Spark SQL parameters* section in [Amazon Redshift integration for Apache Spark](#).

For your convenience, we reiterate certain new options here:

Name	Required	Default	Description
autopushdown	No	TRUE	Applies predicate and query pushdown by capturing and analyzing the Spark logical plans for SQL operations. The operations are translated into a

Name	Required	Default	Description
			SQL query, and then run in Amazon Redshift to improve performance.
autopushdown.s3_result_cache	No	FALSE	Caches the SQL query to unload data for Amazon S3 path mapping in memory so that the same query doesn't need to run again in the same Spark session. Only supported when autopushdown is enabled.
unload_s3_format	No	PARQUET	<p>PARQUET - Unloads the query results in Parquet format.</p> <p>TEXT - Unloads the query results in pipe-delimited text format.</p>
sse_kms_key	No	N/A	The AWS SSE-KMS key to use for encryption during UNLOAD operations instead of the default encryption for AWS.

Name	Required	Default	Description
extracopyoptions	No	N/A	<p>A list of extra options to append to the Amazon Redshift COPYcommand when loading data, such as TRUNCATECOLUMNS or MAXERROR n (for other options see <a href="#">COPY: Optional parameters</a>).</p> <p>Note that because these options are appended to the end of the COPY command, only options that make sense at the end of the command can be used. That should cover most possible use cases.</p>
csvnullstring (experimental)	No	NULL	<p>The String value to write for nulls when using the CSV tempformat . This should be a value that doesn't appear in your actual data.</p>

These new parameters can be used in the following ways.

### New options for performance improvement

The new connector introduces some new performance improvement options:

- `autopushdown`: Enabled by default.
- `autopushdown.s3_result_cache`: Disabled by default.
- `unload_s3_format`: PARQUET by default.

For information about using these options, see [Amazon Redshift integration for Apache Spark](#).

We recommend that you don't turn on `autopushdown.s3_result_cache` when you have mixed read and write operations because the cached results might contain stale information. The option `unload_s3_format` is set to PARQUET by default for the UNLOAD command, to improve performance and reduce storage cost. To use the UNLOAD command default behavior, reset the option to TEXT.

### New encryption option for reading

By default, the data in the temporary folder that AWS Glue uses when it reads data from the Amazon Redshift table is encrypted using SSE-S3 encryption. To use customer managed keys from AWS Key Management Service (AWS KMS) to encrypt your data, you can set up (`"sse_kms_key" # kmsKey`) where `kmsKey` is the [key ID from AWS KMS](#), instead of the legacy setting option (`"extraunloadoptions" # s"ENCRYPTED KMS_KEY_ID '$kmsKey'"`) in AWS Glue version 3.0.

```
datasource0 = glueContext.create_dynamic_frame.from_catalog(
  database = "database-name",
  table_name = "table-name",
  redshift_tmp_dir = args["TempDir"],
  additional_options = {"sse_kms_key": "<KMS_KEY_ID>"},
  transformation_ctx = "datasource0"
)
```

### Support IAM-based JDBC URL

The new connector supports an IAM-based JDBC URL so you don't need to pass in a user/password or secret. With an IAM-based JDBC URL, the connector uses the job runtime role to access to the Amazon Redshift data source.

Step 1: Attach the following minimal required policy to your AWS Glue job runtime role.

```
{
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Sid": "VisualEditor0",
    "Effect": "Allow",
    "Action": "redshift:GetClusterCredentials",
    "Resource": [
      "arn:aws:redshift:<region>:<account>:dbgroup:<cluster name>/*",
      "arn:aws:redshift:*:<account>:dbuser:*/*",
      "arn:aws:redshift:<region>:<account>:dbname:<cluster name>/<database
name>"
    ]
  },
  {
    "Sid": "VisualEditor1",
    "Effect": "Allow",
    "Action": "redshift:DescribeClusters",
    "Resource": "*"
  }
]
}

```

Step 2: Use the IAM-based JDBC URL as follows. Specify a new option `DbUser` with the Amazon Redshift user name that you're connecting with.

```

conn_options = {
  // IAM-based JDBC URL
  "url": "jdbc:redshift:iam://<cluster name>:<region>/<database name>",
  "dbtable": dbtable,
  "redshiftTmpDir": redshiftTmpDir,
  "aws_iam_role": aws_iam_role,
  "DbUser": "<Redshift User name>" // required for IAM-based JDBC URL
}

redshift_write = glueContext.write_dynamic_frame.from_options(
  frame=dyf,
  connection_type="redshift",
  connection_options=conn_options
)

redshift_read = glueContext.create_dynamic_frame.from_options(
  connection_type="redshift",
  connection_options=conn_options
)

```

**Note**

A `DynamicFrame` currently only supports an IAM-based JDBC URL with a `DbUser` in the `GlueContext.create_dynamic_frame.from_options` workflow.

**Migrating from AWS Glue version 3.0 to version 4.0**

In AWS Glue 4.0, ETL jobs have access to a new Amazon Redshift Spark connector and a new JDBC driver with different options and configuration. The new Amazon Redshift connector and driver are written with performance in mind, and keep transactional consistency of your data. These products are documented in the Amazon Redshift documentation. For more information, see:

- [Amazon Redshift integration for Apache Spark](#)
- [Amazon Redshift JDBC driver, version 2.1](#)

**Table/column names and identifiers restriction**

The new Amazon Redshift Spark connector and driver have a more restricted requirement for the Redshift table name. For more information, see [Names and identifiers](#) to define your Amazon Redshift table name. The job bookmark workflow might not work with a table name that doesn't match the rules and with certain characters, such as a space.

If you have legacy tables with names that don't conform to the [Names and identifiers](#) rules and see issues with bookmarks (jobs reprocessing old Amazon Redshift table data), we recommend that you rename your table names. For more information, see [ALTER TABLE examples](#).

**Default tempformat change in Dataframe**

The AWS Glue version 3.0 Spark connector defaults the `tempformat` to CSV while writing to Amazon Redshift. To be consistent, in AWS Glue version 3.0, the `DynamicFrame` still defaults the `tempformat` to use CSV. If you've previously used Spark Dataframe APIs directly with the Amazon Redshift Spark connector, you can explicitly set the `tempformat` to CSV in the `DataframeReader/Writer` options. Otherwise, `tempformat` defaults to AVRO in the new Spark connector.

**Behavior change: map Amazon Redshift data type REAL to Spark data type FLOAT instead of DOUBLE**

In AWS Glue version 3.0, Amazon Redshift REAL is converted to a Spark `DOUBLE` type. The new Amazon Redshift Spark connector has updated the behavior so that the Amazon Redshift `REAL`

type is converted to, and back from, the Spark FLOAT type. If you have a legacy use case where you still want the Amazon Redshift REAL type to be mapped to a Spark DOUBLE type, you can use the following workaround:

- For a `DynamicFrame`, map the `Float` type to a `Double` type with `DynamicFrame.ApplyMapping`. For a `Dataframe`, you need to use `cast`.

Code example:

```
dyf_cast = dyf.apply_mapping([('a', 'long', 'a', 'long'), ('b', 'float', 'b',  
  'double')])
```

## Kafka connections

Designates a connection to a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster.

You can read and write to Kafka data streams using information stored in a Data Catalog table, or by providing information to directly access the data stream. You can read information from Kafka into a Spark `DataFrame`, then convert it to a AWS Glue `DynamicFrame`. You can write `DynamicFrames` to Kafka in a JSON format. If you directly access the data stream, use these options to provide the information about how to access the data stream.

If you use `getCatalogSource` or `create_data_frame_from_catalog` to consume records from a Kafka streaming source, or `getCatalogSink` or `write_dynamic_frame_from_catalog` to write records to Kafka, and the job has the Data Catalog database and table name information, and can use that to obtain some basic parameters for reading from the Kafka streaming source. If you use `getSource`, `getCatalogSink`, `getSourceWithFormat`, `getSinkWithFormat`, `createDataFrameFromOptions` or `create_data_frame_from_options`, or `write_dynamic_frame_from_catalog`, you must specify these basic parameters using the connection options described here.

You can specify the connection options for Kafka using the following arguments for the specified methods in the `GlueContext` class.

- `Scala`
  - `connectionOptions`: Use with `getSource`, `createDataFrameFromOptions`, `getSink`
  - `additionalOptions`: Use with `getCatalogSource`, `getCatalogSink`

- `options`: Use with `getSourceWithFormat`, `getSinkWithFormat`
- Python
  - `connection_options`: Use with `create_data_frame_from_options`, `write_dynamic_frame_from_options`
  - `additional_options`: Use with `create_data_frame_from_catalog`, `write_dynamic_frame_from_catalog`
  - `options`: Use with `getSource`, `getSink`

For notes and restrictions about streaming ETL jobs, consult [the section called “Streaming ETL notes and restrictions”](#).

## Configure Kafka

There are no AWS prerequisites to connecting to Kafka streams available through the internet.

You can create a AWS Glue Kafka connection to manage your connection credentials. For more information, see [the section called “Creating a connection for a Kafka data stream”](#). In your AWS Glue job configuration, provide `connectionName` as an **Additional network connection**, then, in your method call, provide `connectionName` to the `connectionName` parameter.

In certain cases, you will need to configure additional prerequisites:

- If using Amazon Managed Streaming for Apache Kafka with IAM authentication, you will need appropriate IAM configuration.
- If using Amazon Managed Streaming for Apache Kafka within an Amazon VPC, you will need appropriate Amazon VPC configuration. You will need to create a AWS Glue connection that provides Amazon VPC connection information. You will need your job configuration to include the AWS Glue connection as an **Additional network connection**.

For more information about Streaming ETL job prerequisites, consult [the section called “Streaming ETL jobs”](#).

## Example: Reading from Kafka streams

Used in conjunction with [the section called “forEachBatch”](#).

Example for Kafka streaming source:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "startingOffsets": "earliest",
    "inferSchema": "true",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.create_data_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

## Example: Writing to Kafka streams

Examples for writing to Kafka:

Example with the `getSink` method:

```
data_frame_datasource0 =
glueContext.getSink(
  connectionType="kafka",
  connectionOptions={
    JsonOptions("""{
      "connectionName": "ConfluentKafka",
      "classification": "json",
      "topic": "kafka-auth-topic",
      "typeOfData": "kafka"}
    """))},
transformationContext="dataframe_ApacheKafka_node1711729173428")
.getDataFrame()
```

Example with the `write_dynamic_frame.from_options` method:

```
kafka_options =
  { "connectionName": "ConfluentKafka",
    "topicName": "kafka-auth-topic",
    "classification": "json"
  }
data_frame_datasource0 =
  glueContext.write_dynamic_frame.from_options(connection_type="kafka",
  connection_options=kafka_options)
```

## Kafka connection option reference

When reading, use the following connection options with "connectionType": "kafka":

- "bootstrap.servers" (Required) A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.
- "security.protocol" (Required) The protocol used to communicate with brokers. The possible values are "SSL" or "PLAINTEXT".
- "topicName" (Required) A comma-separated list of topics to subscribe to. You must specify one and only one of "topicName", "assign" or "subscribePattern".
- "assign": (Required) A JSON string specifying the specific TopicPartitions to consume. You must specify one and only one of "topicName", "assign" or "subscribePattern".

Example: `'{"topicA":[0,1],"topicB":[2,4]}'`

- "subscribePattern": (Required) A Java regex string that identifies the topic list to subscribe to. You must specify one and only one of "topicName", "assign" or "subscribePattern".

Example: `'topic.*'`

- "classification" (Required) The file format used by the data in the record. Required unless provided through the Data Catalog.
- "delimiter" (Optional) The value separator used when classification is CSV. Default is `","`.
- "startingOffsets": (Optional) The starting position in the Kafka topic to read data from. The possible values are "earliest" or "latest". The default value is "latest".
- "startingTimestamp": (Optional, supported only for AWS Glue version 4.0 or later) The Timestamp of the record in the Kafka topic to read data from. The possible value is a Timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: `"2023-04-04T08:00:00-04:00"`.

Note: Only one of 'startingOffsets' or 'startingTimestamp' can be present in the Connection Options list of the AWS Glue streaming script, including both these properties will result in job failure.

- "endingOffsets": (Optional) The end point when a batch query is ended. Possible values are either "latest" or a JSON string that specifies an ending offset for each TopicPartition.

For the JSON string, the format is `'{"topicA":{"0":23,"1":-1},"topicB":{"0":-1}}'`. The value -1 as an offset represents "latest".

- "pollTimeoutMs": (Optional) The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is 512.
- "numRetries": (Optional) The number of times to retry before failing to fetch Kafka offsets. The default value is 3.
- "retryIntervalMs": (Optional) The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is 10.
- "maxOffsetsPerTrigger": (Optional) The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across topicPartitions of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.
- "minPartitions": (Optional) The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.
- "includeHeaders": (Optional) Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue\_streaming\_kafka\_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in AWS Glue version 3.0 or later.
- "schema": (Required when inferSchema set to false) The schema to use to process the payload. If classification is avro the provided schema must be in the Avro schema format. If the classification is not avro the provided schema must be in the DDL schema format.

The following are schema examples.

Example in DDL schema format

```
'column1' INT, 'column2' STRING , 'column3' FLOAT
```

Example in Avro schema format

```
{
  "type": "array",
  "items":
  {
    "type": "record",
    "name": "test",
    "fields":
    [
      {
```

```
    "name": "_id",
    "type": "string"
  },
  {
    "name": "index",
    "type": [
      "int",
      "string",
      "float"
    ]
  }
]
```

- **"inferSchema"**: (Optional) The default value is 'false'. If set to 'true', the schema will be detected at runtime from the payload within `foreachbatch`.
- **"avroSchema"**: (Deprecated) Parameter used to specify a schema of Avro data when Avro format is used. This parameter is now deprecated. Use the `schema` parameter.
- **"addRecordTimestamp"**: (Optional) When this option is set to 'true', the data output will contain an additional column named `__src_timestamp` that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.
- **"emitConsumerLagMetrics"**: (Optional) When the option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in AWS Glue to CloudWatch. The metric's name is `glue.driver.streaming.maxConsumerLagInMs`. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

When writing, use the following connection options with `"connectionType": "kafka"`:

- **"connectionName"** (Required) Name of the AWS Glue connection used to connect to the Kafka cluster (similar to Kafka source).
- **"topic"** (Required) If a topic column exists then its value is used as the topic when writing the given row to Kafka, unless the topic configuration option is set. That is, the `topic` configuration option overrides the topic column.

- "partition" (Optional) If a valid partition number is specified, that partition will be used when sending the record.

If no partition is specified but a key is present, a partition will be chosen using a hash of the key.

If neither key nor partition is present, a partition will be chosen based on sticky partitioning those changes when at least batch.size bytes are produced to the partition.

- "key" (Optional) Used for partitioning if partition is null.
- "classification" (Optional) The file format used by the data in the record. We only support JSON, CSV and Avro.

With Avro format, we can provide a custom avroSchema to serialize with, but note that this needs to be provided on the source for deserializing as well. Else, by default it uses the Apache AvroSchema for serializing.

Additionally, you can fine-tune the Kafka sink as required by updating the [Kafka producer configuration parameters](#). Note that there is no allow listing on connection options, all the key-value pairs are persisted on the sink as is.

However, there is a small deny list of options that will not take effect. For more information, see [Kafka specific configurations](#).

## Azure Cosmos DB connections

You can use AWS Glue for Spark to read from and write to existing containers in Azure Cosmos DB using the NoSQL API in AWS Glue 4.0 and later versions. You can define what to read from Azure Cosmos DB with a SQL query. You connect to Azure Cosmos DB using an Azure Cosmos DB Key stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Azure Cosmos DB for NoSQL, consult [the Azure documentation](#).

## Configuring Azure Cosmos DB connections

To connect to Azure Cosmos DB from AWS Glue, you will need to create and store your Azure Cosmos DB Key in a AWS Secrets Manager secret, then associate that secret with a Azure Cosmos DB AWS Glue connection.

## Prerequisites:

- In Azure, you will need to identify or generate an Azure Cosmos DB Key for use by AWS Glue, `cosmosKey`. For more information, see [Secure access to data in Azure Cosmos DB](#) in the Azure documentation.

### To configure a connection to Azure Cosmos DB:

1. In AWS Secrets Manager, create a secret using your Azure Cosmos DB Key. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `spark.cosmos.accountKey` with the value *cosmosKey*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select Azure Cosmos DB.
  - When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue Azure Cosmos DB connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

### Reading from Azure Cosmos DB for NoSQL containers

#### Prerequisites:

- A Azure Cosmos DB for NoSQL container you would like to read from. You will need identification information for the container.

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

- A AWS Glue Azure Cosmos DB connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to Azure Cosmos DB*. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azurecosmos_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="azurecosmos",  
    connection_options={  
        "connectionName": connectionName,  
        "spark.cosmos.database": cosmosDBName,  
        "spark.cosmos.container": cosmosContainerName,  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
azurecosmos_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="azurecosmos",  
    connection_options={  
        "connectionName": "connectionName",  
        "spark.cosmos.database": cosmosDBName,  
        "spark.cosmos.container": cosmosContainerName,  
        "spark.cosmos.read.customQuery": "query"  
    }  
)
```

## Writing to Azure Cosmos DB for NoSQL containers

This example writes information from an existing DynamicFrame, *dynamicFrame* to Azure Cosmos DB. If the container already has information, AWS Glue will append data from your DynamicFrame. If the information in the container has a different schema from the information you write, you will run into errors.

### Prerequisites:

- A Azure Cosmos DB table you would like to write to. You will need identification information for the container. **You must create the container before calling the connection method.**

An Azure Cosmos for NoSQL container is identified by its database and container. You must provide the database, *cosmosDBName*, and container, *cosmosContainerName*, names when connecting to the Azure Cosmos for NoSQL API.

- A AWS Glue Azure Cosmos DB connection configured to provide auth and network location information. To acquire this, complete the steps in the previous procedure, *To configure a connection to Azure Cosmos DB*. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azurecosmos_write = glueContext.write_dynamic_frame.from_options(  
    frame=dynamicFrame,  
    connection_type="azurecosmos",  
    connection_options={  
        "connectionName": connectionName,  
        "spark.cosmos.database": cosmosDBName,  
        "spark.cosmos.container": cosmosContainerName  
    }  
)
```

### Azure Cosmos DB connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue Azure Cosmos DB connection configured to provide auth and network location information to your connection method.
- `spark.cosmos.database` — Required. Used for Read/Write. Valid Values: database names. Azure Cosmos DB for NoSQL database name.
- `spark.cosmos.container` — Required. Used for Read/Write. Valid Values: container names. Azure Cosmos DB for NoSQL container name.
- `spark.cosmos.read.customQuery` — Used for Read. Valid Values: SELECT SQL queries. Custom query to select documents to be read.

### Azure SQL connections

You can use AWS Glue for Spark to read from and write to tables on Azure SQL Managed Instances in AWS Glue 4.0 and later versions. You can define what to read from Azure SQL with a SQL query.

You connect to Azure SQL using user and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Azure SQL, consult the [Azure SQL documentation](#).

## Configuring Azure SQL connections

To connect to Azure SQL from AWS Glue, you will need to create and store your Azure SQL credentials in a AWS Secrets Manager secret, then associate that secret with a Azure SQL AWS Glue connection.

### To configure a connection to Azure SQL:

1. In AWS Secrets Manager, create a secret using your Azure SQL credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `user` with the value *azuresqlUsername*.
  - When selecting **Key/value pairs**, create a pair for the key `password` with the value *azuresqlPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
  - When selecting a **Connection type**, select Azure SQL.
  - When providing **Azure SQL URL**, provide a JDBC endpoint URL.

The URL must be in the following format:

```
jdbc:sqlserver://databaseServerName:databasePort;databaseName=azuresqlDBName
```

AWS Glue requires the following URL properties:

- `databaseName` – A default database in Azure SQL to connect to.

For more information about JDBC URLs for Azure SQL Managed Instances, see the [Microsoft documentation](#).

- When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue Azure SQL connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Reading from Azure SQL tables

### Prerequisites:

- A Azure SQL table you would like to read from. You will need identification information for the table, *databaseName* and *tableIdentifier*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the `dbtable`.

- A AWS Glue Azure SQL connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Azure SQL* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azuresql_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type="azuresql",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableIdentifier"  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
azuresql_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="azuresql",
```

```
connection_options={
    "connectionName": "connectionName",
    "query": "query"
}
)
```

## Writing to Azure SQL tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to Azure SQL. If the table already has information, AWS Glue will append data from your DynamicFrame.

### Prerequisites:

- A Azure SQL table you would like to write to. You will need identification information for the table, *databaseName* and *tableIdentifier*.

An Azure SQL table is identified by its database, schema and table name. You must provide the database name and table name when connecting to Azure SQL. You also must provide the schema if it is not the default, "public". Database is provided through a URL property in *connectionName*, schema and table name through the *dbtable*.

- Azure SQL auth information. Complete the steps in the previous procedure, *To configure a connection to Azure SQL* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
azuresql_write = glueContext.write_dynamic_frame.from_options(
    connection_type="azuresql",
    connection_options={
        "connectionName": "connectionName",
        "dbtable": "tableIdentifier"
    }
)
```

## Azure SQL connection option reference

- *connectionName* — Required. Used for Read/Write. The name of a AWS Glue Azure SQL connection configured to provide auth information to your connection method.
- *databaseName* — Used for Read/Write. Valid Values: Azure SQL database names. The name of the database in Azure SQL to connect to.

- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. Valid Values: Names of Azure SQL tables, or period separated schema/table name combinations. Used to specify the table and schema that identify the table to connect to. The default schema is "public". If your table is in a non-default schema, provide this information in the form *schemaName.tableName*.
- `query` — Used for Read. A Transact-SQL SELECT query defining what should be retrieved when reading from Azure SQL. For more information, see the [Microsoft documentation](#).

## BigQuery connections

You can use AWS Glue for Spark to read from and write to tables in Google BigQuery in AWS Glue 4.0 and later versions. You can read from BigQuery with a Google SQL query. You connect to BigQuery using credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Google BigQuery, see the [Google Cloud BigQuery website](#).

## Configuring BigQuery connections

To connect to Google BigQuery from AWS Glue, you will need to create and store your Google Cloud Platform credentials in a AWS Secrets Manager secret, then associate that secret with a Google BigQuery AWS Glue connection.

### To configure a connection to BigQuery:

1. In Google Cloud Platform, create and identify relevant resources:
  - Create or identify a GCP project containing BigQuery tables you would like to connect to.
  - Enable the BigQuery API. For more information, see [Use the BigQuery Storage Read API to read table data](#).
2. In Google Cloud Platform, create and export service account credentials:

You can use the BigQuery credentials wizard to expedite this step: [Create credentials](#).

To create a service account in GCP, follow the tutorial available in [Create service accounts](#).

- When selecting **project**, select the project containing your BigQuery table.
- When selecting GCP IAM roles for your service account, add or create a role that would grant appropriate permissions to run BigQuery jobs to read, write or create BigQuery tables.

To create credentials for your service account, follow the tutorial available in [Create a service account key](#).

- When selecting key type, select **JSON**.

You should now have downloaded a JSON file with credentials for your service account. It should look similar to the following:

```
{
  "type": "service_account",
  "project_id": "*****",
  "private_key_id": "*****",
  "private_key": "*****",
  "client_email": "*****",
  "client_id": "*****",
  "auth_uri": "https://accounts.google.com/o/oauth2/auth",
  "token_uri": "https://oauth2.googleapis.com/token",
  "auth_provider_x509_cert_url": "https://www.googleapis.com/oauth2/v1/certs",
  "client_x509_cert_url": "*****",
  "universe_domain": "googleapis.com"
}
```

3. base64 encode your downloaded credentials file. On an AWS CloudShell session or similar, you can do this from the command line by running `cat credentialsFile.json | base64 -w 0`. Retain the output of this command, *credentialString*.
4. In AWS Secrets Manager, create a secret using your Google Cloud Platform credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `credentials` with the value *credentialString*.
5. In the AWS Glue Data Catalog, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select Google BigQuery.
  - When selecting an **AWS Secret**, provide *secretName*.

6. Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
7. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Reading from BigQuery tables

### Prerequisites:

- A BigQuery table you would like to read from. You will need the BigQuery table and dataset names, in the form [dataset].[table]. Let's call this *tableName*.
- The billing project for the BigQuery table. You will need the name of the project, *parentProject*. If there is no billing parent project, use the project containing the table.
- BigQuery auth information. Complete the steps *To manage your connection credentials with AWS Glue* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
bigquery_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="bigquery",  
    connection_options={  
        "connectionName": "connectionName",  
        "parentProject": "parentProject",  
        "sourceType": "table",  
        "table": "tableName",  
    }  
)
```

You can also provide a query, to filter the results returned to your DynamicFrame. You will need to configure query, sourceType, viewsEnabled and materializationDataset.

For example:

### Additional prerequisites:

You will need to create or identify a BigQuery dataset, *materializationDataset*, where BigQuery can write materialized views for your queries.

You will need to grant appropriate GCP IAM permissions to your service account to create tables in *materializationDataset*.

```
glueContext.create_dynamic_frame.from_options(  
    connection_type="bigquery",  
    connection_options={  
        "connectionName": "connectionName",  
        "materializationDataset": materializationDataset,  
        "parentProject": "parentProject",  
        "viewsEnabled": "true",  
        "sourceType": "query",  
        "query": "select * from bqtest.test"  
    }  
)
```

## Writing to BigQuery tables

This example writes directly to the BigQuery service. BigQuery also supports the "indirect" writing method. For more information about configuring indirect writes, see [the section called "Using indirect write with Google BigQuery"](#).

### Prerequisites:

- A BigQuery table you would like to write to. You will need the BigQuery table and dataset names, in the form [dataset].[table]. You can also provide a new table name that will automatically be created. Let's call this *tableName*.
- The billing project for the BigQuery table. You will need the name of the project, *parentProject*. If there is no billing parent project, use the project containing the table.
- BigQuery auth information. Complete the steps *To manage your connection credentials with AWS Glue* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
bigquery_write = glueContext.write_dynamic_frame.from_options(  
    frame=frameToWrite,  
    connection_type="bigquery",  
    connection_options={  
        "connectionName": "connectionName",
```

```
    "parentProject": "parentProject",
    "writeMethod": "direct",
    "table": "tableName",
  }
)
```

## BigQuery connection option reference

- **project** — Default: Google Cloud service account default. Used for Read/Write. The name of a Google Cloud project associated with your table.
- **table** — (Required) Used for Read/Write. The name of your BigQuery table in the format `[[project:]dataset.]`.
- **dataset** — Required when not defined through the `table` option. Used for Read/Write. The name of the dataset containing your BigQuery table.
- **parentProject** — Default: Google Cloud service account default. Used for Read/Write. The name of a Google Cloud project associated with `project` used for billing.
- **sourceType** — Used for Read. Required when reading. Valid Values: `table`, `query` Informs AWS Glue of whether you will read by table or by query.
- **materializationDataset** — Used for Read. Valid Values: strings. The name of a BigQuery dataset used to store materializations for views.
- **viewsEnabled** — Used for Read. Default: `false`. Valid Values: `true`, `false`. Configures whether BigQuery will use views.
- **query** — Used for Read. Used when `viewsEnabled` is `true`. A GoogleSQL DQL query.
- **temporaryGcsBucket** — Used for Write. Required when `writeMethod` is set to default (`indirect`). Name of a Google Cloud Storage bucket used to store an intermediate form of your data while writing to BigQuery.
- **writeMethod** — Default: `indirect`. Valid Values: `direct`, `indirect`. Used for Write. Specifies the method used to write your data.
  - If set to `direct`, your connector will write using the BigQuery Storage Write API.
  - If set to `indirect`, you connector will write to Google Cloud Storage, then transfer it to BigQuery using a load operation. Your Google Cloud service account will need appropriate GCS permissions.

## Using indirect write with Google BigQuery

This example uses indirect write, which writes data to Google Cloud Storage and copies it to Google BigQuery.

### Prerequisites:

You will need a temporary Google Cloud Storage bucket, *temporaryBucket*.

The GCP IAM role for AWS Glue's GCP service account will need appropriate GCS permissions to access *temporaryBucket*.

### Additional Configuration:

#### To configure indirect write with BigQuery:

1. Assess [the section called "Configuring BigQuery"](#) and locate or redownload your GCP credentials JSON file. Identify *secretName*, the AWS Secrets Manager secret for the Google BigQuery AWS Glue connection used in your job.
2. Upload your credentials JSON file to an appropriately secure Amazon S3 location. Retain the path to the file, *s3secretpath* for future steps.
3. Edit *secretName*, adding the `spark.hadoop.google.cloud.auth.service.account.json.keyfile` key. Set the value to *s3secretpath*.
4. Grant your AWS Glue job Amazon S3 IAM permissions to access *s3secretpath*.

You can now provide your temporary GCS bucket location to your write method. You do not need to provide `writeMethod`, as `indirect` is historically the default.

```
bigquery_write = glueContext.write_dynamic_frame.from_options(  
    frame=frameToWrite,  
    connection_type="bigquery",  
    connection_options={  
        "connectionName": "connectionName",  
        "parentProject": "parentProject",  
        "temporaryGcsBucket": "temporaryBucket",  
        "table": "tableName",  
    }  
)
```

## JDBC connections

Certain, typically relational, database types support connecting through the JDBC standard. For more information about JDBC, see the [Java JDBC API](#) documentation. AWS Glue natively supports connecting to certain databases through their JDBC connectors - the JDBC libraries are provided in AWS Glue Spark jobs. When connecting to these database types using AWS Glue libraries, you have access to a standard set of options.

The JDBC connectionType values include the following:

- "connectionType": "sqlserver": Designates a connection to a Microsoft SQL Server database.
- "connectionType": "mysql": Designates a connection to a MySQL database.
- "connectionType": "oracle": Designates a connection to an Oracle database.
- "connectionType": "postgresql": Designates a connection to a PostgreSQL database.
- "connectionType": "redshift": Designates a connection to an Amazon Redshift database. For more information, see [the section called "Redshift connections"](#).

The following table lists the JDBC driver versions that AWS Glue supports.

Product	JDBC driver versions for Glue 4.0	JDBC driver versions for Glue 3.0	JDBC driver versions for Glue 0.9, 1.0, 2.0
Microsoft SQL Server	9.4.0	7.x	6.x
MySQL	8.0.23	8.0.23	5.1
Oracle Database	21.7	21.1	11.2
PostgreSQL	42.3.6	42.2.18	42.1.x
MongoDB	4.7.2	4.0.0	2.0.0
Amazon Redshift *	redshift-jdbc42-2.1.0.16	redshift-jdbc41-1.2.12.1017	redshift-jdbc41-1.2.12.1017

\* For the Amazon Redshift connection type, all other option name/value pairs that are included in connection options for a JDBC connection, including formatting options, are passed directly to the

underlying SparkSQL DataSource. In AWS Glue with Spark jobs in AWS Glue 4.0 and later versions, the AWS Glue native connector for Amazon Redshift uses the Amazon Redshift integration for Apache Spark. For more information see [Amazon Redshift integration for Apache Spark](#). In previous versions, see [Amazon Redshift data source for Spark](#).

To configure your Amazon VPC to connect to Amazon RDS data stores using JDBC, refer to [the section called "Setting up Amazon VPC to connect to Amazon RDS data stores"](#).

### Note

AWS Glue jobs are only associated with one subnet during a run. This may impact your ability to connect to multiple data sources through the same job. This behavior is not limited to JDBC sources.

## Topics

- [JDBC connection option reference](#)
- [Use sampleQuery](#)
- [Use custom JDBC driver](#)
- [Reading from JDBC tables in parallel](#)
- [Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from AWS Glue](#)

## JDBC connection option reference

If you already have a JDBC AWS Glue connection defined, you can reuse the configuration properties defined in it, such as: url, user and password; so you don't have to specify them in the code as connection options. This feature is available in AWS Glue 3.0 and later versions. To do so, use the following connection properties:

- "useConnectionProperties": Set it to "true" to indicate you want to use the configuration from a connection.
- "connectionName": Enter the connection name to retrieve the configuration from, the connection must be defined in the same region as the job.

Use these connection options with JDBC connections:

- "url": (Required) The JDBC URL for the database.

- "dbtable": (Required) The database table to read from. For JDBC data stores that support schemas within a database, specify `schema.table-name`. If a schema is not provided, then the default "public" schema is used.
- "user": (Required) The user name to use when connecting.
- "password": (Required) The password to use when connecting.
- (Optional) The following options allow you to supply a custom JDBC driver. Use these options if you must use a driver that AWS Glue does not natively support.

ETL jobs can use different JDBC driver versions for the data source and target, even if the source and target are the same database product. This allows you to migrate data between source and target databases with different versions. To use these options, you must first upload the JAR file of the JDBC driver to Amazon S3.

- "customJdbcDriverS3Path": The Amazon S3 path of the custom JDBC driver.
- "customJdbcDriverClassName": The class name of JDBC driver.
- "bulkSize": (Optional) Used to configure parallel inserts for speeding up bulk loads into JDBC targets. Specify an integer value for the degree of parallelism to use when writing or inserting data. This option is helpful for improving the performance of writes into databases such as the Arch User Repository (AUR).
- "hashfield" (Optional) A string, used to specify the name of a column in the JDBC table to be used to divide the data into partitions when reading from JDBC tables in parallel. Provide "hashfield" OR "hashexpression". For more information, see [the section called "Reading from JDBC in parallel"](#).
- "hashexpression" (Optional) A SQL select clause returning a whole number. Used to divide the data in a JDBC table into partitions when reading from JDBC tables in parallel. Provide "hashfield" OR "hashexpression". For more information, see [the section called "Reading from JDBC in parallel"](#).
- "hashpartitions" (Optional) A positive integer. Used to specify the number of parallel reads of the JDBC table when reading from JDBC tables in parallel. Default: 7. For more information, see [the section called "Reading from JDBC in parallel"](#).
- "sampleQuery": (Optional) A custom SQL query statement. Used to specify a subset of information in a table to retrieve a sample of the table contents. **When configured without regard to your data, it can be less efficient than DynamicFrame methods, causing timeouts or out of memory errors.** For more information, see [the section called "Use sampleQuery"](#).

- "enablePartitioningForSampleQuery": (Optional) A boolean. Default: false. Used to enable reading from JDBC tables in parallel when specifying sampleQuery. **If set to true, sampleQuery must end with "where" or "and" for AWS Glue to append partitioning conditions.** For more information, see [the section called "Use sampleQuery"](#).
- "sampleSize": (Optional) A positive integer. Limits the number of rows returned by the sample query. Works only when enablePartitioningForSampleQuery is true. If partitioning is not enabled, you should instead directly add "limit x" in the sampleQuery to limit the size. For more information, see [the section called "Use sampleQuery"](#).

## Use sampleQuery

This section explains how to use sampleQuery, sampleSize and enablePartitioningForSampleQuery.

sampleQuery can be an efficient way to sample a few rows of your dataset. By default, the query is run by a single executor. When configured without regard to your data, it can be less efficient than DynamicFrame methods, causing timeouts or out of memory errors. Running SQL on the underlying database as part of your ETL pipeline is generally only needed for performance purposes. If you are trying to preview a few rows of your dataset, consider using [the section called "show"](#). If you are trying to transform your dataset using SQL, consider using [the section called "toDF"](#) to define a SparkSQL transform against your data in a DataFrame form.

While your query may manipulate a variety of tables, dbtable remains required.

## Using sampleQuery to retrieve a sample of your table

When using default sampleQuery behavior to retrieve a sample of your data, AWS Glue does not expect substantial throughput, so it runs your query on a single executor. In order to limit the data you provide and not cause performance problems, we suggest you provide SQL with a LIMIT clause.

## Example Use sampleQuery without partitioning

The following code example shows how to use sampleQuery without partitioning.

```
//A full sql query statement.  
val query = "select name from $tableName where age > 0 limit 1"  
val connectionOptions = JsonOptions(Map(  
  "url" -> url,  
  "dbtable" -> tableName,
```

```
"user" -> user,
"password" -> password,
"sampleQuery" -> query ))
val dyf = glueContext.getSource("mysql", connectionOptions)
    .getDynamicFrame()
```

## Using sampleQuery against larger datasets

If you're reading a large dataset, you might need to enable JDBC partitioning to query a table in parallel. For more information, see [the section called "Reading from JDBC in parallel"](#). To use `sampleQuery` with JDBC partitioning, set `enablePartitioningForSampleQuery` to `true`. Enabling this feature requires you to make some changes to your `sampleQuery`.

When using JDBC partitioning with `sampleQuery`, your query must end with "where" or "and" for AWS Glue to append partitioning conditions.

If you would like to limit the results of your `sampleQuery` when reading from JDBC tables in parallel, set the "sampleSize" parameter rather than specifying a LIMIT clause.

## Example Use sampleQuery with JDBC partitioning

The following code example shows how to use `sampleQuery` with JDBC partitioning.

```
//note that the query should end with "where" or "and" if use with JDBC partitioning.
val query = "select name from $tableName where age > 0 and"

//Enable JDBC partitioning by setting hashfield.
//to use sampleQuery with partitioning, set enablePartitioningForSampleQuery.
//use sampleSize to limit the size of returned data.
val connectionOptions = JsonOptions(Map(
    "url" -> url,
    "dbtable" -> tableName,
    "user" -> user,
    "password" -> password,
    "hashfield" -> primaryKey,
    "sampleQuery" -> query,
    "enablePartitioningForSampleQuery" -> true,
    "sampleSize" -> "1" ))
val dyf = glueContext.getSource("mysql", connectionOptions)
    .getDynamicFrame()
```

## Notes and Restrictions:

Sample queries cannot be used together with job bookmarks. The bookmark state will be ignored when configuration for both are provided.

## Use custom JDBC driver

The following code examples show how to read from and write to JDBC databases with custom JDBC drivers. They demonstrate reading from one version of a database product, and writing to a later version of the same product.

### Python

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions

        |"password": "pwd"}""").stripMargin)
    }

    private def customJDBCdriverJsonOptions(url: String, customJdbcDriverS3Path:
String, customJdbcDriverClassName: String): JsonOptions = {
    new JsonOptions(
        s""""{"url": "${url}",
        |"dbtable":"test",
        |"user": "admin",
        |"password": "pwd",
        |"customJdbcDriverS3Path": "${customJdbcDriverS3Path}",
        |"customJdbcDriverClassName" :
        "${customJdbcDriverClassName}"}""").stripMargin)
    }
}
```

## Reading from JDBC tables in parallel

You can set properties of your JDBC table to enable AWS Glue to read data in parallel. When you set certain properties, you instruct AWS Glue to run parallel SQL queries against logical partitions of your data. You can control partitioning by setting a hash field or a hash expression. You can also control the number of parallel reads that are used to access your data.

Reading from JDBC tables in parallel is an optimization technique that may improve performance. For more information about the process of identifying when this technique is appropriate, consult [Reduce the amount of data scan](#) in the *Best practices for performance tuning AWS Glue for Apache Spark jobs* guide on AWS Prescriptive Guidance.

To enable parallel reads, you can set key-value pairs in the `parameters` field of your table structure. Use JSON notation to set a value for the parameter field of your table. For more information about editing the properties of a table, see [Viewing and editing table details](#). You can also enable parallel reads when you call the ETL (extract, transform, and load) methods `create_dynamic_frame_from_options` and `create_dynamic_frame_from_catalog`. For more information about specifying options in these methods, see [from\\_options](#) and [from\\_catalog](#).

You can use this method for JDBC tables, that is, most tables whose base data is a JDBC data store. These properties are ignored when reading Amazon Redshift and Amazon S3 tables.

## hashfield

Set `hashfield` to the name of a column in the JDBC table to be used to divide the data into partitions. For best results, this column should have an even distribution of values to spread the data between partitions. This column can be of any data type. AWS Glue generates non-overlapping queries that run in parallel to read the data partitioned by this column. For example, if your data is evenly distributed by month, you can use the `month` column to read each month of data in parallel.

```
'hashfield': 'month'
```

AWS Glue creates a query to hash the field value to a partition number and runs the query for all partitions in parallel. To use your own query to partition a table read, provide a `hashexpression` instead of a `hashfield`.

## hashexpression

Set `hashexpression` to an SQL expression (conforming to the JDBC database engine grammar) that returns a whole number. A simple expression is the name of any numeric column in the table. AWS Glue generates SQL queries to read the JDBC data in parallel using the `hashexpression` in the `WHERE` clause to partition data.

For example, use the numeric column `customerID` to read data partitioned by a customer number.

```
'hashexpression': 'customerID'
```

To have AWS Glue control the partitioning, provide a `hashfield` instead of a `hashexpression`.

## hashpartitions

Set `hashpartitions` to the number of parallel reads of the JDBC table. If this property is not set, the default value is 7.

For example, set the number of parallel reads to 5 so that AWS Glue reads your data with five queries (or fewer).

```
'hashpartitions': '5'
```

## Setting up Amazon VPC for JDBC connections to Amazon RDS data stores from AWS Glue

When using JDBC to connect to databases in Amazon RDS, you will need to perform additional setup. To enable AWS Glue components to communicate with Amazon RDS, you must set up access to your Amazon RDS data stores in Amazon VPC. To enable AWS Glue to communicate between its components, specify a security group with a self-referencing inbound rule for all TCP ports. By creating a self-referencing rule, you can restrict the source to the same security group in the VPC. A self-referencing rule will not open the VPC to all networks. The default security group for your VPC might already have a self-referencing inbound rule for ALL Traffic.

### To set up access between AWS Glue and Amazon RDS data stores

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Amazon RDS console, identify the security group(s) used to control access to your Amazon RDS database.

In the left navigation pane, choose **Databases**, then select the instance you would like to connect to from the list in the main pane.

In the database detail page, find **VPC security groups** on the **Connectivity & security** tab.

3. Based on your network architecture, identify which associated security group is best to modify to allow access for the AWS Glue service. Save its name, *database-security-group* for future reference. If there is no appropriate security group, follow the directions to [Provide access to your DB instance in your VPC by creating a security group](#) in the Amazon RDS documentation.
4. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
5. In the Amazon VPC console, identify how to update *database-security-group*.

In the left navigation pane, choose **Security groups**, then select *database-security-group* from the list in the main pane.

- Identify the security group ID for *database-security-group*, *database-sg-id*. Save it for future reference.

In the security group detail page, find **Security group ID**.

- Alter the inbound rules for *database-security-group*, add a self-referencing rule to allow AWS Glue components to communicate. Specifically, add or confirm that there is a rule where **Type** is All TCP, **Protocol** is TCP, **Port Range** includes all ports, and **Source** is *database-sg-id*. Verify that the security group you have entered for **Source** is the same as the security group you are editing.

In the security group detail page, select **Edit inbound rules**.

The inbound rule looks similar to this:

Type	Protocol	Port range	Source
All TCP	TCP	0–65535	<i>database-sg-id</i>

- Add rules for outbound traffic.

In the security group detail page, select **Edit outbound rules**.

If your security group allows all outbound traffic, you do not need separate rules. For example:

Type	Protocol	Port range	Destination
All Traffic	ALL	ALL	0.0.0.0/0

If your network architecture is designed for you to restrict outbound traffic, create the following outbound rules:

Create a self-referencing rule where **Type** is All TCP, **Protocol** is TCP, **Port Range** includes all ports, and **Destination** is *database-sg-id*. Verify that the security group you have entered for **Destination** is the same as the security group you are editing.

If using an Amazon S3 VPC endpoint, add an HTTPS rule to allow traffic from the VPC to Amazon S3. Create a rule where **Type** is HTTPS, **Protocol** is TCP, **Port Range** is 443 and **Destination** is the ID of the managed prefix list for the Amazon S3 gateway endpoint, *s3-*

*prefix-list-id*. For more information about prefix lists and Amazon S3 gateway endpoints, see [Gateway endpoints for Amazon S3](#) in the Amazon VPC documentation.

For example:

Type	Protocol	Port range	Destination
All TCP	TCP	0–65535	<i>database-sg-id</i>
HTTPS	TCP	443	<i>s3-prefix-list-id</i>

## MongoDB connections

You can use AWS Glue for Spark to read from and write to tables in MongoDB and MongoDB Atlas in AWS Glue 4.0 and later versions. You can connect to MongoDB using username and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about MongoDB, consult the [MongoDB documentation](#).

## Configuring MongoDB connections

To connect to MongoDB from AWS Glue, you will need your MongoDB credentials, *mongodbUser* and *mongodbPass*.

To connect to MongoDB from AWS Glue, you may need some prerequisites:

- If your MongoDB instance is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the MongoDB instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your MongoDB instance and this location. Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

You can then proceed to configure AWS Glue for use with MongoDB.

## To configure a connection to MongoDB:

1. Optionally, in AWS Secrets Manager, create a secret using your MongoDB credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

- When selecting **Key/value pairs**, create a pair for the key `username` with the value *mongodbUser*.

When selecting **Key/value pairs**, create a pair for the key `password` with the value *mongodbPass*.

2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.

- When selecting a **Connection type**, select **MongoDB** or **MongoDB Atlas**.
- When selecting **MongoDB URL** or **MongoDB Atlas URL**, provide the hostname of your MongoDB instance.

A MongoDB URL is provided in the format  
`mongodb://mongoHost:mongoPort/mongoDBname`.

A MongoDB Atlas URL is provided in the format `mongodb+srv://mongoHost:mongoPort/mongoDBname`.

Providing the default database for the connection, *mongoDBname* is optional.

- If you chose to create an Secrets Manager secret, choose the AWS Secrets Manager **Credential type**.

Then, in **AWS Secret** provide *secretName*.

- If you choose to provide **Username and password**, provide *mongodbUser* and *mongodbPass*.

3. In the following situations, you may require additional configuration:

- For MongoDB instances hosted on AWS in an Amazon VPC

- You will need to provide Amazon VPC connection information to the AWS Glue connection that defines your MongoDB security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue MongoDB connection, you will need to perform the following actions before calling your connection method:

- If you chose to create an Secrets Manager secret, grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

To use your AWS Glue MongoDB connection in AWS Glue for Spark, provide the `connectionName` option in your connection method call. Alternatively, you can follow the steps in [the section called "Integrating with MongoDB"](#) to use the connection in conjunction with the AWS Glue Data Catalog.

## Reading from MongoDB using a AWS Glue connection

### Prerequisites:

- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- A AWS Glue MongoDB connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to MongoDB* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
mongodb_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="mongodb",  
    connection_options={  
        "connectionName": "connectionName",  
        "database": "mongodbName",  
        "collection": "mongodbCollection",
```

```

    "partitioner":
      "com.mongodb.spark.sql.connector.read.partitionner.SinglePartitionPartitioner",
      "partitionerOptions.partitionSizeMB": "10",
      "partitionerOptions.partitionKey": "_id",
      "disableUpdateUri": "false",
    }
  )

```

## Writing to MongoDB tables

This example writes information from an existing `DynamicFrame`, *dynamicFrame* to MongoDB.

### Prerequisites:

- A MongoDB collection you would like to write to. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- A AWS Glue MongoDB connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to MongoDB* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```

glueContext.write_dynamic_frame.from_options(
  frame=dynamicFrame,
  connection_type="mongodb",
  connection_options={
    "connectionName": "connectionName",
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "disableUpdateUri": "false",
    "retryWrites": "false",
  },
)

```

## Reading and writing to MongoDB tables

This example writes information from an existing `DynamicFrame`, *dynamicFrame* to MongoDB.

### Prerequisites:

- A MongoDB collection you would like to read from. You will need identification information for the collection.

A MongoDB collection you would like to write to. You will need identification information for the collection.

A MongoDB collection is identified by a database name and a collection name, *mongodbName*, *mongodbCollection*.

- MongoDB auth information, *mongodbUser* and *mongodbPassword*.

For example:

Python

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext, SparkConf
from awsglue.context import GlueContext
from awsglue.job import Job
import time

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

job = Job(glueContext)
job.init(args['JOB_NAME'], args)

output_path = "s3://some_bucket/output/" + str(time.time()) + "/"
mongo_uri = "mongodb://<mongo-instanced-ip-address>:27017"
mongo_ssl_uri = "mongodb://<mongo-instanced-ip-address>:27017"
write_uri = "mongodb://<mongo-instanced-ip-address>:27017"

read_mongo_options = {
    "uri": mongo_uri,
    "database": "mongodbName",
    "collection": "mongodbCollection",
    "username": "mongodbUsername",
```

```
"password": "mongodbPassword",
"partitioner": "MongoSamplePartitioner",
"partitionerOptions.partitionSizeMB": "10",
"partitionerOptions.partitionKey": "_id"}

ssl_mongo_options = {
  "uri": mongo_ssl_uri,
  "database": "mongodbName",
  "collection": "mongodbCollection",
  "ssl": "true",
  "ssl.domain_match": "false"
}

write_mongo_options = {
  "uri": write_uri,
  "database": "mongodbName",
  "collection": "mongodbCollection",
  "username": "mongodbUsername",
  "password": "mongodbPassword",
}

# Get DynamicFrame from MongoDB
dynamic_frame =
  glueContext.create_dynamic_frame.from_options(connection_type="mongodb",
  connection_options=read_mongo_options)

# Write DynamicFrame to MongoDB
glueContext.write_dynamic_frame.from_options(dynamicFrame,
  connection_type="mongodb", connection_options=write_mongo_options)

job.commit()
```

## Scala

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.DynamicFrame
import org.apache.spark.SparkContext
```

```

import scala.collection.JavaConverters._

object GlueApp {
  val DEFAULT_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  val WRITE_URI: String = "mongodb://<mongo-instanced-ip-address>:27017"
  lazy val defaultJsonOption = jsonOptions(DEFAULT_URI)
  lazy val writeJsonOption = jsonOptions(WRITE_URI)
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)

    // Get DynamicFrame from MongoDB
    val dynamicFrame: DynamicFrame = glueContext.getSource("mongodb",
defaultJsonOption).getDynamicFrame()

    // Write DynamicFrame to MongoDB
    glueContext.getSink("mongodb", writeJsonOption).writeDynamicFrame(dynamicFrame)

    Job.commit()
  }

  private def jsonOptions(uri: String): JsonOptions = {
    new JsonOptions(
      s""""{"uri": "${uri}",
        |"database": "mongodbName",
        |"collection": "mongodbCollection",
        |"username": "mongodbUsername",
        |"password": "mongodbPassword",
        |"ssl": "true",
        |"ssl.domain_match": "false",
        |"partitioner": "MongoSamplePartitioner",
        |"partitionerOptions.partitionSizeMB": "10",
        |"partitionerOptions.partitionKey": "_id"}"""".stripMargin)
  }
}

```

## MongoDB connection option reference

Designates a connection to MongoDB. Connection options differ for a source connection and a sink connection.

These connection properties are shared between source and sink connections:

- `connectionName` — Used for Read/Write. The name of a AWS Glue MongoDB connection configured to provide auth and networking information to your connection method. When a AWS Glue connection is configured as described in the previous section, [the section called “Configuring MongoDB”](#), providing `connectionName` will replace the need to provide the `"uri"`, `"username"` and `"password"` connection options.
- `"uri"`: (Required) The MongoDB host to read from, formatted as `mongodb://<host>:<port>`. Used in AWS Glue versions prior to AWS Glue 4.0.
- `"connection.uri"`: (Required) The MongoDB host to read from, formatted as `mongodb://<host>:<port>`. Used in AWS Glue 4.0 and later versions.
- `"username"`: (Required) The MongoDB user name.
- `"password"`: (Required) The MongoDB password.
- `"database"`: (Required) The MongoDB database to read from. This option can also be passed in `additional_options` when calling `glue_context.create_dynamic_frame_from_catalog` in your job script.
- `"collection"`: (Required) The MongoDB collection to read from. This option can also be passed in `additional_options` when calling `glue_context.create_dynamic_frame_from_catalog` in your job script.

### **"connectionType": "mongodb" as source**

Use the following connection options with `"connectionType": "mongodb"` as a source:

- `"ssl"`: (Optional) If `true`, initiates an SSL connection. The default is `false`.
- `"ssl.domain_match"`: (Optional) If `true` and `ssl` is `true`, domain match check is performed. The default is `true`.
- `"batchSize"`: (Optional): The number of documents to return per batch, used within the cursor of internal batches.
- `"partitioner"`: (Optional): The class name of the partitioner for reading input data from MongoDB. The connector provides the following partitioners:
  - `MongoDefaultPartitioner` (default) (Not supported in AWS Glue 4.0)
  - `MongoSamplePartitioner` (Requires MongoDB 3.2 or later) (Not supported in AWS Glue 4.0)
  - `MongoShardedPartitioner` (Not supported in AWS Glue 4.0)

- `MongoSplitVectorPartitioner` (Not supported in AWS Glue 4.0)
- `MongoPaginateByCountPartitioner` (Not supported in AWS Glue 4.0)
- `MongoPaginateBySizePartitioner` (Not supported in AWS Glue 4.0)
- `com.mongodb.spark.sql.connector.read.partitionner.SinglePartitionPartitioner`
- `com.mongodb.spark.sql.connector.read.partitionner.ShardedPartitioner`
- `com.mongodb.spark.sql.connector.read.partitionner.PaginateIntoPartitionsPartitioner`
- `"partitionerOptions"` (Optional): Options for the designated partitioner. The following options are supported for each partitioner:
  - `MongoSamplePartitioner`: `partitionKey`, `partitionSizeMB`, `samplesPerPartition`
  - `MongoShardedPartitioner`: `shardkey`
  - `MongoSplitVectorPartitioner`: `partitionKey`, `partitionSizeMB`
  - `MongoPaginateByCountPartitioner`: `partitionKey`, `numberOfPartitions`
  - `MongoPaginateBySizePartitioner`: `partitionKey`, `partitionSizeMB`

For more information about these options, see [Partitioner Configuration](#) in the MongoDB documentation.

### **"connectionType": "mongodb" as sink**

Use the following connection options with `"connectionType": "mongodb"` as a sink:

- `"ssl"`: (Optional) If `true`, initiates an SSL connection. The default is `false`.
- `"ssl.domain_match"`: (Optional) If `true` and `ssl` is `true`, domain match check is performed. The default is `true`.
- `"extendedBsonTypes"`: (Optional) If `true`, allows extended BSON types when writing data to MongoDB. The default is `true`.
- `"replaceDocument"`: (Optional) If `true`, replaces the whole document when saving datasets that contain an `_id` field. If `false`, only fields in the document that match the fields in the dataset are updated. The default is `true`.
- `"maxBatchSize"`: (Optional): The maximum batch size for bulk operations when saving data. The default is 512.
- `"retryWrites"`: (Optional): Automatically retry certain write operations a single time if AWS Glue encounters a network error.

## SAP HANA connections

You can use AWS Glue for Spark to read from and write to tables in SAP HANA in AWS Glue 4.0 and later versions. You can define what to read from SAP HANA with a SQL query. You connect to SAP HANA using JDBC credentials stored in AWS Secrets Manager through a AWS Glue SAP HANA connection.

For more information about SAP HANA JDBC, consult [the SAP HANA documentation](#).

### Configuring SAP HANA connections

To connect to SAP HANA from AWS Glue, you will need to create and store your SAP HANA credentials in a AWS Secrets Manager secret, then associate that secret with a SAP HANA AWS Glue connection. You will need to configure network connectivity between your SAP HANA service and AWS Glue.

To connect to SAP HANA, you may need some prerequisites:

- If your SAP HANA service is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the SAP HANA service without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your SAP HANA endpoint and this location. Your job will need to establish a TCP connection with your SAP HANA JDBC port. For more information about SAP HANA ports, see the [SAP HANA documentation](#). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

- There are no additional prerequisites if your SAP HANA endpoint is internet accessible.

### To configure a connection to SAP HANA:

1. In AWS Secrets Manager, create a secret using your SAP HANA credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key `user` with the value *saphanaUsername*.

- When selecting **Key/value pairs**, create a pair for the key password with the value *saphanaPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for future use in AWS Glue.
    - When selecting a **Connection type**, select SAP HANA.
    - When providing **SAP HANA URL**, provide the URL for your instance.

SAP HANA JDBC URLs are in the form

`jdbc:sap://saphanaHostname:saphanaPort/?databaseName=saphanaDBname,Parameter`

AWS Glue requires the following JDBC URL parameters:

- `databaseName` – A default database in SAP HANA to connect to.
- When selecting an **AWS Secret**, provide *secretName*.

After creating a AWS Glue SAP HANA connection, you will need to perform the following steps before running your AWS Glue job:

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Reading from SAP HANA tables

### Prerequisites:

- A SAP HANA table you would like to read from. You will need identification information for the table.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in `connectionName`.

- A AWS Glue SAP HANA connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to SAP HANA* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
saphana_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type="saphana",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableIdentifier",  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
saphana_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="saphana",  
    connection_options={  
        "connectionName": "connectionName",  
        "query": "query"  
    }  
)
```

## Writing to SAP HANA tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to SAP HANA. If the table already has information, AWS Glue will error.

### Prerequisites:

- A SAP HANA table you would like to write to.

A table can be specified with a SAP HANA table name and schema name, in the form *schemaName.tableName*. The schema name and "." separator are not required if the table is in the default schema, "public". Call this *tableIdentifier*. Note that the database is provided as a JDBC URL parameter in *connectionName*.

- SAP HANA auth information. Complete the steps in the previous procedure, *To configure a connection to SAP HANA* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
options = {
  "connectionName": "connectionName",
  "dbtable": 'tableIdentifier'
}

saphana_write = glueContext.write_dynamic_frame.from_options(
  frame=dynamicFrame,
  connection_type="saphana",
  connection_options=options
)
```

### SAP HANA connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue SAP HANA connection configured to provide auth and networking information to your connection method.
- `databaseName` — Used for Read/Write. Valid Values: names of databases in SAP HANA. Name of database to connect to.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. Valid Values: contents of a SAP HANA SQL FROM clause. Identifies a table in SAP HANA to connect to. You may also provide other SQL than a table name, such as a subquery. For more information, see the [From clause](#) in the SAP HANA documentation.
- `query` — Used for Read. A SAP HANA SQL SELECT query defining what should be retrieved when reading from SAP HANA.

### Snowflake connections

You can use AWS Glue for Spark to read from and write to tables in Snowflake in AWS Glue 4.0 and later versions. You can read from Snowflake with a SQL query. You can connect to Snowflake using a user and password. You can refer to Snowflake credentials stored in AWS Secrets Manager through the AWS Glue Data Catalog. Data Catalog Snowflake credentials for AWS Glue for Spark are stored separately from Data Catalog Snowflake credentials for crawlers. You must choose a SNOWFLAKE type connection and not a JDBC type connection configured to connect to Snowflake.

For more information about Snowflake, see the [Snowflake website](#). For more information about Snowflake on AWS, see [Snowflake Data Warehouse on Amazon Web Services](#).

## Configuring Snowflake connections

There are no AWS prerequisites to connecting to Snowflake databases available through the internet.

Optionally, you can perform the following configuration to manage your connection credentials with AWS Glue.

### To manage your connection credentials with AWS Glue

1. In Snowflake, generate a user, *snowflakeUser* and password, *snowflakePassword*.
2. In AWS Secrets Manager, create a secret using your Snowflake credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for *snowflakeUser* with the key `sfUser`.
  - When selecting **Key/value pairs**, create a pair for *snowflakePassword* with the key `sfPassword`.
  - When selecting **Key/value pairs**, you can provide your Snowflake warehouse with the key `sfWarehouse`.
3. In the AWS Glue Data Catalog, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select Snowflake.
  - When selecting **Snowflake URL**, provide the URL of your Snowflake instance. The URL will use a hostname in the form *account\_identifier*.snowflakecomputing.com.
  - When selecting an **AWS Secret**, provide *secretName*.
4. In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

In the following situations, you may require the following:

- For Snowflake hosted on AWS in an Amazon VPC

- You will need appropriate Amazon VPC configuration for Snowflake. For more information on how to configure your Amazon VPC, consult [AWS PrivateLink & Snowflake](#) in the Snowflake documentation.
- You will need appropriate Amazon VPC configuration for AWS Glue. [the section called “VPC endpoints \(AWS PrivateLink\)”](#).
- You will need to create a AWS Glue Data Catalog connection that provides Amazon VPC connection information (in addition to the id of an AWS Secrets Manager secret that defines your Snowflake security credentials). Your URL will change when using AWS PrivateLink, as described in the Snowflake documentation linked in a previous item.
- You will need your job configuration in include the Data Catalog connection as an **Additional network connection**.

## Reading from Snowflake tables

**Prerequisites:** A Snowflake table you would like to read from. You will need the Snowflake table name, *tableName*. You will need your Snowflake url *snowflakeUrl*, username *snowflakeUser* and password *snowflakePassword*. If your Snowflake user does not have a default namespace set, you will need the Snowflake database name, *databaseName* and the schema name *schemaName*. Additionally, if your Snowflake user does not have a default warehouse set, you will need a warehouse name *warehouseName*.

For example:

**Additional Prerequisites:** Complete the steps *To manage your connection credentials with AWS Glue* to configure *snowflakeUrl*, *snowflakeUsername* and *snowflakePassword*. To review these steps, see [the section called “Configuring Snowflake”](#), the previous section. To select which **Additional network connection** to connect with, we will use the *connectionName* parameter.

```
snowflake_read = glueContext.create_dynamic_frame.from_options(  
    connection_type="snowflake",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName",  
        "sfDatabase": "databaseName",  
        "sfSchema": "schemaName",  
        "sfWarehouse": "warehouseName",  
    }  
)
```

Additionally, you can use the `autopushdown` and `query` parameters to read a portion of a Snowflake table. This can be substantially more efficient than filtering your results after they have been loaded into Spark. Consider an example where all sales are stored in the same table, but you only need to analyze sales from a certain store on holidays. If that information is stored in the table, you could use predicate pushdown to retrieve the results as follows:

```
snowflake_node = glueContext.create_dynamic_frame.from_options(  
    connection_type="snowflake",  
    connection_options={  
        "autopushdown": "on",  
        "query": "select * from sales where store='1' and IsHoliday='TRUE'",  
        "connectionName": "snowflake-glue-conn",  
        "sfDatabase": "databaseName",  
        "sfSchema": "schemaName",  
        "sfWarehouse": "warehouseName",  
    }  
)
```

## Writing to Snowflake tables

**Prerequisites:** A Snowflake database you would like to write to. You will need a current or desired table name, *tableName*. You will need your Snowflake url *snowflakeUrl*, username *snowflakeUser* and password *snowflakePassword*. If your Snowflake user does not have a default namespace set, you will need the Snowflake database name, *databaseName* and the schema name *schemaName*. Additionally, if your Snowflake user does not have a default warehouse set, you will need a warehouse name *warehouseName*.

For example:

**Additional Prerequisites:** Complete the steps *To manage your connection credentials with AWS Glue* to configure *snowflakeUrl*, *snowflakeUsername* and *snowflakePassword*. To review these steps, see [the section called "Configuring Snowflake"](#), the previous section. To select which **Additional network connection** to connect with, we will use the `connectionName` parameter.

```
glueContext.write_dynamic_frame.from_options(  
    connection_type="snowflake",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName",  
        "sfDatabase": "databaseName",
```

```
    "sfSchema": "schemaName",
    "sfWarehouse": "warehouseName",
  },
)
```

## Snowflake connection option reference

The Snowflake connection type takes the following connection options:

You can retrieve some of the parameters in this section from a Data Catalog connection (`sfUrl`, `sfUser`, `sfPassword`), in which case you are not required to provide them. You can do this by providing the parameter `connectionName`.

You can retrieve some of the parameters in this section from an AWS Secrets Manager secret (`sfUser`, `sfPassword`), in which case you are not required to provide them. The secret must provide the content under the `sfUser` and `sfPassword` keys. You can do this by providing the parameter `secretId`.

The following parameters are used generally when connecting to Snowflake.

- `sfDatabase` — Required if a user default is not set in Snowflake. Used for Read/Write. The database to use for the session after connecting.
- `sfSchema` — Required if a user default is not set in Snowflake. Used for Read/Write. The schema to use for the session after connecting.
- `sfWarehouse` — Required if a user default is not set in Snowflake. Used for Read/Write. The default virtual warehouse to use for the session after connecting.
- `sfRole` — Required if a user default is not set in Snowflake. Used for Read/Write. The default security role to use for the session after connecting.
- `sfUrl` — (Required) Used for Read/Write. Specifies the hostname for your account in the following format: *account\_identifier*.snowflakecomputing.com. For more information about account identifiers, see [Account Identifiers](#) in the Snowflake documentation.
- `sfUser` — (Required) Used for Read/Write. Login name for the Snowflake user.
- `sfPassword` — (Required unless `pem_private_key` provided) Used for Read/Write. Password for the Snowflake user.
- `dbtable` — Required when working with full tables. Used for Read/Write. The name of the table to be read or the table to which data is written. When reading, all columns and records are retrieved.

- `pem_private_key` — Used for Read/Write. An unencrypted b64-encoded private key string. The private key for the Snowflake user. It is common to copy this out of a PEM file. For more information, see [Key-pair authentication and key-pair rotation](#) in the Snowflake documentation.
- `query` — Required when reading with a query. Used for Read. The exact query (SELECT statement) to run

The following options are used to configure specific behaviors during the process of connecting to Snowflake.

- `preactions` — Used for Read/Write. Valid Values: Semicolon separated list of SQL statements as String. SQL statements run before data is transferred between AWS Glue and Snowflake. If a statement contains `%s`, the `%s` is replaced with the table name referenced for the operation.
- `postactions` — Used for Read/Write. SQL statements run after data is transferred between AWS Glue and Snowflake. If a statement contains `%s`, the `%s` is replaced with the table name referenced for the operation.
- `autopushdown` — Default: "on". Valid Values: "on", "off". This parameter controls whether automatic query pushdown is enabled. If pushdown is enabled, then when a query is run on Spark, if part of the query can be "pushed down" to the Snowflake server, it is pushed down. This improves performance of some queries. For information about whether your query can be pushed down, consult [Pushdown](#) in the Snowflake documentation.

Additionally, some of the options available on the Snowflake Spark connector may be supported in AWS Glue. For more information about options available on the Snowflake Spark connector, see [Setting Configuration Options for the Connector](#) in the Snowflake documentation.

### **Snowflake connector limitations**

Connecting to Snowflake with AWS Glue for Spark is subject to the following limitations.

- This connector does not support job bookmarks. For more information about job bookmarks, see [the section called "Tracking processed data using job bookmarks"](#).
- This connector does not support Snowflake reads and writes through tables in the AWS Glue Data Catalog using the `create_dynamic_frame.from_catalog` and `write_dynamic_frame.from_catalog` methods.
- This connector does not support connecting to Snowflake with credentials other than user and password.

- This connector is not supported within streaming jobs.
- This connector supports SELECT statement based queries when retrieving information (such as with the query parameter). Other kind of queries (such as SHOW, DESC, or DML statements) are not supported.
- Snowflake limits the size of query text (i.e. SQL statements) submitted through Snowflake clients to 1 MB per statement. For more details, see [Limits on Query Text Size](#).

## Teradata Vantage connections

You can use AWS Glue for Spark to read from and write to existing tables in Teradata Vantage in AWS Glue 4.0 and later versions. You can define what to read from Teradata with a SQL query. You can connect to Teradata using username and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Teradata, consult the [Teradata documentation](#)

## Configuring Teradata connections

To connect to Teradata from AWS Glue, you will need to create and store your Teradata credentials in an AWS Secrets Manager secret, then associate that secret with a AWS Glue Teradata connection. If your Teradata instance is in an Amazon VPC, you will also need to provide networking options to your AWS Glue Teradata connection.

To connect to Teradata from AWS Glue, you may need some prerequisites:

- If you are accessing your Teradata environment through Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Teradata environment. We discourage accessing the Teradata environment over the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Teradata instance and this location. Your job will need to establish a TCP connection with your Teradata client port. For more information about Teradata ports, see the [Teradata documentation](#).

Based on your network layout, secure VPC connectivity may require changes in Amazon VPC and other networking services. For more information about AWS connectivity, consult [AWS Connectivity Options](#) in the Teradata documentation.

## To configure a AWS Glue Teradata connection:

1. In your Teradata configuration, identify or create a user and password AWS Glue will connect with, *teradataUser* and *teradataPassword*. For more information, consult [Vantage Security Overview](#) in the Teradata documentation.
2. In AWS Secrets Manager, create a secret using your Teradata credentials. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.
  - When selecting **Key/value pairs**, create a pair for the key user with the value *teradataUsername*.
  - When selecting **Key/value pairs**, create a pair for the key password with the value *teradataPassword*.
3. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
  - When selecting a **Connection type**, select Teradata.
  - When providing **JDBC URL**, provide the URL for your instance. You can also hardcode certain comma separated connection parameters in your JDBC URL. The URL must conform to the following format:  
`jdbc:teradata://teradataHostname/ParameterName=ParameterValue,ParameterName`

Supported URL parameters include:

  - DATABASE– name of database on host to access by default.
  - DBS\_PORT– the database port, used when running on a nonstandard port.
  - When selecting a **Credential type**, select **AWS Secrets Manager**, then set **AWS Secret** to *secretName*.
4. In the following situations, you may require additional configuration:
  - For Teradata instances hosted on AWS in an Amazon VPC
    - You will need to provide Amazon VPC connection information to the AWS Glue connection that defines your Teradata security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue Teradata connection, you will need to perform the following steps before calling your connection method.

- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Reading from Teradata

### Prerequisites:

- A Teradata table you would like to read from. You will need the table name, *tableName*.
- A AWS Glue Teradata connection configured to provide auth information. Complete the steps *To configure a connection to Teradata* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.

For example:

```
teradata_read_table = glueContext.create_dynamic_frame.from_options(  
    connection_type="teradata",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName"  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame. You will need to configure query.

For example:

```
teradata_read_query = glueContext.create_dynamic_frame.from_options(  
    connection_type="teradata",  
    connection_options={  
        "connectionName": "connectionName",  
        "query": "query"  
    }  
)
```

## Writing to Teradata tables

**Prerequisites:** A Teradata table you would like to write to, *tableName*. **You must create the table before calling the connection method.**

For example:

```
teradata_write = glueContext.write_dynamic_frame.from_options(  
    connection_type="teradata",  
    connection_options={  
        "connectionName": "connectionName",  
        "dbtable": "tableName"  
    }  
)
```

### Teradata connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue Teradata connection configured to provide auth and networking information to your connection method.
- `dbtable` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata.

### Vertica connections

You can use AWS Glue for Spark to read from and write to tables in Vertica in AWS Glue 4.0 and later versions. You can define what to read from Vertica with a SQL query. You connect to Vertica using username and password credentials stored in AWS Secrets Manager through a AWS Glue connection.

For more information about Vertica, consult the [Vertica documentation](#).

### Configuring Vertica connections

To connect to Vertica from AWS Glue, you will need to create and store your Vertica credentials in a AWS Secrets Manager secret, then associate that secret with a Vertica AWS Glue connection. If your Vertica instance is in an Amazon VPC, you will also need to provide networking options to your AWS Glue Vertica connection. You will need an Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database.

To connect to Vertica from AWS Glue, you will need some prerequisites:

- An Amazon S3 bucket or folder to use for temporary storage when reading from and writing to the database, referred to by *tempS3Path*.

 **Note**

When using Vertica in AWS Glue job data previews, temporary files may not be automatically removed from *tempS3Path*. To ensure the removal of temporary files, directly end the data preview session by choosing **End session** in the **Data preview** pane. If you cannot guarantee the data preview session is ended directly, consider setting Amazon S3 Lifecycle configuration to remove old data. We recommend removing data older than 49 hours, based on maximum job runtime plus a margin. For more information about configuring Amazon S3 Lifecycle, see [Managing your storage lifecycle](#) in the Amazon S3 documentation.

- An IAM policy with appropriate permissions to your Amazon S3 path you can associate with your AWS Glue job role.
- If your Vertica instance is in an Amazon VPC, configure Amazon VPC to allow your AWS Glue job to communicate with the Vertica instance without traffic traversing the public internet.

In Amazon VPC, identify or create a **VPC**, **Subnet** and **Security group** that AWS Glue will use while executing the job. Additionally, you need to ensure Amazon VPC is configured to permit network traffic between your Vertica instance and this location. Your job will need to establish a TCP connection with your Vertica client port, (default 5433). Based on your network layout, this may require changes to security group rules, Network ACLs, NAT Gateways and Peering connections.

You can then proceed to configure AWS Glue for use with Vertica.

**To configure a connection to Vertica:**

1. In AWS Secrets Manager, create a secret using your Vertica credentials, *verticaUsername* and *verticaPassword*. To create a secret in Secrets Manager, follow the tutorial available in [Create an AWS Secrets Manager secret](#) in the AWS Secrets Manager documentation. After creating the secret, keep the Secret name, *secretName* for the next step.

- When selecting **Key/value pairs**, create a pair for the key user with the value *verticaUsername*.
  - When selecting **Key/value pairs**, create a pair for the key password with the value *verticaPassword*.
2. In the AWS Glue console, create a connection by following the steps in [the section called "Adding an AWS Glue connection"](#). After creating the connection, keep the connection name, *connectionName*, for the next step.
    - When selecting a **Connection type**, select Vertica.
    - When selecting **Vertica Host**, provide the hostname of your Vertica installation.
    - When selecting **Vertica Port**, the port your Vertica installation is available through.
    - When selecting an **AWS Secret**, provide *secretName*.
  3. In the following situations, you may require additional configuration:
    - For Vertica instances hosted on AWS in an Amazon VPC
      - Provide Amazon VPC connection information to the AWS Glue connection that defines your Vertica security credentials. When creating or updating your connection, set **VPC**, **Subnet** and **Security groups** in **Network options**.

After creating a AWS Glue Vertica connection, you will need to perform the following steps before calling your connection method.

- Grant the IAM role associated with your AWS Glue job permissions to *tempS3Path*.
- Grant the IAM role associated with your AWS Glue job permission to read *secretName*.
- In your AWS Glue job configuration, provide *connectionName* as an **Additional network connection**.

## Reading from Vertica

### Prerequisites:

- A Vertica table you would like to read from. You will need the Vertica database name, *dbName* and the table name, *tableName*.

- A AWS Glue Vertica connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Vertica* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.
- A Amazon S3 bucket or folder to use for temporary storage, mentioned previously. You will need the name, *tempS3Path*. You will need to connect to this location using the s3a protocol.

For example:

```
dynamicFrame = glueContext.create_dynamic_frame.from_options(  
    connection_type="vertica",  
    connection_options={  
        "connectionName": "connectionName",  
        "staging_fs_url": "s3a://tempS3Path",  
        "db": "dbName",  
        "table": "tableName",  
    }  
)
```

You can also provide a SELECT SQL query, to filter the results returned to your DynamicFrame or to access a dataset from multiple tables.

For example:

```
dynamicFrame = glueContext.create_dynamic_frame.from_options(  
    connection_type="vertica",  
    connection_options={  
        "connectionName": "connectionName",  
        "staging_fs_url": "s3a://tempS3Path",  
        "db": "dbName",  
        "query": "select * FROM tableName",  
    },  
)
```

## Writing to Vertica tables

This example writes information from an existing DynamicFrame, *dynamicFrame* to Vertica. If the table already has information, AWS Glue will append data from your DynamicFrame.

### Prerequisites:

- A current or desired table name, *tableName*, you would like to write to. You will also need the corresponding Vertica database name, *dbName*.
- A AWS Glue Vertica connection configured to provide auth information. Complete the steps in the previous procedure, *To configure a connection to Vertica* to configure your auth information. You will need the name of the AWS Glue connection, *connectionName*.
- A Amazon S3 bucket or folder to use for temporary storage, mentioned previously. You will need the name, *tempS3Path*. You will need to connect to this location using the s3a protocol.

For example:

```
glueContext.write_dynamic_frame.from_options(  
    frame=dynamicFrame,  
    connection_type="vertica",  
    connection_options={  
        "connectionName": "connectionName",  
        "staging_fs_url": "s3a://tempS3Path",  
        "db": "dbName",  
        "table": "tableName",  
    }  
)
```

### Vertica connection option reference

- `connectionName` — Required. Used for Read/Write. The name of a AWS Glue Vertica connection configured to provide auth and networking information to your connection method.
- `db` — Required. Used for Read/Write. The name of a database in Vertica your connection method will interact with.
- `dbSchema` — Required if needed to identify your table. Used for Read/Write. Default: `public`. The name of a schema your connection method will interact with.
- `table` — Required for writing, required for reading unless `query` is provided. Used for Read/Write. The name of a table your connection method will interact with.
- `query` — Used for Read. A SELECT SQL query defining what should be retrieved when reading from Teradata.
- `staging_fs_url` — Required. Used for Read/Write. Valid Values: s3a URLs. The URL of a Amazon S3 bucket or folder to use for temporary storage.

## Custom and AWS Marketplace connectionType values

These include the following:

- "connectionType": "marketplace.athena": Designates a connection to an Amazon Athena data store. The connection uses a connector from AWS Marketplace.
- "connectionType": "marketplace.spark": Designates a connection to an Apache Spark data store. The connection uses a connector from AWS Marketplace.
- "connectionType": "marketplace.jdbc": Designates a connection to a JDBC data store. The connection uses a connector from AWS Marketplace.
- "connectionType": "custom.athena": Designates a connection to an Amazon Athena data store. The connection uses a custom connector that you upload to AWS Glue Studio.
- "connectionType": "custom.spark": Designates a connection to an Apache Spark data store. The connection uses a custom connector that you upload to AWS Glue Studio.
- "connectionType": "custom.jdbc": Designates a connection to a JDBC data store. The connection uses a custom connector that you upload to AWS Glue Studio.

### Connection options for type custom.jdbc or marketplace.jdbc

- `className` – String, required, driver class name.
- `connectionName` – String, required, name of the connection that is associated with the connector.
- `url` – String, required, JDBC URL with placeholders (`{}`) which are used to build the connection to the data source. The placeholder `{secretKey}` is replaced with the secret of the same name in AWS Secrets Manager. Refer to the data store documentation for more information about constructing the URL.
- `secretId` or `user/password` – String, required, used to retrieve credentials for the URL.
- `dbTable` or `query` – String, required, the table or SQL query to get the data from. You can specify either `dbTable` or `query`, but not both.
- `partitionColumn` – String, optional, the name of an integer column that is used for partitioning. This option works only when it's included with `lowerBound`, `upperBound`, and `numPartitions`. This option works the same way as in the Spark SQL JDBC reader. For more information, see [JDBC To Other Databases](#) in the *Apache Spark SQL, DataFrames and Datasets Guide*.

The `lowerBound` and `upperBound` values are used to decide the partition stride, not for filtering the rows in table. All rows in the table are partitioned and returned.

### Note

When using a query instead of a table name, you should validate that the query works with the specified partitioning condition. For example:

- If your query format is "SELECT col1 FROM table1", then test the query by appending a WHERE clause at the end of the query that uses the partition column.
- If your query format is "SELECT col1 FROM table1 WHERE col2=val", then test the query by extending the WHERE clause with AND and an expression that uses the partition column.

- `lowerBound` – Integer, optional, the minimum value of `partitionColumn` that is used to decide partition stride.
- `upperBound` – Integer, optional, the maximum value of `partitionColumn` that is used to decide partition stride.
- `numPartitions` – Integer, optional, the number of partitions. This value, along with `lowerBound` (inclusive) and `upperBound` (exclusive), form partition strides for generated WHERE clause expressions that are used to split the `partitionColumn`.

### Important

Be careful with the number of partitions because too many partitions might cause problems on your external database systems.

- `filterPredicate` – String, optional, extra condition clause to filter data from source. For example:

```
BillingCity='Mountain View'
```

When using a *query* instead of a *table* name, you should validate that the query works with the specified `filterPredicate`. For example:

- If your query format is "SELECT col1 FROM table1", then test the query by appending a WHERE clause at the end of the query that uses the filter predicate.

- If your query format is "SELECT col1 FROM table1 WHERE col2=val", then test the query by extending the WHERE clause with AND and an expression that uses the filter predicate.
- `dataTypeMapping` – Dictionary, optional, custom data type mapping that builds a mapping from a **JDBC** data type to a **Glue** data type. For example, the option "dataTypeMapping": {"FLOAT": "STRING"} maps data fields of JDBC type FLOAT into the Java String type by calling the `ResultSet.getString()` method of the driver, and uses it to build AWS Glue records. The `ResultSet` object is implemented by each driver, so the behavior is specific to the driver you use. Refer to the documentation for your JDBC driver to understand how the driver performs the conversions.
- The AWS Glue data types supported currently are:
  - DATE
  - STRING
  - TIMESTAMP
  - INT
  - FLOAT
  - LONG
  - BIGDECIMAL
  - BYTE
  - SHORT
  - DOUBLE

The JDBC data types supported are [Java8 java.sql.types](#).

The default data type mappings (from JDBC to AWS Glue) are:

- DATE -> DATE
- VARCHAR -> STRING
- CHAR -> STRING
- LONGNVARCHAR -> STRING
- TIMESTAMP -> TIMESTAMP
- INTEGER -> INT
- FLOAT -> FLOAT
- REAL -> FLOAT
- BIT -> BOOLEAN

- BOOLEAN -> BOOLEAN
- BIGINT -> LONG
- DECIMAL -> BIGDECIMAL
- NUMERIC -> BIGDECIMAL
- TINYINT -> SHORT
- SMALLINT -> SHORT
- DOUBLE -> DOUBLE

If you use a custom data type mapping with the option `dataTypeMapping`, then you can override a default data type mapping. Only the JDBC data types listed in the `dataTypeMapping` option are affected; the default mapping is used for all other JDBC data types. You can add mappings for additional JDBC data types if needed. If a JDBC data type is not included in either the default mapping or a custom mapping, then the data type converts to the AWS Glue `STRING` data type by default.

The following Python code example shows how to read from JDBC databases with AWS Marketplace JDBC drivers. It demonstrates reading from a database and writing to an S3 location.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)
## @type: DataSource
## @args: [connection_type = "marketplace.jdbc", connection_options =
{"dataTypeMapping":{"INTEGER":"STRING"},"upperBound":"200","query":"select id,
name, department from department where id < 200","numPartitions":"4",
"partitionColumn":"id","lowerBound":"0","connectionName":"test-connection-
jdbc"},
```

```

    transformation_ctx = "DataSource0"]
## @return: DataSource0
## @inputs: []
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
    "marketplace.jdbc", connection_options = {"dataTypeMapping":{"INTEGER":"STRING"},
    "upperBound":"200","query":"select id, name, department from department where
    id < 200","numPartitions":"4","partitionColumn":"id","lowerBound":"0",
    "connectionName":"test-connection-jdbc"}, transformation_ctx = "DataSource0")
## @type: ApplyMapping
## @args: [mappings = [("department", "string", "department", "string"), ("name",
"string",
    "name", "string"), ("id", "int", "id", "int")], transformation_ctx =
"Transform0"]
## @return: Transform0
## @inputs: [frame = DataSource0]
Transform0 = ApplyMapping.apply(frame = DataSource0, mappings = [("department",
"string",
    "department", "string"), ("name", "string", "name", "string"), ("id", "int",
"id", "int")],
    transformation_ctx = "Transform0")
## @type: DataSink
## @args: [connection_type = "s3", format = "json", connection_options = {"path":
"s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
## @return: DataSink0
## @inputs: [frame = Transform0]
DataSink0 = glueContext.write_dynamic_frame.from_options(frame = Transform0,
    connection_type = "s3", format = "json", connection_options = {"path":
    "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
job.commit()

```

## Connection options for type custom.athena or marketplace.athena

- `className` – String, required, driver class name. When you're using the Athena-CloudWatch connector, this parameter value is the prefix of the class Name (for example, "com.amazonaws.athena.connectors"). The Athena-CloudWatch connector is composed of two classes: a metadata handler and a record handler. If you supply the common prefix here, then the API loads the correct classes based on that prefix.
- `tableName` – String, required, the name of the CloudWatch log stream to read. This code snippet uses the special view name `all_log_streams`, which means that the dynamic data frame returned will contain data from all log streams in the log group.

- `schemaName` – String, required, the name of the CloudWatch log group to read from. For example, `/aws-glue/jobs/output`.
- `connectionName` – String, required, name of the connection that is associated with the connector.

For additional options for this connector, see the [Amazon Athena CloudWatch Connector README](#) file on GitHub.

The following Python code example shows how to read from an Athena data store using an AWS Marketplace connector. It demonstrates reading from Athena and writing to an S3 location.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)
## @type: DataSource
## @args: [connection_type = "marketplace.athena", connection_options =
  {"tableName":"all_log_streams","schemaName":"/aws-glue/jobs/output",
   "connectionName":"test-connection-athena"}, transformation_ctx = "DataSource0"]
## @return: DataSource0
## @inputs: []
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
  "marketplace.athena", connection_options = {"tableName":"all_log_streams",,
  "schemaName":"/aws-glue/jobs/output","connectionName":
  "test-connection-athena"}, transformation_ctx = "DataSource0")
## @type: ApplyMapping
## @args: [mappings = [("department", "string", "department", "string"), ("name",
"string",
  "name", "string"), ("id", "int", "id", "int")], transformation_ctx =
"Transform0"]
## @return: Transform0
```

```

## @inputs: [frame = DataSource0]
Transform0 = ApplyMapping.apply(frame = DataSource0, mappings = [("department",

## @return: DataSink0
## @inputs: [frame = Transform0]
DataSink0 = glueContext.write_dynamic_frame.from_options(frame = Transform0,
    connection_type = "s3", format = "json", connection_options = {"path":
"s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
job.commit()

```

## Connection options for type custom.spark or marketplace.spark

- `className` – String, required, connector class name.
- `secretId` – String, optional, used to retrieve credentials for the connector connection.
- `connectionName` – String, required, name of the connection that is associated with the connector.
- Other options depend on the data store. For example, OpenSearch configuration options start with the prefix `es`, as described in the [Elasticsearch for Apache Hadoop](#) documentation. Spark connections to Snowflake use options such as `sfUser` and `sfPassword`, as described in [Using the Spark Connector](#) in the *Connecting to Snowflake* guide.

The following Python code example shows how to read from an OpenSearch data store using a `marketplace.spark` connection.

```

import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

## @params: [JOB_NAME]
args = getResolvedOptions(sys.argv, ['JOB_NAME'])

```

```

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)
## @type: DataSource
## @args: [connection_type = "marketplace.spark", connection_options =
{"path":"test",
  "es.nodes.wan.only":"true","es.nodes":"https://<AWS endpoint>",
  "connectionName":"test-spark-es","es.port":"443"}, transformation_ctx =
"DataSource0"]
## @return: DataSource0
## @inputs: []
DataSource0 = glueContext.create_dynamic_frame.from_options(connection_type =
  "marketplace.spark", connection_options = {"path":"test","es.nodes.wan.only":
  "true","es.nodes":"https://<AWS endpoint>","connectionName":
  "test-spark-es","es.port":"443"}, transformation_ctx = "DataSource0")
## @type: DataSink
## @args: [connection_type = "s3", format = "json", connection_options = {"path":
  "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0"]
## @return: DataSink0
## @inputs: [frame = DataSource0]
DataSink0 = glueContext.write_dynamic_frame.from_options(frame = DataSource0,
  connection_type = "s3", format = "json", connection_options = {"path":
  "s3://<S3 path>/", "partitionKeys": []}, transformation_ctx = "DataSink0")
job.commit()

```

## General options

The options in this section are provided as `connection_options`, but do not specifically apply to one connector.

The following parameters are used generally when configuring bookmarks. They may apply to Amazon S3 or JDBC workflows. For more information, see [the section called "Using job bookmarks"](#).

- `jobBookmarkKeys` — Array of column names.
- `jobBookmarkKeysSortOrder` — String defining how to compare values based on sort order. Valid values: "asc", "desc".
- `useS3ListImplementation` — Used to manage memory performance when listing Amazon S3 bucket contents. For more information, see [Optimize memory management in AWS Glue](#).

## Data format options for inputs and outputs in AWS Glue for Spark

These pages offer information about feature support and configuration parameters for data formats supported by AWS Glue for Spark. See the following for a description of the usage and applicability of this information.

### Feature support across data formats in AWS Glue

Each data format may support different AWS Glue features. The following common features may or may not be supported based on your format type. Refer to the documentation for your data format to understand how to leverage our features to meet your requirements.

Read	AWS Glue can recognize and interpret this data format without additional resources, such as connectors.
Write	AWS Glue can write data in this format without additional resources. You can include third-party libraries in your job and use standard Apache Spark functions to write data, as you would in other Spark environments. For more information about including libraries, see <a href="#">the section called "Python libraries"</a> .
Stream read	AWS Glue can recognize and interpret this data format from an Apache Kafka, Amazon Managed Streaming for Apache Kafka or Amazon Kinesis message stream. We expect streams to present data in a consistent format, so they are read in as DataFrames .
Group small files	AWS Glue can group files together to batch work sent to each node when performing AWS Glue transforms. This can significantly improve performance for workloads involving large amounts of small files. For more information, see <a href="#">the section called "Grouping input files"</a> .

**Job bookmarks** AWS Glue can track the progress of transform s performing the same work on the same dataset across job runs with job bookmarks. This can improve performance for workloads involving datasets where work only needs to be done on new data since the last job run. For more information, see [the section called “Tracking processed data using job bookmarks”](#).

## Parameters used to interact with data formats in AWS Glue

Certain AWS Glue connection types support multiple format types, requiring you to specify information about your data format with a `format_options` object when using methods like `GlueContext.write_dynamic_frame.from_options`.

- `s3` – For more information, see Connection types and options for ETL in AWS Glue: [S3 connection parameters](#). You can also view the documentation for the methods facilitating this connection type: [the section called “create\\_dynamic\\_frame\\_from\\_options”](#) and [the section called “write\\_dynamic\\_frame\\_from\\_options”](#) in Python and the corresponding Scala methods [the section called “getSourceWithFormat”](#) and [the section called “getSinkWithFormat”](#).
- `kinesis` – For more information, see Connection types and options for ETL in AWS Glue: [Kinesis connection parameters](#). You can also view the documentation for the method facilitating this connection type: [the section called “create\\_data\\_frame\\_from\\_options”](#) and the corresponding Scala method [the section called “createDataFrameFromOptions”](#).
- `kafka` – For more information, see Connection types and options for ETL in AWS Glue: [Kafka connection parameters](#). You can also view the documentation for the method facilitating this connection type: [the section called “create\\_data\\_frame\\_from\\_options”](#) and the corresponding Scala method [the section called “createDataFrameFromOptions”](#).

Some connection types do not require `format_options`. For example, in normal use, a JDBC connection to a relational database retrieves data in a consistent, tabular data format. Therefore, reading from a JDBC connection would not require `format_options`.

Some methods to read and write data in glue do not require `format_options`. For example, using `GlueContext.create_dynamic_frame.from_catalog` with AWS Glue crawlers. Crawlers determine the shape of your data. When using crawlers, a AWS Glue classifier will examine your data to make smart decisions about how to represent your data format. It will then store a representation of your data in the AWS Glue Data Catalog, which can be used within a AWS Glue ETL script to retrieve your data with the `GlueContext.create_dynamic_frame.from_catalog` method. Crawlers remove the need to manually specify information about your data format.

For jobs that access AWS Lake Formation governed tables, AWS Glue supports reading and writing all formats supported by Lake Formation governed tables. For the current list of supported formats for AWS Lake Formation governed tables, see [Notes and Restrictions for Governed Tables](#) in the *AWS Lake Formation Developer Guide*.

### Note

For writing Apache Parquet, AWS Glue ETL only supports writing to a governed table by specifying an option for a custom Parquet writer type optimized for Dynamic Frames. When writing to a governed table with the `parquet` format, you should add the key `useGlueParquetWriter` with a value of `true` in the table parameters.

## Using the CSV format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the CSV data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the comma-separated value (CSV) format. This format is a minimal, row-based data format. CSVs often don't strictly conform to a standard, but you can refer to [RFC 4180](#) and [RFC 7111](#) for more information.

You can use AWS Glue to read CSVs from Amazon S3 and from streaming sources as well as write CSVs to Amazon S3. You can read and write bzip and gzip archives containing CSV files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common AWS Glue features support the CSV format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Supported	Supported

### Example: Read CSV files or folders from S3

**Prerequisites:** You will need the S3 paths (s3path) to the CSV files or folders that you want to read.

**Configuration:** In your function options, specify `format="csv"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the reader interacts with S3 in `connection_options`. For details, see [Connection types and options for ETL in AWS Glue: S3 connection parameters](#). You can configure how the reader interprets CSV files in your `format_options`. For details, see [CSV Configuration Reference](#).

The following AWS Glue ETL script shows the process of reading CSV files or folders from S3.

We provide a custom CSV reader with performance optimizations for common workflows through the `optimizePerformance` configuration key. To determine if this reader is right for your workload, see [the section called "Using optimized CSV reader"](#).

## Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
# Example: Read CSV from S3
# For show, we handle a CSV with a header row. Set the withHeader option.
# Consider whether optimizePerformance is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="csv",
    format_options={
        "withHeader": True,
        # "optimizePerformance": True,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .format("csv")\
    .option("header", "true")\
    .load("s3://s3path")
```

## Scala

For this example, use the [getSourceWithFormat](#) operation.

```
// Example: Read CSV from S3
// For show, we handle a CSV with a header row. Set the withHeader option.
// Consider whether optimizePerformance is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
```

```
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"withHeader": true}"""),
      connectionType="s3",
      format="csv",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
val dataframe = spark.read
  .option("header", "true")
  .format("csv")
  .load("s3://s3path")
```

### Example: Write CSV files and folders to S3

**Prerequisites:** You will need an initialized DataFrame (`dataFrame`) or a DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

**Configuration:** In your function options, specify `format="csv"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the writer interacts with S3 in `connection_options`. For details, see [Connection types and options for ETL in AWS Glue: S3 connection parameters](#). You can configure how your operation writes the contents of your files in `format_options`. For details, see [CSV Configuration Reference](#). The following AWS Glue ETL script shows the process of writing CSV files and folders to S3.

#### Python

For this example, use the [write\\_dynamic\\_frame\\_from\\_options](#) method.

```
# Example: Write CSV to S3
```

```
# For show, customize how we write string type values. Set quoteChar to -1 so our
values are not quoted.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    connection_options={"path": "s3://s3path"},
    format="csv",
    format_options={
        "quoteChar": -1,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame.write\
    .format("csv")\
    .option("quote", None)\
    .mode("append")\
    .save("s3://s3path")
```

## Scala

For this example, use the [getSinkWithFormat](#) method.

```
// Example: Write CSV to S3
// For show, customize how we write string type values. Set quoteChar to -1 so our
values are not quoted.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
    def main(sysArgs: Array[String]): Unit = {
        val spark: SparkContext = new SparkContext()
```

```

val glueContext: GlueContext = new GlueContext(spark)

glueContext.getSinkWithFormat(
  connectionType="s3",
  options=JsonOptions("""{"path": "s3://s3path"}"""),
  format="csv"
).writeDynamicFrame(dynamicFrame)
}
}

```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```

dataFrame.write
  .format("csv")
  .option("quote", null)
  .mode("Append")
  .save("s3://s3path")

```

## CSV configuration reference

You can use the following `format_options` wherever AWS Glue libraries specify `format="csv"`:

- `separator` – Specifies the delimiter character. The default is a comma, but any other character can be specified.
  - **Type:** Text, **Default:** `,`
- `escaper` – Specifies a character to use for escaping. This option is used only when reading CSV files, not writing. If enabled, the character that immediately follows is used as-is, except for a small set of well-known escapes (`\n`, `\r`, `\t`, and `\0`).
  - **Type:** Text, **Default:** none
- `quoteChar` – Specifies the character to use for quoting. The default is a double quote. Set this to `-1` to turn off quoting entirely.
  - **Type:** Text, **Default:** `'"`
- `multiLine` – Specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `True` if any record spans multiple lines. Enabling `multiLine` might decrease performance because it requires more cautious file-splitting while parsing.
  - **Type:** Boolean, **Default:** `false`

- `withHeader` – Specifies whether to treat the first line as a header. This option can be used in the `DynamicFrameReader` class.
  - **Type:** Boolean, **Default:** `false`
- `writeHeader` – Specifies whether to write the header to output. This option can be used in the `DynamicFrameWriter` class.
  - **Type:** Boolean, **Default:** `true`
- `skipFirst` – Specifies whether to skip the first data line.
  - **Type:** Boolean, **Default:** `false`
- `optimizePerformance` – Specifies whether to use the advanced SIMD CSV reader along with Apache Arrow–based columnar memory formats. Only available in AWS Glue 3.0+.
  - **Type:** Boolean, **Default:** `false`
- `strictCheckForQuoting` – When writing CSVs, Glue may add quotes to values it interprets as strings. This is done to prevent ambiguity in what is written out. To save time when deciding what to write, Glue may quote in certain situations where quotes are not necessary. Enabling a strict check will perform a more intensive computation and will only quote when strictly necessary. Only available in AWS Glue 3.0+.
  - **Type:** Boolean, **Default:** `false`

## Optimize read performance with vectorized SIMD CSV reader

AWS Glue version 3.0 adds an optimized CSV reader that can significantly speed up overall job performance compared to row-based CSV readers.

The optimized reader:

- Uses CPU SIMD instructions to read from disk
- Immediately writes records to memory in a columnar format (Apache Arrow)
- Divides the records into batches

This saves processing time when records would be batched or converted to a columnar format later on. Some examples are when changing schemas or retrieving data by column.

To use the optimized reader, set "optimizePerformance" to true in the `format_options` or `table` property.

```
glueContext.create_dynamic_frame.from_options(  
    frame = datasource1,  
    connection_type = "s3",  
    connection_options = {"paths": ["s3://s3path"]},  
    format = "csv",  
    format_options={  
        "optimizePerformance": True,  
        "separator": ",",  
    },  
    transformation_ctx = "datasink2")
```

## Limitations for the vectorized CSV reader

Note the following limitations of the vectorized CSV reader:

- It doesn't support the `multiLine` and `escaper` format options. It uses the default escaper of double quote char `'\"'`. When these options are set, AWS Glue automatically falls back to using the row-based CSV reader.
- It doesn't support creating a `DynamicFrame` with [ChoiceType](#).
- It doesn't support creating a `DynamicFrame` with [error records](#).
- It doesn't support reading CSV files with multibyte characters such as Japanese or Chinese characters.

## Using the Parquet format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Parquet data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the Parquet format. This format is a performance-oriented, column-based data format. For an introduction to the format by the standard authority see, [Apache Parquet Documentation Overview](#).

You can use AWS Glue to read Parquet files from Amazon S3 and from streaming sources as well as write Parquet files to Amazon S3. You can read and write bzip and gzip archives containing Parquet files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common AWS Glue features support the Parquet format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Unsupported	Supported*

\* Supported in AWS Glue version 1.0+

### Example: Read Parquet files or folders from S3

**Prerequisites:** You will need the S3 paths (`s3path`) to the Parquet files or folders that you want to read.

**Configuration:** In your function options, specify `format="parquet"`. In your `connection_options`, use the `paths` key to specify your `s3path`.

You can configure how the reader interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in AWS Glue: S3 connection parameters](#).

You can configure how the reader interprets Parquet files in your `format_options`. For details, see [Parquet Configuration Reference](#).

The following AWS Glue ETL script shows the process of reading Parquet files or folders from S3:

Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
# Example: Read Parquet from S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type = "s3",
    connection_options = {"paths": ["s3://s3path/"]},
    format = "parquet"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read.parquet("s3://s3path/")
```

## Scala

For this example, use the [getSourceWithFormat](#) method.

```
// Example: Read Parquet from S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="parquet",
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
spark.read.parquet("s3://s3path/")
```

## Example: Write Parquet files and folders to S3

**Prerequisites:** You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

**Configuration:** In your function options, specify `format="parquet"`. In your `connection_options`, use the `paths` key to specify `s3path`.

You can further alter how the writer interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in AWS Glue: S3 connection parameters](#). You can configure how your operation writes the contents of your files in `format_options`. For details, see [Parquet Configuration Reference](#).

The following AWS Glue ETL script shows the process of writing Parquet files and folders to S3.

We provide a custom Parquet writer with performance optimizations for DynamicFrames, through the `useGlueParquetWriter` configuration key. To determine if this writer is right for your workload, see [Glue Parquet Writer](#).

## Python

For this example, use the [write\\_dynamic\\_frame\\_from\\_options](#) method.

```
# Example: Write Parquet to S3
# Consider whether useGlueParquetWriter is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="parquet",
    connection_options={
        "path": "s3://s3path",
    },
    format_options={
        # "useGlueParquetWriter": True,
    },
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.parquet("s3://s3path/")
```

## Scala

For this example, use the [getSinkWithFormat](#) method.

```
// Example: Write Parquet to S3
// Consider whether useGlueParquetWriter is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="parquet"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
df.write.parquet("s3://s3path/")
```

## Parquet configuration reference

You can use the following `format_options` wherever AWS Glue libraries specify `format="parquet"`:

- `useGlueParquetWriter` – Specifies the use of a custom Parquet writer that has performance optimizations for DynamicFrame workflows. For usage details, see [Glue Parquet Writer](#).
  - **Type:** Boolean, **Default:** false
- `compression` – Specifies the compression codec used. Values are fully compatible with `org.apache.parquet.hadoop.metadata.CompressionCodecName`.
  - **Type:** Enumerated Text, **Default:** "snappy"
  - Values: "uncompressed", "snappy", "gzip", and "lzo"

- `blockSize` – Specifies the size in bytes of a row group being buffered in memory. You use this for tuning performance. Size should divide exactly into a number of megabytes.
  - **Type:** Numerical, **Default:**134217728
  - The default value is equal to 128 MB.
- `pageSize` – Specifies the size in bytes of a page. You use this for tuning performance. A page is the smallest unit that must be read fully to access a single record.
  - **Type:** Numerical, **Default:**1048576
  - The default value is equal to 1 MB.

### Note

Additionally, any options that are accepted by the underlying SparkSQL code can be passed to this format by way of the `connection_options` map parameter. For example, you can set a Spark configuration such as [mergeSchema](#) for the AWS Glue Spark reader to merge the schema for all files.

## Optimize write performance with AWS Glue Parquet writer

### Note

The AWS Glue Parquet writer has historically been accessed through the `glueparquet` format type. This access pattern is no longer advocated. Instead, use the `parquet` type with `useGlueParquetWriter` enabled.

The AWS Glue Parquet writer has performance enhancements that allow faster Parquet file writes. The traditional writer computes a schema before writing. The Parquet format doesn't store the schema in a quickly retrievable fashion, so this might take some time. With the AWS Glue Parquet writer, a pre-computed schema isn't required. The writer computes and modifies the schema dynamically, as data comes in.

Note the following limitations when you specify `useGlueParquetWriter`:

- The writer supports only schema evolution (such as adding or removing columns), but not changing column types, such as with `ResolveChoice`.

- The writer doesn't support writing empty DataFrames—for example, to write a schema-only file. When integrating with the AWS Glue Data Catalog by setting `enableUpdateCatalog=True`, attempting to write an empty DataFrame will not update the Data Catalog. This will result in creating a table in the Data Catalog without a schema.

If your transform doesn't require these limitations, turning on the AWS Glue Parquet writer should increase performance.

## Using the XML format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the XML data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the XML format. This format represents highly configurable, rigidly defined data structures that aren't row or column based. XML is highly standardized. For an introduction to the format by the standard authority, see [XML Essentials](#).

You can use AWS Glue to read XML files from Amazon S3, as well as bzip and gzip archives containing XML files. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common AWS Glue features support the XML format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Unsupported	Unsupported	Supported	Supported

### Example: Read XML from S3

The XML reader takes an XML tag name. It examines elements with that tag within its input to infer a schema and populates a DynamicFrame with corresponding values. The AWS Glue XML functionality behaves similarly to the [XML Data Source for Apache Spark](#). You might be able to gain insight around basic behavior by comparing this reader to that project's documentation.

**Prerequisites:** You will need the S3 paths (`s3path`) to the XML files or folders that you want to read, and some information about your XML file. You will also need the tag for the XML element you want to read, `xmlTag`.

**Configuration:** In your function options, specify `format="xml"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can further configure how the reader interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in AWS Glue: S3 connection parameters](#). In your `format_options`, use the `rowTag` key to specify `xmlTag`. You can further configure how the reader interprets XML files in your `format_options`. For details, see [XML Configuration Reference](#).

The following AWS Glue ETL script shows the process of reading XML files or folders from S3.

## Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
# Example: Read XML from S3
# Set the rowTag option to configure the reader.

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="xml",
    format_options={"rowTag": "xmlTag"},
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\
    .format("xml")\
    .option("rowTag", "xmlTag")\
    .load("s3://s3path")
```

## Scala

For this example, use the [getSourceWithFormat](#) operation.

```
// Example: Read XML from S3
// Set the rowTag option to configure the reader.
```

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkSession

val glueContext = new GlueContext(SparkContext.getOrCreate())
val sparkSession: SparkSession = glueContext.getSparkSession

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val dynamicFrame = glueContext.getSourceWithFormat(
      formatOptions=JsonOptions("""{"rowTag": "xmlTag"}"""),
      connectionType="s3",
      format="xml",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}
```

You can also use DataFrames in a script (`org.apache.spark.sql.DataFrame`).

```
val dataframe = spark.read
  .option("rowTag", "xmlTag")
  .format("xml")
  .load("s3://s3path")
```

## XML configuration reference

You can use the following `format_options` wherever AWS Glue libraries specify `format="xml"`:

- `rowTag` – Specifies the XML tag in the file to treat as a row. Row tags cannot be self-closing.
  - **Type:** Text, **Required**
- `encoding` – Specifies the character encoding. It can be the name or alias of a [Charset](#) supported by our runtime environment. We don't make specific guarantees around encoding support, but major encodings should work.
  - **Type:** Text, **Default:** "UTF-8"
- `excludeAttribute` – Specifies whether you want to exclude attributes in elements or not.
  - **Type:** Boolean, **Default:** false
- `treatEmptyValuesAsNulls` – Specifies whether to treat white space as a null value.

- **Type:** Boolean, **Default:** false
- **attributePrefix** – A prefix for attributes to differentiate them from child element text. This prefix is used for field names.
  - **Type:** Text, **Default:** "\_"
- **valueTag** – The tag used for a value when there are attributes in the element that have no child.
  - **Type:** Text, **Default:** "\_VALUE"
- **ignoreSurroundingSpaces** – Specifies whether the white space that surrounds values should be ignored.
  - **Type:** Boolean, **Default:** false
- **withSchema** – Contains the expected schema, in situations where you want to override the inferred schema. If you don't use this option, AWS Glue infers the schema from the XML data.
  - **Type:** Text, **Default:** Not applicable
  - The value should be a JSON object that represents a `StructType`.

## Manually specify the XML schema

### Manual XML schema example

This is an example of using the `withSchema` format option to specify the schema for XML data.

```
from awsglue.gluetypes import *

schema = StructType([
    Field("id", IntegerType()),
    Field("name", StringType()),
    Field("nested", StructType([
        Field("x", IntegerType()),
        Field("y", StringType()),
        Field("z", ChoiceType([IntegerType(), StringType()]))
    ]))
])

datasource0 = create_dynamic_frame_from_options(
    connection_type,
    connection_options={"paths": ["s3://xml_bucket/someprefix"]},
    format="xml",
    format_options={"withSchema": json.dumps(schema.jsonValue())},
```

```
transformation_ctx = ""
)
```

## Using the Avro format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Avro data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the Avro format. This format is a performance-oriented, row-based data format. For an introduction to the format by the standard authority see, [Apache Avro 1.8.2 Documentation](#).

You can use AWS Glue to read Avro files from Amazon S3 and from streaming sources as well as write Avro files to Amazon S3. You can read and write bzip2 and gzip archives containing Avro files from S3. Additionally, you can write deflate, snappy, and xz archives containing Avro files. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common AWS Glue operations support the Avro format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported*	Unsupported	Supported

\*Supported with restrictions. For more information, see [the section called "Notes and restrictions for Avro streaming sources"](#).

### Example: Read Avro files or folders from S3

**Prerequisites:** You will need the S3 paths (s3path) to the Avro files or folders that you want to read.

**Configuration:** In your function options, specify `format="avro"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue: [the section called "S3 connection parameters"](#). You can configure how the reader interprets Avro files in your `format_options`. For details, see [Avro Configuration Reference](#).

The following AWS Glue ETL script shows the process of reading Avro files or folders from S3:

## Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="avro"
)
```

## Scala

For this example, use the [getSourceWithFormat](#) operation.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.sql.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="avro",
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")
    ).getDynamicFrame()
  }
}
```

## Example: Write Avro files and folders to S3

**Prerequisites:** You will need an initialized DataFrame (dataFrame) or DynamicFrame (dynamicFrame). You will also need your expected S3 output path, s3path.

**Configuration:** In your function options, specify `format="avro"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue: [the section called "S3 connection parameters"](#). You can alter how the writer interprets Avro files in your `format_options`. For details, see [Avro Configuration Reference](#).

The following AWS Glue ETL script shows the process of writing Avro files or folders to S3.

## Python

For this example, use the [write\\_dynamic\\_frame\\_from\\_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="avro",
    connection_options={
        "path": "s3://s3path"
    }
)
```

## Scala

For this example, use the [getSinkWithFormat](#) method.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
```

```

    options=JsonOptions("""{"path": "s3://s3path"}"""),
    format="avro"
  ).writeDynamicFrame(dynamicFrame)
}
}

```

## Avro configuration reference

You can use the following `format_options` values wherever AWS Glue libraries specify `format="avro"`:

- `version` — Specifies the version of Apache Avro reader/writer format to support. The default is "1.7". You can specify `format_options={"version": "1.8"}` to enable Avro logical type reading and writing. For more information, see the [Apache Avro 1.7.7 Specification](#) and [Apache Avro 1.8.2 Specification](#).

The Apache Avro 1.8 connector supports the following logical type conversions:

For the reader: this table shows the conversion between Avro data type (logical type and Avro primitive type) and AWS Glue `DynamicFrame` data type for Avro reader 1.7 and 1.8.

Avro Data Type: Logical Type	Avro Data Type: Avro Primitive Type	GlueDynamicFrame Data Type: Avro Reader 1.7	GlueDynamicFrame Data Type: Avro Reader 1.8
Decimal	bytes	BINARY	Decimal
Decimal	fixed	BINARY	Decimal
Date	int	INT	Date
Time (millisecond)	int	INT	INT
Time (microsecond)	long	LONG	LONG
Timestamp (millisecond)	long	LONG	Timestamp

Avro Data Type: Logical Type	Avro Data Type: Avro Primitive Type	GlueDynamicFrame Data Type: Avro Reader 1.7	GlueDynamicFrame Data Type: Avro Reader 1.8
Timestamp (microsecond)	long	LONG	LONG
Duration (not a logical type)	fixed of 12	BINARY	BINARY

For the writer: this table shows the conversion between AWS Glue DynamicFrame data type and Avro data type for Avro writer 1.7 and 1.8.

AWS Glue DynamicFrame Data Type	Avro Data Type: Avro Writer 1.7	Avro Data Type: Avro Writer 1.8
Decimal	String	decimal
Date	String	date
Timestamp	String	timestamp-micros

### Avro Spark DataFrame support

In order to use Avro from the Spark DataFrame API, you need to install the Spark Avro plugin for the corresponding Spark version. The version of Spark available in your job is determined by your AWS Glue version. For more information about Spark versions, see [the section called "AWS Glue versions"](#). This plugin is maintained by Apache, we do not make specific guarantees of support.

In AWS Glue 2.0 - use version 2.4.3 of the Spark Avro plugin. You can find this JAR on Maven Central, see [org.apache.spark:spark-avro\\_2.12:2.4.3](#).

In AWS Glue 3.0 - use version 3.1.1 of the Spark Avro plugin. You can find this JAR on Maven Central, see [org.apache.spark:spark-avro\\_2.12:3.1.1](#).

To include extra JARs in a AWS Glue ETL job, use the `--extra-jars` job parameter. For more information about job parameters, see [the section called "Job parameters"](#). You can also configure this parameter in the AWS Management Console.

## Using the grokLog format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in a loosely structured plaintext format, this document introduces you available features for using your data in AWS Glue through Grok patterns.

AWS Glue supports using Grok patterns. Grok patterns are similar to regular expression capture groups. They recognize patterns of character sequences in a plaintext file and give them a type and purpose. In AWS Glue, their primary purpose is to read logs. For an introduction to the Grok by the authors, see [Logstash Reference: Grok filter plugin](#).

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Not Applicable	Supported	Supported	Unsupported

## grokLog configuration reference

You can use the following `format_options` values with `format="grokLog"`:

- `logFormat` — Specifies the Grok pattern that matches the log's format.
- `customPatterns` — Specifies additional Grok patterns used here.
- `MISSING` — Specifies the signal to use in identifying missing values. The default is `' - '`.
- `LineCount` — Specifies the number of lines in each log record. The default is `' 1 '`, and currently only single-line records are supported.
- `StrictMode` — A Boolean value that specifies whether strict mode is turned on. In strict mode, the reader doesn't do automatic type conversion or recovery. The default value is `"false"`.

## Using the Ion format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the Ion data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the Ion format. This format represents data structures (that aren't row or column based) in interchangeable binary and plaintext representations. For an introduction to the format by the authors, see [Amazon Ion](#). (For more information, see the [Amazon Ion Specification](#).)

You can use AWS Glue to read Ion files from Amazon S3. You can read bzip and gzip archives containing Ion files from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common AWS Glue operations support the Ion format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Unsupported	Unsupported	Supported	Unsupported

### Example: Read Ion files and folders from S3

**Prerequisites:** You will need the S3 paths (s3path) to the Ion files or folders that you want to read.

**Configuration:** In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see Connection types and options for ETL in AWS Glue: [the section called "S3 connection parameters"](#).

The following AWS Glue ETL script shows the process of reading Ion files or folders from S3:

Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
# Example: Read ION from S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="ion"
)

```

## Scala

For this example, use the [getSourceWithFormat](#) operation.

```

// Example: Read ION from S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    val dynamicFrame = glueContext.getSourceWithFormat(
      connectionType="s3",
      format="ion",
      options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
  }
}

```

## Ion configuration reference

There are no `format_options` values for `format="ion"`.

## Using the JSON format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the JSON data format, this document introduces you to available features for using your data in AWS Glue.

AWS Glue supports using the JSON format. This format represents data structures with consistent shape but flexible contents, that aren't row or column based. JSON is defined by parallel standards issued by several authorities, one of which is ECMA-404. For an introduction to the format by a commonly referenced source, see [Introducing JSON](#).

You can use AWS Glue to read JSON files from Amazon S3, as well as bzip and gzip compressed JSON files. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Supported	Supported

### Example: Read JSON files or folders from S3

**Prerequisites:** You will need the S3 paths (s3path) to the JSON files or folders you would like to read.

**Configuration:** In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can further alter how your read operation will traverse s3 in the connection options, consult [the section called "S3 connection parameters"](#) for details. You can configure how the reader interprets JSON files in your `format_options`. For details, see [JSON Configuration Reference](#).

The following AWS Glue ETL script shows the process of reading JSON files or folders from S3:

Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
# Example: Read JSON from S3
# For show, we handle a nested JSON file that we can limit with the JsonPath
# parameter
# For show, we also handle a JSON where a single entry spans multiple lines
# Consider whether optimizePerformance is right for your workflow.

from pyspark.context import SparkContext
from awsglue.context import GlueContext
```

```

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)
spark = glueContext.spark_session

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="json",
    format_options={
        "jsonPath": "$.id",
        "multiline": True,
        # "optimizePerformance": True, -> not compatible with jsonPath, multiline
    }
)

```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```

dataFrame = spark.read\
    .option("multiline", "true")\
    .json("s3://s3path")

```

## Scala

For this example, use the [getSourceWithFormat](#) operation.

```

// Example: Read JSON from S3
// For show, we handle a nested JSON file that we can limit with the JsonPath
parameter
// For show, we also handle a JSON where a single entry spans multiple lines
// Consider whether optimizePerformance is right for your workflow.

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
    def main(sysArgs: Array[String]): Unit = {
        val spark: SparkContext = new SparkContext()
        val glueContext: GlueContext = new GlueContext(spark)

        val dynamicFrame = glueContext.getSourceWithFormat(
            formatOptions=JsonOptions("""{"jsonPath": "$.id", "multiline": true,
            "optimizePerformance":false}"""),

```

```

        connectionType="s3",
        format="json",
        options=JsonOptions("""{"paths": ["s3://s3path"], "recurse": true}""")
    ).getDynamicFrame()
}
}

```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```

val dataframe = spark.read
    .option("multiLine", "true")
    .json("s3://s3path")

```

### Example: Write JSON files and folders to S3

**Prerequisites:** You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

**Configuration:** In your function options, specify `format="json"`. In your `connection_options`, use the `paths` key to specify `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see [Data format options for ETL inputs and outputs in AWS Glue](#) : [the section called "S3 connection parameters"](#). You can configure how the writer interprets JSON files in your `format_options`. For details, see [JSON Configuration Reference](#).

The following AWS Glue ETL script shows the process of writing JSON files or folders from S3:

Python

For this example, use the [write\\_dynamic\\_frame.from\\_options](#) method.

```

# Example: Write JSON to S3

from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,

```

```

    connection_type="s3",
    connection_options={"path": "s3://s3path"},
    format="json"
)

```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.json("s3://s3path/")
```

## Scala

For this example, use the [getSinkWithFormat](#) method.

```

// Example: Write JSON to S3

import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="json"
    ).writeDynamicFrame(dynamicFrame)
  }
}

```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.json("s3://s3path")
```

## Json configuration reference

You can use the following `format_options` values with `format="json"`:

- `jsonPath` — A [JsonPath](#) expression that identifies an object to be read into records. This is particularly useful when a file contains records nested inside an outer array. For example, the following JsonPath expression targets the `id` field of a JSON object.

```
format="json", format_options={"jsonPath": "$.id"}
```

- `multiLine` — A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `"true"` if any record spans multiple lines. The default value is `"false"`, which allows for more aggressive file-splitting during parsing.
- `optimizePerformance` — A Boolean value that specifies whether to use the advanced SIMD JSON reader along with Apache Arrow based columnar memory formats. Only available in AWS Glue 3.0. Not compatible with `multiLine` or `jsonPath`. Providing either of those options will instruct AWS Glue to fall back to the standard reader.
- `withSchema` — A String value that specifies a table schema in the format described in [the section called "Specify XML schema"](#). Only used with `optimizePerformance` when reading from non-Catalog connections.

## Using vectorized SIMD JSON reader with Apache Arrow columnar format

AWS Glue version 3.0 adds a vectorized reader for JSON data. It performs 2x faster under certain conditions, compared to the standard reader. This reader comes with certain limitations users should be aware of before use, documented in this section.

To use the optimized reader, set `"optimizePerformance"` to `True` in the `format_options` or table property. You will also need to provide `withSchema` unless reading from the catalog. `withSchema` expects an input as described in the [the section called "Specify XML schema"](#)

```
// Read from S3 data source
glueContext.create_dynamic_frame.from_options(
    connection_type = "s3",
    connection_options = {"paths": ["s3://s3path"]},
    format = "json",
    format_options={
        "optimizePerformance": True,
        "withSchema": SchemaString
    })
```

```
// Read from catalog table
glueContext.create_dynamic_frame.from_catalog(
    database = database,
    table_name = table,
    additional_options = {
        // The vectorized reader for JSON can read your schema from a catalog table
        property.
        "optimizePerformance": True,
    })
```

For more information about the building a *SchemaString* in the AWS Glue library, see [the section called "Types"](#).

### Limitations for the vectorized CSV reader

Note the following limitations:

- JSON elements with nested objects or array values are not supported. If provided, AWS Glue will fall back to the standard reader.
- A schema must be provided, either from the Catalog or with `withSchema`.
- Not compatible with `multiLine` or `jsonPath`. Providing either of those options will instruct AWS Glue to fall back to the standard reader.
- Providing input records that do not match the input schema will cause the reader to fail.
- [Error records](#) will not be created.
- JSON files with multi-byte characters (such as Japanese or Chinese characters) are not supported.

### Using the ORC format in AWS Glue

AWS Glue retrieves data from sources and writes data to targets stored and transported in various data formats. If your data is stored or transported in the ORC data format, this document introduces you available features for using your data in AWS Glue.

AWS Glue supports using the ORC format. This format is a performance-oriented, column-based data format. For an introduction to the format by the standard authority see, [Apache Orc](#).

You can use AWS Glue to read ORC files from Amazon S3 and from streaming sources as well as write ORC files to Amazon S3. You can read and write bzip and gzip archives containing ORC files

from S3. You configure compression behavior on the [S3 connection parameters](#) instead of in the configuration discussed on this page.

The following table shows which common AWS Glue operations support the ORC format option.

Read	Write	Streaming read	Group small files	Job bookmarks
Supported	Supported	Supported	Unsupported	Supported*

\*Supported in AWS Glue version 1.0+

### Example: Read ORC files or folders from S3

**Prerequisites:** You will need the S3 paths (`s3path`) to the ORC files or folders that you want to read.

**Configuration:** In your function options, specify `format="orc"`. In your `connection_options`, use the `paths` key to specify your `s3path`. You can configure how the reader interacts with S3 in the `connection_options`. For details, see [Connection types and options for ETL in AWS Glue: the section called "S3 connection parameters"](#).

The following AWS Glue ETL script shows the process of reading ORC files or folders from S3:

Python

For this example, use the [create\\_dynamic\\_frame.from\\_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

dynamicFrame = glueContext.create_dynamic_frame.from_options(
    connection_type="s3",
    connection_options={"paths": ["s3://s3path"]},
    format="orc"
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
dataFrame = spark.read\  
    .orc("s3://s3path")
```

## Scala

For this example, use the [getSourceWithFormat](#) operation.

```
import com.amazonaws.services.glue.util.JsonOptions  
import com.amazonaws.services.glue.GlueContext  
import org.apache.spark.sql.SparkContext  
  
object GlueApp {  
  def main(sysArgs: Array[String]): Unit = {  
    val spark: SparkContext = new SparkContext()  
    val glueContext: GlueContext = new GlueContext(spark)  
  
    val dynamicFrame = glueContext.getSourceWithFormat(  
      connectionType="s3",  
      format="orc",  
      options=JsonOptions("""{"paths": ["s3://s3path"]}""")  
    ).getDynamicFrame()  
  }  
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
val dataFrame = spark.read\  
    .orc("s3://s3path")
```

## Example: Write ORC files and folders to S3

**Prerequisites:** You will need an initialized DataFrame (`dataFrame`) or DynamicFrame (`dynamicFrame`). You will also need your expected S3 output path, `s3path`.

**Configuration:** In your function options, specify `format="orc"`. In your connection options, use the `paths` key to specify `s3path`. You can further alter how the writer interacts with S3 in the `connection_options`. For details, see Data format options for ETL inputs and outputs in AWS Glue: [the section called "S3 connection parameters"](#). The following code example shows the process:

## Python

For this example, use the [write\\_dynamic\\_frame.from\\_options](#) method.

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext

sc = SparkContext.getOrCreate()
glueContext = GlueContext(sc)

glueContext.write_dynamic_frame.from_options(
    frame=dynamicFrame,
    connection_type="s3",
    format="orc",
    connection_options={
        "path": "s3://s3path"
    }
)
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.orc("s3://s3path/")
```

## Scala

For this example, use the [getSinkWithFormat](#) method.

```
import com.amazonaws.services.glue.util.JsonOptions
import com.amazonaws.services.glue.{DynamicFrame, GlueContext}
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)

    glueContext.getSinkWithFormat(
      connectionType="s3",
      options=JsonOptions("""{"path": "s3://s3path"}"""),
      format="orc"
    ).writeDynamicFrame(dynamicFrame)
  }
}
```

```
}
```

You can also use DataFrames in a script (`pyspark.sql.DataFrame`).

```
df.write.orc("s3://s3path/")
```

## ORC configuration reference

There are no `format_options` values for `format="orc"`. However, any options that are accepted by the underlying SparkSQL code can be passed to it by way of the `connection_options` map parameter.

## Using data lake frameworks with AWS Glue ETL jobs

Open-source data lake frameworks simplify incremental data processing for files that you store in data lakes built on Amazon S3. AWS Glue 3.0 and later supports the following open-source data lake frameworks:

- Apache Hudi
- Linux Foundation Delta Lake
- Apache Iceberg

We provide native support for these frameworks so that you can read and write data that you store in Amazon S3 in a transactionally consistent manner. There's no need to install a separate connector or complete extra configuration steps in order to use these frameworks in AWS Glue ETL jobs.

When you manage datasets through the AWS Glue Data Catalog, you can use AWS Glue methods to read and write data lake tables with Spark DataFrames. You can also read and write Amazon S3 data using the Spark DataFrame API.

In this video, you can learn about the basics of how Apache Hudi, Apache Iceberg, and Delta Lake work. You'll see how to insert, update, and delete data in your data lake and how each of these frameworks works.

## Topics

- [Limitations](#)
- [Using the Hudi framework in AWS Glue](#)

- [Using the Delta Lake framework in AWS Glue](#)
- [Using the Iceberg framework in AWS Glue](#)

## Limitations

Consider the following limitations before you use data lake frameworks with AWS Glue.

- The following AWS Glue `GlueContext` methods for `DynamicFrame` don't support reading and writing data lake framework tables. Use the `GlueContext` methods for `DataFrame` or Spark `DataFrame` API instead.
  - The following `GlueContext` methods for `DynamicFrame` are not supported with Lake Formation permission control:
    - `create_dynamic_frame.from_catalog`
    - `write_dynamic_frame.from_catalog`
    - `getDynamicFrame`
    - `writeDynamicFrame`
  - The following `GlueContext` methods for `DataFrame` are supported with Lake Formation permission control:
    - `create_data_frame.from_catalog`
    - `write_data_frame.from_catalog`
    - `getDataFrame`
    - `writeDataFrame`
- [Grouping small files](#) is not supported.
- [Job bookmarks](#) are not supported.
- Apache Hudi 0.10.1 for AWS Glue 3.0 doesn't support Hudi Merge on Read (MoR) tables.
- `ALTER TABLE ... RENAME TO` is not available for Apache Iceberg 0.13.1 for AWS Glue 3.0.

## Limitations for data lake format tables managed by Lake Formation permissions

The data lake formats are integrated with AWS Glue ETL via Lake Formation permissions. Creating a `DynamicFrame` using `create_dynamic_frame` is not supported. For more information, see the following examples:

- [Example: Read and write Iceberg table with Lake Formation permission control](#)

- [Example: Read and write Hudi table with Lake Formation permission control](#)
- [Example: Read and write Delta Lake table with Lake Formation permission control](#)

 **Note**

The integration with AWS Glue ETL via Lake Formation permissions for Apache Hudi, Apache Iceberg, and Delta Lake is supported only in AWS Glue version 4.0.

Apache Iceberg has the best integration with AWS Glue ETL via Lake Formation permissions. It supports almost all operations and includes SQL support.

Hudi supports most basic operations with the exception of administrative operations. This is because these options generally are done via writing of dataframes and specified via `additional_options`. You need to use AWS Glue APIs to create DataFrames for your operations as SparkSQL is not supported.

Delta Lake only supports the reading and appending and overwriting of table data. Delta Lake requires the use of their own libraries to be able to perform various tasks such as updates.

The following features are not available for Iceberg tables managed by Lake Formation permissions.

- Compaction using AWS Glue ETL
- Spark SQL support via AWS Glue ETL

The following are limitations of Hudi tables managed by Lake Formation permissions:

- Removal of orphaned files

The following are limitations of Delta Lake tables managed by Lake Formation permissions:

- All features other than inserting and reading from Delta Lake tables.

## Using the Hudi framework in AWS Glue

AWS Glue 3.0 and later supports Apache Hudi framework for data lakes. Hudi is an open-source data lake storage framework that simplifies incremental data processing and data pipeline

development. This topic covers available features for using your data in AWS Glue when you transport or store your data in a Hudi table. To learn more about Hudi, see the official [Apache Hudi documentation](#).

You can use AWS Glue to perform read and write operations on Hudi tables in Amazon S3, or work with Hudi tables using the AWS Glue Data Catalog. Additional operations including insert, update, and all of the [Apache Spark operations](#) are also supported.

### Note

Apache Hudi 0.10.1 for AWS Glue 3.0 doesn't support Hudi Merge on Read (MoR) tables.

The following table lists the Hudi version that is included in each AWS Glue version.

AWS Glue version	Supported Hudi version
4.0	0.12.1
3.0	0.10.1

To learn more about the data lake frameworks that AWS Glue supports, see [Using data lake frameworks with AWS Glue ETL jobs](#).

## Enabling Hudi

To enable Hudi for AWS Glue, complete the following tasks:

- Specify `hudi` as a value for the `--dataLake-formats` job parameter. For more information, see [AWS Glue job parameters](#).
- Create a key named `--conf` for your AWS Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Hudi tables.

```
spark.serializer=org.apache.spark.serializer.KryoSerializer --conf
spark.sql.hive.convertMetastoreParquet=false
```

- Lake Formation permission support for Hudi is enabled by default for AWS Glue 4.0. No additional configuration is needed for reading/writing to Lake Formation-registered Hudi tables.

To read a registered Hudi table, the AWS Glue job IAM role must have the SELECT permission. To write to a registered Hudi table, the AWS Glue job IAM role must have the SUPER permission. To learn more about managing Lake Formation permissions, see [Granting and revoking permissions on Data Catalog resources](#).

## Using a different Hudi version

To use a version of Hudi that AWS Glue doesn't support, specify your own Hudi JAR files using the `--extra-jars` job parameter. Do not include `hudi` as a value for the `--dataLake-formats` job parameter.

### Example: Write a Hudi table to Amazon S3 and register it in the AWS Glue Data Catalog

This example script demonstrates how to write a Hudi table to Amazon S3 and register the table to the AWS Glue Data Catalog. The example uses the Hudi [Hive Sync tool](#) to register the table.

#### Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [AWS Glue job parameters](#).

## Python

```
# Example: Create a Hudi table from a DataFrame
# and register the table to Glue Data Catalog

additional_options={
    "hoodie.table.name": "<your_table_name>",
    "hoodie.datasource.write.storage.type": "COPY_ON_WRITE",
    "hoodie.datasource.write.operation": "upsert",
    "hoodie.datasource.write.recordkey.field": "<your_recordkey_field>",
    "hoodie.datasource.write.precombine.field": "<your_precombine_field>",
    "hoodie.datasource.write.partitionpath.field": "<your_partitionkey_field>",
    "hoodie.datasource.write.hive_style_partitioning": "true",
    "hoodie.datasource.hive_sync.enable": "true",
    "hoodie.datasource.hive_sync.database": "<your_database_name>",
    "hoodie.datasource.hive_sync.table": "<your_table_name>",
    "hoodie.datasource.hive_sync.partition_fields": "<your_partitionkey_field>",
```

```

    "hoodie.datasource.hive_sync.partition_extractor_class":
    "org.apache.hudi.hive.MultiPartKeyValueExtractor",
    "hoodie.datasource.hive_sync.use_jdbc": "false",
    "hoodie.datasource.hive_sync.mode": "hms",
    "path": "s3://<s3Path/>"
}

dataFrame.write.format("hudi") \
  .options(**additional_options) \
  .mode("overwrite") \
  .save()

```

## Scala

```

// Example: Example: Create a Hudi table from a DataFrame
// and register the table to Glue Data Catalog

val additionalOptions = Map(
  "hoodie.table.name" -> "<your_table_name>",
  "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
  "hoodie.datasource.write.operation" -> "upsert",
  "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
  "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
  "hoodie.datasource.write.partitionpath.field" -> "<your_partitionkey_field>",
  "hoodie.datasource.write.hive_style_partitioning" -> "true",
  "hoodie.datasource.hive_sync.enable" -> "true",
  "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
  "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
  "hoodie.datasource.hive_sync.partition_fields" -> "<your_partitionkey_field>",
  "hoodie.datasource.hive_sync.partition_extractor_class" ->
  "org.apache.hudi.hive.MultiPartKeyValueExtractor",
  "hoodie.datasource.hive_sync.use_jdbc" -> "false",
  "hoodie.datasource.hive_sync.mode" -> "hms",
  "path" -> "s3://<s3Path/>")

dataFrame.write.format("hudi")
  .options(additionalOptions)
  .mode("append")
  .save()

```

## Example: Read a Hudi table from Amazon S3 using the AWS Glue Data Catalog

This example reads the Hudi table that you created in the [Example: Write a Hudi table to Amazon S3 and register it in the AWS Glue Data Catalog](#) from Amazon S3.

### Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [AWS Glue job parameters](#).

## Python

For this example, use the [GlueContext.create\\_data\\_frame.from\\_catalog\(\)](#) method.

```
# Example: Read a Hudi table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

dataFrame = glueContext.create_data_frame.from_catalog(
    database = "<your_database_name>",
    table_name = "<your_table_name>"
)
```

## Scala

For this example, use the [getCatalogSource](#) method.

```
// Example: Read a Hudi table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
```

```
val glueContext: GlueContext = new GlueContext(spark)

val dataframe = glueContext.getCatalogSource(
  database = "<your_database_name>",
  tableName = "<your_table_name>"
).getDataFrame()
}
}
```

### Example: Update and insert a DataFrame into a Hudi table in Amazon S3

This example uses the AWS Glue Data Catalog to insert a DataFrame into the Hudi table that you created in [Example: Write a Hudi table to Amazon S3 and register it in the AWS Glue Data Catalog](#).

#### Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [AWS Glue job parameters](#).

## Python

For this example, use the [GlueContext.write\\_data\\_frame.from\\_catalog\(\)](#) method.

```
# Example: Upsert a Hudi table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
  frame = dataframe,
  database = "<your_database_name>",
  table_name = "<your_table_name>",
  additional_options={
    "hoodie.table.name": "<your_table_name>",
    "hoodie.datasource.write.storage.type": "COPY_ON_WRITE",
    "hoodie.datasource.write.operation": "upsert",
```

```

"hoodie.datasource.write.recordkey.field": "<your_recordkey_field>",
"hoodie.datasource.write.precombine.field": "<your_precombine_field>",
"hoodie.datasource.write.partitionpath.field": "<your_partitionkey_field>",
"hoodie.datasource.write.hive_style_partitioning": "true",
"hoodie.datasource.hive_sync.enable": "true",
"hoodie.datasource.hive_sync.database": "<your_database_name>",
"hoodie.datasource.hive_sync.table": "<your_table_name>",
"hoodie.datasource.hive_sync.partition_fields": "<your_partitionkey_field>",
"hoodie.datasource.hive_sync.partition_extractor_class":
"org.apache.hudi.hive.MultiPartKeysValueExtractor",
"hoodie.datasource.hive_sync.use_jdbc": "false",
"hoodie.datasource.hive_sync.mode": "hms"
}
)

```

## Scala

For this example, use the [getCatalogSink](#) method.

```

// Example: Upsert a Hudi table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = JsonOptions(Map(
        "hoodie.table.name" -> "<your_table_name>",
        "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
        "hoodie.datasource.write.operation" -> "upsert",
        "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
        "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
        "hoodie.datasource.write.partitionpath.field" ->
"<your_partitionkey_field>",
        "hoodie.datasource.write.hive_style_partitioning" -> "true",
        "hoodie.datasource.hive_sync.enable" -> "true",
        "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
        "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
        "hoodie.datasource.hive_sync.partition_fields" ->
"<your_partitionkey_field>",

```

```

        "hoodie.datasource.hive_sync.partition_extractor_class" ->
"org.apache.hudi.hive.MultiPartKeyValueExtractor",
        "hoodie.datasource.hive_sync.use_jdbc" -> "false",
        "hoodie.datasource.hive_sync.mode" -> "hms"
    )))
    .writeDataFrame(dataFrame, glueContext)
}
}

```

### Example: Read a Hudi table from Amazon S3 using Spark

This example reads a Hudi table from Amazon S3 using the Spark DataFrame API.

#### Python

```

# Example: Read a Hudi table from S3 using a Spark DataFrame

dataFrame = spark.read.format("hudi").load("s3://<s3path/>")

```

#### Scala

```

// Example: Read a Hudi table from S3 using a Spark DataFrame

val dataFrame = spark.read.format("hudi").load("s3://<s3path/>")

```

### Example: Write a Hudi table to Amazon S3 using Spark

This example writes a Hudi table to Amazon S3 using Spark.

#### Python

```

# Example: Write a Hudi table to S3 using a Spark DataFrame

dataFrame.write.format("hudi") \
    .options(**additional_options) \
    .mode("overwrite") \
    .save("s3://<s3Path/>")

```

#### Scala

```

// Example: Write a Hudi table to S3 using a Spark DataFrame

```

```
dataFrame.write.format("hudi")
  .options(additionalOptions)
  .mode("overwrite")
  .save("s3://<s3path/>")
```

## Example: Read and write Hudi table with Lake Formation permission control

This example reads and writes a Hudi table with Lake Formation permission control.

1. Create a Hudi table and register it in Lake Formation.
  - a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see [Registering an Amazon S3 location](#). You can register it either from the Lake Formation console or by using the AWS CLI:

```
aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
folder> --use-service-linked-role --region <REGION>
```

Once you register an Amazon S3 location, any AWS Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as `true` in the `GetTable` call.

- b. Create a Hudi table that points to the registered Amazon S3 path through the Spark dataframe API:

```
hudi_options = {
  'hoodie.table.name': table_name,
  'hoodie.datasource.write.storage.type': 'COPY_ON_WRITE',
  'hoodie.datasource.write.recordkey.field': 'product_id',
  'hoodie.datasource.write.table.name': table_name,
  'hoodie.datasource.write.operation': 'upsert',
  'hoodie.datasource.write.precombine.field': 'updated_at',
  'hoodie.datasource.write.hive_style_partitioning': 'true',
  'hoodie.upsert.shuffle.parallelism': 2,
  'hoodie.insert.shuffle.parallelism': 2,
  'path': <S3_TABLE_LOCATION>,
  'hoodie.datasource.hive_sync.enable': 'true',
  'hoodie.datasource.hive_sync.database': database_name,
  'hoodie.datasource.hive_sync.table': table_name,
  'hoodie.datasource.hive_sync.use_jdbc': 'false',
  'hoodie.datasource.hive_sync.mode': 'hms'
```

```

}

df_products.write.format("hudi") \
  .options(**hudi_options) \
  .mode("overwrite") \
  .save()

```

2. Grant Lake Formation permission to the AWS Glue job IAM role. You can either grant permissions from the Lake Formation console, or using the AWS CLI. For more information, see [Granting table permissions using the Lake Formation console and the named resource method](#)
3. Read the Hudi table registered in Lake Formation. The code is same as reading a non-registered Hudi table. Note that the AWS Glue job IAM role needs to have the SELECT permission for the read to succeed.

```

val dataframe = glueContext.getCatalogSource(
  database = "<your_database_name>",
  tableName = "<your_table_name>"
).getDataFrame()

```

4. Write to a Hudi table registered in Lake Formation. The code is same as writing to a non-registered Hudi table. Note that the AWS Glue job IAM role needs to have the SUPER permission for the write to succeed.

```

glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
  additionalOptions = JsonOptions(Map(
    "hoodie.table.name" -> "<your_table_name>",
    "hoodie.datasource.write.storage.type" -> "COPY_ON_WRITE",
    "hoodie.datasource.write.operation" -> "<write_operation>",
    "hoodie.datasource.write.recordkey.field" -> "<your_recordkey_field>",
    "hoodie.datasource.write.precombine.field" -> "<your_precombine_field>",
    "hoodie.datasource.write.partitionpath.field" -> "<your_partitionkey_field>",
    "hoodie.datasource.write.hive_style_partitioning" -> "true",
    "hoodie.datasource.hive_sync.enable" -> "true",
    "hoodie.datasource.hive_sync.database" -> "<your_database_name>",
    "hoodie.datasource.hive_sync.table" -> "<your_table_name>",
    "hoodie.datasource.hive_sync.partition_fields" ->
"<your_partitionkey_field>",
    "hoodie.datasource.hive_sync.partition_extractor_class" ->
"org.apache.hudi.hive.MultiPartKeyValueExtractor",
    "hoodie.datasource.hive_sync.use_jdbc" -> "false",
    "hoodie.datasource.hive_sync.mode" -> "hms"
  )))

```

```
.writeDataFrame(dataFrame, glueContext)
```

## Using the Delta Lake framework in AWS Glue

AWS Glue 3.0 and later supports the Linux Foundation Delta Lake framework. Delta Lake is an open-source data lake storage framework that helps you perform ACID transactions, scale metadata handling, and unify streaming and batch data processing. This topic covers available features for using your data in AWS Glue when you transport or store your data in a Delta Lake table. To learn more about Delta Lake, see the official [Delta Lake documentation](#).

You can use AWS Glue to perform read and write operations on Delta Lake tables in Amazon S3, or work with Delta Lake tables using the AWS Glue Data Catalog. Additional operations such as insert, update, and [Table batch reads and writes](#) are also supported. When you use Delta Lake tables, you also have the option to use methods from the Delta Lake Python library such as `DeltaTable.forPath`. For more information about the Delta Lake Python library, see Delta Lake's Python documentation.

The following table lists the version of Delta Lake included in each AWS Glue version.

AWS Glue version	Supported Delta Lake version
4.0	2.1.0
3.0	1.0.0

To learn more about the data lake frameworks that AWS Glue supports, see [Using data lake frameworks with AWS Glue ETL jobs](#).

## Enabling Delta Lake for AWS Glue

To enable Delta Lake for AWS Glue, complete the following tasks:

- Specify `delta` as a value for the `--datalake-formats` job parameter. For more information, see [AWS Glue job parameters](#).
- Create a key named `--conf` for your AWS Glue job, and set it to the following value. Alternatively, you can set the following configuration using `SparkConf` in your script. These settings help Apache Spark correctly handle Delta Lake tables.

```
spark.sql.extensions=io.delta.sql.DeltaSparkSessionExtension --conf
spark.sql.catalog.spark_catalog=org.apache.spark.sql.delta.catalog.DeltaCatalog --conf
spark.delta.logStore.class=org.apache.spark.sql.delta.storage.S3SingleDriverLogStore
```

- Lake Formation permission support for Delta tables is enabled by default for AWS Glue 4.0. No additional configuration is needed for reading/writing to Lake Formation-registered Delta tables. To read a registered Delta table, the AWS Glue job IAM role must have the SELECT permission. To write to a registered Delta table, the AWS Glue job IAM role must have the SUPER permission. To learn more about managing Lake Formation permissions, see [Granting and revoking permissions on Data Catalog resources](#).

## Using a different Delta Lake version

To use a version of Delta lake that AWS Glue doesn't support, specify your own Delta Lake JAR files using the `--extra-jars` job parameter. Do not include `delta` as a value for the `--datalake-formats` job parameter. To use the Delta Lake Python library in this case, you must specify the library JAR files using the `--extra-py-files` job parameter. The Python library comes packaged in the Delta Lake JAR files.

### Example: Write a Delta Lake table to Amazon S3 and register it to the AWS Glue Data Catalog

The following AWS Glue ETL script demonstrates how to write a Delta Lake table to Amazon S3 and register the table to the AWS Glue Data Catalog.

#### Python

```
# Example: Create a Delta Lake table from a DataFrame
# and register the table to Glue Data Catalog

additional_options = {
    "path": "s3://<s3Path>"
}
dataFrame.write \
    .format("delta") \
    .options(**additional_options) \
    .mode("append") \
    .partitionBy("<your_partitionkey_field>") \
    .saveAsTable("<your_database_name>.<your_table_name>")
```

## Scala

```
// Example: Example: Create a Delta Lake table from a DataFrame
// and register the table to Glue Data Catalog

val additional_options = Map(
  "path" -> "s3://<s3Path>"
)
dataFrame.write.format("delta")
  .options(additional_options)
  .mode("append")
  .partitionBy("<your_partitionkey_field>")
  .saveAsTable("<your_database_name>.<your_table_name>")
```

### Example: Read a Delta Lake table from Amazon S3 using the AWS Glue Data Catalog

The following AWS Glue ETL script reads the Delta Lake table that you created in [Example: Write a Delta Lake table to Amazon S3 and register it to the AWS Glue Data Catalog](#).

## Python

For this example, use the [create\\_data\\_frame\\_from\\_catalog](#) method.

```
# Example: Read a Delta Lake table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame_from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

## Scala

For this example, use the [getCatalogSource](#) method.

```
// Example: Read a Delta Lake table from Glue Data Catalog
```

```
import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val df = glueContext.getCatalogSource("<your_database_name>",
    "<your_table_name>",
      additionalOptions = additionalOptions)
      .getDataFrame()
  }
}
```

### Example: Insert a DataFrame into a Delta Lake table in Amazon S3 using the AWS Glue Data Catalog

This example inserts data into the Delta Lake table that you created in [Example: Write a Delta Lake table to Amazon S3 and register it to the AWS Glue Data Catalog](#).

#### Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [AWS Glue job parameters](#).

## Python

For this example, use the [write\\_data\\_frame\\_from\\_catalog](#) method.

```
# Example: Insert into a Delta Lake table in S3 using Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame_from_catalog(
```

```

    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)

```

## Scala

For this example, use the [getCatalogSink](#) method.

```

// Example: Insert into a Delta Lake table in S3 using Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = additionalOptions)
      .writeDataFrame(dataFrame, glueContext)
  }
}

```

## Example: Read a Delta Lake table from Amazon S3 using the Spark API

This example reads a Delta Lake table from Amazon S3 using the Spark API.

## Python

```

# Example: Read a Delta Lake table from S3 using a Spark DataFrame

dataFrame = spark.read.format("delta").load("s3://<s3path/>")

```

## Scala

```

// Example: Read a Delta Lake table from S3 using a Spark DataFrame

val dataFrame = spark.read.format("delta").load("s3://<s3path/>")

```

## Example: Write a Delta Lake table to Amazon S3 using Spark

This example writes a Delta Lake table to Amazon S3 using Spark.

### Python

```
# Example: Write a Delta Lake table to S3 using a Spark DataFrame

dataFrame.write.format("delta") \
    .options(**additional_options) \
    .mode("overwrite") \
    .partitionBy("<your_partitionkey_field>") \
    .save("s3://<s3Path>")
```

### Scala

```
// Example: Write a Delta Lake table to S3 using a Spark DataFrame

dataFrame.write.format("delta")
    .options(additionalOptions)
    .mode("overwrite")
    .partitionBy("<your_partitionkey_field>")
    .save("s3://<s3path/>")
```

## Example: Read and write Delta Lake table with Lake Formation permission control

This example reads and writes a Delta Lake table with Lake Formation permission control.

### 1. Create a Delta table and register it in Lake Formation

- a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see [Registering an Amazon S3 location](#). You can register it either from the Lake Formation console or by using the AWS CLI:

```
aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
folder> --use-service-linked-role --region <REGION>
```

Once you register an Amazon S3 location, any AWS Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as true in the `GetTable` call.

- b. Create a Delta table that points to the registered Amazon S3 path through Spark:

**Note**

The following are Python examples.

```
dataFrame.write \  
  .format("delta") \  
  .mode("overwrite") \  
  .partitionBy("<your_partitionkey_field>") \  
  .save("s3://<the_s3_path>")
```

After the data has been written to Amazon S3, use the AWS Glue crawler to create a new Delta catalog table. For more information, see [Introducing native Delta Lake table support with AWS Glue crawlers](#).

You can also create the table manually through the AWS Glue CreateTable API.

2. Grant Lake Formation permission to the AWS Glue job IAM role. You can either grant permissions from the Lake Formation console, or using the AWS CLI. For more information, see [Granting table permissions using the Lake Formation console and the named resource method](#)
3. Read the Delta table registered in Lake Formation. The code is same as reading a non-registered Delta table. Note that the AWS Glue job IAM role needs to have the SELECT permission for the read to succeed.

```
# Example: Read a Delta Lake table from Glue Data Catalog  
  
df = glueContext.create_data_frame.from_catalog(  
    database="<your_database_name>",  
    table_name="<your_table_name>",  
    additional_options=additional_options  
)
```

4. Write to a Delta table registered in Lake Formation. The code is same as writing to a non-registered Delta table. Note that the AWS Glue job IAM role needs to have the SUPER permission for the write to succeed.

By default AWS Glue uses Append as saveMode. You can change it by setting the saveMode option in additional\_options. For information about saveMode support in Delta tables, see [Write to a table](#).

```
glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

## Using the Iceberg framework in AWS Glue

AWS Glue 3.0 and later supports the Apache Iceberg framework for data lakes. Iceberg provides a high-performance table format that works just like a SQL table. This topic covers available features for using your data in AWS Glue when you transport or store your data in an Iceberg table. To learn more about Iceberg, see the official [Apache Iceberg documentation](#).

You can use AWS Glue to perform read and write operations on Iceberg tables in Amazon S3, or work with Iceberg tables using the AWS Glue Data Catalog. Additional operations including insert, update, and all [Spark Queries](#) [Spark Writes](#) are also supported.

### Note

ALTER TABLE ... RENAME TO is not available for Apache Iceberg 0.13.1 for AWS Glue 3.0.

The following table lists the version of Iceberg included in each AWS Glue version.

AWS Glue version	Supported Iceberg version
4.0	1.0.0
3.0	0.13.1

To learn more about the data lake frameworks that AWS Glue supports, see [Using data lake frameworks with AWS Glue ETL jobs](#).

## Enabling the Iceberg framework

To enable Iceberg for AWS Glue, complete the following tasks:

- Specify `iceberg` as a value for the `--datalake-formats` job parameter. For more information, see [AWS Glue job parameters](#).
- Create a key named `--conf` for your AWS Glue job, and set it to the following value. Alternatively, you can set the following configuration using SparkConf in your script. These settings help Apache Spark correctly handle Iceberg tables.

```
spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
--conf spark.sql.catalog.glue_catalog=org.apache.iceberg.spark.SparkCatalog
--conf spark.sql.catalog.glue_catalog.warehouse=s3://<your-warehouse-dir>/
--conf spark.sql.catalog.glue_catalog.catalog-impl=org.apache.iceberg.aws.glue.GlueCatalog
--conf spark.sql.catalog.glue_catalog.io-impl=org.apache.iceberg.aws.s3.S3FileIO
```

If you are reading or writing to Iceberg tables that are registered with Lake Formation, add the following configuration to enable Lake Formation support. Note that only AWS Glue 4.0 supports Iceberg tables registered with Lake Formation:

```
--conf spark.sql.catalog.glue_catalog.glue.lakeformation-enabled=true
--conf spark.sql.catalog.glue_catalog.glue.id=<table-catalog-id>
```

If you use AWS Glue 3.0 with Iceberg 0.13.1, you must set the following additional configurations to use Amazon DynamoDB lock manager to ensure atomic transaction. AWS Glue 4.0 uses optimistic locking by default. For more information, see [Iceberg AWS Integrations](#) in the official Apache Iceberg documentation.

```
--conf spark.sql.catalog.glue_catalog.lock-impl=org.apache.iceberg.aws.glue.DynamoLockManager
--conf spark.sql.catalog.glue_catalog.lock.table=<your-dynamodb-table-name>
```

## Using a different Iceberg version

To use a version of Iceberg that AWS Glue doesn't support, specify your own Iceberg JAR files using the `--extra-jars` job parameter. Do not include `iceberg` as a value for the `--datalake-formats` parameter.

## Enabling encryption for Iceberg tables

**Note**

Iceberg tables have their own mechanisms to enable server-side encryption. You should enable this configuration in addition to AWS Glue's security configuration.

To enable server-side encryption on Iceberg tables, review the guidance from the [Iceberg documentation](#).

**Example: Write an Iceberg table to Amazon S3 and register it to the AWS Glue Data Catalog**

This example script demonstrates how to write an Iceberg table to Amazon S3. The example uses [Iceberg AWS Integrations](#) to register the table to the AWS Glue Data Catalog.

**Python**

```
# Example: Create an Iceberg table from a DataFrame
# and register the table to Glue Data Catalog

dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

query = f"""
CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
TBLPROPERTIES ("format-version"="2")
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

**Scala**

```
// Example: Example: Create an Iceberg table from a DataFrame
// and register the table to Glue Data Catalog

dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

val query = """CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
TBLPROPERTIES ("format-version"="2")
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

Alternatively, you can write an Iceberg table to Amazon S3 and the Data Catalog using Spark methods.

Prerequisites: You will need to provision a catalog for the Iceberg library to use. When using the AWS Glue Data Catalog, AWS Glue makes this straightforward. The AWS Glue Data Catalog is pre-configured for use by the Spark libraries as `glue_catalog`. Data Catalog tables are identified by a *databaseName* and a *tableName*. For more information about the AWS Glue Data Catalog, see [Data discovery and cataloging](#).

If you are not using the AWS Glue Data Catalog, you will need to provision a catalog through the Spark APIs. For more information, see [Spark Configuration](#) in the Iceberg documentation.

This example writes an Iceberg table to Amazon S3 and the Data Catalog using Spark.

### Python

```
# Example: Write an Iceberg table to S3 on the Glue Data Catalog

# Create (equivalent to CREATE TABLE AS SELECT)
dataFrame.writeTo("glue_catalog.databaseName.tableName") \
    .tableProperty("format-version", "2") \
    .create()

# Append (equivalent to INSERT INTO)
dataFrame.writeTo("glue_catalog.databaseName.tableName") \
    .tableProperty("format-version", "2") \
    .append()
```

### Scala

```
// Example: Write an Iceberg table to S3 on the Glue Data Catalog

// Create (equivalent to CREATE TABLE AS SELECT)
dataFrame.writeTo("glue_catalog.databaseName.tableName")
    .tableProperty("format-version", "2")
    .create()

// Append (equivalent to INSERT INTO)
dataFrame.writeTo("glue_catalog.databaseName.tableName")
    .tableProperty("format-version", "2")
    .append()
```

## Example: Read an Iceberg table from Amazon S3 using the AWS Glue Data Catalog

This example reads the Iceberg table that you created in [Example: Write an Iceberg table to Amazon S3 and register it to the AWS Glue Data Catalog](#).

### Python

For this example, use the [GlueContext.create\\_data\\_frame.from\\_catalog\(\)](#) method.

```
# Example: Read an Iceberg table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

### Scala

For this example, use the [getCatalogSource](#) method.

```
// Example: Read an Iceberg table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext

object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val df = glueContext.getCatalogSource("<your_database_name>",
"<your_table_name>",
      additionalOptions = additionalOptions)
      .getDataFrame()
  }
}
```

## Example: Insert a DataFrame into an Iceberg table in Amazon S3 using the AWS Glue Data Catalog

This example inserts data into the Iceberg table that you created in [Example: Write an Iceberg table to Amazon S3 and register it to the AWS Glue Data Catalog](#).

### Note

This example requires you to set the `--enable-glue-datacatalog` job parameter in order to use the AWS Glue Data Catalog as an Apache Spark Hive metastore. To learn more, see [AWS Glue job parameters](#).

## Python

For this example, use the [GlueContext.write\\_data\\_frame.from\\_catalog\(\)](#) method.

```
# Example: Insert into an Iceberg table from Glue Data Catalog

from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

## Scala

For this example, use the [getCatalogSink](#) method.

```
// Example: Insert into an Iceberg table from Glue Data Catalog

import com.amazonaws.services.glue.GlueContext
import org.apache.spark.SparkContext
```

```
object GlueApp {
  def main(sysArgs: Array[String]): Unit = {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    glueContext.getCatalogSink("<your_database_name>", "<your_table_name>",
      additionalOptions = additionalOptions)
      .writeDataFrame(dataFrame, glueContext)
  }
}
```

### Example: Read an Iceberg table from Amazon S3 using Spark

Prerequisites: You will need to provision a catalog for the Iceberg library to use. When using the AWS Glue Data Catalog, AWS Glue makes this straightforward. The AWS Glue Data Catalog is pre-configured for use by the Spark libraries as `glue_catalog`. Data Catalog tables are identified by a *databaseName* and a *tableName*. For more information about the AWS Glue Data Catalog, see [Data discovery and cataloging](#).

If you are not using the AWS Glue Data Catalog, you will need to provision a catalog through the Spark APIs. For more information, see [Spark Configuration](#) in the Iceberg documentation.

This example reads an Iceberg table in Amazon S3 from the Data Catalog using Spark.

#### Python

```
# Example: Read an Iceberg table on S3 as a DataFrame from the Glue Data Catalog
dataFrame = spark.read.format("iceberg").load("glue_catalog.<databaseName>.<tableName>")
```

#### Scala

```
// Example: Read an Iceberg table on S3 as a DataFrame from the Glue Data Catalog
val dataFrame =
  spark.read.format("iceberg").load("glue_catalog.<databaseName>.<tableName>")
```

### Example: Read and write Iceberg table with Lake Formation permission control

This example reads and writes an Iceberg table with Lake Formation permission control.

## 1. Create an Iceberg table and register it in Lake Formation:

- a. To enable Lake Formation permission control, you'll first need to register the table Amazon S3 path on Lake Formation. For more information, see [Registering an Amazon S3 location](#). You can register it either from the Lake Formation console or by using the AWS CLI:

```
aws lakeformation register-resource --resource-arn arn:aws:s3:::<s3-bucket>/<s3-
folder> --use-service-linked-role --region <REGION>
```

Once you register an Amazon S3 location, any AWS Glue table pointing to the location (or any of its child locations) will return the value for the `IsRegisteredWithLakeFormation` parameter as `true` in the `GetTable` call.

- b. Create an Iceberg table that points to the registered path through Spark SQL:

### Note

The following are Python examples.

```
dataFrame.createOrReplaceTempView("tmp_<your_table_name>")

query = f"""
CREATE TABLE glue_catalog.<your_database_name>.<your_table_name>
USING iceberg
AS SELECT * FROM tmp_<your_table_name>
"""
spark.sql(query)
```

You can also create the table manually through AWS Glue `CreateTable` API. For more information, see [Creating Apache Iceberg tables](#).

2. Grant Lake Formation permission to the job IAM role. You can either grant permissions from the Lake Formation console, or using the AWS CLI. For more information, see: <https://docs.aws.amazon.com/lake-formation/latest/dg/granting-table-permissions.html>
3. Read an Iceberg table registered with Lake Formation. The code is same as reading a non-registered Iceberg table. Note that your AWS Glue job IAM role needs to have the `SELECT` permission for the read to succeed.

```
# Example: Read an Iceberg table from the AWS Glue Data Catalog
```

```
from awsglue.context import GlueContext
from pyspark.context import SparkContext

sc = SparkContext()
glueContext = GlueContext(sc)

df = glueContext.create_data_frame.from_catalog(
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

4. Write to an Iceberg table registered with Lake Formation. The code is same as writing to a non-registered Iceberg table. Note that your AWS Glue job IAM role needs to have the SUPER permission for the write to succeed.

```
glueContext.write_data_frame.from_catalog(
    frame=dataFrame,
    database="<your_database_name>",
    table_name="<your_table_name>",
    additional_options=additional_options
)
```

## Shared configuration reference

You can use the following `format_options` values with any format type.

- `attachFilename` — A string in the appropriate format to be used as a column name. If you provide this option, the name of the source file for the record will be appended to the record. The parameter value will be used as the column name.
- `attachTimestamp` — A string in the appropriate format to be used as a column name. If you provide this option, the modification time of the source file for the record will be appended to the record. The parameter value will be used as the column name.

## AWS Glue Data Catalog support for Spark SQL jobs

The AWS Glue Data Catalog is an Apache Hive metastore-compatible catalog. You can configure your AWS Glue jobs and development endpoints to use the Data Catalog as an external Apache Hive metastore. You can then directly run Apache Spark SQL queries against the tables stored in

the Data Catalog. AWS Glue dynamic frames integrate with the Data Catalog by default. However, with this feature, Spark SQL jobs can start using the Data Catalog as an external Hive metastore.

This feature requires network access to the AWS Glue API endpoint. For AWS Glue jobs with connections located in private subnets, you must configure either a VPC endpoint or NAT gateway to provide the network access. For information about configuring a VPC endpoint, see [Setting up network access to data stores](#). To create a NAT gateway, see [NAT Gateways](#) in the *Amazon VPC User Guide*.

You can configure AWS Glue jobs and development endpoints by adding the `--enable-glue-catalog` argument to job arguments and development endpoint arguments respectively. Passing this argument sets certain configurations in Spark that enable it to access the Data Catalog as an external Hive metastore. It also [enables Hive support](#) in the `SparkSession` object created in the AWS Glue job or development endpoint.

To enable the Data Catalog access, check the **Use AWS Glue Data Catalog as the Hive metastore** check box in the **Catalog options** group on the **Add job** or **Add endpoint** page on the console. Note that the IAM role used for the job or development endpoint should have `glue:CreateDatabase` permissions. A database called "default" is created in the Data Catalog if it does not exist.

Lets look at an example of how you can use this feature in your Spark SQL jobs. The following example assumes that you have crawled the US legislators dataset available at `s3://awsglue-datasets/examples/us-legislators`.

To serialize/deserialize data from the tables defined in the AWS Glue Data Catalog, Spark SQL needs the [Hive SerDe](#) class for the format defined in the AWS Glue Data Catalog in the classpath of the spark job.

SerDes for certain common formats are distributed by AWS Glue. The following are the Amazon S3 links for these:

- [JSON](#)
- [XML](#)
- [Grok](#)

Add the JSON SerDe as an [extra JAR to the development endpoint](#). For jobs, you can add the SerDe using the `--extra-jars` argument in the arguments field. For more information, see [AWS Glue job parameters](#).

Here is an example input JSON to create a development endpoint with the Data Catalog enabled for Spark SQL.

```
{
  "EndpointName": "Name",
  "RoleArn": "role_ARN",
  "PublicKey": "public_key_contents",
  "NumberOfNodes": 2,
  "Arguments": {
    "--enable-glue-datacatalog": ""
  },
  "ExtraJarsS3Path": "s3://crawler-public/json/serde/json-serde.jar"
}
```

Now query the tables created from the US legislators dataset using Spark SQL.

```
>>> spark.sql("use legislators")
DataFrame[]
>>> spark.sql("show tables").show()
+-----+-----+-----+
| database|      tableName|isTemporary|
+-----+-----+-----+
|legislators|    areas_json|      false|
|legislators|  countries_json|      false|
|legislators|   events_json|      false|
|legislators|  memberships_json|      false|
|legislators|  organizations_json|      false|
|legislators|    persons_json|      false|
+-----+-----+-----+
>>> spark.sql("describe memberships_json").show()
+-----+-----+-----+
|      col_name|data_type|      comment|
+-----+-----+-----+
|      area_id|  string|from deserializer|
|  on_behalf_of_id|  string|from deserializer|
|  organization_id|  string|from deserializer|
|          role|  string|from deserializer|
|      person_id|  string|from deserializer|
|legislative_perio...|  string|from deserializer|
|      start_date|  string|from deserializer|
|      end_date|  string|from deserializer|
```

```
+-----+-----+-----+
```

If the SerDe class for the format is not available in the job's classpath, you will see an error similar to the following.

```
>>> spark.sql("describe memberships_json").show()

Caused by: MetaException(message:java.lang.ClassNotFoundException Class
org.openx.data.jsonserde.JsonSerDe not found)
    at
org.apache.hadoop.hive.metastore.MetaStoreUtils.getDeserializer(MetaStoreUtils.java:399)
    at
org.apache.hadoop.hive.ql.metadata.Table.getDeserializerFromMetaStore(Table.java:276)
    ... 64 more
```

To view only the distinct `organization_ids` from the `memberships` table, run the following SQL query.

```
>>> spark.sql("select distinct organization_id from memberships_json").show()
+-----+
|  organization_id|
+-----+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+-----+
```

If you need to do the same with dynamic frames, run the following.

```
>>> memberships = glueContext.create_dynamic_frame.from_catalog(database="legislators",
    table_name="memberships_json")
>>> memberships.toDF().createOrReplaceTempView("memberships")
>>> spark.sql("select distinct organization_id from memberships").show()
+-----+
|  organization_id|
+-----+
|d56acebe-8fdc-47b...|
|8fa6c3d2-71dc-478...|
+-----+
```

While DynamicFrames are optimized for ETL operations, enabling Spark SQL to access the Data Catalog directly provides a concise way to run complex SQL statements or port existing applications.

## Using job bookmarks

AWS Glue for Spark uses job bookmarks to track data that has already been processed. For a summary of the job bookmarks feature and what it supports, see [the section called “Tracking processed data using job bookmarks”](#). When programming a AWS Glue job with bookmarks, you have access to flexibility unavailable in visual jobs.

- When reading from JDBC, you can specify the column(s) to use as bookmark keys in your AWS Glue script.
- You can chose which `transformation_ctx` to apply to each method call.

*Always call `job.init` in the beginning of the script and the `job.commit` in the end of the script with appropriately configured parameters.* These two functions initialize the bookmark service and update the state change to the service. Bookmarks won't work without calling them.

### Specify bookmark keys

For JDBC workflows, the bookmark keeps track of which rows your job has read by comparing the values of key fields to a bookmarked value. This is not necessary or applicable for Amazon S3 workflows. When writing a AWS Glue script without the visual editor, you can specify which column to track with bookmarks. You can also specify multiple columns. Gaps in the sequence of values are permitted when specifying user-defined bookmark keys.

#### Warning

If user-defined bookmarks keys are used, they must each be strictly monotonically increasing or decreasing. When selecting additional fields for a compound key, fields for concepts like "minor versions" or "revision numbers" do not meet this criteria, since their values are reused throughout your dataset.

You can specify `jobBookmarkKeys` and `jobBookmarkKeysSortOrder` in the following ways:

- `create_dynamic_frame.from_catalog` — Use `additional_options`.
- `create_dynamic_frame.from_options` — Use `connection_options`.

## Transformation context

Many of the AWS Glue PySpark dynamic frame methods include an optional parameter named `transformation_ctx`, which is a unique identifier for the ETL operator instance. The `transformation_ctx` parameter is used to identify state information within a job bookmark for the given operator. Specifically, AWS Glue uses `transformation_ctx` to index the key to the bookmark state.

### Warning

The `transformation_ctx` serves as the key to search the bookmark state for a specific source in your script. For the bookmark to work properly, you should always keep the source and the associated `transformation_ctx` consistent. Changing the source property or renaming the `transformation_ctx` may make the previous bookmark invalid and the time stamp based filtering may not yield the correct result.

For job bookmarks to work properly, enable the job bookmark parameter and set the `transformation_ctx` parameter. If you don't pass in the `transformation_ctx` parameter, then job bookmarks are not enabled for a dynamic frame or a table used in the method. For example, if you have an ETL job that reads and joins two Amazon S3 sources, you might choose to pass the `transformation_ctx` parameter only to those methods that you want to enable bookmarks. If you reset the job bookmark for a job, it resets all transformations that are associated with the job regardless of the `transformation_ctx` used.

For more information about the `DynamicFrameReader` class, see [DynamicFrameReader class](#). For more information about PySpark extensions, see [AWS Glue PySpark extensions reference](#).

## Examples

### Example

The following is an example of a generated script for an Amazon S3 data source. The portions of the script that are required for using job bookmarks are shown in italics. For more information about these elements see the [GlueContext class](#) API, and the [DynamicFrameWriter class](#) API.

```
# Sample Script
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
```

```
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])
sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = "database",
    table_name = "relatedqueries_csv",
    transformation_ctx = "datasource0"
)

applymapping1 = ApplyMapping.apply(
    frame = datasource0,
    mappings = [("col0", "string", "name", "string"), ("col1", "string", "number",
"string")],
    transformation_ctx = "applymapping1"
)

datasink2 = glueContext.write_dynamic_frame.from_options(
    frame = applymapping1,
    connection_type = "s3",
    connection_options = {"path": "s3://input_path"},
    format = "json",
    transformation_ctx = "datasink2"
)

job.commit()
```

## Example

The following is an example of a generated script for a JDBC source. The source table is an employee table with the empno column as the primary key. Although by default the job uses a sequential primary key as the bookmark key if no bookmark key is specified, because empno is not necessarily sequential—there could be gaps in the values—it does not qualify as a default bookmark key. Therefore, the script explicitly designates empno as the bookmark key. That portion of the code is shown in italics.

```
import sys
from awsglue.transforms import *
from awsglue.utils import getResolvedOptions
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.job import Job

args = getResolvedOptions(sys.argv, ['JOB_NAME'])

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)
job.init(args['JOB_NAME'], args)

datasource0 = glueContext.create_dynamic_frame.from_catalog(
    database = "hr",
    table_name = "emp",
    transformation_ctx = "datasource0",
    additional_options = {"jobBookmarkKeys":["empno"],"jobBookmarkKeysSortOrder":"asc"}
)

applymapping1 = ApplyMapping.apply(
    frame = datasource0,
    mappings = [("ename", "string", "ename", "string"), ("hrly_rate", "decimal(38,0)",
"hrly_rate", "decimal(38,0)"), ("comm", "decimal(7,2)", "comm", "decimal(7,2)"),
("hiredate", "timestamp", "hiredate", "timestamp"), ("empno", "decimal(5,0)", "empno",
"decimal(5,0)"), ("mgr", "decimal(5,0)", "mgr", "decimal(5,0)"), ("photo", "string",
"photo", "string"), ("job", "string", "job", "string"), ("deptno", "decimal(3,0)",
"deptno", "decimal(3,0)"), ("ssn", "decimal(9,0)", "ssn", "decimal(9,0)"), ("sal",
"decimal(7,2)", "sal", "decimal(7,2)"]],
    transformation_ctx = "applymapping1"
)

datasink2 = glueContext.write_dynamic_frame.from_options(
    frame = applymapping1,
    connection_type = "s3",
    connection_options = {"path": "s3://hr/employees"},

    transformation_ctx = "datasink2"
)

job.commit()
```

## Using Sensitive Data Detection outside AWS Glue Studio

AWS Glue Studio allows you to detect sensitive data, however, you can also use the Sensitive Data Detection functionality outside of AWS Glue Studio.

For a full list of managed sensitive data types, see [Managed data types](#).

### Detecting Sensitive Data Detection using AWS Managed PII types

AWS Glue provides two APIs in a AWS Glue ETL job. These are `detect()` and `classifyColumns()`:

```
detect(frame: DynamicFrame,
       entityTypesToDetect: Seq[String],
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame

detect(frame: DynamicFrame,
       detectionParameters: JsonOptions,
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame

classifyColumns(frame: DynamicFrame,
               entityTypesToDetect: Seq[String],
               sampleFraction: Double = 0.1,
               thresholdFraction: Double = 0.1,
               detectionSensitivity: String = "LOW")
```

You can use the `detect()` API to identify AWS Managed PII types and custom entity types. A new column is automatically created with the detection result. The `classifyColumns()` API returns a map where keys are column names and values are list of detected entity types. `SampleFraction` indicates the fraction of the data to sample when scanning for PII entities whereas `ThresholdFraction` indicates the fraction of the data that must be met in order for a column to be identified as PII data.

### Row-level detection

In the example, the job is performing the following actions using the `detect()` and `classifyColumns()` APIs:

- reading data from an Amazon S3 bucket and turns it into a dynamicFrame
- detecting instances of "Email" and "Credit Card" in the dynamicFrame
- returning a dynamicFrame with original values plus one column which encompasses detection result for each row
- writing the returned dynamicFrame in another Amazon S3 path

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame=
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node1650160158526").getDynamicFrame()

    val frameWithDetectedPII = EntityDetector.detect(frame, Seq("EMAIL",
"CREDIT_CARD"))

    glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="someCtx",
format="json").writeDynamicFrame(frameWithDetectedPII)

    Job.commit()
  }
}
```

## Row-level detection with fine-grained actions

In the example, the job is performing the following actions using the `detect()` APIs:

- reading data from an Amazon S3 bucket and turns it into a `dynamicFrame`
- detecting sensitive data types for "USA\_PTIN", " BANK\_ACCOUNT", "USA\_SSN", "USA\_PASSPORT\_NUMBER" , and "PHONE\_NUMBER" in the `dynamicFrame`
- returning a `dynamicFrame` with modified masked values plus one column which encompasses detection result for each row
- writing the returned `dynamicFrame` in another Amazon S3 path

In contrast with the above `detect()` API, this uses fine-grained actions for entity types to detect. For more information, see [Detection parameters for using detect\(\)](#).

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame =
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node_source").getDynamicFrame()

    val detectionParameters = JsonOptions(
      """
      {
```

```

    "USA_DRIVING_LICENSE": [{
      "action": "PARTIAL_REDACT",
      "sourceColumns": ["Driving License"],
      "actionOptions": {
        "matchPattern": "[0-9]",
        "redactChar": "*"
      }
    }],
    "BANK_ACCOUNT": [{
      "action": "DETECT",
      "sourceColumns": ["*"]
    }],
    "USA_SSN": [{
      "action": "SHA256_HASH",
      "sourceColumns": ["SSN"]
    }],
    "IP_ADDRESS": [{
      "action": "REDACT",
      "sourceColumns": ["IP Address"],
      "actionOptions": {"redactText": "*****"}
    }],
    "PHONE_NUMBER": [{
      "action": "PARTIAL_REDACT",
      "sourceColumns": ["Phone Number"],
      "actionOptions": {
        "numLeftCharsToExclude": 1,
        "numRightCharsToExclude": 0,
        "redactChar": "*"
      }
    }
  ]
}
"""
)

```

```

val frameWithDetectedPII = EntityDetector.detect(frame, detectionParameters,
"DetectedEntities", "HIGH")

```

```

glueContext.getSinkWithFormat(connectionType="s3", options=JsonOptions("""{"path":
"s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="AmazonS3_node_target",
format="json").writeDynamicFrame(frameWithDetectedPII)

```

```

Job.commit()
}

```

```
}
```

## Column-level detection

In the example, the job is performing the following actions using the `classifyColumns()` APIs:

- reading data from an Amazon S3 bucket and turns it into a `dynamicFrame`
- detecting instances of "Email" and "Credit Card" in the `dynamicFrame`
- set parameters to sample 100% of the column, mark an entity as detected if it is in 10% of cells, and have "LOW" sensitivity
- returns a map where keys are column names and values are list of detected entity types
- writing the returned `dynamicFrame` in another Amazon S3 path

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.DynamicFrame
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame =
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar":
"\\"", "withHeader": true, "separator": ",", "optimizePerformance": false}"""),
connectionType="s3", format="csv", options=JsonOptions("""{"paths": ["s3://
pathToSource"], "recurse": true}"""), transformationContext="frame").getDynamicFrame()

    import glueContext.sparkSession.implicits._

    val detectedDataFrame = EntityDetector.classifyColumns(
```

```

    frame,
    entityTypeToDetect = Seq("CREDIT_CARD", "PHONE_NUMBER"),
    sampleFraction = 1.0,
    thresholdFraction = 0.1,
    detectionSensitivity = "LOW"
  )
  val detectedDF = (detectedDataFrame).toSeq.toDF("columnName", "entityTypes")
  val DetectSensitiveData_node = DynamicFrame(detectedDF, glueContext)

  glueContext.getSinkWithFormat(connectionType="s3", options=JsonOptions("""{"path":
"s3://pathToOutput", "partitionKeys": []}"""), transformationContext="someCtx",
format="json").writeDynamicFrame(DetectSensitiveData_node)

  Job.commit()
}
}

```

## Detecting Sensitive Data Detection using AWS CustomEntityType PII types

You can define custom entities through AWS Studio. However, to use this feature out of AWS Studio, you have to first define the custom entity types and then add the defined custom entity types to the list of `entityTypesToDetect`.

If you have specific sensitive data types in your data (such as 'Employee Id'), you can create custom entities by calling the `CreateCustomEntityType()` API. The following example defines the custom entity type 'EMPLOYEE\_ID' to the `CreateCustomEntityType()` API with the request parameters:

```

{
  "name": "EMPLOYEE_ID",
  "regexString": "\\d{4}-\\d{3}",
  "contextWords": ["employee"]
}

```

Then, modify the job to use the new custom sensitive data type by adding the custom entity type (EMPLOYEE\_ID) to the `EntityDetector()` API:

```

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._
import com.amazonaws.services.glue.ml.EntityDetector

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    val frame=
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar": "\"",
"withHeader": true, "separator": ","}"""), connectionType="s3", format="csv",
options=JsonOptions("""{"paths": ["s3://pathToSource"], "recurse": true}"""),
transformationContext="AmazonS3_node1650160158526").getDynamicFrame()

    val frameWithDetectedPII = EntityDetector.detect(frame, Seq("EMAIL",
"CREDIT_CARD", "EMPLOYEE_ID"))

    glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://pathToOutput/", "partitionKeys": []}"""),
transformationContext="someCtx",
format="json").writeDynamicFrame(frameWithDetectedPII)

    Job.commit()
  }
}

```

### Note

If a custom sensitive data type is defined with the same name as an existing managed entity type, then the custom sensitive data type will take precedent and overwrite the managed entity type's logic.

## Detection parameters for using detect()

This method is used for detecting entities in a `DynamicFrame`. It returns a new `DataFrame` with original values and an additional column `outputColumnName` that has PII detection metadata. Custom masking can be done after this `DynamicFrame` is returned within the AWS Glue script, or the `detect()` with fine-grained actions API can be used instead.

```
detect(frame: DynamicFrame,  
       entityTypesToDetect: Seq[String],  
       outputColumnName: String = "DetectedEntities",  
       detectionSensitivity: String = "LOW"): DynamicFrame
```

### Parameters:

- **frame** – (type: `DynamicFrame`) The input `DynamicFrame` containing the data to be processed.
- **entityTypesToDetect** – (type: `[Seq[String]]`) List of entity types to detect. Can be either `Managed Entity Types` or `Custom Entity Types`.
- **outputColumnName** – (type: `String`, default: "DetectedEntities") The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities".
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW") Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

### outputColumnName settings:

The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities". For each row in the output column, the supplementary column includes a map of the column name to the detected entity metadata with the following key-value pairs:

- **entityType** – The detected entity type.
- **start** – The starting position of the detected entity in the original data.
- **end** – The ending position of the detected entity in the original data.
- **actionUsed** – The action performed on the detected entity (e.g., "DETECT," "REDACT," "PARTIAL\_REDACT," "SHA256\_HASH").

**Example:**

```
{
  "DetectedEntities":{
    "SSN Col":[
      {
        "entityType":"USA_SSN",
        "actionUsed":"DETECT",
        "start":4,
        "end":15
      }
    ],
    "Random Data col":[
      {
        "entityType":"BANK_ACCOUNT",
        "actionUsed":"PARTIAL_REDACT",
        "start":4,
        "end":13
      },
      {
        "entityType":"IP_ADDRESS",
        "actionUsed":"REDACT",
        "start":4,
        "end":13
      }
    ]
  }
}
```

**Detection Parameters for detect() with fine grained actions**

This method is used for detecting entities in a `DynamicFrame` using specified parameters. It returns a new `DataFrame` with original values replaced with masked sensitive data and an additional column `outputColumnName` that has PII detection metadata.

```
detect(frame: DynamicFrame,
       detectionParameters: JsonObject,
       outputColumnName: String = "DetectedEntities",
       detectionSensitivity: String = "LOW"): DynamicFrame
```

## Parameters:

- **frame** – (type: `DynamicFrame`): The input `DynamicFrame` containing the data to be processed.
- **detectionParameters** – (type: `JsonOptions`): JSON options specifying parameters for the detection process.
- **outputColumnName** – (type: `String`, default: "DetectedEntities"): The name of the column where detected entities will be stored. If not provided, the default column name is "DetectedEntities".
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW"): Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

## detectionParameters settings

If no settings are included, default values will be used.

- **action** – (type: `String`, options: "DETECT", "REDACT", "PARTIAL\_REDACT", "SHA256\_HASH") Specifies the action to be performed on the entity. Required. Note that actions that perform masking (all but "DETECT") can only perform one action per column. This is a preventative measure for masking coalesced entities.
- **sourceColumns** – (type: `List[String]`, default: ["\*"]) List of source column names to perform detection on for the entity. Defaults to ["\*"] if not present. Raises `IllegalArgumentException` if an invalid column name is used.
- **sourceColumnsToExclude** – (type: `List[String]`) List of source column names to to perform detection on for the entity. Use either `sourceColumns` or `sourceColumnsToExclude`. Raises `IllegalArgumentException` if an invalid column name is used.
- **actionOptions** – Additional options based on the specified action:
  - For "DETECT" and "SHA256\_HASH", no options are allowed.
  - For "REDACT":
    - **redactText** – (type: `String`, default: "\*\*\*\*\*") Text to replace the detected entity.
  - For "PARTIAL\_REDACT":
    - **redactChar** – (type: `String`, default: "\*") Character to replace each detected character in the entity.
    - **matchPattern** – (type: `String`) Regex pattern for partial redaction. Cannot be combined with `numLeftCharsToExclude` or `numRightCharsToExclude`.

- **numLeftCharsToExclude** – (type: `String`, `integer`) Number of left characters to exclude. Cannot be combined with `matchPattern`, but can be used with `numRightCharsToExclude`.
- **numRightCharsToExclude** – (type: `String`, `integer`) Number of right characters to exclude. Cannot be combined with `matchPattern`, but can be used with `numRightCharsToExclude`.

`outputColumnName` settings

[See `outputColumnName` settings](#)

## Detection Parameters for `classifyColumns()`

This method is used for detecting entities in a `DynamicFrame`. It returns a map where keys are column names and values are list of detected entity types. Custom masking can be done after this is returned within the AWS Glue script.

```
classifyColumns(frame: DynamicFrame,  
                entityTypeToDetect: Seq[String],  
                sampleFraction: Double = 0.1,  
                thresholdFraction: Double = 0.1,  
                detectionSensitivity: String = "LOW")
```

Parameters:

- **frame** – (type: `DynamicFrame`) The input `DynamicFrame` containing the data to be processed.
- **entityTypesToDetect** – (type: `Seq[String]`) List of entity types to detect. Can be either Managed Entity Types or Custom Entity Types.
- **sampleFraction** – (type: `Double`, default: 10%) The fraction of the data to sample when scanning for PII entities.
- **thresholdFraction** – (type: `Double`, default: 10%): The fraction of the data that must be met in order for a column to be identified as PII data.
- **detectionSensitivity** – (type: `String`, options: "LOW" or "HIGH", default: "LOW") Specifies the sensitivity of the detection process. Valid options are "LOW" or "HIGH". If not provided, the default sensitivity is set to "LOW".

## Managed Sensitive Data Types

### Global entities

Data Type	Category	Description
PERSON_NAME	Universal	The name of the person.
EMAIL	Personal	The email address.
IP_ADDRESS	Computer	The IP address
MAC_ADDRESS	Personal	The MAC address.

### US data types

Data Type	Description
BANK_ACCOUNT	The bank account number. Not specific to a country or region, however, only US and Canadian account formats are detected.
CREDIT_CARD	The credit card number.
PHONE_NUMBER	The phone number. Not specific to a country or region, however, only US and Canadian phone numbers are detected at this time.
USA_ATIN	The US Adoption Taxpayer Identification Number issued by the Internal Revenue Service.
USA_CPT_CODE	The CPT Code (US specific).
USA_DEA_NUMBER	The DEA number (US specific).
USA_DRIVING_LICENSE	The driver license number (US specific).
USA_HCPCS_CODE	The HCPCS code (US specific).

Data Type	Description
USA_HEALTH_INSURANCE_CLAIM_NUMBER	Health Insurance Claim Number (US specific).
USA_ITIN	The ITIN (for US persons or entities).
USA_MEDICARE_BENEFICIARY_IDENTIFIER	Medicare Beneficiary Identifier (US specific).
USA_NATIONAL_DRUG_CODE	The NDC code (US specific).
USA_NATIONAL_PROVIDER_IDENTIFIER	The National Provider Identifier number (US specific).
USA_PASSPORT_NUMBER	The passport number (for US persons).
USA_PTIN	The US Preparer Tax Identification Number issued by the Internal Revenue Service.
USA_SSN	The social security number (for US persons).

### Argentina data types

Data Type	Description
ARGENTINA_TAX_IDENTIFICATION_NUMBER	Argentina Tax Identification Number. Also known as CUIT or CUIL.

### Australian data types

Data Type	Description
AUSTRALIA_BUSINESS_NUMBER	Australia Business Number (ABN). A unique identifier issued by the Australian Business Register (ABR) to identify businesses to the government and community.

Data Type	Description
AUSTRALIA_COMPANY_NUMBER	Australia Company Number (ACN). Unique identifier issued by the Australian Securities and Investments Commission.
AUSTRALIA_DRIVING_LICENSE	A driver's license number for Australia.
AUSTRALIA_MEDICARE_NUMBER	Australian Medicare Number. Personal identifier issued by the Australian Health Insurance Commission.
AUSTRALIA_PASSPORT_NUMBER	Australian passport number.
AUSTRALIA_TAX_FILE_NUMBER	Australia Tax File Number (TFN). Issued by the Australian Taxation Office (ATO) to taxpayers (individual, company, etc) for tax dealings.

### Austria data types

Data Type	Description
AUSTRIA_DRIVING_LICENSE	The driver license number (Austria specific).
AUSTRIA_PASSPORT_NUMBER	The passport number (Austria specific).
AUSTRIA_SSN	The social security number (for Austria persons).
AUSTRIA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Austria specific).
AUSTRIA_VALUE_ADDED_TAX	Value-Added Tax (Austria specific).

### Balkans data types

Data Type	Description
BOSNIA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Bosnia-Herzegovina citizens.
KOSOVO_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Kosovo.
MACEDONIA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number for Macedonia.
MONTENEGRO_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Montenegro.
SERBIA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Serbia.
SERBIA_VALUE_ADDED_TAX	Value-Added Tax (Serbia specific).
VOJVODINA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Vojvodina.

### Belgium data types

Data Type	Description
BELGIUM_DRIVING_LICENSE	The driver license number (Belgium specific).
BELGIUM_NATIONAL_IDENTIFICATION_NUMBER	The Belgian National Number (BNN).
BELGIUM_PASSPORT_NUMBER	The passport number (Belgium specific).
BELGIUM_TAX_IDENTIFICATION_NUMBER	Tax identification number (Belgium specific).
BELGIUM_VALUE_ADDED_TAX	Value-Added Tax (Belgium specific).

### Brazil data types

Data Type	Description
BRAZIL_BANK_ACCOUNT	The bank account number (Brazil specific).
BRAZIL_NATIONAL_IDENTIFICATION_NUMBER	The national identifier (Brazil specific).
BRAZIL_NATIONAL_REGISTRY_OF_LEGAL_ENTITIES_NUMBER	The identification number issued to companies (Brazil specific), also known as the CNPJ.
BRAZIL_NATURAL_PERSON_REGISTRY_NUMBER	Natural Person Registry Number, also known as CPF.

### Bulgaria data types

Data Type	Description
BULGARIA_DRIVING_LICENSE	The driver license number (Bulgaria specific).
BULGARIA_UNIFORM_CIVIL_NUMBER	Unified Civil Number (EGN) that serves as a national identification number.
BULGARIA_VALUE_ADDED_TAX	Value-Added Tax (Bulgaria specific).

### Canada data types

Data Type	Description
CANADA_DRIVING_LICENSE	The driver license number (Canada specific).
CANADA_GOVERNMENT_IDENTIFICATION_CARD_NUMBER	The national identifier (Canada specific).
CANADA_PASSPORT_NUMBER	The passport number (Canada specific).
CANADA_PERMANENT_RESIDENCE_NUMBER	Permanent residence number (PR Card number).

Data Type	Description
CANADA_PERSONAL_HEALTH_NUMBER	The unique identifier for healthcare (PHN number).
CANADA_SOCIAL_INSURANCE_NUMBER	The social insurance number (SIN) in Canada.

### Chile data types

Data Type	Description
CHILE_DRIVING_LICENSE	The driver license number (Chile specific).
CHILE_NATIONAL_IDENTIFICATION_NUMBER	The Chile national identifier, also known as RUT or RUN.

### China, Hong Kong, Macau, and Taiwan data types

Data Type	Description
CHINA_IDENTIFICATION	The China identifier.
CHINA_LICENSE_PLATE_NUMBER	The driver license number (China specific).
CHINA_MAINLAND_TRAVEL_PERMIT_ID_HONG_KONG_MACAU	The Mainland Travel Permit for Hong Kong and Macao Residents.
CHINA_MAINLAND_TRAVEL_PERMIT_ID_TAIWAN	The Mainland Travel Permit for Taiwan Residents issued by Government of the People's Republic of China (PRC).
CHINA_PASSPORT_NUMBER	The passport number (China specific).
CHINA_PHONE_NUMBER	The phone number (China specific).
HONG_KONG_IDENTITY_CARD	The official identity document issued by the Immigration Department of Hong Kong.

Data Type	Description
MACAU_RESIDENT_IDENTITY_CARD	The Macau Resident Identity Card or BIR is an official identity card issued by the Identification Services Bureau of Macau.
TAIWAN_NATIONAL_IDENTIFICATION_NUMBER	The national identifier (Taiwan specific).
TAIWAN_PASSPORT_NUMBER	The passport number (Taiwan specific).

### Colombia data types

Data Type	Description
COLOMBIA_PERSONAL_IDENTIFICATION_NUMBER	Unique identifier assigned to Colombians at birth.
COLOMBIA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Colombia specific).

### Croatia data types

Data Type	Description
CROATIA_DRIVING_LICENSE	The driver license number (Croatia specific).
CROATIA_IDENTITY_NUMBER	The national identifier (Croatia specific).
CROATIA_PASSPORT_NUMBER	The passport number (Croatia specific).
CROATIA_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (OIB).

### Cyprus data types

Data Type	Description
CYPRUS_DRIVING_LICENSE	The driver license number (Cyprus specific).
CYPRUS_NATIONAL_IDENTIFICATION_NUMBER	The Cypriot identity card.
CYPRUS_PASSPORT_NUMBER	The passport number (Cyprus specific).
CYPRUS_TAX_IDENTIFICATION_NUMBER	Tax identification number (Cyprus specific).
CYPRUS_VALUE_ADDED_TAX	Value-Added Tax (Cyprus specific).

### Czechia data types

Data Type	Description
CZECHIA_DRIVING_LICENSE	The driver license number (Czechia specific).
CZECHIA_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (Czechia specific).
CZECHIA_VALUE_ADDED_TAX	Value-Added Tax (Czechia specific).

### Denmark data types

Data Type	Description
DENMARK_DRIVING_LICENSE	The driver license number (Denmark specific).
DENMARK_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (Denmark specific).
DENMARK_TAX_IDENTIFICATION_NUMBER	Tax identification number (Denmark specific).
DENMARK_VALUE_ADDED_TAX	Value-Added Tax (Denmark specific).

## Estonia data types

Data Type	Description
ESTONIA_DRIVING_LICENSE	The driver license number (Estonia specific).
ESTONIA_PASSPORT_NUMBER	The passport number (Estonia specific).
ESTONIA_PERSONAL_IDENTIFICATION_CODE	The personal identifier number (Estonia specific).
ESTONIA_VALUE_ADDED_TAX	Value-Added Tax (Estonia specific).

## Finland data types

Data Type	Description
FINLAND_DRIVING_LICENSE	The driver license number (Finland specific).
FINLAND_HEALTH_INSURANCE_NUMBER	The health insurance number (Finland specific) .
FINLAND_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Finland specific).
FINLAND_PASSPORT_NUMBER	The passport number (Finland specific).
FINLAND_VALUE_ADDED_TAX	Value-Added Tax (Finland specific).

## France data types

Data Type	Description
FRANCE_BANK_ACCOUNT	The bank account number (France specific).
FRANCE_DRIVING_LICENSE	The driver license number (France specific).
FRANCE_HEALTH_INSURANCE_NUMBER	France health insurance number.

Data Type	Description
FRANCE_INSEE_CODE	France social security, SSN, or NIR number.
FRANCE_NATIONAL_IDENTIFICATION_NUMBER	France national identifier number (CNI).
FRANCE_PASSPORT_NUMBER	The passport number (France specific).
FRANCE_TAX_IDENTIFICATION_NUMBER	Tax identification number (France specific).
FRANCE_VALUE_ADDED_TAX	Value-Added Tax (France specific).

### Germany data types

Data Type	Description
GERMANY_BANK_ACCOUNT	The bank account number (Germany specific).
GERMANY_DRIVING_LICENSE	The driver license number (Germany specific).
GERMANY_PASSPORT_NUMBER	The passport number (Germany specific).
GERMANY_PERSONAL_IDENTIFICATION_NUMBER	The personal identification number (Germany specific).
GERMANY_TAX_IDENTIFICATION_NUMBER	Tax identification number (Germany specific).
GERMANY_VALUE_ADDED_TAX	Value-Added Tax (Germany specific).

### Greece data types

Data Type	Description
GREECE_DRIVING_LICENSE	The driver license number (Greece specific).
GREECE_PASSPORT_NUMBER	The passport number (Greece specific).

Data Type	Description
GREECE_SSN	The social security number (for Greece persons).
GREECE_TAX_IDENTIFICATION_NUMBER	Tax identification number (Greece specific).
GREECE_VALUE_ADDED_TAX	Value-Added Tax (Greece specific).

### Hungary data types

Data Type	Description
HUNGARY_DRIVING_LICENSE	The driver license number (Hungary specific).
HUNGARY_PASSPORT_NUMBER	The passport number (Hungary specific).
HUNGARY_SSN	The social security number (for Hungary persons).
HUNGARY_TAX_IDENTIFICATION_NUMBER	Tax identification number (Hungary specific).
HUNGARY_VALUE_ADDED_TAX	Value-Added Tax (Hungary specific).

### Iceland data types

Data Type	Description
ICELAND_NATIONAL_IDENTIFICATION_NUMBER	The national identifier (Iceland specific).
ICELAND_PASSPORT_NUMBER	The passport number (Iceland specific).
ICELAND_VALUE_ADDED_TAX	Value-Added Tax (Iceland specific).

### India data types

Data Type	Description
INDIA_AADHAAR_NUMBER	Aadhaar identification number issued by the Unique Identification Authority of India.
INDIA_PERMANENT_ACCOUNT_NUMBER	India Permanent Account Number (PAN).

### Indonesia data types

Data Type	Description
INDONESIA_IDENTITY_CARD_NUMBER	The national identifier (Indonesia specific).

### Ireland data types

Data Type	Description
IRELAND_DRIVING_LICENSE	The driver license number (Ireland specific).
IRELAND_PASSPORT_NUMBER	The passport number (Ireland specific).
IRELAND_PERSONAL_PUBLIC_SERVICE_NUMBER	Ireland personal public service number (PPS).
IRELAND_TAX_IDENTIFICATION_NUMBER	Tax identification number (Ireland specific).
IRELAND_VALUE_ADDED_TAX	Value-Added Tax (Ireland specific).

### Israel data types

Data Type	Description
ISRAEL_IDENTIFICATION_NUMBER	The national identifier (Israel specific).

### Italy data types

Data Type	Description
ITALY_BANK_ACCOUNT	The bank account number (Italy specific).
ITALY_DRIVING_LICENSE	The driver license number (Italy specific).
ITALY_FISCAL_CODE	The identifier number, also known as the Italian Codice Fiscale.
ITALY_PASSPORT_NUMBER	The passport number (Italy specific).
ITALY_VALUE_ADDED_TAX	Value-Added Tax (Italy specific).

### Japan data types

Data Type	Description
JAPAN_BANK_ACCOUNT	Japan bank account.
JAPAN_DRIVING_LICENSE	A driver's license number for Japan.
JAPAN_MY_NUMBER	The unique identifier for Japan citizens or corporations used for tax administration, social security administration, and disaster response
JAPAN_PASSPORT_NUMBER	Japan passport number.

### Korea data types

Data Type	Description
KOREA_PASSPORT_NUMBER	The passport number (Korea specific).
KOREA_RESIDENCE_REGISTRATION_NUMBER_FOR_CITIZENS	Korea residence registrant number for residents.

Data Type	Description
KOREA_RESIDENCE_REGISTRATIO N_NUMBER_FOR_FOREIGNERS	Korea residence registrant number for foreigners.

### Latvia data types

Data Type	Description
LATVIA_DRIVING_LICENSE	The driver license number (Latvia specific).
LATVIA_PASSPORT_NUMBER	The passport number (Latvia specific).
LATVIA_PERSONAL_IDENTIFICATION_NUMBE R	The personal identifier number (Latvia specific).
LATVIA_VALUE_ADDED_TAX	Value-Added Tax (Latvia specific).

### Liechtenstein data types

Data Type	Description
LIECHTENSTEIN_NATIONAL_IDENTIFICATIO N_NUMBER	The national identifier (Liechtenstein specific).
LIECHTENSTEIN_PASSPORT_NUMBER	The passport number (Liechtenstein specific).
LIECHTENSTEIN_TAX_IDENTIFICATION_NUM BER	Tax identification number (Liechtenstein specific).

### Lithuania data types

Data Type	Description
LITHUANIA_DRIVING_LICENSE	The driver license number (Lithuania specific).

Data Type	Description
LITHUANIA_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (Lithuania specific).
LITHUANIA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Lithuania specific).
LITHUANIA_VALUE_ADDED_TAX	Value-Added Tax (Lithuania specific).

### Luxembourg data types

Data Type	Description
LUXEMBOURG_DRIVING_LICENSE	The driver license number (Luxembourg specific).
LUXEMBOURG_NATIONAL_INDIVIDUAL_NUMBER	The national identifier (Luxembourg specific).
LUXEMBOURG_PASSPORT_NUMBER	The passport number (Luxembourg specific).
LUXEMBOURG_TAX_IDENTIFICATION_NUMBER	Tax identification number (Luxembourg specific).
LUXEMBOURG_VALUE_ADDED_TAX	Value-Added Tax (Luxembourg specific).

### Malaysia data types

Data Type	Description
MALAYSIA_MYKAD_NUMBER	The national identifier (Malaysia specific).
MALAYSIA_PASSPORT_NUMBER	The passport number (Malaysia specific).

### Malta data types

Data Type	Description
MALTA_DRIVING_LICENSE	The driver license number (Malta specific).
MALTA_NATIONAL_IDENTIFICATION_NUMBER	The national identifier (Malta specific).
MALTA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Malta specific).
MALTA_VALUE_ADDED_TAX	Value-Added Tax (Malta specific).

### Mexico data types

Data Type	Description
MEXICO_CLABE_NUMBER	Mexico CLABE (Clave Bancaria Estandarizada) bank number).
MEXICO_DRIVING_LICENSE	The driver license number (Mexico specific).
MEXICO_PASSPORT_NUMBER	The passport number (Mexico specific).
MEXICO_TAX_IDENTIFICATION_NUMBER	Tax identification number (Mexico specific).
MEXICO_UNIQUE_POPULATION_REGISTER_CODE	The Clave Única de Registro de Población (CURP) unique identity code for Mexico.

### Netherlands data types

Data Type	Description
NETHERLANDS_CITIZEN_SERVICE_NUMBER	Netherlands citizen number (BSN, burgerservicenummer).
NETHERLANDS_DRIVING_LICENSE	The driver license number (Netherlands specific).
NETHERLANDS_PASSPORT_NUMBER	The passport number (Netherlands specific).

Data Type	Description
NETHERLANDS_TAX_IDENTIFICATION_NUMBER	Tax identification number (Netherlands specific).
NETHERLANDS_VALUE_ADDED_TAX	Value-Added Tax (Netherlands specific).
NETHERLANDS_BANK_ACCOUNT	The bank account number (Netherlands specific).

### New Zealand data types

Data Type	Description
NEW_ZEALAND_DRIVING_LICENSE	The driver license number (New Zealand specific).
NEW_ZEALAND_NATIONAL_HEALTH_INDEX_NUMBER	New Zealand national health index number.
NEW_ZEALAND_TAX_IDENTIFICATION_NUMBER	Tax identification number, also known as inland revenue number (New Zealand specific).

### Norway data types

Data Type	Description
NORWAY_BIRTH_NUMBER	Norwegian national identity number.
NORWAY_DRIVING_LICENSE	The driver license number (Norway specific).
NORWAY_HEALTH_INSURANCE_NUMBER	Norway health insurance number.
NORWAY_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Norway specific).
NORWAY_VALUE_ADDED_TAX	Value-Added Tax (Norway specific).

## Philippines data types

Data Type	Description
PHILIPPINES_DRIVING_LICENSE	The driver license number (Philippines specific)
PHILIPPINES_PASSPORT_NUMBER	The passport number (Philippines specific).

## Poland data types

Data Type	Description
POLAND_DRIVING_LICENSE	The driver license number (Poland specific).
POLAND_IDENTIFICATION_NUMBER	The Poland identifier.
POLAND_PASSPORT_NUMBER	The passport number (Poland specific).
POLAND_REGON_NUMBER	The REGON identifier number, also known as the Statistical Identification Number.
POLAND_SSN	The social security number (for Poland persons).
POLAND_TAX_IDENTIFICATION_NUMBER	Tax identification number (Poland specific).
POLAND_VALUE_ADDED_TAX	Value-Added Tax (Poland specific).

## Portugal data types

Data Type	Description
PORTUGAL_DRIVING_LICENSE	The driver license number (Portugal specific).
PORTUGAL_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Portugal specific).

Data Type	Description
PORTUGAL_PASSPORT_NUMBER	The passport number (Portugal specific).
PORTUGAL_TAX_IDENTIFICATION_NUMBER	Tax identification number (Portugal specific).
PORTUGAL_VALUE_ADDED_TAX	Value-Added Tax (Portugal specific).

### Romania data types

Data Type	Description
ROMANIA_DRIVING_LICENSE	The driver license number (Romania specific).
ROMANIA_NUMERICAL_PERSONAL_CODE	The personal identifier number (Romania specific).
ROMANIA_PASSPORT_NUMBER	The passport number (Romania specific).
ROMANIA_VALUE_ADDED_TAX	Value-Added Tax (Romania specific).

### Singapore data types

Data Type	Description
SINGAPORE_DRIVING_LICENSE	The driver license number (Singapore specific).
SINGAPORE_NATIONAL_REGISTRY_IDENTIFICATION_NUMBER	The national registration identity card for Singapore.
SINGAPORE_PASSPORT_NUMBER	The passport number (Singapore specific).
SINGAPORE_UNIQUE_ENTITY_NUMBER	The Unique Entity Number for Singapore.

### Slovakia data types

Data Type	Description
SLOVAKIA_DRIVING_LICENSE	The driver license number (Slovakia specific).
SLOVAKIA_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Slovakia specific).
SLOVAKIA_PASSPORT_NUMBER	The passport number (Slovakia specific).
SLOVAKIA_VALUE_ADDED_TAX	Value-Added Tax (Slovakia specific).

### Slovenia data types

Data Type	Description
SLOVENIA_DRIVING_LICENSE	The driver license number (Slovenia specific).
SLOVENIA_PASSPORT_NUMBER	The passport number (Slovenia specific).
SLOVENIA_TAX_IDENTIFICATION_NUMBER	Tax identification number (Slovenia specific).
SLOVENIA_UNIQUE_MASTER_CITIZEN_NUMBER	Unique master citizen number (JMBG) for Slovenia citizens.
SLOVENIA_VALUE_ADDED_TAX	Value-Added Tax (Slovenia specific).

### South Africa data types

Data Type	Description
SOUTH_AFRICA_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (South Africa specific).

### Spain data types

Data Type	Description
SPAIN_BANK_ACCOUNT	The bank account number (Spain specific).
SPAIN_DNI	The national identity card (Documento Nacional de Identidad) of Spain.
SPAIN_DRIVING_LICENSE	The driver license number (Spain specific).
SPAIN_NIE	The foreigner identity number (Spain specific), also known as the NIE.
SPAIN_NIF	Tax identification number (Spain specific), also known as the NIF.
SPAIN_PASSPORT_NUMBER	The passport number (Spain specific).
SPAIN_SSN	The social security number (for Spain persons).
SPAIN_VALUE_ADDED_TAX	Value-Added Tax (Spain specific).

### Sri Lanka data types

Data Type	Description
SRI_LANKA_NATIONAL_IDENTIFICATION_NUMBER	The national identifier (Sri Lanka specific).

### Sweden data types

Data Type	Description
SWEDEN_DRIVING_LICENSE	The driver license number (Sweden specific).
SWEDEN_PASSPORT_NUMBER	The passport number (Sweden specific).
SWEDEN_PERSONAL_IDENTIFICATION_NUMBER	The national identifier number (Sweden specific).

Data Type	Description
SWEDEN_TAX_IDENTIFICATION_NUMBER	Sweden tax identification number (personnummer).
SWEDEN_VALUE_ADDED_TAX	Value-Added Tax (Sweden specific).

### Switzerland data types

Data Type	Description
SWITZERLAND_AHV	The social security number for Swiss persons (AHV).
SWITZERLAND_HEALTH_INSURANCE_NUMBER	Swiss health insurance number.
SWITZERLAND_PASSPORT_NUMBER	The passport number (Switzerland specific).
SWITZERLAND_VALUE_ADDED_TAX	Value-Added Tax (Switzerland specific).

### Thailand data types

Data Type	Description
THAILAND_PASSPORT_NUMBER	The passport number (Thailand specific).
THAILAND_PERSONAL_IDENTIFICATION_NUMBER	The personal identifier number (Thailand specific).

### Turkey data types

Data Type	Description
TURKEY_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Turkey specific).

Data Type	Description
TURKEY_PASSPORT_NUMBER	The passport number (Turkey specific).
TURKEY_VALUE_ADDED_TAX	Value-Added Tax (Turkey specific).

### Ukraine data types

Data Type	Description
UKRAINE_INDIVIDUAL_IDENTIFICATION_NUMBER	The unique identifier (Ukraine specific).
UKRAINE_PASSPORT_NUMBER_DOMESTIC	The domestic passport number (Ukraine specific).
UKRAINE_PASSPORT_NUMBER_INTERNATIONAL	The international passport number (Ukraine specific).

### United Arab Emirates (UAE) data types

Data Type	Description
UNITED_ARAB_EMIRATES_PERSONAL_NUMBER	The personal identifier number (UAE specific).

### UK data types

Data Type	Description
UK_BANK_ACCOUNT	United Kingdom (UK) bank account.
UK_BANK_SORT_CODE	United Kingdom (UK) bank sort code. Sort codes are bank codes used to route money transfers between banks within their respective

Data Type	Description
	e countries via their respective clearance organizations.
UK_DRIVING_LICENSE	The driver's license number for the United Kingdom of Great Britain and Northern Ireland (UK specific)
UK_ELECTORAL_ROLL_NUMBER	The Electoral Roll Number (ERN) is the identification number issued to an individual for UK election registration. The format of this number is specified by the UK Government Standards of the UK Cabinet Office.
UK_NATIONAL_HEALTH_SERVICE_NUMBER	The National Health Service (NHS) number is the unique number allocated to a registered user of public health services in the United Kingdom.
UK_NATIONAL_INSURANCE_NUMBER	The National Insurance number (NINO) is a number used in the United Kingdom (UK) to identify an individual for the national insurance program or social security system. The number is sometimes referred to as NI No or NINO.
UK_PASSPORT_NUMBER	United Kingdom (UK) passport number.
UK_UNIQUE_TAXPAYER_REFERENCE_NUMBER	The United Kingdom (UK) Unique Taxpayer Reference (UTR) number. An identifier used by the UK government to manage the taxation system.

Data Type	Description
UK_VALUE_ADDED_TAX	VAT is a consumption tax that is borne by the end consumer. VAT is paid for each transaction in the manufacturing and distribution process. For the United Kingdom, the VAT number is issued by the VAT office for the region in which the business is established.
UK_PHONE_NUMBER	United Kingdom (UK) phone number.

### Venezuela data types

Data Type	Description
VENEZUELA_DRIVING_LICENSE	The driver license number (Venezuela specific).
VENEZUELA_NATIONAL_IDENTIFICATION_NUMBER	The national identifier number (Venezuela specific).
VENEZUELA_VALUE_ADDED_TAX	Value-Added Tax (Venezuela specific).

### Using fine-grained sensitive data detection

#### Note

Fine-grained actions is only available in AWS Glue 3.0 and 4.0. This includes the AWS Glue Studio experience. The persistent audit log changes are also not available in 2.0. All AWS Glue Studio 3.0 and 4.0 visual jobs will have a script created that automatically uses fine-grained actions APIs.

The Detect Sensitive Data transform provides the ability to detect, mask, or remove entities that you define, or are pre-defined by AWS Glue. Fine-grained actions further allows you to apply a specific action per entity. Additional benefits include:

- Improved performance as actions are being applied as soon data is detected.

- The option to include or exclude specific columns.
- The ability to use partial masking. This allows you to mask detected sensitive data entities partially, rather than masking the entire string. Both simple params with offsets and regex are supported.

The following are code snippets of sensitive data detection APIs and fine-grained actions used in the sample jobs referenced in the next section.

**Detect API** – fine-grained actions use the new `detectionParameters` parameter:

```
def detect(  
  frame: DynamicFrame,  
  detectionParameters: JsonOptions,  
  outputColumnName: String = "DetectedEntities",  
  detectionSensitivity: String = "LOW"  
): DynamicFrame = {}
```

## Using Sensitive Data Detection APIs with fine-grained actions

Sensitive data detection APIs using **detect** analyzes the data given, determines if the rows or columns are Sensitive Data Entity Types, and will run actions specified by the user for each Entity type.

## Using the detect API with fine-grained actions

Use the **detect** API and specify the `outputColumnName` and `detectionParameters`.

```
object GlueApp {  
  def main(sysArgs: Array[String]) {  
  
    val spark: SparkContext = new SparkContext()  
    val glueContext: GlueContext = new GlueContext(spark)  
  
    // @params: [JOB_NAME]  
    val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME").toArray)  
    Job.init(args("JOB_NAME"), glueContext, args.asJava)  
  
    // Script generated for node S3 bucket. Creates DataFrame from data stored in  
    S3.
```

```

    val S3bucket_node1 =
glueContext.getSourceWithFormat(formatOptions=JsonOptions("""{"quoteChar":
"\\"", "withHeader": true, "separator": ",", "optimizePerformance": false}"""),
connectionType="s3", format="csv", options=JsonOptions("""{"paths":
["s3://189657479688-ddevansh-pii-test-bucket/tiny_pii.csv"], "recurse": true}"""),
transformationContext="S3bucket_node1").getDynamicFrame()

    // Script generated for node Detect Sensitive Data. Will run detect API for the
DataFrame
    // detectionParameter contains information on which EntityType are being
detected
    // and what actions are being applied to them when detected.
val DetectSensitiveData_node2 = EntityDetector.detect(
    frame = S3bucket_node1,
    detectionParameters = JsonOptions(
        """
        {
            "PHONE_NUMBER": [
                {
                    "action": "PARTIAL_REDACT",
                    "actionOptions": {
                        "numLeftCharsToExclude": "3",
                        "numRightCharsToExclude": "4",
                        "redactChar": "#"
                    },
                    "sourceColumnsToExclude": [ "Passport No", "DL NO#" ]
                }
            ],
            "USA_PASSPORT_NUMBER": [
                {
                    "action": "SHA256_HASH",
                    "sourceColumns": [ "Passport No" ]
                }
            ],
            "USA_DRIVING_LICENSE": [
                {
                    "action": "REDACT",
                    "actionOptions": {
                        "redactText": "USA_DL"
                    },
                    "sourceColumns": [ "DL NO#" ]
                }
            ]
        }
        """
    )
)

```

```
        }
        ""
    ),
    outputColumnName = "DetectedEntities"
)

// Script generated for node S3 bucket. Store Results of detect to S3 location
val S3bucket_node3 = glueContext.getSinkWithFormat(connectionType="s3",
options=JsonOptions("""{"path": "s3://189657479688-ddevansh-pii-test-bucket/
test-output/", "partitionKeys": []}"""), transformationContext="S3bucket_node3",
format="json").writeDynamicFrame(DetectSensitiveData_node2)

Job.commit()
}
```

The above script will create a DataFrame from a location in Amazon S3 and then it will run the detect API. Since the detect API requires the field `detectionParameters` (a map of the entity name to a list all of the action settings to be used for that entity) is represented by AWS Glue's `JsonOptions` object, it will also allow us to extend the functionality of the API.

For each action specified per entity, enter a list of all column names to which to apply the entity/action combination. This allows you to customize the entities to detect for every column in your dataset and skip entities that you know are not in a specific column. This also allows your jobs to be more performant by not performing unnecessary detection calls those entities and allows you to perform actions unique to each column and entity combination.

Taking a closer look at the `detectionParameters`, there are three entity types in the sample job. These are `Phone Number`, `USA_PASSPORT_NUMBER`, and `USA_DRIVING_LICENSE`. For each of these entity types AWS Glue will run different actions which are either `PARTIAL_REDACT`, `SHA256_HASH`, `REDACT`, and `DETECT`. Each of the Entity Types also have `sourceColumns` to apply to and/or `sourceColumnsToExclude` if detected.

#### Note

Only one edit-in-place action (`PARTIAL_REDACT`, `SHA256_HASH`, or `REDACT`) can be used per column but the `DETECT` action can be used with any of these actions.

The `detectionParameters` field has the below layout:

```

ENTITY_NAME -> List[Actions]
{
  "ENTITY_NAME": [{
    Action, // required
    ColumnSpecs,
    ActionOptionsMap
  }],
  "ENTITY_NAME2": [{
    ...
  }]
}

```

The types of actions and actionOptions are listed below:

```

DETECT
{
  # Required
  "action": "DETECT",
  # Optional, depending on action chosen
  "actionOptions": {
    // There are no actionOptions for DETECT
  },
  # 1 of below required, both can also used
  "sourceColumns": [
    "COL_1", "COL_2", ..., "COL_N"
  ],
  "sourceColumnsToExclude": [
    "COL_5"
  ]
}

SHA256_HASH
{
  # Required
  "action": "SHA256_HASH",
  # Required or optional, depending on action chosen
  "actionOptions": {
    // There are no actionOptions for SHA256_HASH
  },

  # 1 of below required, both can also used

```

```

"sourceColumns": [
    "COL_1", "COL_2", ..., "COL_N"
],
"sourceColumnsToExclude": [
    "COL_5"
]
}

```

#### REDACT

```

{
    # Required
    "action": "REDACT",
    # Required or optional, depending on action chosen
    "actionOptions": {
        // The text that is being replaced
        "redactText": "USA_DL"
    },

    # 1 of below required, both can also used
    "sourceColumns": [
        "COL_1", "COL_2", ..., "COL_N"
    ],
    "sourceColumnsToExclude": [
        "COL_5"
    ]
}

```

#### PARTIAL\_REDACT

```

{
    # Required
    "action": "PARTIAL_REDACT",
    # Required or optional, depending on action chosen
    "actionOptions": {
        // number of characters to not redact from the left side
        "numLeftCharsToExclude": "3",
        // number of characters to not redact from the right side
        "numRightCharsToExclude": "4",
        // the partial redact will be made with this redacted character
        "redactChar": "#",
        // regex pattern for partial redaction
        "matchPattern": "[0-9]"
    },

    # 1 of below required, both can also used

```

```

"sourceColumns": [
  "COL_1", "COL_2", ..., "COL_N"
],
"sourceColumnsToExclude": [
  "COL_5"
]
}

```

Once the script runs, results are output to the given Amazon S3 location. You can view your data in Amazon S3 but with the selected entity types being sensitized based on the selected action. In the case, we would have a rows that would have that looked like this:

```

{
  "Name": "Colby Schuster",
  "Address": "39041 Antonietta Vista, South Rodgerside, Nebraska 24151",
  "Car Owned": "Fiat",
  "Email": "Kitty46@gmail.com",
  "Company": "O'Reilly Group",
  "Job Title": "Dynamic Functionality Facilitator",
  "ITIN": "991-22-2906",
  "Username": "Cassandre.Kub43",
  "SSN": "914-22-2906",
  "DOB": "2020-08-27",
  "Phone Number": "1-2#####1718",
  "Bank Account No": "69741187",
  "Credit Card Number": "6441-6289-6867-2162-2711",
  "Passport No": "94f311e93a623c72ccb6fc46cf5f5b0265ccb42c517498a0f27fd4c43b47111e",
  "DL NO#": "USA_DL"
}

```

In the above script, the Phone Number was partially redacted with #. The Passport No was changed into a SHA256 hash. The DL NO# was detected as a USA driver license number and was redacted to "USA\_DL" just like it was stated in the detectionParameters.

### Note

The classifyColumns API is not available for use with fine-grained actions due to the nature of the API. This API performs column sampling (adjustable by the user but has default

values) to perform detection more quickly. Fine-grained actions require iterating over every value for this reason.

## Persistent Audit Log

A new feature introduced with fine-grained actions (but also available when using the normal APIs) is the presence of a persistent audit log. Currently, running the detect API adds an additional column (defaults to `DetectedEntities` but customizable through the `outputColumnName` parameter with PII detection metadata. This now has an "actionUsed" metadata key, which is one of `DETECT`, `PARTIAL_REDACT`, `SHA256_HASH`, `REDACT`.

```
"DetectedEntities": {
  "Credit Card Number": [
    {
      "entityType": "CREDIT_CARD",
      "actionUsed": "DETECT",
      "start": 0,
      "end": 19
    }
  ],
  "Phone Number": [
    {
      "entityType": "PHONE_NUMBER",
      "actionUsed": "REDACT",
      "start": 0,
      "end": 14
    }
  ]
}
```

Even customers using APIs without fine-grained actions such as `detect(entityTypesToDetect, outputColumnName)` will see this persistent audit log in the resulting dataframe.

Customers using APIs with fine-grained actions will see all of the actions, regardless of if they are redacted or not. Example:

```

+-----+-----
+-----
+
| Credit Card Number | Phone Number |
|                               | DetectedEntities |
+-----+-----
+-----
+
| 622126741306XXXX | +12#####7890 | {"Credit Card Number":
[{"entityType":"CREDIT_CARD","actionUsed":"PARTIAL_REDACT","start":0,"end":16}], "Phone
Number":
[{"entityType":"PHONE_NUMBER","actionUsed":"PARTIAL_REDACT","start":0,"end":12}]} |
| 6221 2674 1306 XXXX | +12#####7890 | {"Credit Card Number":
[{"entityType":"CREDIT_CARD","actionUsed":"PARTIAL_REDACT","start":0,"end":19}], "Phone
Number":
[{"entityType":"PHONE_NUMBER","actionUsed":"PARTIAL_REDACT","start":0,"end":14}]} |
| 6221-2674-1306-XXXX | 22#####7890 | {"Credit Card Number":
[{"entityType":"CREDIT_CARD","actionUsed":"PARTIAL_REDACT","start":0,"end":19}], "Phone
Number":
[{"entityType":"PHONE_NUMBER","actionUsed":"PARTIAL_REDACT","start":0,"end":14}]} |
+-----+-----
+-----
+

```

If you do not want to see the **DetectedEntities** column, you can simply drop the additional column in a custom script.

## AWS Glue Visual Job API

AWS Glue provides an API that allows customers to create data integration jobs using the AWS Glue API from a JSON object that represents a visual step workflow. Customers can then use the visual editor in AWS Glue Studio to work with these jobs.

For more information on Visual Job API data types, see [Visual Job API](#).

### Topics

- [API design and CRUD APIs](#)
- [Getting started](#)
- [Visual job limitations](#)

## API design and CRUD APIs

The `CreateJob` and `UpdateJob` [APIs](#) now support an additional optional parameter, `codeGenConfigurationNodes`. Providing a non-empty JSON structure for this field will result in the DAG being registered in AWS Glue Studio for the created job and the associated code being generated. A null value or empty string for this field on job create will be ignored.

Updates to the `codeGenConfigurationNodes` field will be done through the `UpdateJob` AWS Glue API in a similar way as `CreateJob`. The entire field should be specified in `UpdateJob` where the DAG has been changed as desired. A null value provided will be ignored and no update to the DAG would be performed. An empty structure or string will cause the `codeGenConfigurationNodes` to be set as empty and any previous DAG removed. The `GetJob` API will return a DAG if one exists. The `DeleteJob` API will also delete any associated DAG.

### Getting started

To create a job, use the [CreateJob action](#). The `CreateJob` request input will have an additional field 'codeGenConfigurationNodes' where you can get specify the DAG object in JSON.

Things to keep in mind:

- The 'codeGenConfigurationNodes' field is a map of `nodeId` to node.
- Each node begins with a key identifying what kind of node it is.
- There can only be one key specified since a node can only be of one type.
- The input field contains the parent nodes of the current node.

The following is a JSON representation of a **CreateJob** input.

```
{
  "node-1": {
    "S3CatalogSource": {
      "Table": "csvFormattedTable",
      "PartitionPredicate": "",
      "Name": "S3 bucket",
      "AdditionalOptions": {},
      "Database": "myDatabase"
    }
  },
  "node-3": {
    "S3DirectTarget": {
```

        "FromPath": ["myheader2"]
      },
      {
        "FromType": "long",
        "ToType": "long",
        "Dropped": false,
        "ToKey": "myheader3",
        "FromPath": ["myheader3"]
      }
    ]
  }
}
```

## Updating and getting jobs

Since *UpdateJob* will also have a 'codegenConfigurationNodes' field, the input format will be the same. See [UpdateJob](#) Action.

The *GetJob* action will return a 'codegenConfigurationNodes' field in the same format as well. See [GetJob](#) Action.

### Visual job limitations

Since the 'codegenConfigurationNodes' parameter has been added to existing APIs, any limitations in those APIs will be inherited. In addition, the codegenConfigurationNodes and some nodes will be limited in size. See [Job Structure](#) for more information.

## Programming Ray scripts

AWS Glue makes it easy to write and run Ray scripts. This section describes the supported Ray capabilities that are available in AWS Glue for Ray. You program Ray scripts in Python.

Your custom script must be compatible with the version of Ray that's defined by the `Runtime` field in your job definition. For more information about `Runtime` in the Jobs API, see [the section called "Jobs"](#). For information about each runtime environment, see [the section called "Supported Ray runtime environments"](#).

### Topics

- [Tutorial: Writing an ETL script in AWS Glue for Ray](#)
- [Using Ray Core and Ray Data in AWS Glue for Ray](#)
- [Providing files and Python libraries to Ray jobs](#)
- [Connecting to data in Ray jobs](#)

## Tutorial: Writing an ETL script in AWS Glue for Ray

Ray gives you the ability to write and scale distributed tasks natively in Python. AWS Glue for Ray offers serverless Ray environments that you can access from both jobs and interactive sessions (Ray interactive sessions are in preview). The AWS Glue job system provides a consistent way to manage and run your tasks—on a schedule, from a trigger, or from the AWS Glue console.

Combining these AWS Glue tools creates a powerful toolchain that you can use for extract, transform, and load (ETL) workloads, a popular use case for AWS Glue. In this tutorial, you will learn the basics of putting together this solution.

We also support using AWS Glue for Spark for your ETL workloads. For a tutorial on writing a AWS Glue for Spark script, see [the section called “Tutorial: Writing a Spark script”](#). For more information about available engines, see [the section called “AWS Glue for Spark and AWS Glue for Ray”](#). Ray is capable of addressing many different kinds of tasks in analytics, machine learning (ML), and application development.

In this tutorial, you will extract, transform, and load a CSV dataset that is hosted in Amazon Simple Storage Service (Amazon S3). You will begin with the New York City Taxi and Limousine Commission (TLC) Trip Record Data Dataset, which is stored in a public Amazon S3 bucket. For more information about this dataset, see the [Registry of Open Data on AWS](#).

You will transform your data with predefined transforms that are available in the Ray Data library. Ray Data is a dataset preparation library designed by Ray and included by default in AWS Glue for Ray environments. For more information about libraries included by default, see [the section called “Modules provided with Ray jobs”](#). You will then write your transformed data to an Amazon S3 bucket that you control.

**Prerequisites** – For this tutorial, you need an AWS account with access to AWS Glue and Amazon S3.

## Step 1: Create a bucket in Amazon S3 to hold your output data

You will need an Amazon S3 bucket that you control to serve as a sink for data created in this tutorial. You can create this bucket with the following procedure.

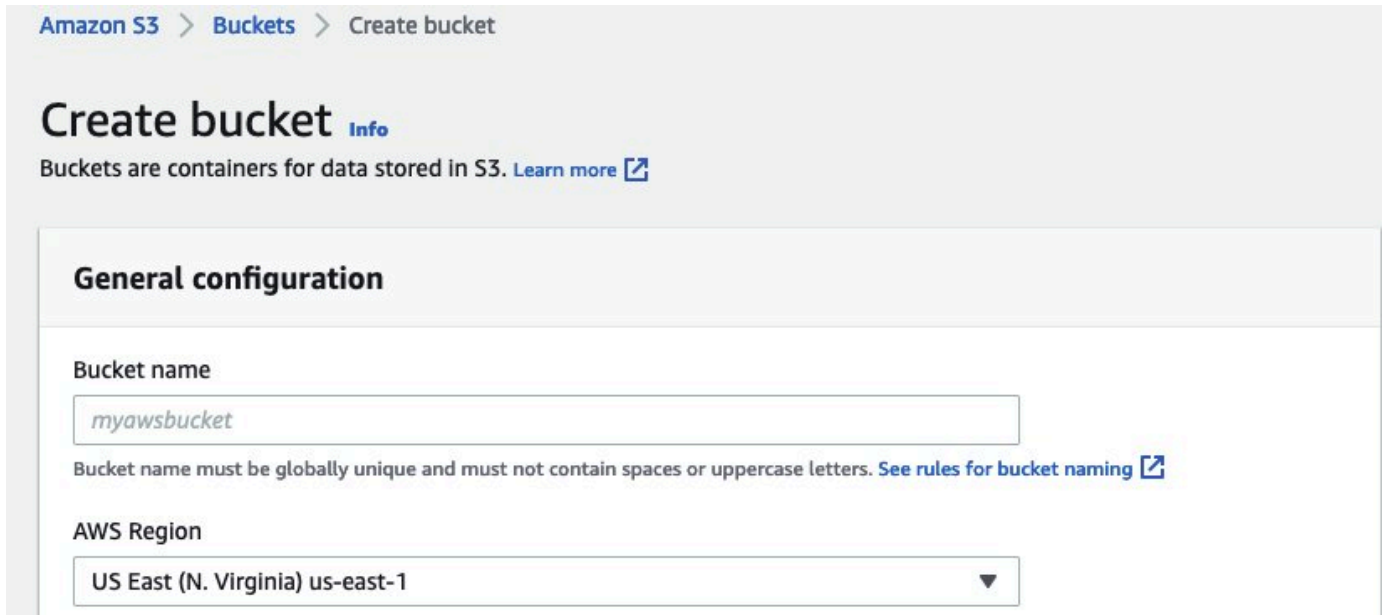

### Note

If you want to write your data to an existing bucket that you control, you can skip this step. Take note of *yourBucketName*, the existing bucket's name, to use in later steps.

### To create a bucket for your Ray job output

- Create a bucket by following the steps in [Creating a bucket](#) in the *Amazon S3 User Guide*.
  - When choosing a bucket name, take note of *yourBucketName*, which you will refer to in later steps.
  - For other configuration, the suggested settings provided in the Amazon S3 console should work fine in this tutorial.

As an example, the bucket creation dialog box might look like this in the Amazon S3 console.

The screenshot shows the 'Create bucket' dialog box in the Amazon S3 console. The breadcrumb navigation at the top reads 'Amazon S3 > Buckets > Create bucket'. The main heading is 'Create bucket' with an 'Info' link. Below the heading is a descriptive sentence: 'Buckets are containers for data stored in S3. [Learn more](#)'. The 'General configuration' section contains two input fields: 'Bucket name' with the text 'myawsbucket' and 'AWS Region' with a dropdown menu set to 'US East (N. Virginia) us-east-1'. A note below the bucket name field states: 'Bucket name must be globally unique and must not contain spaces or uppercase letters. [See rules for bucket naming](#)'.

## Step 2: Create an IAM role and policy for your Ray job

Your job will need an AWS Identity and Access Management (IAM) role with the following:

- Permissions granted by the `AWSGlueServiceRole` managed policy. These are the basic permissions that are necessary to run an AWS Glue job.
- Read access level permissions for the `nyc-t1c/*` Amazon S3 resource.
- Write access level permissions for the `yourBucketName/*` Amazon S3 resource.
- A trust relationship that allows the `glue.amazonaws.com` principal to assume the role.

You can create this role with the following procedure.

### To create an IAM role for your AWS Glue for Ray job

#### Note

You can create an IAM role by following many different procedures. For more information or options about how to provision IAM resources, see the [AWS Identity and Access Management documentation](#).

1. Create a policy that defines the previously outlined Amazon S3 permissions by following the steps in [Creating IAM policies \(console\) with the visual editor](#) in the *IAM User Guide*.
  - When selecting a service, choose Amazon S3.
  - When selecting permissions for your policy, attach the following sets of actions for the following resources (mentioned previously):
    - Read access level permissions for the `nyc-tlc/*` Amazon S3 resource.
    - Write access level permissions for the `yourBucketName/*` Amazon S3 resource.
  - When selecting the policy name, take note of *YourPolicyName*, which you will refer to in a later step.
2. Create a role for your AWS Glue for Ray job by following the steps in [Creating a role for an AWS service \(console\)](#) in the *IAM User Guide*.
  - When selecting a trusted AWS service entity, choose Glue. This will automatically populate the necessary trust relationship for your job.
  - When selecting policies for the permissions policy, attach the following policies:
    - `AWSGlueServiceRole`
    - *YourPolicyName*
  - When selecting the role name, take note of *YourRoleName*, which you will refer to in later steps.

### Step 3: Create and run an AWS Glue for Ray job

In this step, you create an AWS Glue job using the AWS Management Console, provide it with a sample script, and run the job. When you create a job, it creates a place in the console for you to store, configure, and edit your Ray script. For more information about creating jobs, see [the section called "Signing in to the console"](#).

In this tutorial, we address the following ETL scenario: you would like to read the January 2022 records from the New York City TLC Trip Record dataset, add a new column (`tip_rate`) to the dataset by combining data in existing columns, then remove a number of columns that aren't relevant to your current analysis, and then you would like to write the results to *yourBucketName*. The following Ray script performs these steps:

```
import ray
import pandas
```

```

from ray import data

ray.init('auto')

ds = ray.data.read_csv("s3://nyc-tlc/opendata_repo/opendata_webconvert/yellow/
yellow_tripdata_2022-01.csv")

# Add the given new column to the dataset and show the sample record after adding a new
column
ds = ds.add_column( "tip_rate", lambda df: df["tip_amount"] / df["total_amount"])

# Dropping few columns from the underlying Dataset
ds = ds.drop_columns(["payment_type", "fare_amount", "extra", "tolls_amount",
"improvement_surcharge"])

ds.write_parquet("s3://yourBucketName/ray/tutorial/output/")

```

## To create and run an AWS Glue for Ray job

1. In the AWS Management Console, navigate to the AWS Glue landing page.
2. In the side navigation pane, choose **ETL Jobs**.
3. In **Create job**, choose **Ray script editor**, and then choose **Create**, as in the following illustration.

**AWS Glue Studio** [Info](#)

**Create job** [Info](#) **Create**

- Visual with a source and target**  
Start with a source, ApplyMapping transform, and target.
- Visual with a blank canvas**  
Author using an interactive visual interface.
- Spark script editor**  
Write or upload your own Spark code.
- Python Shell script editor**  
Write or upload your own Python shell script.
- Jupyter Notebook**  
Write your own code in a Jupyter Notebook for interactive development.
- Ray script editor**  
Write your own code to run on Ray.

**Options** [Info](#)

- Create a new script with boilerplate code**
- Upload and edit an existing script**  
Choose a local file.

4. Paste the full text of the script into the **Script** pane, and replace any existing text.
5. Navigate to **Job details** and set the **IAM Role** property to *YourRoleName*.

6. Choose **Save**, and then choose **Run**.

## Step 4: Inspect your output

After running your AWS Glue job, you should validate that the output matches the expectations of this scenario. You can do so with the following procedure.

### To validate whether your Ray job ran successfully

1. On the job details page, navigate to **Runs**.
2. After a few minutes, you should see a run with a **Run status** of **Succeeded**.
3. Navigate to the Amazon S3 console at <https://console.aws.amazon.com/s3/> and inspect *yourBucketName*. You should see files written to your output bucket.
4. Read the Parquet files and verify their contents. You can do this with your existing tools. If you don't have a process for validating Parquet files, you can do this in the AWS Glue console with an AWS Glue interactive session, using either Spark or Ray (in preview).

In an interactive session, you have access to Ray Data, Spark, or pandas libraries, which are provided by default (based on your choice of engine). To verify your file contents, you can use common inspection methods that are available in those libraries—methods like `count`, `schema`, and `show`. For more information about interactive sessions in the console, see [Using notebooks with AWS Glue Studio and AWS Glue](#).

Because you have confirmed that files have been written to the bucket, you can say with relative certainty that if your output has problems, they are not related to IAM configuration. Configure your session with *yourRoleName* to have access to the relevant files.

If you don't see the expected outcomes, examine the troubleshooting content in this guide to identify and remediate the source of the error. To interpret job run error states, see [the section called "Job run statuses"](#). You can find the troubleshooting content in the [Troubleshooting AWS Glue](#) chapter. For specific errors that are related to Ray jobs, see [the section called "Troubleshooting Ray errors"](#) in the troubleshooting chapter.

## Next steps

You have now seen and performed an ETL process using AWS Glue for Ray from end to end. You can use the following resources to understand what tools AWS Glue for Ray provides to transform and interpret your data at scale.

- For more information about Ray's task model, see [the section called “Using Ray Core and Ray Data in AWS Glue for Ray”](#). For more experience in using Ray tasks, follow the examples in the Ray Core documentation. See [Ray Core: Ray Tutorials and Examples \(2.4.0\)](#) in the Ray documentation.
- For guidance about available data management libraries in AWS Glue for Ray, see [the section called “Connecting to data”](#). For more experience using Ray Data to transform and write datasets, follow the examples in the Ray Data documentation. See [Ray Data: Examples \(2.4.0\)](#).
- For more information about configuring AWS Glue for Ray jobs, see [the section called “Working with Ray jobs”](#).
- For more information about writing AWS Glue for Ray scripts, continue reading the documentation in this section.

## Using Ray Core and Ray Data in AWS Glue for Ray

Ray is a framework for scaling up Python scripts by distributing work across a cluster. You can use Ray as a solution to many sorts of problems, so Ray provides libraries to optimize certain tasks. In AWS Glue, we focus on using Ray to transform large datasets. AWS Glue offers support for Ray Data and parts of Ray Core to facilitate this task.

### What is Ray Core?

The first step of building a distributed application is identifying and defining work that can be performed concurrently. Ray Core contains the parts of Ray that you use to define tasks that can be performed concurrently. Ray provides reference and quick start information that you can use to learn the tools they provide. For more information, see [What is Ray Core?](#) and [Ray Core Quick Start](#). For more information about effectively defining concurrent tasks in Ray, see [Tips for first-time users](#).

#### Ray tasks and actors

In AWS Glue for Ray documentation, we might refer to *tasks* and *actors*, which are core concepts in Ray.

Ray uses Python functions and classes as the building blocks of a distributed computing system. Much like when Python functions and variables become "methods" and "attributes" when used in a class, functions become "tasks" and classes become "actors" when they're used in Ray to send code to workers. You can identify functions and classes that might be used by Ray by the `@ray.remote` annotation.

Tasks and actors are configurable, they have a lifecycle, and they take up compute resources throughout their life. Code that throws errors can be traced back to a task or actor when you're finding the root cause of problems. Thus, these terms might come up when you're learning how to configure, monitor, or debug AWS Glue for Ray jobs. To begin learning how to effectively use tasks and actors to build a distributed application, see [Key Concepts](#) in the Ray docs.

## Ray Core in AWS Glue for Ray

AWS Glue for Ray environments manage cluster formation and scaling, as well as collecting and visualizing logs. Because we manage these concerns, we consequently limit access to and support for the APIs in Ray Core that would be used to address these concerns in an open-source cluster.

In the managed Ray2.4 runtime environment, we do not support:

- [Ray Core CLI](#)
- [Ray State CLI](#)
- `ray.util.metrics` Prometheus metric utility methods:
  - [Counter](#)
  - [Gauge](#)
  - [Histogram](#)
- Other debugging tools:
  - [ray.util.pdb.set\\_trace](#)
  - [ray.util.inspect\\_serializability](#)
  - [ray.timeline](#)

## What is Ray Data?

When you're connecting to data sources and destinations, handling datasets, and initiating common transforms, Ray Data is a straightforward methodology for using Ray to solve problems transforming Ray datasets. For more information about using Ray Data, see [Ray Datasets: Distributed Data Preprocessing](#).

You can use Ray Data or other tools to access your data. For more information on accessing your data in Ray, see [the section called "Connecting to data"](#).

## Ray Data in AWS Glue for Ray

Ray Data is supported and provided by default in the managed Ray2.4 runtime environment. For more information about provided modules, see [the section called “Modules provided with Ray jobs”](#).

## Providing files and Python libraries to Ray jobs

This section provides information that you need for using Python libraries with AWS Glue Ray jobs. You can use certain common libraries included by default in all Ray jobs. You can also provide your own Python libraries to your Ray job.

### Modules provided with Ray jobs

You can perform data integration workflows in a Ray job with the following provided packages. These packages are available by default in Ray jobs.

AWS Glue version 4.0

In AWS Glue 4.0, the Ray (Ray2.4 runtime) environment provides the following packages:

- boto3 == 1.26.133
- ray == 2.4.0
- pyarrow == 11.0.0
- pandas == 1.5.3
- numpy == 1.24.3
- fsspec == 2023.4.0

This list includes all packages that would be installed with `ray[data] == 2.4.0`. Ray Data is supported out of box.

### Providing files to your Ray job

You can provide files to your Ray job with the `--working-dir` parameter. Provide this parameter with a path to a .zip file hosted on Amazon S3. Within the .zip file, your files must be contained in a single top-level directory. No other files should be at the top level.

Your files will be distributed to each Ray node before your script begins to run. Consider how this might impact the disk space that's available to each Ray node. Available disk space is determined by the `WorkerType` set in the job configuration. If you want to provide your job data at scale, this mechanism is not the right solution. For more information on providing data to your job, see [the section called "Connecting to data"](#).

Your files will be accessible as if the directory was provided to Ray through the `working_dir` parameter. For example, to read a file named `sample.txt` in your `.zip` file's top-level directory, you could call:

```
@ray.remote
def do_work():
    f = open("sample.txt", "r")
    print(f.read())
```

For more information about `working_dir`, see the [Ray documentation](#). This feature behaves similarly to Ray's native capabilities.

## Additional Python modules for Ray jobs

### Additional modules from PyPI

Ray jobs use the Python Package Installer (`pip3`) to install additional modules to be used by a Ray script. You can use the `--pip-install` parameter with a list of comma-separated Python modules to add a new module or change the version of an existing module.

For example, to update or add a new `scikit-learn` module, use the following key-value pair:

```
"--pip-install", "scikit-learn==0.21.3"
```

If you have custom modules or custom patches, you can distribute your own libraries from Amazon S3 with the `--s3-py-modules` parameter. Before uploading your distribution, it might need to be repackaged and rebuilt. Follow the guidelines in [the section called "Including Python code in Ray jobs"](#).

### Custom distributions from Amazon S3

Custom distributions should adhere to Ray packaging guidelines for dependencies. You can find out how to build these distributions in the following section. For more information about how Ray sets up dependencies, see [Environment Dependencies](#) in the Ray documentation.

To include a custom distributable after assessing its contents, upload your distributable to a bucket available to the job's IAM role. Specify the Amazon S3 path to a Python zip archive in your parameter configuration. If you're providing multiple distributables, separate them by comma. For example:

```
"--s3-py-modules", "s3://s3bucket/pythonPackage.zip"
```

## Limitations

Ray jobs do not support compiling native code in the job environment. You can be limited by this if your Python dependencies transitively depend on native, compiled code. Ray jobs can run provided binaries, but they must be compiled for Linux on ARM64. This means you might be able to use the contents of `aarch64manylinux` wheels. You can provide your native dependencies in a compiled form by repackaging a wheel to Ray standards. Typically, this means removing `dist-info` folders so that there is only one folder at the root at the archive.

You cannot upgrade the version of `ray` or `ray[data]` using this parameter. In order to use a new version of Ray, you will need to change the runtime field on your job, after we have released support for it. For more information about supported Ray versions, see [the section called "AWS Glue versions"](#).

## Including Python code in Ray jobs

The Python Software Foundation offers standardized behaviors for packaging Python files for use across different runtimes. Ray introduces limitations to packaging standards that you should be aware of. AWS Glue does not specify packaging standards beyond those specified to Ray. The following instructions provide standard guidance on packaging simple Python packages.

Package your files in a `.zip` archive. A directory should be at the root of the archive. **There should be no other files at the root level of the archive, or this may lead to unexpected behavior.** The root directory is the package, and its name is used to refer to your Python code when importing it.

If you provide a distribution in this form to a Ray job with `--s3-py-modules`, you will be able to import Python code from your package in your Ray script.

Your package can provide a single Python module with some Python files, or you can package together many modules. When repackaging dependencies, such as libraries from PyPI, **check for hidden files and metadata directories** inside of those packages.

**⚠ Warning**

Certain OS behaviors make it difficult to properly follow these packaging instructions.

- OSX may add hidden files such as `__MACOSX` to your zip file at the top level.
- Windows may add your files to a folder inside the zip automatically, unintentionally creating a nested folder.

The following procedures assume you are interacting with your files in Amazon Linux 2 or a similar OS that provides a distribution of the Info-ZIP `zip` and `zipinfo` utilities. We recommend using these tools to prevent unexpected behaviors.

To package Python files for use in Ray

1. Create a temporary directory with your package name, then confirm your working directory is its parent directory. You can do this with the following commands:

```
cd parent_directory
mkdir temp_dir
```

2. Copy your files into the temporary directory, then confirm your directory structure. The contents of this directory will be directly accessed as your Python module. You can do this with the following command:

```
ls -AR temp_dir
# my_file_1.py
# my_file_2.py
```

3. Compress your temporary folder using `zip`. You can do this with the following commands:

```
zip -r zip_file.zip temp_dir
```

4. Confirm your file is properly packaged. `zip_file.zip` should now be found in your working directory. You can inspect it with the following command:

```
zipinfo -l zip_file.zip
# temp_dir/
# temp_dir/my_file_1.py
```

```
# temp_dir/my_file_2.py
```

To repackage a Python package for use in Ray.

1. Create a temporary directory with your package name, then confirm your working directory is its parent directory. You can do this with the following commands:

```
cd parent_directory  
mkdir temp_dir
```

2. Decompress your package and copy the contents into your temporary directory. Remove files related to your previous packaging standard, leaving only the contents of the module. Confirm your file structure looks correct with the following command:

```
ls -AR temp_dir  
# my_module  
# my_module/__init__.py  
# my_module/my_file_1.py  
# my_module/my_submodule/__init__.py  
# my_module/my_submodule/my_file_2.py  
# my_module/my_submodule/my_file_3.py
```

3. Compress your temporary folder using zip. You can do this with the following commands:

```
zip -r zip_file.zip temp_dir
```

4. Confirm your file is properly packaged. *zip\_file.zip* should now be found in your working directory. You can inspect it with the following command:

```
zipinfo -1 zip_file.zip  
# temp_dir/my_module/  
# temp_dir/my_module/__init__.py  
# temp_dir/my_module/my_file_1.py  
# temp_dir/my_module/my_submodule/  
# temp_dir/my_module/my_submodule/__init__.py  
# temp_dir/my_module/my_submodule/my_file_2.py  
# temp_dir/my_module/my_submodule/my_file_3.py
```

## Connecting to data in Ray jobs

AWS Glue Ray jobs can use a broad array of Python packages that are designed for you to quickly integrate data. We provide a minimal set of dependencies in order to not clutter your environment. For more information about what is included by default, see [the section called “Modules provided with Ray jobs”](#).

### Note

AWS Glue extract, transform, and load (ETL) provides the DynamicFrame abstraction to streamline ETL workflows where you resolve schema differences between rows in your dataset. AWS Glue ETL provides additional features—job bookmarks and grouping input files. We don't currently provide corresponding features in Ray jobs.

AWS Glue for Spark provides direct support for connecting to certain data formats, sources and sinks. In Ray, AWS SDK for pandas and current third-party libraries substantively cover that need. You will need to consult those libraries to understand what capabilities are available.

AWS Glue for Ray integration with Amazon VPC is not currently available. Resources in Amazon VPC will not be accessible without a public route. For more information about using AWS Glue with Amazon VPC, see [the section called “VPC endpoints \(AWS PrivateLink\)”](#).

## Common libraries for working with data in Ray

**Ray Data** – Ray Data provides methods to handle common data formats, sources and sinks. For more information about supported formats and sources in Ray Data, see [Input/Output](#) in the Ray Data documentation. Ray Data is an opinionated library, rather than a general-purpose library, for handling datasets.

Ray provides certain guidance around use cases where Ray Data might be the best solution for your job. For more information, see [Ray use cases](#) in the Ray documentation.

**AWS SDK for pandas (awswrangler)** – AWS SDK for pandas is an AWS product that delivers clean, tested solutions for reading from and writing to AWS services when your transformations manage data with pandas DataFrames. For more information about supported formats and sources in the AWS SDK for pandas, see the [API Reference](#) in the AWS SDK for pandas documentation.

For examples of how to read and write data with the AWS SDK for pandas, see [Quick Start](#) in the AWS SDK for pandas documentation. The AWS SDK for pandas doesn't provide transforms for your data. It only provides support for reading and writing from sources.

**Modin** – Modin is a Python library that implements common pandas operations in a distributable way. For more information about Modin, see the [Modin documentation](#). Modin itself doesn't provide support for reading and writing from sources. It provides distributed implementations of common transforms. Modin is supported by the AWS SDK for pandas.

When you run Modin and the AWS SDK for pandas together in a Ray environment, you can perform common ETL tasks with performant results. For more information about using Modin with the AWS SDK for pandas, see [At scale](#) in the AWS SDK for pandas documentation.

**Other frameworks** – For more information about frameworks that Ray supports, see [The Ray Ecosystem](#) in the Ray documentation. We don't provide support for other frameworks in AWS Glue for Ray.

## Connecting to data through the Data Catalog

Managing your data through the Data Catalog in conjunction with Ray jobs is supported with the AWS SDK for pandas. For more information, see [Glue Catalog](#) on the AWS SDK for pandas website.

## Using this service with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
<a href="#">AWS SDK for C++</a>	<a href="#">AWS SDK for C++ code examples</a>
<a href="#">AWS CLI</a>	<a href="#">AWS CLI code examples</a>
<a href="#">AWS SDK for Go</a>	<a href="#">AWS SDK for Go code examples</a>
<a href="#">AWS SDK for Java</a>	<a href="#">AWS SDK for Java code examples</a>
<a href="#">AWS SDK for JavaScript</a>	<a href="#">AWS SDK for JavaScript code examples</a>
<a href="#">AWS SDK for Kotlin</a>	<a href="#">AWS SDK for Kotlin code examples</a>
<a href="#">AWS SDK for .NET</a>	<a href="#">AWS SDK for .NET code examples</a>
<a href="#">AWS SDK for PHP</a>	<a href="#">AWS SDK for PHP code examples</a>
<a href="#">AWS Tools for PowerShell</a>	<a href="#">Tools for PowerShell code examples</a>
<a href="#">AWS SDK for Python (Boto3)</a>	<a href="#">AWS SDK for Python (Boto3) code examples</a>
<a href="#">AWS SDK for Ruby</a>	<a href="#">AWS SDK for Ruby code examples</a>
<a href="#">AWS SDK for Rust</a>	<a href="#">AWS SDK for Rust code examples</a>
<a href="#">AWS SDK for SAP ABAP</a>	<a href="#">AWS SDK for SAP ABAP code examples</a>
<a href="#">AWS SDK for Swift</a>	<a href="#">AWS SDK for Swift code examples</a>

For examples specific to this service, see [AWS Glue API code examples using AWS SDKs](#).

 **Example availability**

Can't find what you need? Request a code example by using the **Provide feedback** link at the bottom of this page.

# AWS Glue API

This section describes data types and primitives used by AWS Glue SDKs and Tools. There are three general ways to interact with AWS Glue programmatically outside of the AWS Management Console, each with its own documentation:

- Language SDK libraries allow you to access AWS resources from common programming languages. Find more information at [Tools to Build on AWS](#).
- The AWS CLI allows you to access AWS resources from the command line. Find more information at [AWS CLI Command Reference](#).
- AWS CloudFormation allows you to define a set of AWS resources to be provisioned together consistently. Find more information at [AWS CloudFormation: AWS Glue resource type reference](#).

This section documents shared primitives independently of these SDKs and Tools. Tools use the [AWS Glue Web API Reference](#) to communicate with AWS.

## Security APIs in AWS Glue

The Security API describes the security data types, and the API related to security in AWS Glue.

### Data types

- [DataCatalogEncryptionSettings structure](#)
- [EncryptionAtRest structure](#)
- [ConnectionPasswordEncryption structure](#)
- [EncryptionConfiguration structure](#)
- [S3Encryption structure](#)
- [CloudWatchEncryption structure](#)
- [JobBookmarksEncryption structure](#)
- [SecurityConfiguration structure](#)
- [GluePolicy structure](#)

### DataCatalogEncryptionSettings structure

Contains configuration information for maintaining Data Catalog security.

## Fields

- `EncryptionAtRest` – An [EncryptionAtRest](#) object.

Specifies the encryption-at-rest configuration for the Data Catalog.

- `ConnectionPasswordEncryption` – A [ConnectionPasswordEncryption](#) object.

When connection password protection is enabled, the Data Catalog uses a customer-provided key to encrypt the password as part of `CreateConnection` or `UpdateConnection` and store it in the `ENCRYPTED_PASSWORD` field in the connection properties. You can enable catalog encryption or only password encryption.

## EncryptionAtRest structure

Specifies the encryption-at-rest configuration for the Data Catalog.

### Fields

- `CatalogEncryptionMode` – *Required:* UTF-8 string (valid values: `DISABLED` | `SSE-KMS="SSEKMS"` | `SSE-KMS-WITH-SERVICE-ROLE="SSEKMSWITHSERVICEROLE"`).

The encryption-at-rest mode for encrypting Data Catalog data.

- `SseAwsKmsKeyId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the AWS KMS key to use for encryption at rest.

- `CatalogEncryptionServiceRole` – UTF-8 string, matching the [Custom string pattern #24](#).

The role that AWS Glue assumes to encrypt and decrypt the Data Catalog objects on the caller's behalf.

## ConnectionPasswordEncryption structure

The data structure used by the Data Catalog to encrypt the password as part of `CreateConnection` or `UpdateConnection` and store it in the `ENCRYPTED_PASSWORD` field in the connection properties. You can enable catalog encryption or only password encryption.

When a `CreationConnection` request arrives containing a password, the Data Catalog first encrypts the password using your AWS KMS key. It then encrypts the whole connection object again if catalog encryption is also enabled.

This encryption requires that you set AWS KMS key permissions to enable or restrict access on the password key according to your security requirements. For example, you might want only administrators to have decrypt permission on the password key.

## Fields

- `ReturnConnectionPasswordEncrypted` – *Required*: Boolean.

When the `ReturnConnectionPasswordEncrypted` flag is set to "true", passwords remain encrypted in the responses of `GetConnection` and `GetConnections`. This encryption takes effect independently from catalog encryption.

- `AwsKmsKeyId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

An AWS KMS key that is used to encrypt the connection password.

If connection password protection is enabled, the caller of `CreateConnection` and `UpdateConnection` needs at least `kms:Encrypt` permission on the specified AWS KMS key, to encrypt passwords before storing them in the Data Catalog.

You can set the decrypt permission to enable or restrict access on the password key according to your security requirements.

## EncryptionConfiguration structure

Specifies an encryption configuration.

### Fields

- `S3Encryption` – An array of [S3Encryption](#) objects.

The encryption configuration for Amazon Simple Storage Service (Amazon S3) data.

- `CloudWatchEncryption` – A [CloudWatchEncryption](#) object.

The encryption configuration for Amazon CloudWatch.

- `JobBookmarksEncryption` – A [JobBookmarksEncryption](#) object.

The encryption configuration for job bookmarks.

## S3Encryption structure

Specifies how Amazon Simple Storage Service (Amazon S3) data should be encrypted.

### Fields

- `S3EncryptionMode` – UTF-8 string (valid values: `DISABLED` | `SSE-KMS="SSEKMS"` | `SSE-S3="SSES3"`).

The encryption mode to use for Amazon S3 data.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #25](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

## CloudWatchEncryption structure

Specifies how Amazon CloudWatch data should be encrypted.

### Fields

- `CloudWatchEncryptionMode` – UTF-8 string (valid values: `DISABLED` | `SSE-KMS="SSEKMS"`).

The encryption mode to use for CloudWatch data.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #25](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

## JobBookmarksEncryption structure

Specifies how job bookmark data should be encrypted.

### Fields

- `JobBookmarksEncryptionMode` – UTF-8 string (valid values: `DISABLED` | `CSE-KMS="CSEKMS"`).

The encryption mode to use for job bookmarks data.

- `KmsKeyArn` – UTF-8 string, matching the [Custom string pattern #25](#).

The Amazon Resource Name (ARN) of the KMS key to be used to encrypt the data.

## SecurityConfiguration structure

Specifies a security configuration.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration.

- `CreatedTimeStamp` – Timestamp.

The time at which this security configuration was created.

- `EncryptionConfiguration` – An [EncryptionConfiguration](#) object.

The encryption configuration associated with this security configuration.

## GluePolicy structure

A structure for returning a resource policy.

### Fields

- `PolicyInJson` – UTF-8 string, at least 2 bytes long.

Contains the requested policy document, in JSON format.

- `PolicyHash` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Contains the hash value associated with this policy.

- `CreateTime` – Timestamp.

The date and time at which the policy was created.

- `UpdateTime` – Timestamp.

The date and time at which the policy was last updated.

## Operations

- [GetDataCatalogEncryptionSettings](#) action (Python: `get_data_catalog_encryption_settings`)
- [PutDataCatalogEncryptionSettings](#) action (Python: `put_data_catalog_encryption_settings`)
- [PutResourcePolicy](#) action (Python: `put_resource_policy`)
- [GetResourcePolicy](#) action (Python: `get_resource_policy`)
- [DeleteResourcePolicy](#) action (Python: `delete_resource_policy`)
- [CreateSecurityConfiguration](#) action (Python: `create_security_configuration`)
- [DeleteSecurityConfiguration](#) action (Python: `delete_security_configuration`)
- [GetSecurityConfiguration](#) action (Python: `get_security_configuration`)
- [GetSecurityConfigurations](#) action (Python: `get_security_configurations`)
- [GetResourcePolicies](#) action (Python: `get_resource_policies`)

## GetDataCatalogEncryptionSettings action (Python: `get_data_catalog_encryption_settings`)

Retrieves the security configuration for a specified catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog to retrieve the security configuration for. If none is provided, the AWS account ID is used by default.

### Response

- `DataCatalogEncryptionSettings` – A [DataCatalogEncryptionSettings](#) object.

The requested security configuration.

## Errors

- `InternalServiceException`
- `InvalidInputException`
- `OperationTimeoutException`

## PutDataCatalogEncryptionSettings action (Python: `put_data_catalog_encryption_settings`)

Sets the security configuration for a specified catalog. After the configuration has been set, the specified encryption is applied to every catalog write thereafter.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog to set the security configuration for. If none is provided, the AWS account ID is used by default.

- `DataCatalogEncryptionSettings` – *Required:* A [DataCatalogEncryptionSettings](#) object.

The security configuration to set.

### Response

- *No Response parameters.*

## Errors

- `InternalServiceException`
- `InvalidInputException`
- `OperationTimeoutException`

## PutResourcePolicy action (Python: `put_resource_policy`)

Sets the Data Catalog resource policy for access control.

## Request

- `PolicyInJson` – *Required*: UTF-8 string, at least 2 bytes long.

Contains the policy document to set, in JSON format.

- `ResourceArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

Do not use. For internal use only.

- `PolicyHashCondition` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The hash value returned when the previous policy was set using `PutResourcePolicy`. Its purpose is to prevent concurrent modifications of a policy. Do not use this parameter if no previous policy has been set.

- `PolicyExistsCondition` – UTF-8 string (valid values: `MUST_EXIST` | `NOT_EXIST` | `NONE`).

A value of `MUST_EXIST` is used to update a policy. A value of `NOT_EXIST` is used to create a new policy. If a value of `NONE` or a null value is used, the call does not depend on the existence of a policy.

- `EnableHybrid` – UTF-8 string (valid values: `TRUE` | `FALSE`).

If `'TRUE'`, indicates that you are using both methods to grant cross-account access to Data Catalog resources:

- By directly updating the resource policy with `PutResourcePolicy`
- By using the **Grant permissions** command on the AWS Management Console.

Must be set to `'TRUE'` if you have already used the Management Console to grant cross-account access, otherwise the call fails. Default is `'FALSE'`.

## Response

- `PolicyHash` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A hash of the policy that has just been set. This must be included in a subsequent call that overwrites or updates this policy.

## Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `ConditionCheckFailureException`

## GetResourcePolicy action (Python: `get_resource_policy`)

Retrieves a specified resource policy.

### Request

- `ResourceArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The ARN of the AWS Glue resource for which to retrieve the resource policy. If not supplied, the Data Catalog resource policy is returned. Use `GetResourcePolicies` to view all existing resource policies. For more information see [Specifying AWS Glue Resource ARNs](#).

### Response

- `PolicyInJson` – UTF-8 string, at least 2 bytes long.

Contains the requested policy document, in JSON format.

- `PolicyHash` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Contains the hash value associated with this policy.

- `CreateTime` – Timestamp.

The date and time at which the policy was created.

- `UpdateTime` – Timestamp.

The date and time at which the policy was last updated.

## Errors

- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException
- InvalidInputException

## DeleteResourcePolicy action (Python: delete\_resource\_policy)

Deletes a specified policy.

### Request

- PolicyHashCondition – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The hash value returned when this policy was set.

- ResourceArn – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The ARN of the AWS Glue resource for the resource policy to be deleted.

### Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException
- InvalidInputException
- ConditionCheckFailureException

## CreateSecurityConfiguration action (Python: `create_security_configuration`)

Creates a new security configuration. A security configuration is a set of security properties that can be used by AWS Glue. You can use a security configuration to encrypt data at rest. For information about using security configurations in AWS Glue, see [Encrypting Data Written by Crawlers, Jobs, and Development Endpoints](#).

### Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name for the new security configuration.

- `EncryptionConfiguration` – *Required:* An [EncryptionConfiguration](#) object.

The encryption configuration for the new security configuration.

### Response

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name assigned to the new security configuration.

- `CreatedTimestamp` – Timestamp.

The time at which the new security configuration was created.

### Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`

## DeleteSecurityConfiguration action (Python: delete\_security\_configuration)

Deletes a specified security configuration.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration to delete.

### Response

- *No Response parameters.*

### Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

## GetSecurityConfiguration action (Python: get\_security\_configuration)

Retrieves a specified security configuration.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration to retrieve.

### Response

- SecurityConfiguration – A [SecurityConfiguration](#) object.

The requested security configuration.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetSecurityConfigurations action (Python: `get_security_configurations`)

Retrieves a list of all security configurations.

### Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

### Response

- `SecurityConfigurations` – An array of [SecurityConfiguration](#) objects.

A list of security configurations.

- `NextToken` – UTF-8 string.

A continuation token, if there are more security configurations to return.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`

- `OperationTimeoutException`

## GetResourcePolicies action (Python: `get_resource_policies`)

Retrieves the resource policies set on individual resources by AWS Resource Access Manager during cross-account permission grants. Also retrieves the Data Catalog resource policy.

If you enabled metadata encryption in Data Catalog settings, and you do not have permission on the AWS KMS key, the operation can't return the Data Catalog resource policy.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

### Response

- `GetResourcePoliciesResponseList` – An array of [GluePolicy](#) objects.

A list of the individual resource policies and the account-level resource policy.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last resource policy available.

### Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`

# Catalog API

The Catalog API describes the data types and API related to working with catalogs in AWS Glue.

## Topics

- [Database API](#)
- [Table API](#)
- [Partition API](#)
- [Connection API](#)
- [User-defined Function API](#)
- [Importing an Athena catalog to AWS Glue](#)

## Database API

The Database API describes database data types, and includes the API for creating, deleting, locating, updating, and listing databases.

## Data types

- [Database structure](#)
- [DatabaseInput structure](#)
- [PrincipalPermissions structure](#)
- [DataLakePrincipal structure](#)
- [DatabaseIdentifier structure](#)
- [FederatedDatabase structure](#)

## Database structure

The Database object represents a logical grouping of tables that might reside in a Hive metastore or an RDBMS.

## Fields

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database. For Hive compatibility, this is folded to lowercase when it is stored.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the database.

- **LocationUri** – Uniform resource identifier (uri), not less than 1 or more than 1024 bytes long, matching the [URI address multi-line string pattern](#).

The location of the database (for example, an HDFS path).

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define parameters and properties of the database.

- **CreateTime** – Timestamp.

The time at which the metadata database was created in the catalog.

- **CreateTableDefaultPermissions** – An array of [PrincipalPermissions](#) objects.

Creates a set of default permissions on the table for principals. Used by AWS Lake Formation. Not used in the normal course of AWS Glue operations.

- **TargetDatabase** – A [DatabaseIdentifier](#) object.

A `DatabaseIdentifier` structure that describes a target database for resource linking.

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides.

- **FederatedDatabase** – A [FederatedDatabase](#) object.

A `FederatedDatabase` structure that references an entity outside the AWS Glue Data Catalog.

## DatabaseInput structure

The structure used to create or update a database.

### Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database. For Hive compatibility, this is folded to lowercase when it is stored.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the database.

- **LocationUri** – Uniform resource identifier (uri), not less than 1 or more than 1024 bytes long, matching the [URI address multi-line string pattern](#).

The location of the database (for example, an HDFS path).

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define parameters and properties of the database.

These key-value pairs define parameters and properties of the database.

- **CreateTableDefaultPermissions** – An array of [PrincipalPermissions](#) objects.

Creates a set of default permissions on the table for principals. Used by AWS Lake Formation. Not used in the normal course of AWS Glue operations.

- **TargetDatabase** – A [DatabaseIdentifier](#) object.

A `DatabaseIdentifier` structure that describes a target database for resource linking.

- **FederatedDatabase** – A [FederatedDatabase](#) object.

A `FederatedDatabase` structure that references an entity outside the AWS Glue Data Catalog.

## PrincipalPermissions structure

Permissions granted to a principal.

### Fields

- **Principal** – A [DataLakePrincipal](#) object.  
The principal who is granted permissions.
- **Permissions** – An array of UTF-8 strings.  
The permissions that are granted to the principal.

## DataLakePrincipal structure

The AWS Lake Formation principal.

### Fields

- **DataLakePrincipalIdentifier** – UTF-8 string, not less than 1 or more than 255 bytes long.  
An identifier for the AWS Lake Formation principal.

## DatabaseIdentifier structure

A structure that describes a target database for resource linking.

### Fields

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).  
The ID of the Data Catalog in which the database resides.
- **DatabaseName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).  
The name of the catalog database.
- **Region** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Region of the target database.

## FederatedDatabase structure

A database that points to an entity outside the AWS Glue Data Catalog.

### Fields

- `Identifier` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated database.

- `ConnectionName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to the external metastore.

## Operations

- [CreateDatabase action \(Python: `create\_database`\)](#)
- [UpdateDatabase action \(Python: `update\_database`\)](#)
- [DeleteDatabase action \(Python: `delete\_database`\)](#)
- [GetDatabase action \(Python: `get\_database`\)](#)
- [GetDatabases action \(Python: `get\_databases`\)](#)

## CreateDatabase action (Python: `create_database`)

Creates a new database in a Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the database. If none is provided, the AWS account ID is used by default.

- DatabaseInput – *Required:* A [DatabaseInput](#) object.

The metadata for the database.

- Tags – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags you assign to the database.

## Response

- *No Response parameters.*

## Errors

- InvalidInputException
- AlreadyExistsException
- ResourceNumberLimitExceededException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException
- ConcurrentModificationException
- FederatedResourceAlreadyExistsException

## UpdateDatabase action (Python: update\_database)

Updates an existing database definition in a Data Catalog.

### Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the metadata database resides. If none is provided, the AWS account ID is used by default.

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to update in the catalog. For Hive compatibility, this is folded to lowercase.

- DatabaseInput – *Required*: A [DatabaseInput](#) object.

A DatabaseInput object specifying the new definition of the metadata database in the catalog.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException
- ConcurrentModificationException

## DeleteDatabase action (Python: delete\_database)

Removes a specified database from a Data Catalog.

### Note

After completing this operation, you no longer have access to the tables (and all table versions and partitions that might belong to the tables) and the user-defined functions in the deleted database. AWS Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources, before calling DeleteDatabase, use DeleteTableVersion or BatchDeleteTableVersion, DeletePartition or BatchDeletePartition, DeleteUserDefinedFunction, and DeleteTable or BatchDeleteTable, to delete any resources that belong to the database.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides. If none is provided, the AWS account ID is used by default.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to delete. For Hive compatibility, this must be all lowercase.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## GetDatabase action (Python: `get_database`)

Retrieves the definition of a specified database.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the database resides. If none is provided, the AWS account ID is used by default.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to retrieve. For Hive compatibility, this should be all lowercase.

## Response

- Database – A [Database](#) object.

The definition of the specified database in the Data Catalog.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `FederationSourceException`

## GetDatabases action (Python: `get_databases`)

Retrieves all databases defined in a given Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog from which to retrieve Databases. If none is provided, the AWS account ID is used by default.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 100.

The maximum number of databases to return in one response.

- `ResourceShareType` – UTF-8 string (valid values: FOREIGN | ALL | FEDERATED).

Allows you to specify that you want to list the databases shared with your account. The allowable values are FEDERATED, FOREIGN or ALL.

- If set to FEDERATED, will list the federated databases (referencing an external entity) shared with your account.
- If set to FOREIGN, will list the databases shared with your account.
- If set to ALL, will list the databases shared with your account, as well as the databases in your local account.

## Response

- DatabaseList – *Required*: An array of [Database](#) objects.

A list of Database objects from the specified catalog.

- NextToken – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

## Errors

- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

## Table API

The Table API describes data types and operations associated with tables.

### Data types

- [Table structure](#)
- [TableInput structure](#)
- [FederatedTable structure](#)
- [Column structure](#)

- [StorageDescriptor structure](#)
- [SchemaReference structure](#)
- [SerDeInfo structure](#)
- [Order structure](#)
- [SkewedInfo structure](#)
- [TableVersion structure](#)
- [TableError structure](#)
- [TableVersionError structure](#)

## Table structure

Represents a collection of related data organized in columns and rows.

### Fields

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table name. For Hive compatibility, this must be entirely lowercase.

- DatabaseName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table metadata resides. For Hive compatibility, this must be all lowercase.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the table.

- `Owner` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The owner of the table.

- `CreateTime` – Timestamp.

The time when the table definition was created in the Data Catalog.

- `UpdateTime` – Timestamp.

The last time that the table was updated.

- `LastAccessTime` – Timestamp.

The last time that the table was accessed. This is usually taken from HDFS, and might not be reliable.

- `LastAnalyzedTime` – Timestamp.

The last time that column statistics were computed for this table.

- `Retention` – Number (integer), not more than None.

The retention time for this table.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

A storage descriptor containing information about the physical storage of this table.

- `PartitionKeys` – An array of [Column](#) objects.

A list of columns by which the table is partitioned. Only primitive types are supported as partition keys.

When you create a table used by Amazon Athena, and you do not specify any `partitionKeys`, you must at least set the value of `partitionKeys` to an empty list. For example:

```
"PartitionKeys": []
```

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of AWS Glue operations. If the table is a `VIRTUAL_VIEW`, certain Athena configuration encoded in base64.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of AWS Glue operations.

- `TableType` – UTF-8 string, not more than 255 bytes long.

The type of this table. AWS Glue will create tables with the `EXTERNAL_TABLE` type. Other services, such as Athena, may create tables with additional table types.

AWS Glue related table types:

`EXTERNAL_TABLE`

Hive compatible attribute - indicates a non-Hive managed table.

`GOVERNED`

Used by AWS Lake Formation. The AWS Glue Data Catalog understands `GOVERNED`.

- `Parameters` – A map array of key-value pairs.

Each key is a `Key` string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define properties associated with the table.

- `CreatedBy` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The person or entity who created the table.

- `IsRegisteredWithLakeFormation` – Boolean.

Indicates whether the table has been registered with AWS Lake Formation.

- `TargetTable` – A [TableIdentifier](#) object.

A `TableIdentifier` structure that describes a target table for resource linking.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the table resides.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the table version.

- `FederatedTable` – A [FederatedTable](#) object.

A `FederatedTable` structure that references an entity outside the AWS Glue Data Catalog.

- `ViewDefinition` – A [ViewDefinition](#) object.

A structure that contains all the information that defines the view, including the dialect or dialects for the view, and the query.

- `IsMultiDialectView` – Boolean.

Specifies whether the view supports the SQL dialects of one or more different query engines and can therefore be read by those engines.

## TableInput structure

A structure used to define a table.

### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table name. For Hive compatibility, this is folded to lowercase when it is stored.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the table.

- `Owner` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table owner. Included for Apache Hive compatibility. Not used in the normal course of AWS Glue operations.

- `LastAccessTime` – Timestamp.

The last time that the table was accessed.

- `LastAnalyzedTime` – Timestamp.

The last time that column statistics were computed for this table.

- `Retention` – Number (integer), not more than `None`.

The retention time for this table.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

A storage descriptor containing information about the physical storage of this table.

- `PartitionKeys` – An array of [Column](#) objects.

A list of columns by which the table is partitioned. Only primitive types are supported as partition keys.

When you create a table used by Amazon Athena, and you do not specify any `partitionKeys`, you must at least set the value of `partitionKeys` to an empty list. For example:

```
"PartitionKeys": []
```

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of AWS Glue operations. If the table is a `VIRTUAL_VIEW`, certain Athena configuration encoded in base64.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

Included for Apache Hive compatibility. Not used in the normal course of AWS Glue operations.

- `TableType` – UTF-8 string, not more than 255 bytes long.

The type of this table. AWS Glue will create tables with the `EXTERNAL_TABLE` type. Other services, such as Athena, may create tables with additional table types.

AWS Glue related table types:

`EXTERNAL_TABLE`

Hive compatible attribute - indicates a non-Hive managed table.

`GOVERNED`

Used by AWS Lake Formation. The AWS Glue Data Catalog understands `GOVERNED`.

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define properties associated with the table.

- **TargetTable** – A [TableIdentifier](#) object.

A `TableIdentifier` structure that describes a target table for resource linking.

- **ViewDefinition** – A [ViewDefinitionInput](#) object.

A structure that contains all the information that defines the view, including the dialect or dialects for the view, and the query.

## FederatedTable structure

A table that points to an entity outside the AWS Glue Data Catalog.

### Fields

- **Identifier** – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated table.

- **DatabaseIdentifier** – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the federated database.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to the external metastore.

## Column structure

A column in a Table.

## Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the Column.

- **Type** – UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The data type of the Column.

- **Comment** – Comment string, not more than 255 bytes long, matching the [Single-line string pattern](#).

A free-form text comment.

- **Parameters** – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define properties associated with the column.

## StorageDescriptor structure

Describes the physical storage of table data.

### Fields

- **Columns** – An array of [Column](#) objects.

A list of the Columns in the table.

- **Location** – Location string, not more than 2056 bytes long, matching the [URI address multi-line string pattern](#).

The physical location of the table. By default, this takes the form of the warehouse location, followed by the database location in the warehouse, followed by the table name.

- **AdditionalLocations** – An array of UTF-8 strings.

A list of locations that point to the path where a Delta table is located.

- `InputFormat` – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The input format: `SequenceFileInputFormat` (binary), or `TextInputFormat`, or a custom format.

- `OutputFormat` – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The output format: `SequenceFileOutputFormat` (binary), or `IgnoreKeyTextOutputFormat`, or a custom format.

- `Compressed` – Boolean.

True if the data in the table is compressed, or False if not.

- `NumberOfBuckets` – Number (integer).

Must be specified if the table contains any dimension columns.

- `SerdeInfo` – A [SerDeInfo](#) object.

The serialization/deserialization (SerDe) information.

- `BucketColumns` – An array of UTF-8 strings.

A list of reducer grouping columns, clustering columns, and bucketing columns in the table.

- `SortColumns` – An array of [Order](#) objects.

A list specifying the sort order of each bucket in the table.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

The user-supplied properties in key-value form.

- `SkewedInfo` – A [SkewedInfo](#) object.

The information about values that appear frequently in a column (skewed values).

- `StoredAsSubDirectories` – Boolean.

True if the table data is stored in subdirectories, or False if not.

- SchemaReference – A [SchemaReference](#) object.

An object that references a schema stored in the AWS Glue Schema Registry.

When creating a table, you can pass an empty list of columns for the schema, and instead use a schema reference.

## SchemaReference structure

An object that references a schema stored in the AWS Glue Schema Registry.

### Fields

- SchemaId – A [SchemaId](#) object.

A structure that contains schema identity fields. Either this or the SchemaVersionId has to be provided.

- SchemaVersionId – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique ID assigned to a version of the schema. Either this or the SchemaId has to be provided.

- SchemaVersionNumber – Number (long), not less than 1 or more than 100000.

The version number of the schema.

## SerDeInfo structure

Information about a serialization/deserialization program (SerDe) that serves as an extractor and loader.

### Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the SerDe.

- `SerializationLibrary` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Usually the class that implements the SerDe. An example is `org.apache.hadoop.hive.serde2.columnar.ColumnarSerDe`.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define initialization parameters for the SerDe.

## Order structure

Specifies the sort order of a sorted column.

### Fields

- `Column` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the column.

- `SortOrder` – *Required:* Number (integer), not more than 1.

Indicates that the column is sorted in ascending order (`= 1`), or in descending order (`= 0`).

## SkewedInfo structure

Specifies skewed values in a table. Skewed values are those that occur with very high frequency.

### Fields

- `SkewedColumnNames` – An array of UTF-8 strings.

A list of names of columns that contain skewed values.

- `SkewedColumnValues` – An array of UTF-8 strings.

A list of values that appear so frequently as to be considered skewed.

- **SkewedColumnValueLocationMaps** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A mapping of skewed values to the columns that contain them.

## TableVersion structure

Specifies a version of a table.

### Fields

- **Table** – A [Table](#) object.

The table in question.

- **VersionId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID value that identifies this table version. A **VersionId** is a string representation of an integer. Each version is incremented by 1.

## TableError structure

An error record for table operations.

### Fields

- **TableName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this must be entirely lowercase.

- **ErrorDetail** – An [ErrorDetail](#) object.

The details about the error.

## TableVersionError structure

An error record for table-version operations.

## Fields

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table in question.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID value of the version in question. A `VersionID` is a string representation of an integer. Each version is incremented by 1.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the error.

## SortCriterion structure

Specifies a field to sort by and a sort order.

### Fields

- `FieldName` – Value string, not more than 1024 bytes long.

The name of the field on which to sort.

- `Sort` – UTF-8 string (valid values: `ASC="ASCENDING" | DESC="DESCENDING"`).

An ascending or descending sort.

## TableIdentifier structure

A structure that describes a target table for resource linking.

### Fields

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the table resides.

- **DatabaseName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database that contains the target table.

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the target table.

- **Region** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Region of the target table.

## KeySchemaElement structure

A partition key pair consisting of a name and a type.

### Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of a partition key.

- **Type** – *Required:* UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The type of a partition key.

## PartitionIndex structure

A structure for a partition index.

### Fields

- **Keys** – *Required:* An array of UTF-8 strings, at least 1 string.

The keys for the partition index.

- **IndexName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition index.

## PartitionIndexDescriptor structure

A descriptor for a partition index in a table.

### Fields

- **IndexName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition index.

- **Keys** – *Required:* An array of [KeySchemaElement](#) objects, at least 1 structure.

A list of one or more keys, as `KeySchemaElement` structures, for the partition index.

- **IndexStatus** – *Required:* UTF-8 string (valid values: CREATING | ACTIVE | DELETING | FAILED).

The status of the partition index.

The possible statuses are:

- **CREATING:** The index is being created. When an index is in a CREATING state, the index or its table cannot be deleted.
- **ACTIVE:** The index creation succeeds.
- **FAILED:** The index creation fails.
- **DELETING:** The index is deleted from the list of indexes.
- **BackfillErrors** – An array of [BackfillError](#) objects.

A list of errors that can occur when registering partition indexes for an existing table.

## BackfillError structure

A list of errors that can occur when registering partition indexes for an existing table.

These errors give the details about why an index registration failed and provide a limited number of partitions in the response, so that you can fix the partitions at fault and try registering the index again. The most common set of errors that can occur are categorized as follows:

- **EncryptedPartitionError:** The partitions are encrypted.

- **InvalidPartitionTypeDataError:** The partition value doesn't match the data type for that partition column.
- **MissingPartitionValueError:** The partitions are encrypted.
- **UnsupportedPartitionCharacterError:** Characters inside the partition value are not supported. For example: U+0000 , U+0001, U+0002.
- **InternalError:** Any error which does not belong to other error codes.

## Fields

- **Code** – UTF-8 string (valid values: ENCRYPTED\_PARTITION\_ERROR | INTERNAL\_ERROR | INVALID\_PARTITION\_TYPE\_DATA\_ERROR | MISSING\_PARTITION\_VALUE\_ERROR | UNSUPPORTED\_PARTITION\_CHARACTER\_ERROR).

The error code for an error that occurred when registering partition indexes for an existing table.

- **Partitions** – An array of [PartitionValueList](#) objects.

A list of a limited number of partitions in the response.

## IcebergInput structure

A structure that defines an Apache Iceberg metadata table to create in the catalog.

### Fields

- **MetadataOperation** – *Required:* UTF-8 string (valid values: CREATE).

A required metadata operation. Can only be set to CREATE.

- **Version** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The table version for the Iceberg table. Defaults to 2.

## OpenTableFormatInput structure

A structure representing an open format table.

## Fields

- `IcebergInput` – An [IcebergInput](#) object.

Specifies an `IcebergInput` structure that defines an Apache Iceberg metadata table.

## ViewDefinition structure

A structure containing details for representations.

### Fields

- `IsProtected` – Boolean.

You can set this flag as true to instruct the engine not to push user-provided operations into the logical plan of the view during query planning. However, setting this flag does not guarantee that the engine will comply. Refer to the engine's documentation to understand the guarantees provided, if any.

- `Definer` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

The definer of a view in SQL.

- `SubObjects` – An array of UTF-8 strings, not more than 10 strings.

A list of table Amazon Resource Names (ARNs).

- `Representations` – An array of [ViewRepresentation](#) objects, not less than 1 or more than 1000 structures.

A list of representations.

## ViewDefinitionInput structure

A structure containing details for creating or updating an AWS Glue view.

### Fields

- `IsProtected` – Boolean.

You can set this flag as true to instruct the engine not to push user-provided operations into the logical plan of the view during query planning. However, setting this flag does not guarantee

that the engine will comply. Refer to the engine's documentation to understand the guarantees provided, if any.

- `Definer` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

The definer of a view in SQL.

- `Representations` – An array of [ViewRepresentationInput](#) objects, not less than 1 or more than 10 structures.

A list of structures that contains the dialect of the view, and the query that defines the view.

- `SubObjects` – An array of UTF-8 strings, not more than 10 strings.

A list of base table ARNs that make up the view.

## ViewRepresentation structure

A structure that contains the dialect of the view, and the query that defines the view.

### Fields

- `Dialect` – UTF-8 string (valid values: REDSHIFT | ATHENA | SPARK).

The dialect of the query engine.

- `DialectVersion` – UTF-8 string, not less than 1 or more than 255 bytes long.

The version of the dialect of the query engine. For example, 3.0.0.

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

The SELECT query provided by the customer during CREATE VIEW DDL. This SQL is not used during a query on a view (`ViewExpandedText` is used instead). `ViewOriginalText` is used for cases like SHOW CREATE VIEW where users want to see the original DDL command that created the view.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

The expanded SQL for the view. This SQL is used by engines while processing a query on a view. Engines may perform operations during view creation to transform `ViewOriginalText` to `ViewExpandedText`. For example:

- Fully qualified identifiers: `SELECT * from table1 -> SELECT * from db1.table1`

- `IsStale` – Boolean.

Dialects marked as stale are no longer valid and must be updated before they can be queried in their respective query engines.

## ViewRepresentationInput structure

A structure containing details of a representation to update or create a Lake Formation view.

### Fields

- `Dialect` – UTF-8 string (valid values: REDSHIFT | ATHENA | SPARK).

A parameter that specifies the engine type of a specific representation.

- `DialectVersion` – UTF-8 string, not less than 1 or more than 255 bytes long.

A parameter that specifies the version of the engine of a specific representation.

- `ViewOriginalText` – UTF-8 string, not more than 409600 bytes long.

A string that represents the original SQL query that describes the view.

- `ValidationConnection` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to be used to validate the specific representation of the view.

- `ViewExpandedText` – UTF-8 string, not more than 409600 bytes long.

A string that represents the SQL query that describes the view with expanded resource ARNs

## Operations

- [CreateTable action \(Python: `create\_table`\)](#)
- [UpdateTable action \(Python: `update\_table`\)](#)
- [DeleteTable action \(Python: `delete\_table`\)](#)
- [BatchDeleteTable action \(Python: `batch\_delete\_table`\)](#)
- [GetTable action \(Python: `get\_table`\)](#)
- [GetTables action \(Python: `get\_tables`\)](#)
- [GetTableVersion action \(Python: `get\_table\_version`\)](#)

- [GetTableVersions action \(Python: get\\_table\\_versions\)](#)
- [DeleteTableVersion action \(Python: delete\\_table\\_version\)](#)
- [BatchDeleteTableVersion action \(Python: batch\\_delete\\_table\\_version\)](#)
- [SearchTables action \(Python: search\\_tables\)](#)
- [GetPartitionIndexes action \(Python: get\\_partition\\_indexes\)](#)
- [CreatePartitionIndex action \(Python: create\\_partition\\_index\)](#)
- [DeletePartitionIndex action \(Python: delete\\_partition\\_index\)](#)
- [GetColumnStatisticsForTable action \(Python: get\\_column\\_statistics\\_for\\_table\)](#)
- [UpdateColumnStatisticsForTable action \(Python: update\\_column\\_statistics\\_for\\_table\)](#)
- [DeleteColumnStatisticsForTable action \(Python: delete\\_column\\_statistics\\_for\\_table\)](#)

## CreateTable action (Python: create\_table)

Creates a new table definition in the Data Catalog.

### Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the Table. If none is supplied, the AWS account ID is used by default.

- `databaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog database in which to create the new table. For Hive compatibility, this name is entirely lowercase.

- `tableInput` – *Required:* A [TableInput](#) object.

The TableInput object that defines the metadata table to create in the catalog.

- `partitionIndexes` – An array of [PartitionIndex](#) objects, not more than 3 structures.

A list of partition indexes, PartitionIndex structures, to create in the table.

- `transactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The ID of the transaction.

- `OpenTableFormatInput` – An [OpenTableFormatInput](#) object.

Specifies an `OpenTableFormatInput` structure when creating an open format table.

## Response

- *No Response parameters.*

## Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `EntityNotFoundException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ConcurrentModificationException`
- `ResourceNotReadyException`

## UpdateTable action (Python: `update_table`)

Updates a metadata table in the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `TableInput` – *Required*: A [TableInput](#) object.

An updated `TableInput` object to define the metadata table in the catalog.

- `SkipArchive` – Boolean.

By default, `UpdateTable` always creates an archived version of the table before updating it. However, if `skipArchive` is set to true, `UpdateTable` does not create the archived version.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The transaction ID at which to update the table contents.

- `VersionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The version ID at which to update the table contents.

- `ViewUpdateAction` – UTF-8 string (valid values: `ADD` | `REPLACE` | `ADD_OR_REPLACE` | `DROP`).

The operation to be performed when updating the view.

- `Force` – Boolean.

A flag that can be set to true to ignore matching storage descriptor and subobject matching requirements.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

- ResourceNumberLimitExceededException
- GlueEncryptionException
- ResourceNotReadyException

## DeleteTable action (Python: delete\_table)

Removes a table definition from the Data Catalog.

### Note

After completing this operation, you no longer have access to the table versions and partitions that belong to the deleted table. AWS Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources, before calling `DeleteTable`, use `DeleteTableVersion` or `BatchDeleteTableVersion`, and `DeletePartition` or `BatchDeletePartition`, to delete any resources that belong to the table.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table to be deleted. For Hive compatibility, this name is entirely lowercase.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The transaction ID at which to delete the table contents.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- ConcurrentModificationException
- ResourceNotReadyException

## BatchDeleteTable action (Python: `batch_delete_table`)

Deletes multiple tables at once.

### Note

After completing this operation, you no longer have access to the table versions and partitions that belong to the deleted table. AWS Glue deletes these "orphaned" resources asynchronously in a timely manner, at the discretion of the service.

To ensure the immediate deletion of all related resources, before calling `BatchDeleteTable`, use `DeleteTableVersion` or `BatchDeleteTableVersion`, and `DeletePartition` or `BatchDeletePartition`, to delete any resources that belong to the table.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the tables to delete reside. For Hive compatibility, this name is entirely lowercase.

- `TablesToDelete` – *Required*: An array of UTF-8 strings, not more than 100 strings.

A list of the table to delete.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The transaction ID at which to delete the table contents.

## Response

- `Errors` – An array of [TableError](#) objects.

A list of errors encountered in attempting to delete the specified tables.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ResourceNotReadyException`

## GetTable action (Python: `get_table`)

Retrieves the `Table` definition in a Data Catalog for a specified table.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table for which to retrieve the definition. For Hive compatibility, this name is entirely lowercase.

- `TransactionId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The transaction ID at which to read the table contents.

- `QueryAsOfTime` – Timestamp.

The time as of when to read the table contents. If not set, the most recent transaction commit time will be used. Cannot be specified along with `TransactionId`.

## Response

- `Table` – A [Table](#) object.

The `Table` object that defines the specified table.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `ResourceNotReadyException`
- `FederationSourceException`
- `FederationSourceRetryableException`

## GetTables action (Python: get\_tables)

Retrieves the definitions of some or all of the tables in a given Database.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the AWS account ID is used by default.

- **DatabaseName** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog whose tables to list. For Hive compatibility, this name is entirely lowercase.

- **Expression** – UTF-8 string, not more than 2048 bytes long, matching the [Single-line string pattern](#).

A regular expression pattern. If present, only those tables whose names match the pattern are returned.

- **NextToken** – UTF-8 string.

A continuation token, included if this is a continuation call.

- **MaxResults** – Number (integer), not less than 1 or more than 100.

The maximum number of tables to return in a single response.

- **TransactionId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The transaction ID at which to read the table contents.

- **QueryAsOfTime** – Timestamp.

The time as of when to read the table contents. If not set, the most recent transaction commit time will be used. Cannot be specified along with `TransactionId`.

### Response

- **TableList** – An array of [Table](#) objects.

A list of the requested Table objects.

- NextToken – UTF-8 string.

A continuation token, present if the current list segment is not the last.

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException
- GlueEncryptionException
- FederationSourceException
- FederationSourceRetryableException

## GetTableVersion action (Python: `get_table_version`)

Retrieves a specified version of a table.

### Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the AWS account ID is used by default.

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- TableName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- **VersionId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID value of the table version to be retrieved. A VersionID is a string representation of an integer. Each version is incremented by 1.

## Response

- **TableVersion** – A [TableVersion](#) object.

The requested table version.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## GetTableVersions action (Python: `get_table_versions`)

Retrieves a list of strings that identify available versions of a specified table.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- `NextToken` – UTF-8 string.

A continuation token, if this is not the first call.

- `MaxResults` – Number (integer), not less than 1 or more than 100.

The maximum number of table versions to return in one response.

## Response

- `TableVersions` – An array of [TableVersion](#) objects.

A list of strings identifying available versions of the specified table.

- `NextToken` – UTF-8 string.

A continuation token, if the list of available versions does not include the last one.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## DeleteTableVersion action (Python: `delete_table_version`)

Deletes a specified version of a table.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- `VersionId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the table version to be deleted. A `VersionID` is a string representation of an integer. Each version is incremented by 1.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## BatchDeleteTableVersion action (Python: `batch_delete_table_version`)

Deletes a specified batch of versions of a table.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the tables reside. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in the catalog in which the table resides. For Hive compatibility, this name is entirely lowercase.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table. For Hive compatibility, this name is entirely lowercase.

- `VersionIds` – *Required*: An array of UTF-8 strings, not more than 100 strings.

A list of the IDs of versions to be deleted. A `VersionId` is a string representation of an integer. Each version is incremented by 1.

## Response

- `Errors` – An array of [TableVersionError](#) objects.

A list of errors encountered while trying to delete the specified table versions.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## SearchTables action (Python: `search_tables`)

Searches a set of tables based on properties in the table metadata as well as on the parent database. You can search against text or filter conditions.

You can only get tables that you have access to based on the security policies defined in Lake Formation. You need at least a read-only access to the table for it to be returned. If you do not

have access to all the columns in the table, these columns will not be searched against when returning the list of tables back to you. If you have access to the columns but not the data in the columns, those columns and the associated metadata for those columns will be included in the search.

## Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique identifier, consisting of *account\_id*.

- **NextToken** – UTF-8 string.

A continuation token, included if this is a continuation call.

- **Filters** – An array of [PropertyPredicate](#) objects.

A list of key-value pairs, and a comparator used to filter the search results. Returns all entities matching the predicate.

The `Comparator` member of the `PropertyPredicate` struct is used only for time fields, and can be omitted for other field types. Also, when comparing string values, such as when `Key=Name`, a fuzzy match algorithm is used. The `Key` field (for example, the value of the `Name` field) is split on certain punctuation characters, for example, `-`, `:`, `#`, etc. into tokens. Then each token is exact-match compared with the `Value` member of `PropertyPredicate`. For example, if `Key=Name` and `Value=link`, tables named `customer-link` and `xx-link-yy` are returned, but `xxlinkyy` is not returned.

- **SearchText** – Value string, not more than 1024 bytes long.

A string used for a text search.

Specifying a value in quotes filters based on an exact match to the value.

- **SortCriteria** – An array of [SortCriterion](#) objects, not more than 1 structures.

A list of criteria for sorting the results by a field name, in an ascending or descending order.

- **MaxResults** – Number (integer), not less than 1 or more than 1000.

The maximum number of tables to return in a single response.

- **ResourceShareType** – UTF-8 string (valid values: `FOREIGN` | `ALL` | `FEDERATED`).

Allows you to specify that you want to search the tables shared with your account. The allowable values are FOREIGN or ALL.

- If set to FOREIGN, will search the tables shared with your account.
- If set to ALL, will search the tables shared with your account, as well as the tables in your local account.

## Response

- NextToken – UTF-8 string.

A continuation token, present if the current list segment is not the last.

- TableList – An array of [Table](#) objects.

A list of the requested Table objects. The SearchTables response returns only the tables that you have access to.

## Errors

- InternalServiceException
- InvalidInputException
- OperationTimeoutException

## GetPartitionIndexes action (Python: get\_partition\_indexes)

Retrieves the partition indexes associated with a table.

### Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the table resides.

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a database from which you want to retrieve partition indexes.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a table for which you want to retrieve the partition indexes.

- **NextToken** – UTF-8 string.

A continuation token, included if this is a continuation call.

## Response

- **PartitionIndexDescriptorList** – An array of [PartitionIndexDescriptor](#) objects.

A list of index descriptors.

- **NextToken** – UTF-8 string.

A continuation token, present if the current list segment is not the last.

## Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `EntityNotFoundException`
- `ConflictException`

## CreatePartitionIndex action (Python: `create_partition_index`)

Creates a specified partition index in an existing table.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the table resides.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a database in which you want to create a partition index.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a table in which you want to create a partition index.

- `PartitionIndex` – *Required:* A [PartitionIndex](#) object.

Specifies a `PartitionIndex` structure to create a partition index in an existing table.

## Response

- *No Response parameters.*

## Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `EntityNotFoundException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## DeletePartitionIndex action (Python: `delete_partition_index`)

Deletes a specified partition index from an existing table.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog ID where the table resides.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a database from which you want to delete a partition index.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of a table from which you want to delete a partition index.

- `IndexName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition index to be deleted.

## Response

- *No Response parameters.*

## Errors

- `InternalServerErrorException`
- `OperationTimeoutException`
- `InvalidInputException`
- `EntityNotFoundException`
- `ConflictException`
- `GlueEncryptionException`

## GetColumnStatisticsForTable action (Python: `get_column_statistics_for_table`)

Retrieves table statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `GetTable`.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- **ColumnNames** – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of the column names.

## Response

- **ColumnStatisticsList** – An array of [ColumnStatistics](#) objects.

List of ColumnStatistics.

- **Errors** – An array of [ColumnError](#) objects.

List of ColumnStatistics that failed to be retrieved.

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

## UpdateColumnStatisticsForTable action (Python: `update_column_statistics_for_table`)

Creates or updates table statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `UpdateTable`.

## Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- **ColumnStatisticsList** – *Required:* An array of [ColumnStatistics](#) objects, not more than 25 structures.

A list of the column statistics.

## Response

- **Errors** – An array of [ColumnStatisticsError](#) objects.

List of ColumnStatisticsErrors.

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

## DeleteColumnStatisticsForTable action (Python: delete\_column\_statistics\_for\_table)

Retrieves table statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is DeleteTable.

### Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- DatabaseName – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- TableName – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- ColumnName – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the column.

### Response

- *No Response parameters.*

### Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

- `GlueEncryptionException`

## Partition API

The Partition API describes data types and operations used to work with partitions.

### Data types

- [Partition structure](#)
- [PartitionInput structure](#)
- [PartitionSpecWithSharedStorageDescriptor structure](#)
- [PartitionListComposingSpec structure](#)
- [PartitionSpecProxy structure](#)
- [PartitionValueList structure](#)
- [Segment structure](#)
- [PartitionError structure](#)
- [BatchUpdatePartitionFailureEntry structure](#)
- [BatchUpdatePartitionRequestEntry structure](#)
- [StorageDescriptor structure](#)
- [SchemaReference structure](#)
- [SerDeInfo structure](#)
- [SkewedInfo structure](#)

### Partition structure

Represents a slice of table data.

#### Fields

- `Values` – An array of UTF-8 strings.

The values of the partition.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which to create the partition.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database table in which to create the partition.

- `CreationTime` – Timestamp.

The time at which the partition was created.

- `LastAccessTime` – Timestamp.

The last time at which the partition was accessed.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

Provides information about the physical location where the partition is stored.

- `Parameters` – A map array of key-value pairs.

Each key is a `Key` string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define partition parameters.

- `LastAnalyzedTime` – Timestamp.

The last time at which column statistics were computed for this partition.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the partition resides.

## PartitionInput structure

The structure used to create and update a partition.

### Fields

- `Values` – An array of UTF-8 strings.

The values of the partition. Although this parameter is not required by the SDK, you must specify this parameter for a valid input.

The values for the keys for the new partition must be passed as an array of String objects that must be ordered in the same order as the partition keys appearing in the Amazon S3 prefix. Otherwise AWS Glue will add the values to the wrong keys.

- `LastAccessTime` – Timestamp.

The last time at which the partition was accessed.

- `StorageDescriptor` – A [StorageDescriptor](#) object.

Provides information about the physical location where the partition is stored.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define partition parameters.

- `LastAnalyzedTime` – Timestamp.

The last time at which column statistics were computed for this partition.

## PartitionSpecWithSharedStorageDescriptor structure

A partition specification for partitions that share a physical location.

### Fields

- `StorageDescriptor` – A [StorageDescriptor](#) object.

The shared physical storage information.

- `Partitions` – An array of [Partition](#) objects.

A list of the partitions that share this physical location.

## PartitionListComposingSpec structure

Lists the related partitions.

### Fields

- `Partitions` – An array of [Partition](#) objects.

A list of the partitions in the composing specification.

## PartitionSpecProxy structure

Provides a root path to specified partitions.

### Fields

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog database in which the partitions reside.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table that contains the partitions.

- `RootPath` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The root path of the proxy for addressing the partitions.

- `PartitionSpecWithSharedSD` – A [PartitionSpecWithSharedStorageDescriptor](#) object.

A specification of partitions that share the same physical storage location.

- `PartitionListComposingSpec` – A [PartitionListComposingSpec](#) object.

Specifies a list of partitions.

## PartitionValueList structure

Contains a list of values defining partitions.

## Fields

- `Values` – *Required*: An array of UTF-8 strings.

The list of values.

## Segment structure

Defines a non-overlapping region of a table's partitions, allowing multiple requests to be run in parallel.

### Fields

- `SegmentNumber` – *Required*: Number (integer), not more than None.

The zero-based index number of the segment. For example, if the total number of segments is 4, `SegmentNumber` values range from 0 through 3.

- `TotalSegments` – *Required*: Number (integer), not less than 1 or more than 10.

The total number of segments.

## PartitionError structure

Contains information about a partition error.

### Fields

- `PartitionValues` – An array of UTF-8 strings.

The values that define the partition.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the partition error.

## BatchUpdatePartitionFailureEntry structure

Contains information about a batch update partition error.

## Fields

- `PartitionValueList` – An array of UTF-8 strings, not more than 100 strings.

A list of values defining the partitions.

- `ErrorDetail` – An [ErrorDetail](#) object.

The details about the batch update partition error.

## BatchUpdatePartitionRequestEntry structure

A structure that contains the values and structure used to update a partition.

### Fields

- `PartitionValueList` – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of values defining the partitions.

- `PartitionInput` – *Required:* A [PartitionInput](#) object.

The structure used to update a partition.

## StorageDescriptor structure

Describes the physical storage of table data.

### Fields

- `Columns` – An array of [Column](#) objects.

A list of the Columns in the table.

- `Location` – Location string, not more than 2056 bytes long, matching the [URI address multiline string pattern](#).

The physical location of the table. By default, this takes the form of the warehouse location, followed by the database location in the warehouse, followed by the table name.

- `AdditionalLocations` – An array of UTF-8 strings.

A list of locations that point to the path where a Delta table is located.

- `InputFormat` – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The input format: `SequenceFileInputFormat` (binary), or `TextInputFormat`, or a custom format.

- `OutputFormat` – Format string, not more than 128 bytes long, matching the [Single-line string pattern](#).

The output format: `SequenceFileOutputFormat` (binary), or `IgnoreKeyTextOutputFormat`, or a custom format.

- `Compressed` – Boolean.

`True` if the data in the table is compressed, or `False` if not.

- `NumberOfBuckets` – Number (integer).

Must be specified if the table contains any dimension columns.

- `SerdeInfo` – A [SerDeInfo](#) object.

The serialization/deserialization (SerDe) information.

- `BucketColumns` – An array of UTF-8 strings.

A list of reducer grouping columns, clustering columns, and bucketing columns in the table.

- `SortColumns` – An array of [Order](#) objects.

A list specifying the sort order of each bucket in the table.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

The user-supplied properties in key-value form.

- `SkewedInfo` – A [SkewedInfo](#) object.

The information about values that appear frequently in a column (skewed values).

- `StoredAsSubDirectories` – Boolean.

True if the table data is stored in subdirectories, or False if not.

- `SchemaReference` – A [SchemaReference](#) object.

An object that references a schema stored in the AWS Glue Schema Registry.

When creating a table, you can pass an empty list of columns for the schema, and instead use a schema reference.

## SchemaReference structure

An object that references a schema stored in the AWS Glue Schema Registry.

### Fields

- `SchemaId` – A [SchemaId](#) object.

A structure that contains schema identity fields. Either this or the `SchemaVersionId` has to be provided.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique ID assigned to a version of the schema. Either this or the `SchemaId` has to be provided.

- `SchemaVersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

## SerDeInfo structure

Information about a serialization/deserialization program (SerDe) that serves as an extractor and loader.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the SerDe.

- `SerializationLibrary` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Usually the class that implements the SerDe. An example is `org.apache.hadoop.hive.serde2.columnar.ColumnarSerDe`.

- `Parameters` – A map array of key-value pairs.

Each key is a Key string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string, not more than 512000 bytes long.

These key-value pairs define initialization parameters for the SerDe.

## SkewedInfo structure

Specifies skewed values in a table. Skewed values are those that occur with very high frequency.

### Fields

- `SkewedColumnNames` – An array of UTF-8 strings.

A list of names of columns that contain skewed values.

- `SkewedColumnValues` – An array of UTF-8 strings.

A list of values that appear so frequently as to be considered skewed.

- `SkewedColumnValueLocationMaps` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A mapping of skewed values to the columns that contain them.

## Operations

- [CreatePartition action \(Python: `create\_partition`\)](#)
- [BatchCreatePartition action \(Python: `batch\_create\_partition`\)](#)
- [UpdatePartition action \(Python: `update\_partition`\)](#)

- [DeletePartition action \(Python: delete\\_partition\)](#)
- [BatchDeletePartition action \(Python: batch\\_delete\\_partition\)](#)
- [GetPartition action \(Python: get\\_partition\)](#)
- [GetPartitions action \(Python: get\\_partitions\)](#)
- [BatchGetPartition action \(Python: batch\\_get\\_partition\)](#)
- [BatchUpdatePartition action \(Python: batch\\_update\\_partition\)](#)
- [GetColumnStatisticsForPartition action \(Python: get\\_column\\_statistics\\_for\\_partition\)](#)
- [UpdateColumnStatisticsForPartition action \(Python: update\\_column\\_statistics\\_for\\_partition\)](#)
- [DeleteColumnStatisticsForPartition action \(Python: delete\\_column\\_statistics\\_for\\_partition\)](#)

## CreatePartition action (Python: create\_partition)

Creates a new partition.

### Request

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The AWS account ID of the catalog in which the partition is to be created.

- `databaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata database in which the partition is to be created.

- `tableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata table in which the partition is to be created.

- `partitionInput` – *Required:* A [PartitionInput](#) object.

A `PartitionInput` structure defining the partition to be created.

### Response

- *No Response parameters.*

## Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## BatchCreatePartition action (Python: `batch_create_partition`)

Creates one or more partitions in a batch operation.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog in which the partition is to be created. Currently, this should be the AWS account ID.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata database in which the partition is to be created.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata table in which the partition is to be created.

- `PartitionInputList` – *Required:* An array of [PartitionInput](#) objects, not more than 100 structures.

A list of `PartitionInput` structures that define the partitions to be created.

### Response

- `Errors` – An array of [PartitionError](#) objects.

The errors encountered when trying to create the requested partitions.

## Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## UpdatePartition action (Python: `update_partition`)

Updates a partition.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition to be updated resides. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table in question resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table in which the partition to be updated is located.

- `PartitionValueList` – *Required:* An array of UTF-8 strings, not more than 100 strings.

List of partition key values that define the partition to update.

- `PartitionInput` – *Required:* A [PartitionInput](#) object.

The new partition object to update the partition to.

The Values property can't be changed. If you want to change the partition key values for a partition, delete and recreate the partition.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

## DeletePartition action (Python: delete\_partition)

Deletes a specified partition.

### Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition to be deleted resides. If none is provided, the AWS account ID is used by default.

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table in question resides.

- TableName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table that contains the partition to be deleted.

- **PartitionValues** – *Required:* An array of UTF-8 strings.

The values that define the partition.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

## BatchDeletePartition action (Python: `batch_delete_partition`)

Deletes one or more partitions in a batch operation.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition to be deleted resides. If none is provided, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which the table in question resides.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table that contains the partitions to be deleted.

- **PartitionsToDelete** – *Required:* An array of [PartitionValueList](#) objects, not more than 25 structures.

A list of `PartitionInput` structures that define the partitions to be deleted.

## Response

- **Errors** – An array of [PartitionError](#) objects.

The errors encountered when trying to delete the requested partitions.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetPartition action (Python: `get_partition`)

Retrieves information about a specified partition.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partition in question resides. If none is provided, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partition resides.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partition's table.

- **PartitionValues** – *Required:* An array of UTF-8 strings.

The values that define the partition.

## Response

- Partition – A [Partition](#) object.

The requested information, in the form of a `Partition` object.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`
- `FederationSourceException`
- `FederationSourceRetryableException`

## GetPartitions action (Python: `get_partitions`)

Retrieves information about the partitions in a table.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `Expression` – Predicate string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

An expression that filters the partitions to be returned.

The expression uses SQL syntax similar to the SQL WHERE filter clause. The SQL statement parser [JSQLParser](#) parses the expression.

*Operators:* The following are the operators that you can use in the Expression API call:

=

Checks whether the values of the two operands are equal; if yes, then the condition becomes true.

Example: Assume 'variable a' holds 10 and 'variable b' holds 20.

(a = b) is not true.

< >

Checks whether the values of two operands are equal; if the values are not equal, then the condition becomes true.

Example: (a < > b) is true.

>

Checks whether the value of the left operand is greater than the value of the right operand; if yes, then the condition becomes true.

Example: (a > b) is not true.

<

Checks whether the value of the left operand is less than the value of the right operand; if yes, then the condition becomes true.

Example: (a < b) is true.

>=

Checks whether the value of the left operand is greater than or equal to the value of the right operand; if yes, then the condition becomes true.

Example: (a >= b) is not true.

`<=`

Checks whether the value of the left operand is less than or equal to the value of the right operand; if yes, then the condition becomes true.

Example: `(a <= b)` is true.

AND, OR, IN, BETWEEN, LIKE, NOT, IS NULL

Logical operators.

*Supported Partition Key Types:* The following are the supported partition keys.

- `string`
- `date`
- `timestamp`
- `int`
- `bigint`
- `long`
- `tinyint`
- `smallint`
- `decimal`

If an type is encountered that is not valid, an exception is thrown.

The following list shows the valid operators on each type. When you define a crawler, the `partitionKey` type is created as a `STRING`, to be compatible with the catalog partitions.

*Sample API Call:*

### Example

The table `twitter_partition` has three partitions:

```
year = 2015
  year = 2016
  year = 2017
```

## Example

Get partition year equal to 2015

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
--expression "year*='2015'"
```

## Example

Get partition year between 2016 and 2018 (exclusive)

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
--expression "year>'2016' AND year<'2018'"
```

## Example

Get partition year between 2015 and 2018 (inclusive). The following API calls are equivalent to each other:

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
--expression "year>='2015' AND year<='2018'"

aws glue get-partitions --database-name dbname --table-name
twitter_partition
--expression "year BETWEEN 2015 AND 2018"

aws glue get-partitions --database-name dbname --table-name
twitter_partition
--expression "year IN (2015,2016,2017,2018)"
```

## Example

A wildcard partition filter, where the following call output is partition year=2017. A regular expression is not supported in LIKE.

```
aws glue get-partitions --database-name dbname --table-name twitter_partition
--expression "year LIKE '%7'"
```

- NextToken – UTF-8 string.

A continuation token, if this is not the first call to retrieve these partitions.

- **Segment** – A [Segment](#) object.

The segment of the table's partitions to scan in this request.

- **MaxResults** – Number (integer), not less than 1 or more than 1000.

The maximum number of partitions to return in a single response.

- **ExcludeColumnSchema** – Boolean.

When true, specifies not returning the partition column schema. Useful when you are interested only in other partition attributes such as partition values or location. This approach avoids the problem of a large response by not returning duplicate data.

- **TransactionId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #16](#).

The transaction ID at which to read the partition contents.

- **QueryAsOfTime** – Timestamp.

The time as of when to read the partition contents. If not set, the most recent transaction commit time will be used. Cannot be specified along with **TransactionId**.

## Response

- **Partitions** – An array of [Partition](#) objects.

A list of requested partitions.

- **NextToken** – UTF-8 string.

A continuation token, if the returned list of partitions does not include the last one.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

- `GlueEncryptionException`
- `InvalidStateException`
- `ResourceNotReadyException`
- `FederationSourceException`
- `FederationSourceRetryableException`

## BatchGetPartition action (Python: `batch_get_partition`)

Retrieves partitions in a batch request.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `PartitionsToGet` – *Required:* An array of [PartitionValueList](#) objects, not more than 1000 structures.

A list of partition values identifying the partitions to retrieve.

### Response

- `Partitions` – An array of [Partition](#) objects.

A list of the requested partitions.

- `UnprocessedKeys` – An array of [PartitionValueList](#) objects, not more than 1000 structures.

A list of the partition values in the request for which partitions were not returned.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`
- `InvalidStateException`
- `FederationSourceException`
- `FederationSourceRetryableException`

## BatchUpdatePartition action (Python: `batch_update_partition`)

Updates one or more partitions in a batch operation.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog in which the partition is to be updated. Currently, this should be the AWS account ID.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata database in which the partition is to be updated.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the metadata table in which the partition is to be updated.

- `Entries` – *Required:* An array of [BatchUpdatePartitionRequestEntry](#) objects, not less than 1 or more than 100 structures.

A list of up to 100 `BatchUpdatePartitionRequestEntry` objects to update.

## Response

- **Errors** – An array of [BatchUpdatePartitionFailureEntry](#) objects.

The errors encountered when trying to update the requested partitions. A list of [BatchUpdatePartitionFailureEntry](#) objects.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`

## GetColumnStatisticsForPartition action (Python: `get_column_statistics_for_partition`)

Retrieves partition statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `GetPartition`.

## Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- **PartitionValues** – *Required:* An array of UTF-8 strings.

A list of partition values identifying the partition.

- **ColumnNames** – *Required:* An array of UTF-8 strings, not more than 100 strings.

A list of the column names.

## Response

- **ColumnStatisticsList** – An array of [ColumnStatistics](#) objects.

List of ColumnStatistics that failed to be retrieved.

- **Errors** – An array of [ColumnError](#) objects.

Error occurred during retrieving column statistics data.

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

## UpdateColumnStatisticsForPartition action (Python: `update_column_statistics_for_partition`)

Creates or updates partition statistics of columns.

The Identity and Access Management (IAM) permission required for this operation is `UpdatePartition`.

## Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `PartitionValues` – *Required*: An array of UTF-8 strings.

A list of partition values identifying the partition.

- `ColumnStatisticsList` – *Required*: An array of [ColumnStatistics](#) objects, not more than 25 structures.

A list of the column statistics.

## Response

- `Errors` – An array of [ColumnStatisticsError](#) objects.

Error occurred during updating column statistics data.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## DeleteColumnStatisticsForPartition action (Python: `delete_column_statistics_for_partition`)

Delete the partition column statistics of a column.

The Identity and Access Management (IAM) permission required for this operation is `DeletePartition`.

## Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the partitions in question reside. If none is supplied, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the partitions reside.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the partitions' table.

- `PartitionValues` – *Required:* An array of UTF-8 strings.

A list of partition values identifying the partition.

- `ColumnName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the column.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## Connection API

The Connection API describes AWS Glue connection data types, and the API for creating, deleting, updating, and listing connections.

### Data types

- [Connection structure](#)
- [ConnectionInput structure](#)
- [PhysicalConnectionRequirements structure](#)
- [GetConnectionsFilter structure](#)

### Connection structure

Defines a connection to a data source.

#### Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection definition.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the connection.

- **ConnectionType** – UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE).

The type of the connection. Currently, SFTP is not supported.

- **MatchCriteria** – An array of UTF-8 strings, not more than 10 strings.

A list of criteria that can be used in selecting this connection.

- **ConnectionProperties** – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string (valid values: HOST | PORT | USERNAME="USER\_NAME" | PASSWORD | ENCRYPTED\_PASSWORD | JDBC\_DRIVER\_JAR\_URI | JDBC\_DRIVER\_CLASS\_NAME | JDBC\_ENGINE | JDBC\_ENGINE\_VERSION | CONFIG\_FILES | INSTANCE\_ID

| JDBC\_CONNECTION\_URL | JDBC\_ENFORCE\_SSL | CUSTOM\_JDBC\_CERT |  
 SKIP\_CUSTOM\_JDBC\_CERT\_VALIDATION | CUSTOM\_JDBC\_CERT\_STRING |  
 CONNECTION\_URL | KAFKA\_BOOTSTRAP\_SERVERS | KAFKA\_SSL\_ENABLED  
 | KAFKA\_CUSTOM\_CERT | KAFKA\_SKIP\_CUSTOM\_CERT\_VALIDATION |  
 KAFKA\_CLIENT\_KEYSTORE | KAFKA\_CLIENT\_KEYSTORE\_PASSWORD |  
 KAFKA\_CLIENT\_KEY\_PASSWORD | ENCRYPTED\_KAFKA\_CLIENT\_KEYSTORE\_PASSWORD  
 | ENCRYPTED\_KAFKA\_CLIENT\_KEY\_PASSWORD | SECRET\_ID | CONNECTOR\_URL  
 | CONNECTOR\_TYPE | CONNECTOR\_CLASS\_NAME | KAFKA\_SASL\_MECHANISM  
 | KAFKA\_SASL\_PLAIN\_USERNAME | KAFKA\_SASL\_PLAIN\_PASSWORD |  
 ENCRYPTED\_KAFKA\_SASL\_PLAIN\_PASSWORD | KAFKA\_SASL\_SCRAM\_USERNAME  
 | KAFKA\_SASL\_SCRAM\_PASSWORD | KAFKA\_SASL\_SCRAM\_SECRETS\_ARN |  
 ENCRYPTED\_KAFKA\_SASL\_SCRAM\_PASSWORD | KAFKA\_SASL\_GSSAPI\_KEYTAB  
 | KAFKA\_SASL\_GSSAPI\_KRB5\_CONF | KAFKA\_SASL\_GSSAPI\_SERVICE |  
 KAFKA\_SASL\_GSSAPI\_PRINCIPAL | ROLE\_ARN).

Each value is a Value string, not more than 1024 bytes long.

These key-value pairs define parameters for the connection:

- HOST - The host URI: either the fully qualified domain name (FQDN) or the IPv4 address of the database host.
- PORT - The port number, between 1024 and 65535, of the port on which the database host is listening for database connections.
- USER\_NAME - The name under which to log in to the database. The value string for USER\_NAME is "USERNAME".
- PASSWORD - A password, if one is used, for the user name.
- ENCRYPTED\_PASSWORD - When you enable connection password protection by setting `ConnectionPasswordEncryption` in the Data Catalog encryption settings, this field stores the encrypted password.
- JDBC\_DRIVER\_JAR\_URI - The Amazon Simple Storage Service (Amazon S3) path of the JAR file that contains the JDBC driver to use.
- JDBC\_DRIVER\_CLASS\_NAME - The class name of the JDBC driver to use.
- JDBC\_ENGINE - The name of the JDBC engine to use.
- JDBC\_ENGINE\_VERSION - The version of the JDBC engine to use.
- CONFIG\_FILES - (Reserved for future use.)
- INSTANCE\_ID - The instance ID to use.

- `JDBC_CONNECTION_URL` - The URL for connecting to a JDBC data source.
- `JDBC_ENFORCE_SSL` - A Boolean string (true, false) specifying whether Secure Sockets Layer (SSL) with hostname matching is enforced for the JDBC connection on the client. The default is false.
- `CUSTOM_JDBC_CERT` - An Amazon S3 location specifying the customer's root certificate. AWS Glue uses this root certificate to validate the customer's certificate when connecting to the customer database. AWS Glue only handles X.509 certificates. The certificate provided must be DER-encoded and supplied in Base64 encoding PEM format.
- `SKIP_CUSTOM_JDBC_CERT_VALIDATION` - By default, this is false. AWS Glue validates the Signature algorithm and Subject Public Key Algorithm for the customer certificate. The only permitted algorithms for the Signature algorithm are SHA256withRSA, SHA384withRSA or SHA512withRSA. For the Subject Public Key Algorithm, the key length must be at least 2048. You can set the value of this property to true to skip AWS Glue's validation of the customer certificate.
- `CUSTOM_JDBC_CERT_STRING` - A custom JDBC certificate string which is used for domain match or distinguished name match to prevent a man-in-the-middle attack. In Oracle database, this is used as the `SSL_SERVER_CERT_DN`; in Microsoft SQL Server, this is used as the `hostNameInCertificate`.
- `CONNECTION_URL` - The URL for connecting to a general (non-JDBC) data source.
- `SECRET_ID` - The secret ID used for the secret manager of credentials.
- `CONNECTOR_URL` - The connector URL for a MARKETPLACE or CUSTOM connection.
- `CONNECTOR_TYPE` - The connector type for a MARKETPLACE or CUSTOM connection.
- `CONNECTOR_CLASS_NAME` - The connector class name for a MARKETPLACE or CUSTOM connection.
- `KAFKA_BOOTSTRAP_SERVERS` - A comma-separated list of host and port pairs that are the addresses of the Apache Kafka brokers in a Kafka cluster to which a Kafka client will connect to and bootstrap itself.
- `KAFKA_SSL_ENABLED` - Whether to enable or disable SSL on an Apache Kafka connection. Default value is "true".
- `KAFKA_CUSTOM_CERT` - The Amazon S3 URL for the private CA cert file (.pem format). The default is an empty string.

- `KAFKA_SKIP_CUSTOM_CERT_VALIDATION` - Whether to skip the validation of the CA cert file or not. AWS Glue validates for three algorithms: SHA256withRSA, SHA384withRSA and SHA512withRSA. Default value is "false".
- `KAFKA_CLIENT_KEYSTORE` - The Amazon S3 location of the client keystore file for Kafka client side authentication (Optional).
- `KAFKA_CLIENT_KEYSTORE_PASSWORD` - The password to access the provided keystore (Optional).
- `KAFKA_CLIENT_KEY_PASSWORD` - A keystore can consist of multiple keys, so this is the password to access the client key to be used with the Kafka server side key (Optional).
- `ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD` - The encrypted version of the Kafka client keystore password (if the user has the AWS Glue encrypt passwords setting selected).
- `ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD` - The encrypted version of the Kafka client key password (if the user has the AWS Glue encrypt passwords setting selected).
- `KAFKA_SASL_MECHANISM` - "SCRAM-SHA-512", "GSSAPI", "AWS\_MSK\_IAM", or "PLAIN". These are the supported [SASL Mechanisms](#).
- `KAFKA_SASL_PLAIN_USERNAME` - A plaintext username used to authenticate with the "PLAIN" mechanism.
- `KAFKA_SASL_PLAIN_PASSWORD` - A plaintext password used to authenticate with the "PLAIN" mechanism.
- `ENCRYPTED_KAFKA_SASL_PLAIN_PASSWORD` - The encrypted version of the Kafka SASL PLAIN password (if the user has the AWS Glue encrypt passwords setting selected).
- `KAFKA_SASL_SCRAM_USERNAME` - A plaintext username used to authenticate with the "SCRAM-SHA-512" mechanism.
- `KAFKA_SASL_SCRAM_PASSWORD` - A plaintext password used to authenticate with the "SCRAM-SHA-512" mechanism.
- `ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD` - The encrypted version of the Kafka SASL SCRAM password (if the user has the AWS Glue encrypt passwords setting selected).
- `KAFKA_SASL_SCRAM_SECRETS_ARN` - The Amazon Resource Name of a secret in AWS Secrets Manager.
- `KAFKA_SASL_GSSAPI_KEYTAB` - The S3 location of a Kerberos keytab file. A keytab stores long-term keys for one or more principals. For more information, see [MIT Kerberos Documentation: Keytab](#).

- `KAFKA_SASL_GSSAPI_KRB5_CONF` - The S3 location of a Kerberos `krb5.conf` file. A `krb5.conf` stores Kerberos configuration information, such as the location of the KDC server. For more information, see [MIT Kerberos Documentation: krb5.conf](#).
- `KAFKA_SASL_GSSAPI_SERVICE` - The Kerberos service name, as set with `sasl.kerberos.service.name` in your [Kafka Configuration](#).
- `KAFKA_SASL_GSSAPI_PRINCIPAL` - The name of the Kerberos principal used by AWS Glue. For more information, see [Kafka Documentation: Configuring Kafka Brokers](#).
- `PhysicalConnectionRequirements` – A [PhysicalConnectionRequirements](#) object.

The physical connection requirements, such as virtual private cloud (VPC) and `SecurityGroup`, that are needed to make this connection successfully.

- `CreationTime` – Timestamp.

The timestamp of the time that this connection definition was created.

- `LastUpdatedTime` – Timestamp.

The timestamp of the last time the connection definition was updated.

- `LastUpdatedBy` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The user, group, or role that last updated this connection definition.

- `Status` – UTF-8 string (valid values: `READY` | `IN_PROGRESS` | `FAILED`).

The status of the connection. Can be one of: `READY`, `IN_PROGRESS`, or `FAILED`.

- `StatusReason` – UTF-8 string, not less than 1 or more than 16384 bytes long.

The reason for the connection status.

- `LastConnectionValidationTime` – Timestamp.

A timestamp of the time this connection was last validated.

- `AuthenticationConfiguration` – An [AuthenticationConfiguration](#) object.

The authentication properties of the connection.

## ConnectionInput structure

A structure that is used to specify a connection to create or update.

## Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the connection.

- **ConnectionType** – *Required:* UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE).

The type of the connection. Currently, these types are supported:

- **JDBC** - Designates a connection to a database through Java Database Connectivity (JDBC).

JDBC Connections use the following ConnectionParameters.

- **Required:** All of (HOST, PORT, JDBC\_ENGINE) or JDBC\_CONNECTION\_URL.
- **Required:** All of (USERNAME, PASSWORD) or SECRET\_ID.
- **Optional:** JDBC\_ENFORCE\_SSL, CUSTOM\_JDBC\_CERT, CUSTOM\_JDBC\_CERT\_STRING, SKIP\_CUSTOM\_JDBC\_CERT\_VALIDATION. These parameters are used to configure SSL with JDBC.
- **KAFKA** - Designates a connection to an Apache Kafka streaming platform.

KAFKA Connections use the following ConnectionParameters.

- **Required:** KAFKA\_BOOTSTRAP\_SERVERS.
- **Optional:** KAFKA\_SSL\_ENABLED, KAFKA\_CUSTOM\_CERT, KAFKA\_SKIP\_CUSTOM\_CERT\_VALIDATION. These parameters are used to configure SSL with KAFKA.
- **Optional:** KAFKA\_CLIENT\_KEYSTORE, KAFKA\_CLIENT\_KEYSTORE\_PASSWORD, KAFKA\_CLIENT\_KEY\_PASSWORD, ENCRYPTED\_KAFKA\_CLIENT\_KEYSTORE\_PASSWORD, ENCRYPTED\_KAFKA\_CLIENT\_KEY\_PASSWORD. These parameters are used to configure TLS client configuration with SSL in KAFKA.
- **Optional:** KAFKA\_SASL\_MECHANISM. Can be specified as SCRAM-SHA-512, GSSAPI, or AWS\_MSK\_IAM.

- Optional: KAFKA\_SASL\_SCRAM\_USERNAME, KAFKA\_SASL\_SCRAM\_PASSWORD, ENCRYPTED\_KAFKA\_SASL\_SCRAM\_PASSWORD. These parameters are used to configure SASL/SCRAM-SHA-512 authentication with KAFKA.
- Optional: KAFKA\_SASL\_GSSAPI\_KEYTAB, KAFKA\_SASL\_GSSAPI\_KRB5\_CONF, KAFKA\_SASL\_GSSAPI\_SERVICE, KAFKA\_SASL\_GSSAPI\_PRINCIPAL. These parameters are used to configure SASL/GSSAPI authentication with KAFKA.
- MONGODB - Designates a connection to a MongoDB document database.

MONGODB Connections use the following ConnectionParameters.

- Required: CONNECTION\_URL.
- Required: All of (USERNAME, PASSWORD) or SECRET\_ID.
- SALESFORCE - Designates a connection to Salesforce using OAuth authentication.
  - Requires the AuthenticationConfiguration member to be configured.
- NETWORK - Designates a network connection to a data source within an Amazon Virtual Private Cloud environment (Amazon VPC).

NETWORK Connections do not require ConnectionParameters. Instead, provide a PhysicalConnectionRequirements.

- MARKETPLACE - Uses configuration settings contained in a connector purchased from AWS Marketplace to read from and write to data stores that are not natively supported by AWS Glue.

MARKETPLACE Connections use the following ConnectionParameters.

- Required: CONNECTOR\_TYPE, CONNECTOR\_URL, CONNECTOR\_CLASS\_NAME, CONNECTION\_URL.
- Required for JDBC CONNECTOR\_TYPE connections: All of (USERNAME, PASSWORD) or SECRET\_ID.
- CUSTOM - Uses configuration settings contained in a custom connector to read from and write to data stores that are not natively supported by AWS Glue.

SFTP is not supported.

For more information about how optional ConnectionProperties are used to configure features in AWS Glue, consult [AWS Glue connection properties](#).

For more information about how optional `ConnectionProperties` are used to configure features in AWS Glue Studio, consult [Using connectors and connections](#).

- `MatchCriteria` – An array of UTF-8 strings, not more than 10 strings.

A list of criteria that can be used in selecting this connection.

- `ConnectionProperties` – *Required*: A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string (valid values: `HOST` | `PORT` | `USERNAME="USER_NAME"` | `PASSWORD` | `ENCRYPTED_PASSWORD` | `JDBC_DRIVER_JAR_URI` | `JDBC_DRIVER_CLASS_NAME` | `JDBC_ENGINE` | `JDBC_ENGINE_VERSION` | `CONFIG_FILES` | `INSTANCE_ID` | `JDBC_CONNECTION_URL` | `JDBC_ENFORCE_SSL` | `CUSTOM_JDBC_CERT` | `SKIP_CUSTOM_JDBC_CERT_VALIDATION` | `CUSTOM_JDBC_CERT_STRING` | `CONNECTION_URL` | `KAFKA_BOOTSTRAP_SERVERS` | `KAFKA_SSL_ENABLED` | `KAFKA_CUSTOM_CERT` | `KAFKA_SKIP_CUSTOM_CERT_VALIDATION` | `KAFKA_CLIENT_KEYSTORE` | `KAFKA_CLIENT_KEYSTORE_PASSWORD` | `KAFKA_CLIENT_KEY_PASSWORD` | `ENCRYPTED_KAFKA_CLIENT_KEYSTORE_PASSWORD` | `ENCRYPTED_KAFKA_CLIENT_KEY_PASSWORD` | `SECRET_ID` | `CONNECTOR_URL` | `CONNECTOR_TYPE` | `CONNECTOR_CLASS_NAME` | `KAFKA_SASL_MECHANISM` | `KAFKA_SASL_PLAIN_USERNAME` | `KAFKA_SASL_PLAIN_PASSWORD` | `ENCRYPTED_KAFKA_SASL_PLAIN_PASSWORD` | `KAFKA_SASL_SCRAM_USERNAME` | `KAFKA_SASL_SCRAM_PASSWORD` | `KAFKA_SASL_SCRAM_SECRETS_ARN` | `ENCRYPTED_KAFKA_SASL_SCRAM_PASSWORD` | `KAFKA_SASL_GSSAPI_KEYTAB` | `KAFKA_SASL_GSSAPI_KRB5_CONF` | `KAFKA_SASL_GSSAPI_SERVICE` | `KAFKA_SASL_GSSAPI_PRINCIPAL` | `ROLE_ARN`).

Each value is a Value string, not more than 1024 bytes long.

These key-value pairs define parameters for the connection.

- `PhysicalConnectionRequirements` – A [PhysicalConnectionRequirements](#) object.

The physical connection requirements, such as virtual private cloud (VPC) and `SecurityGroup`, that are needed to successfully make this connection.

- `AuthenticationConfiguration` – An [AuthenticationConfigurationInput](#) object.

The authentication properties of the connection. Used for a Salesforce connection.

- `ValidateCredentials` – Boolean.

A flag to validate the credentials during create connection. Used for a Salesforce connection. Default is true.

## PhysicalConnectionRequirements structure

The OAuth client app in GetConnection response.

### Fields

- **SubnetId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The subnet ID used by the connection.

- **SecurityGroupIdList** – An array of UTF-8 strings, not more than 50 strings.

The security group ID list used by the connection.

- **AvailabilityZone** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The connection's Availability Zone.

## GetConnectionsFilter structure

Filters the connection definitions that are returned by the GetConnections API operation.

### Fields

- **MatchCriteria** – An array of UTF-8 strings, not more than 10 strings.

A criteria string that must match the criteria recorded in the connection definition for that connection definition to be returned.

- **ConnectionType** – UTF-8 string (valid values: JDBC | SFTP | MONGODB | KAFKA | NETWORK | MARKETPLACE | CUSTOM | SALESFORCE).

The type of connections to return. Currently, SFTP is not supported.

## Operations

- [CreateConnection action \(Python: create\\_connection\)](#)
- [DeleteConnection action \(Python: delete\\_connection\)](#)
- [GetConnection action \(Python: get\\_connection\)](#)
- [GetConnections action \(Python: get\\_connections\)](#)
- [UpdateConnection action \(Python: update\\_connection\)](#)
- [BatchDeleteConnection action \(Python: batch\\_delete\\_connection\)](#)

### CreateConnection action (Python: create\_connection)

Creates a connection definition in the Data Catalog.

Connections used for creating federated resources require the IAM `glue:PassConnection` permission.

#### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the connection. If none is provided, the AWS account ID is used by default.

- `ConnectionInput` – *Required:* A [ConnectionInput](#) object.

A `ConnectionInput` object defining the connection to create.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags you assign to the connection.

#### Response

- `CreateConnectionStatus` – UTF-8 string (valid values: `READY` | `IN_PROGRESS` | `FAILED`).

The status of the connection creation request. The request can take some time for certain authentication types, for example when creating an OAuth connection with token exchange over VPC.

## Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `GlueEncryptionException`

## DeleteConnection action (Python: `delete_connection`)

Deletes a connection from the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connection resides. If none is provided, the AWS account ID is used by default.

- `ConnectionName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to delete.

### Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `OperationTimeoutException`

## GetConnection action (Python: `get_connection`)

Retrieves a connection definition from the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connection resides. If none is provided, the AWS account ID is used by default.

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection definition to retrieve.

- `HidePassword` – Boolean.

Allows you to retrieve the connection metadata without returning the password. For instance, the AWS Glue console uses this flag to retrieve the connection, and does not display the password. Set this parameter when the caller might not have permission to use the AWS KMS key to decrypt the password, but it does have permission to access the rest of the connection properties.

### Response

- `Connection` – A [Connection](#) object.

The requested connection definition.

### Errors

- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`
- `GlueEncryptionException`

## GetConnections action (Python: `get_connections`)

Retrieves a list of connection definitions from the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connections reside. If none is provided, the AWS account ID is used by default.

- `Filter` – A [GetConnectionsFilter](#) object.

A filter that controls which connections are returned.

- `HidePassword` – Boolean.

Allows you to retrieve the connection metadata without returning the password. For instance, the AWS Glue console uses this flag to retrieve the connection, and does not display the password. Set this parameter when the caller might not have permission to use the AWS KMS key to decrypt the password, but it does have permission to access the rest of the connection properties.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of connections to return in one response.

### Response

- `ConnectionList` – An array of [Connection](#) objects.

A list of requested connection definitions.

- `NextToken` – UTF-8 string.

A continuation token, if the list of connections returned does not include the last of the filtered connections.

## Errors

- EntityNotFoundException
- OperationTimeoutException
- InvalidInputException
- GlueEncryptionException

## UpdateConnection action (Python: update\_connection)

Updates a connection definition in the Data Catalog.

### Request

- CatalogId – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connection resides. If none is provided, the AWS account ID is used by default.

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection definition to update.

- ConnectionInput – *Required:* A [ConnectionInput](#) object.

A ConnectionInput object that redefines the connection in question.

### Response

- *No Response parameters.*

## Errors

- InvalidInputException
- EntityNotFoundException
- OperationTimeoutException
- InvalidInputException
- GlueEncryptionException

## BatchDeleteConnection action (Python: batch\_delete\_connection)

Deletes a list of connection definitions from the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the connections reside. If none is provided, the AWS account ID is used by default.

- `ConnectionNameList` – *Required*: An array of UTF-8 strings, not more than 25 strings.

A list of names of the connections to delete.

### Response

- `Succeeded` – An array of UTF-8 strings.

A list of names of the connection definitions that were successfully deleted.

- `Errors` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a An [ErrorDetail](#) object.

A map of the names of connections that were not successfully deleted to error details.

### Errors

- `InternalServiceException`
- `OperationTimeoutException`

### Authentication configuration

- [AuthenticationConfiguration](#) structure
- [AuthenticationConfigurationInput](#) structure

- [OAuth2Properties structure](#)
- [OAuth2PropertiesInput structure](#)
- [OAuth2ClientApplication structure](#)
- [AuthorizationCodeProperties structure](#)

## AuthenticationConfiguration structure

A structure containing the authentication configuration.

### Fields

- `AuthenticationType` – UTF-8 string (valid values: BASIC | OAUTH2 | CUSTOM).

A structure containing the authentication configuration.

- `SecretArn` – UTF-8 string, matching the [Custom string pattern #11](#).

The secret manager ARN to store credentials.

- `OAuth2Properties` – An [OAuth2Properties](#) object.

The properties for OAuth2 authentication.

## AuthenticationConfigurationInput structure

A structure containing the authentication configuration in the CreateConnection request.

### Fields

- `AuthenticationType` – UTF-8 string (valid values: BASIC | OAUTH2 | CUSTOM).

A structure containing the authentication configuration in the CreateConnection request.

- `SecretArn` – UTF-8 string, matching the [Custom string pattern #11](#).

The secret manager ARN to store credentials in the CreateConnection request.

- `OAuth2Properties` – An [OAuth2PropertiesInput](#) object.

The properties for OAuth2 authentication in the CreateConnection request.

## OAuth2Properties structure

A structure containing properties for OAuth2 authentication.

### Fields

- `OAuth2GrantType` – UTF-8 string (valid values: `AUTHORIZATION_CODE` | `CLIENT_CREDENTIALS` | `JWT_BEARER`).

The OAuth2 grant type. For example, `AUTHORIZATION_CODE`, `JWT_BEARER`, or `CLIENT_CREDENTIALS`.

- `OAuth2ClientApplication` – An [OAuth2ClientApplication](#) object.

The client application type. For example, `AWS_MANAGED` or `USER_MANAGED`.

- `TokenUrl` – UTF-8 string, not more than 256 bytes long, matching the [Custom string pattern #12](#).

The URL of the provider's authentication server, to exchange an authorization code for an access token.

- `TokenUrlParametersMap` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 512 bytes long.

A map of parameters that are added to the token GET request.

## OAuth2PropertiesInput structure

A structure containing properties for OAuth2 in the `CreateConnection` request.

### Fields

- `OAuth2GrantType` – UTF-8 string (valid values: `AUTHORIZATION_CODE` | `CLIENT_CREDENTIALS` | `JWT_BEARER`).

The OAuth2 grant type in the `CreateConnection` request. For example, `AUTHORIZATION_CODE`, `JWT_BEARER`, or `CLIENT_CREDENTIALS`.

- `OAuth2ClientApplication` – An [OAuth2ClientApplication](#) object.

The client application type in the CreateConnection request. For example, `AWS_MANAGED` or `USER_MANAGED`.

- `TokenUrl` – UTF-8 string, not more than 256 bytes long, matching the [Custom string pattern #12](#).

The URL of the provider's authentication server, to exchange an authorization code for an access token.

- `TokenUrlParametersMap` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not less than 1 or more than 512 bytes long.

A map of parameters that are added to the token GET request.

- `AuthorizationCodeProperties` – An [AuthorizationCodeProperties](#) object.

The set of properties required for the the OAuth2 AUTHORIZATION\_CODE grant type.

## OAuth2ClientApplication structure

The OAuth2 client app used for the connection.

### Fields

- `UserManagedClientApplicationClientId` – UTF-8 string, not more than 2048 bytes long, matching the [Custom string pattern #13](#).

The client application clientID if the ClientAppType is `USER_MANAGED`.

- `AWManagedClientApplicationReference` – UTF-8 string, not more than 2048 bytes long, matching the [Custom string pattern #13](#).

The reference to the SaaS-side client app that is AWS managed.

## AuthorizationCodeProperties structure

The set of properties required for the the OAuth2 AUTHORIZATION\_CODE grant type workflow.

## Fields

- `AuthorizationCode` – UTF-8 string, not less than 1 or more than 4096 bytes long, matching the [Custom string pattern #13](#).

An authorization code to be used in the third leg of the `AUTHORIZATION_CODE` grant workflow. This is a single-use code which becomes invalid once exchanged for an access token, thus it is acceptable to have this value as a request parameter.

- `RedirectUri` – UTF-8 string, not more than 512 bytes long, matching the [Custom string pattern #14](#).

The redirect URI where the user gets redirected to by authorization server when issuing an authorization code. The URI is subsequently used when the authorization code is exchanged for an access token.

## User-defined Function API

The User-defined Function API describes AWS Glue data types and operations used in working with functions.

### Data types

- [UserDefinedFunction structure](#)
- [UserDefinedFunctionInput structure](#)

### UserDefinedFunction structure

Represents the equivalent of a Hive user-defined function (UDF) definition.

#### Fields

- `FunctionName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database that contains the function.

- `ClassName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Java class that contains the function code.

- `OwnerName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The owner of the function.

- `OwnerType` – UTF-8 string (valid values: USER | ROLE | GROUP).

The owner type.

- `CreateTime` – Timestamp.

The time at which the function was created.

- `ResourceUris` – An array of [ResourceUri](#) objects, not more than 1000 structures.

The resource URIs for the function.

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which the function resides.

## UserDefinedFunctionInput structure

A structure used to create or update a user-defined function.

### Fields

- `FunctionName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

- `ClassName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Java class that contains the function code.

- `OwnerName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The owner of the function.

- `OwnerType` – UTF-8 string (valid values: `USER` | `ROLE` | `GROUP`).

The owner type.

- `ResourceUris` – An array of [ResourceUri](#) objects, not more than 1000 structures.

The resource URIs for the function.

## Operations

- [CreateUserDefinedFunction action \(Python: `create\_user\_defined\_function`\)](#)
- [UpdateUserDefinedFunction action \(Python: `update\_user\_defined\_function`\)](#)
- [DeleteUserDefinedFunction action \(Python: `delete\_user\_defined\_function`\)](#)
- [GetUserDefinedFunction action \(Python: `get\_user\_defined\_function`\)](#)
- [GetUserDefinedFunctions action \(Python: `get\_user\_defined\_functions`\)](#)

## CreateUserDefinedFunction action (Python: `create_user_defined_function`)

Creates a new function definition in the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog in which to create the function. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database in which to create the function.

- `FunctionInput` – *Required:* An [UserDefinedFunctionInput](#) object.

A `FunctionInput` object that defines the function to create in the Data Catalog.

## Response

- *No Response parameters.*

## Errors

- AlreadyExistsException
- InvalidInputException
- InternalServiceException
- EntityNotFoundException
- OperationTimeoutException
- ResourceNumberLimitExceededException
- GlueEncryptionException

## UpdateUserDefinedFunction action (Python: update\_user\_defined\_function)

Updates an existing function definition in the Data Catalog.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the function to be updated is located. If none is provided, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the function to be updated is located.

- **FunctionName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

- **FunctionInput** – *Required:* An [UserDefinedFunctionInput](#) object.

A [FunctionInput](#) object that redefines the function in the Data Catalog.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException
- GlueEncryptionException

## DeleteUserDefinedFunction action (Python: delete\_user\_defined\_function)

Deletes an existing function definition from the Data Catalog.

### Request

- **CatalogId** – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the function to be deleted is located. If none is supplied, the AWS account ID is used by default.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the function is located.

- **FunctionName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function definition to be deleted.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- InternalServiceException
- OperationTimeoutException

## GetUserDefinedFunction action (Python: `get_user_defined_function`)

Retrieves a specified function definition from the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the function to be retrieved is located. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the function is located.

- `FunctionName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the function.

### Response

- `UserDefinedFunction` – An [UserDefinedFunction](#) object.

The requested function definition.

## Errors

- EntityNotFoundException
- InvalidInputException

- `InternalServiceException`
- `OperationTimeoutException`
- `GlueEncryptionException`

## GetUserDefinedFunctions action (Python: `get_user_defined_functions`)

Retrieves multiple function definitions from the Data Catalog.

### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the functions to be retrieved are located. If none is provided, the AWS account ID is used by default.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the catalog database where the functions are located. If none is provided, functions from all the databases across the catalog will be returned.

- `Pattern` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

An optional function-name pattern string that filters the function definitions returned.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 100.

The maximum number of functions to return in one response.

### Response

- `UserDefinedFunctions` – An array of [UserDefinedFunction](#) objects.

A list of requested function definitions.

- `NextToken` – UTF-8 string.

A continuation token, if the list of functions returned does not include the last requested function.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `GlueEncryptionException`

## Importing an Athena catalog to AWS Glue

The Migration API describes AWS Glue data types and operations having to do with migrating an Athena Data catalog to AWS Glue.

### Data types

- [CatalogImportStatus structure](#)

### CatalogImportStatus structure

A structure containing migration status information.

#### Fields

- `ImportCompleted` – Boolean.

True if the migration has completed, or False otherwise.

- `ImportTime` – Timestamp.

The time that the migration was started.

- `ImportedBy` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the person who initiated the migration.

## Operations

- [ImportCatalogToGlue action \(Python: import\\_catalog\\_to\\_glue\)](#)
- [GetCatalogImportStatus action \(Python: get\\_catalog\\_import\\_status\)](#)

### ImportCatalogToGlue action (Python: import\_catalog\_to\_glue)

Imports an existing Amazon Athena Data Catalog to AWS Glue.

#### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog to import. Currently, this should be the AWS account ID.

#### Response

- *No Response parameters.*

#### Errors

- `InternalServiceException`
- `OperationTimeoutException`

### GetCatalogImportStatus action (Python: get\_catalog\_import\_status)

Retrieves the status of a migration operation.

#### Request

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the catalog to migrate. Currently, this should be the AWS account ID.

## Response

- `ImportStatus` – A [CatalogImportStatus](#) object.

The status of the specified catalog migration.

## Errors

- `InternalServiceException`
- `OperationTimeoutException`

## Table optimizer API

The table optimizer API describes the AWS Glue API for enabling compaction to improve read performance.

## Data types

- [TableOptimizer](#) structure
- [TableOptimizerConfiguration](#) structure
- [TableOptimizerRun](#) structure
- [RunMetrics](#) structure
- [BatchGetTableOptimizerEntry](#) structure
- [BatchTableOptimizer](#) structure
- [BatchGetTableOptimizerError](#) structure

## TableOptimizer structure

Contains details about an optimizer associated with a table.

### Fields

- `type` – UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer. Currently, the only valid value is `compaction`.

- `configuration` – A [TableOptimizerConfiguration](#) object.

A `TableOptimizerConfiguration` object that was specified when creating or updating a table optimizer.

- `lastRun` – A [TableOptimizerRun](#) object.

A `TableOptimizerRun` object representing the last run of the table optimizer.

## TableOptimizerConfiguration structure

Contains details on the configuration of a table optimizer. You pass this configuration when creating or updating a table optimizer.

### Fields

- `roleArn` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Single-line string pattern](#).

A role passed by the caller which gives the service permission to update the resources associated with the optimizer on the caller's behalf.

- `enabled` – Boolean.

Whether table optimization is enabled.

## TableOptimizerRun structure

Contains details for a table optimizer run.

### Fields

- `eventType` – UTF-8 string (valid values: `starting="STARTING"` | `completed="COMPLETED"` | `failed="FAILED"` | `in_progress="IN_PROGRESS"`).

An event type representing the status of the table optimizer run.

- `startTimestamp` – Timestamp.

Represents the epoch timestamp at which the compaction job was started within Lake Formation.

- `endTimeStamp` – Timestamp.

Represents the epoch timestamp at which the compaction job ended.

- `metrics` – A [RunMetrics](#) object.

A `RunMetrics` object containing metrics for the optimizer run.

- `error` – UTF-8 string.

An error that occurred during the optimizer run.

## RunMetrics structure

Metrics for the optimizer run.

### Fields

- `NumberOfBytesCompacted` – UTF-8 string.

The number of bytes removed by the compaction job run.

- `NumberOfFilesCompacted` – UTF-8 string.

The number of files removed by the compaction job run.

- `NumberOfDpus` – UTF-8 string.

The number of DPU hours consumed by the job.

- `JobDurationInHour` – UTF-8 string.

The duration of the job in hours.

## BatchGetTableOptimizerEntry structure

Represents a table optimizer to retrieve in the `BatchGetTableOptimizer` operation.

### Fields

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, at least 1 byte long.

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, at least 1 byte long.

The name of the table.

- `type` – UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

## BatchTableOptimizer structure

Contains details for one of the table optimizers returned by the `BatchGetTableOptimizer` operation.

### Fields

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, at least 1 byte long.

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, at least 1 byte long.

The name of the table.

- `tableOptimizer` – A [TableOptimizer](#) object.

A `TableOptimizer` object that contains details on the configuration and last run of a table optimizer.

## BatchGetTableOptimizerError structure

Contains details on one of the errors in the error list returned by the `BatchGetTableOptimizer` operation.

## Fields

- `error` – An [ErrorDetail](#) object.

An `ErrorDetail` object containing code and message details about the error.

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, at least 1 byte long.

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, at least 1 byte long.

The name of the table.

- `type` – UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

## Operations

- [GetTableOptimizer action \(Python: `get\_table\_optimizer`\)](#)
- [BatchGetTableOptimizer action \(Python: `batch\_get\_table\_optimizer`\)](#)
- [ListTableOptimizerRuns action \(Python: `list\_table\_optimizer\_runs`\)](#)
- [CreateTableOptimizer action \(Python: `create\_table\_optimizer`\)](#)
- [DeleteTableOptimizer action \(Python: `delete\_table\_optimizer`\)](#)
- [UpdateTableOptimizer action \(Python: `update\_table\_optimizer`\)](#)

## GetTableOptimizer action (Python: `get_table_optimizer`)

Returns the configuration of all optimizers associated with a specified table.

### Request

- `CatalogId` – *Required*: Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required*: UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

## Response

- `CatalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `DatabaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `TableOptimizer` – A [TableOptimizer](#) object.

The optimizer associated with the specified table.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`

- `AccessDeniedException`
- `InternalServiceException`
- `ThrottlingException`

## BatchGetTableOptimizer action (Python: `batch_get_table_optimizer`)

Returns the configuration for the specified table optimizers.

### Request

- `Entries` – *Required*: An array of [BatchGetTableOptimizerEntry](#) objects.

A list of `BatchGetTableOptimizerEntry` objects specifying the table optimizers to retrieve.

### Response

- `TableOptimizers` – An array of [BatchTableOptimizer](#) objects.

A list of `BatchTableOptimizer` objects.

- `Failures` – An array of [BatchGetTableOptimizerError](#) objects.

A list of errors from the operation.

### Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`
- `ThrottlingException`

## ListTableOptimizerRuns action (Python: `list_table_optimizer_runs`)

Lists the history of previous optimizer runs for a specific table.

## Request

- `catalogId` – *Required*: Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `tableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `type` – *Required*: UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer. Currently, the only valid value is `compaction`.

- `maxResults` – Number (integer).

The maximum number of optimizer runs to return on each call.

- `nextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- `catalogId` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- `databaseName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `tableName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- NextToken – UTF-8 string.

A continuation token for paginating the returned list of optimizer runs, returned if the current segment of the list is not the last.

- TableOptimizerRuns – An array of [TableOptimizerRun](#) objects.

A list of the optimizer runs associated with a table.

## Errors

- EntityNotFoundException
- AccessDeniedException
- InvalidInputException
- ValidationException
- InternalServiceException
- ThrottlingException

## CreateTableOptimizer action (Python: create\_table\_optimizer)

Creates a new table optimizer for a specific function. `compaction` is the only currently supported optimizer type.

### Request

- CatalogId – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- TableName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- **Type** – *Required*: UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer. Currently, the only valid value is `compaction`.

- **TableOptimizerConfiguration** – *Required*: A [TableOptimizerConfiguration](#) object.

A `TableOptimizerConfiguration` object representing the configuration of a table optimizer.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `ValidationException`
- `InvalidInputException`
- `AccessDeniedException`
- `AlreadyExistsException`
- `InternalServiceException`
- `ThrottlingException`

## DeleteTableOptimizer action (Python: `delete_table_optimizer`)

Deletes an optimizer and all associated metadata for a table. The optimization will no longer be performed on the table.

### Request

- **CatalogId** – *Required*: Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- **Type** – *Required:* UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`
- `ThrottlingException`

## UpdateTableOptimizer action (Python: `update_table_optimizer`)

Updates the configuration for an existing table optimizer.

### Request

- **CatalogId** – *Required:* Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Catalog ID of the table.

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database in the catalog in which the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `Type` – *Required*: UTF-8 string (valid values: `compaction="COMPACTION" | retention="RETENTION" | orphan_file_deletion="ORPHAN_FILE_DELETION"`).

The type of table optimizer. Currently, the only valid value is `compaction`.

- `TableOptimizerConfiguration` – *Required*: A [TableOptimizerConfiguration](#) object.

A `TableOptimizerConfiguration` object representing the configuration of a table optimizer.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `AccessDeniedException`
- `ValidationException`
- `InternalServiceException`
- `ThrottlingException`
- `ConcurrentModificationException`

# Crawlers and classifiers API

The Crawler and classifiers API describes the AWS Glue crawler and classifier data types, and includes the API for creating, deleting, updating, and listing crawlers or classifiers.

## Topics

- [Classifier API](#)

- [Crawler API](#)
- [Column statistics API](#)
- [Crawler scheduler API](#)

## Classifier API

The Classifier API describes AWS Glue classifier data types, and includes the API for creating, deleting, updating, and listing classifiers.

### Data types

- [Classifier structure](#)
- [GrokClassifier structure](#)
- [XMLClassifier structure](#)
- [JsonClassifier structure](#)
- [CsvClassifier structure](#)
- [CreateGrokClassifierRequest structure](#)
- [UpdateGrokClassifierRequest structure](#)
- [CreateXMLClassifierRequest structure](#)
- [UpdateXMLClassifierRequest structure](#)
- [CreateJsonClassifierRequest structure](#)
- [UpdateJsonClassifierRequest structure](#)
- [CreateCsvClassifierRequest structure](#)
- [UpdateCsvClassifierRequest structure](#)

### Classifier structure

Classifiers are triggered during a crawl task. A classifier checks whether a given file is in a format it can handle. If it is, the classifier creates a schema in the form of a `StructType` object that matches that data format.

You can use the standard classifiers that AWS Glue provides, or you can write your own classifiers to best categorize your data sources and specify the appropriate schemas to use for them. A

classifier can be a grok classifier, an XML classifier, a JSON classifier, or a custom CSV classifier, as specified in one of the fields in the `Classifier` object.

## Fields

- `GrokClassifier` – A [GrokClassifier](#) object.

A classifier that uses grok.

- `XMLClassifier` – A [XMLClassifier](#) object.

A classifier for XML content.

- `JsonClassifier` – A [JsonClassifier](#) object.

A classifier for JSON content.

- `CsvClassifier` – A [CsvClassifier](#) object.

A classifier for comma-separated values (CSV).

## GrokClassifier structure

A classifier that uses grok patterns.

### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `Classification` – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches, such as Twitter, JSON, Omniture logs, and so on.

- `CreationTime` – Timestamp.

The time that this classifier was registered.

- `LastUpdated` – Timestamp.

The time that this classifier was last updated.

- `Version` – Number (long).

The version of this classifier.

- `GrokPattern` – *Required*: UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [A Logstash Grok string pattern](#).

The grok pattern applied to a data store by this classifier. For more information, see built-in patterns in [Writing Custom Classifiers](#).

- `CustomPatterns` – UTF-8 string, not more than 16000 bytes long, matching the [URI address multi-line string pattern](#).

Optional custom grok patterns defined by this classifier. For more information, see custom patterns in [Writing Custom Classifiers](#).

## XMLClassifier structure

A classifier for XML content.

### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `Classification` – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches.

- `CreationTime` – Timestamp.

The time that this classifier was registered.

- `LastUpdated` – Timestamp.

The time that this classifier was last updated.

- `Version` – Number (long).

The version of this classifier.

- `RowTag` – UTF-8 string.

The XML tag designating the element that contains each record in an XML document being parsed. This can't identify a self-closing element (closed by `/>`). An empty row element that

contains only attributes can be parsed as long as it ends with a closing tag (for example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not).

## JsonClassifier structure

A classifier for JSON content.

### Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **CreationTime** – Timestamp.

The time that this classifier was registered.

- **LastUpdated** – Timestamp.

The time that this classifier was last updated.

- **Version** – Number (long).

The version of this classifier.

- **JsonPath** – *Required*: UTF-8 string.

A JsonPath string defining the JSON data for the classifier to classify. AWS Glue supports a subset of JsonPath, as described in [Writing JsonPath Custom Classifiers](#).

## CsvClassifier structure

A classifier for custom CSV content.

### Fields

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **CreationTime** – Timestamp.

The time that this classifier was registered.

- `LastUpdated` – Timestamp.

The time that this classifier was last updated.

- `Version` – Number (long).

The version of this classifier.

- `Delimiter` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #10](#).

A custom symbol to denote what separates each column entry in the row.

- `QuoteSymbol` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #10](#).

A custom symbol to denote what combines content into a single column value. It must be different from the column delimiter.

- `ContainsHeader` – UTF-8 string (valid values: UNKNOWN | PRESENT | ABSENT).

Indicates whether the CSV file contains a header.

- `Header` – An array of UTF-8 strings.

A list of strings representing column names.

- `DisableValueTrimming` – Boolean.

Specifies not to trim values before identifying the type of column values. The default value is `true`.

- `AllowSingleColumn` – Boolean.

Enables the processing of files that contain only one column.

- `CustomDatatypeConfigured` – Boolean.

Enables the custom datatype to be configured.

- `CustomDatatypes` – An array of UTF-8 strings.

A list of custom datatypes including "BINARY", "BOOLEAN", "DATE", "DECIMAL", "DOUBLE", "FLOAT", "INT", "LONG", "SHORT", "STRING", "TIMESTAMP".

- `Serde` – UTF-8 string (valid values: OpenCSVSerDe | LazySimpleSerDe | None).

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Valid values are `OpenCSVSerDe`, `LazySimpleSerDe`, and `None`. You can specify the `None` value when you want the crawler to do the detection.

## CreateGrokClassifierRequest structure

Specifies a grok classifier for `CreateClassifier` to create.

### Fields

- `Classification` – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches, such as Twitter, JSON, Omniture logs, Amazon CloudWatch Logs, and so on.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the new classifier.

- `GrokPattern` – *Required*: UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [A Logstash Grok string pattern](#).

The grok pattern used by this classifier.

- `CustomPatterns` – UTF-8 string, not more than 16000 bytes long, matching the [URI address multi-line string pattern](#).

Optional custom grok patterns used by this classifier.

## UpdateGrokClassifierRequest structure

Specifies a grok classifier to update when passed to `UpdateClassifier`.

### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `GrokClassifier`.

- `Classification` – UTF-8 string.

An identifier of the data format that the classifier matches, such as Twitter, JSON, Omniture logs, Amazon CloudWatch Logs, and so on.

- `GrokPattern` – UTF-8 string, not less than 1 or more than 2048 bytes long, matching the [Logstash Grok string pattern](#).

The grok pattern used by this classifier.

- `CustomPatterns` – UTF-8 string, not more than 16000 bytes long, matching the [URI address multi-line string pattern](#).

Optional custom grok patterns used by this classifier.

## CreateXMLClassifierRequest structure

Specifies an XML classifier for `CreateClassifier` to create.

### Fields

- `Classification` – *Required*: UTF-8 string.

An identifier of the data format that the classifier matches.

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `RowTag` – UTF-8 string.

The XML tag designating the element that contains each record in an XML document being parsed. This can't identify a self-closing element (closed by `</>`). An empty row element that contains only attributes can be parsed as long as it ends with a closing tag (for example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not).

## UpdateXMLClassifierRequest structure

Specifies an XML classifier to be updated.

## Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **Classification** – UTF-8 string.

An identifier of the data format that the classifier matches.

- **RowTag** – UTF-8 string.

The XML tag designating the element that contains each record in an XML document being parsed. This cannot identify a self-closing element (closed by `</>`). An empty row element that contains only attributes can be parsed as long as it ends with a closing tag (for example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not).

## CreateJsonClassifierRequest structure

Specifies a JSON classifier for `CreateClassifier` to create.

### Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- **JsonPath** – *Required:* UTF-8 string.

A `JsonPath` string defining the JSON data for the classifier to classify. AWS Glue supports a subset of `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

## UpdateJsonClassifierRequest structure

Specifies a JSON classifier to be updated.

### Fields

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `JsonPath` – UTF-8 string.

A `JsonPath` string defining the JSON data for the classifier to classify. AWS Glue supports a subset of `JsonPath`, as described in [Writing JsonPath Custom Classifiers](#).

## CreateCsvClassifierRequest structure

Specifies a custom CSV classifier for `CreateClassifier` to create.

### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `Delimiter` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #10](#).

A custom symbol to denote what separates each column entry in the row.

- `QuoteSymbol` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #10](#).

A custom symbol to denote what combines content into a single column value. Must be different from the column delimiter.

- `ContainsHeader` – UTF-8 string (valid values: UNKNOWN | PRESENT | ABSENT).

Indicates whether the CSV file contains a header.

- `Header` – An array of UTF-8 strings.

A list of strings representing column names.

- `DisableValueTrimming` – Boolean.

Specifies not to trim values before identifying the type of column values. The default value is true.

- `AllowSingleColumn` – Boolean.

Enables the processing of files that contain only one column.

- `CustomDatatypeConfigured` – Boolean.

Enables the configuration of custom datatypes.

- `CustomDatatypes` – An array of UTF-8 strings.

Creates a list of supported custom datatypes.

- `Serde` – UTF-8 string (valid values: `OpenCSVSerDe` | `LazySimpleSerDe` | `None`).

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Valid values are `OpenCSVSerDe`, `LazySimpleSerDe`, and `None`. You can specify the `None` value when you want the crawler to do the detection.

## UpdateCsvClassifierRequest structure

Specifies a custom CSV classifier to be updated.

### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the classifier.

- `Delimiter` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #10](#).

A custom symbol to denote what separates each column entry in the row.

- `QuoteSymbol` – UTF-8 string, not less than 1 or more than 1 bytes long, matching the [Custom string pattern #10](#).

A custom symbol to denote what combines content into a single column value. It must be different from the column delimiter.

- `ContainsHeader` – UTF-8 string (valid values: `UNKNOWN` | `PRESENT` | `ABSENT`).

Indicates whether the CSV file contains a header.

- `Header` – An array of UTF-8 strings.

A list of strings representing column names.

- `DisableValueTrimming` – Boolean.

Specifies not to trim values before identifying the type of column values. The default value is true.

- `AllowSingleColumn` – Boolean.

Enables the processing of files that contain only one column.

- `CustomDatatypeConfigured` – Boolean.

Specifies the configuration of custom datatypes.

- `CustomDatatypes` – An array of UTF-8 strings.

Specifies a list of supported custom datatypes.

- `Serde` – UTF-8 string (valid values: `OpenCSVSerDe` | `LazySimpleSerDe` | `None`).

Sets the SerDe for processing CSV in the classifier, which will be applied in the Data Catalog. Valid values are `OpenCSVSerDe`, `LazySimpleSerDe`, and `None`. You can specify the `None` value when you want the crawler to do the detection.

## Operations

- [CreateClassifier action \(Python: `create\_classifier`\)](#)
- [DeleteClassifier action \(Python: `delete\_classifier`\)](#)
- [GetClassifier action \(Python: `get\_classifier`\)](#)
- [GetClassifiers action \(Python: `get\_classifiers`\)](#)
- [UpdateClassifier action \(Python: `update\_classifier`\)](#)

### CreateClassifier action (Python: `create_classifier`)

Creates a classifier in the user's account. This can be a `GrokClassifier`, an `XMLClassifier`, a `JsonClassifier`, or a `CsvClassifier`, depending on which field of the request is present.

#### Request

- `GrokClassifier` – A [CreateGrokClassifierRequest](#) object.

A `GrokClassifier` object specifying the classifier to create.

- `XMLClassifier` – A [CreateXMLClassifierRequest](#) object.

An XMLClassifier object specifying the classifier to create.

- JsonClassifier – A [CreateJsonClassifierRequest](#) object.

A JsonClassifier object specifying the classifier to create.

- CsvClassifier – A [CreateCsvClassifierRequest](#) object.

A CsvClassifier object specifying the classifier to create.

## Response

- *No Response parameters.*

## Errors

- AlreadyExistsException
- InvalidInputException
- OperationTimeoutException

## DeleteClassifier action (Python: delete\_classifier)

Removes a classifier from the Data Catalog.

## Request

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the classifier to remove.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException

- `OperationTimeoutException`

## GetClassifier action (Python: `get_classifier`)

Retrieve a classifier by name.

### Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the classifier to retrieve.

### Response

- `Classifier` – A [Classifier](#) object.

The requested classifier.

### Errors

- `EntityNotFoundException`
- `OperationTimeoutException`

## GetClassifiers action (Python: `get_classifiers`)

Lists all classifier objects in the Data Catalog.

### Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The size of the list to return (optional).

- `NextToken` – UTF-8 string.

An optional continuation token.

## Response

- **Classifiers** – An array of [Classifier](#) objects.

The requested list of classifier objects.

- **NextToken** – UTF-8 string.

A continuation token.

## Errors

- `OperationTimeoutException`

## UpdateClassifier action (Python: `update_classifier`)

Modifies an existing classifier (a `GrokClassifier`, an `XMLClassifier`, a `JsonClassifier`, or a `CsvClassifier`, depending on which field is present).

## Request

- **GrokClassifier** – An [UpdateGrokClassifierRequest](#) object.

A `GrokClassifier` object with updated fields.

- **XMLClassifier** – An [UpdateXMLClassifierRequest](#) object.

An `XMLClassifier` object with updated fields.

- **JsonClassifier** – An [UpdateJsonClassifierRequest](#) object.

A `JsonClassifier` object with updated fields.

- **CsvClassifier** – An [UpdateCsvClassifierRequest](#) object.

A `CsvClassifier` object with updated fields.

## Response

- *No Response parameters.*

## Errors

- `InvalidInputException`
- `VersionMismatchException`
- `EntityNotFoundException`
- `OperationTimeoutException`

## Crawler API

The Crawler API describes AWS Glue crawler data types, along with the API for creating, deleting, updating, and listing crawlers.

### Data types

- [Crawler structure](#)
- [Schedule structure](#)
- [CrawlerTargets structure](#)
- [S3Target structure](#)
- [S3DeltaCatalogTarget structure](#)
- [S3DeltaDirectTarget structure](#)
- [JdbcTarget structure](#)
- [MongoDBTarget structure](#)
- [DynamoDBTarget structure](#)
- [DeltaTarget structure](#)
- [IcebergTarget structure](#)
- [HudiTarget structure](#)
- [CatalogTarget structure](#)
- [CrawlerMetrics structure](#)
- [CrawlerHistory structure](#)
- [CrawlsFilter structure](#)
- [SchemaChangePolicy structure](#)
- [LastCrawlInfo structure](#)

- [RecrawlPolicy structure](#)
- [LineageConfiguration structure](#)
- [LakeFormationConfiguration structure](#)

## Crawler structure

Specifies a crawler program that examines a data source and uses classifiers to try to determine its schema. If successful, the crawler records metadata concerning the data source in the AWS Glue Data Catalog.

### Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler.

- **Role** – UTF-8 string.

The Amazon Resource Name (ARN) of an IAM role that's used to access customer resources, such as Amazon Simple Storage Service (Amazon S3) data.

- **Targets** – A [CrawlerTargets](#) object.

A collection of targets to crawl.

- **DatabaseName** – UTF-8 string.

The name of the database in which the crawler's output is stored.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the crawler.

- **Classifiers** – An array of UTF-8 strings.

A list of UTF-8 strings that specify the custom classifiers that are associated with the crawler.

- **RecrawlPolicy** – A [RecrawlPolicy](#) object.

A policy that specifies whether to crawl the entire dataset again, or to crawl only folders that were added since the last crawler run.

- `SchemaChangePolicy` – A [SchemaChangePolicy](#) object.

The policy that specifies update and delete behaviors for the crawler.

- `LineageConfiguration` – A [LineageConfiguration](#) object.

A configuration that specifies whether data lineage is enabled for the crawler.

- `State` – UTF-8 string (valid values: READY | RUNNING | STOPPING).

Indicates whether the crawler is running, or whether a run is pending.

- `TablePrefix` – UTF-8 string, not more than 128 bytes long.

The prefix added to the names of tables that are created.

- `Schedule` – A [Schedule](#) object.

For scheduled crawlers, the schedule when the crawler runs.

- `CrawlElapsedTime` – Number (long).

If the crawler is running, contains the total time elapsed since the last crawl began.

- `CreationTime` – Timestamp.

The time that the crawler was created.

- `LastUpdated` – Timestamp.

The time that the crawler was last updated.

- `LastCrawl` – A [LastCrawlInfo](#) object.

The status of the last crawl, and potentially error information if an error occurred.

- `Version` – Number (long).

The version of the crawler.

- `Configuration` – UTF-8 string.

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see [Setting crawler configuration options](#).

- `CrawlerSecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

The name of the SecurityConfiguration structure to be used by this crawler.

- `LakeFormationConfiguration` – A [LakeFormationConfiguration](#) object.

Specifies whether the crawler should use AWS Lake Formation credentials for the crawler instead of the IAM role credentials.

## Schedule structure

A scheduling object using a cron statement to schedule an event.

### Fields

- `ScheduleExpression` – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- `State` – UTF-8 string (valid values: SCHEDULED | NOT\_SCHEDULED | TRANSITIONING).

The state of the schedule.

## CrawlerTargets structure

Specifies data stores to crawl.

### Fields

- `S3Targets` – An array of [S3Target](#) objects.

Specifies Amazon Simple Storage Service (Amazon S3) targets.

- `JdbcTargets` – An array of [JdbcTarget](#) objects.

Specifies JDBC targets.

- `MongoDBTargets` – An array of [MongoDBTarget](#) objects.

Specifies Amazon DocumentDB or MongoDB targets.

- `DynamoDBTargets` – An array of [DynamoDBTarget](#) objects.

Specifies Amazon DynamoDB targets.

- `CatalogTargets` – An array of [CatalogTarget](#) objects.

Specifies AWS Glue Data Catalog targets.

- `DeltaTargets` – An array of [DeltaTarget](#) objects.

Specifies Delta data store targets.

- `IcebergTargets` – An array of [IcebergTarget](#) objects.

Specifies Apache Iceberg data store targets.

- `HudiTargets` – An array of [HudiTarget](#) objects.

Specifies Apache Hudi data store targets.

## S3Target structure

Specifies a data store in Amazon Simple Storage Service (Amazon S3).

### Fields

- `Path` – UTF-8 string.

The path to the Amazon S3 target.

- `Exclusions` – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- `ConnectionName` – UTF-8 string.

The name of a connection which allows a job or crawler to access data in Amazon S3 within an Amazon Virtual Private Cloud environment (Amazon VPC).

- `SampleSize` – Number (integer).

Sets the number of files in each leaf folder to be crawled when crawling sample files in a dataset. If not set, all the files are crawled. A valid value is an integer between 1 and 249.

- `EventQueueArn` – UTF-8 string.

A valid Amazon SQS ARN. For example, `arn:aws:sqs:region:account:sqs`.

- `DlqEventQueueArn` – UTF-8 string.

A valid Amazon dead-letter SQS ARN. For example, `arn:aws:sqs:region:account:deadLetterQueue`.

## S3DeltaCatalogTarget structure

Specifies a target that writes to a Delta Lake data source in the AWS Glue Data Catalog.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options for the connector.

- **SchemaChangePolicy** – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## S3DeltaDirectTarget structure

Specifies a target that writes to a Delta Lake data source in Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 path of your Delta Lake data source to write to.

- **Compression** – *Required*: UTF-8 string (valid values: uncompressed="UNCOMPRESSED" | snappy="SNAPPY").

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **Format** – *Required*: UTF-8 string (valid values: json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA").

Specifies the data output format for the target.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options for the connector.

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## JdbcTarget structure

Specifies a JDBC data store to crawl.

### Fields

- **ConnectionName** – UTF-8 string.

The name of the connection to use to connect to the JDBC target.

- `Path` – UTF-8 string.

The path of the JDBC target.

- `Exclusions` – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- `EnableAdditionalMetadata` – An array of UTF-8 strings.

Specify a value of `RAWTYPES` or `COMMENTS` to enable additional metadata in table responses. `RAWTYPES` provides the native-level datatype. `COMMENTS` provides comments associated with a column or table in the database.

If you do not need additional metadata, keep the field empty.

## MongoDBTarget structure

Specifies an Amazon DocumentDB or MongoDB data store to crawl.

### Fields

- `ConnectionName` – UTF-8 string.

The name of the connection to use to connect to the Amazon DocumentDB or MongoDB target.

- `Path` – UTF-8 string.

The path of the Amazon DocumentDB or MongoDB target (database/collection).

- `ScanAll` – Boolean.

Indicates whether to scan all the records, or to sample rows from the table. Scanning all the records can take a long time when the table is not a high throughput table.

A value of `true` means to scan all records, while a value of `false` means to sample the records. If no value is specified, the value defaults to `true`.

## DynamoDBTarget structure

Specifies an Amazon DynamoDB table to crawl.

### Fields

- `Path` – UTF-8 string.

The name of the DynamoDB table to crawl.

- `scanAll` – Boolean.

Indicates whether to scan all the records, or to sample rows from the table. Scanning all the records can take a long time when the table is not a high throughput table.

A value of `true` means to scan all records, while a value of `false` means to sample the records. If no value is specified, the value defaults to `true`.

- `scanRate` – Number (double).

The percentage of the configured read capacity units to use by the AWS Glue crawler. Read capacity units is a term defined by DynamoDB, and is a numeric value that acts as rate limiter for the number of reads that can be performed on that table per second.

The valid values are null or a value between 0.1 to 1.5. A null value is used when user does not provide a value, and defaults to 0.5 of the configured Read Capacity Unit (for provisioned tables), or 0.25 of the max configured Read Capacity Unit (for tables using on-demand mode).

## DeltaTarget structure

Specifies a Delta data store to crawl one or more Delta tables.

### Fields

- `DeltaTables` – An array of UTF-8 strings.

A list of the Amazon S3 paths to the Delta tables.

- `ConnectionName` – UTF-8 string.

The name of the connection to use to connect to the Delta table target.

- `WriteManifest` – Boolean.

Specifies whether to write the manifest files to the Delta table path.

- `CreateNativeDeltaTable` – Boolean.

Specifies whether the crawler will create native tables, to allow integration with query engines that support querying of the Delta transaction log directly.

## IcebergTarget structure

Specifies an Apache Iceberg data source where Iceberg tables are stored in Amazon S3.

### Fields

- `Paths` – An array of UTF-8 strings.

One or more Amazon S3 paths that contains Iceberg metadata folders as `s3://bucket/` prefix.

- `ConnectionName` – UTF-8 string.

The name of the connection to use to connect to the Iceberg target.

- `Exclusions` – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- `MaximumTraversalDepth` – Number (integer).

The maximum depth of Amazon S3 paths that the crawler can traverse to discover the Iceberg metadata folder in your Amazon S3 path. Used to limit the crawler run time.

## HudiTarget structure

Specifies an Apache Hudi data source.

### Fields

- `Paths` – An array of UTF-8 strings.

An array of Amazon S3 location strings for Hudi, each indicating the root folder with which the metadata files for a Hudi table resides. The Hudi folder may be located in a child folder of the root folder.

The crawler will scan all folders underneath a path for a Hudi folder.

- `ConnectionName` – UTF-8 string.

The name of the connection to use to connect to the Hudi target. If your Hudi files are stored in buckets that require VPC authorization, you can set their connection properties here.

- `Exclusions` – An array of UTF-8 strings.

A list of glob patterns used to exclude from the crawl. For more information, see [Catalog Tables with a Crawler](#).

- `MaximumTraversalDepth` – Number (integer).

The maximum depth of Amazon S3 paths that the crawler can traverse to discover the Hudi metadata folder in your Amazon S3 path. Used to limit the crawler run time.

## CatalogTarget structure

Specifies an AWS Glue Data Catalog target.

### Fields

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database to be synchronized.

- `Tables` – *Required:* An array of UTF-8 strings, at least 1 string.

A list of the tables to be synchronized.

- `ConnectionName` – UTF-8 string.

The name of the connection for an Amazon S3-backed Data Catalog table to be a target of the crawl when using a `Catalog` connection type paired with a `NETWORK` Connection type.

- `EventQueueArn` – UTF-8 string.

A valid Amazon SQS ARN. For example, `arn:aws:sqs:region:account:sqs`.

- `DlqEventQueueArn` – UTF-8 string.

A valid Amazon dead-letter SQS ARN. For example, `arn:aws:sqs:region:account:deadLetterQueue`.

## CrawlerMetrics structure

Metrics for a specified crawler.

### Fields

- `CrawlerName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler.

- `TimeLeftSeconds` – Number (double), not more than None.

The estimated time left to complete a running crawl.

- `StillEstimating` – Boolean.

True if the crawler is still estimating how long it will take to complete this run.

- `LastRuntimeSeconds` – Number (double), not more than None.

The duration of the crawler's most recent run, in seconds.

- `MedianRuntimeSeconds` – Number (double), not more than None.

The median duration of this crawler's runs, in seconds.

- `TablesCreated` – Number (integer), not more than None.

The number of tables created by this crawler.

- `TablesUpdated` – Number (integer), not more than None.

The number of tables updated by this crawler.

- `TablesDeleted` – Number (integer), not more than None.

The number of tables deleted by this crawler.

## CrawlerHistory structure

Contains the information for a run of a crawler.

### Fields

- `CrawlId` – UTF-8 string.

A UUID identifier for each crawl.

- `State` – UTF-8 string (valid values: RUNNING | COMPLETED | FAILED | STOPPED).

The state of the crawl.

- `StartTime` – Timestamp.

The date and time on which the crawl started.

- `EndTime` – Timestamp.

The date and time on which the crawl ended.

- `Summary` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A run summary for the specific crawl in JSON. Contains the catalog tables and partitions that were added, updated, or deleted.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

If an error occurred, the error message associated with the crawl.

- `LogGroup` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log group string pattern](#).

The log group associated with the crawl.

- `LogStream` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log-stream string pattern](#).

The log stream associated with the crawl.

- `MessagePrefix` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The prefix for a CloudWatch message about this crawl.

- **DPUHour** – Number (double), not more than None.

The number of data processing units (DPU) used in hours for the crawl.

## CrawlsFilter structure

A list of fields, comparators and value that you can use to filter the crawler runs for a specified crawler.

### Fields

- **FieldName** – UTF-8 string (valid values: CRAWL\_ID | STATE | START\_TIME | END\_TIME | DPU\_HOUR).

A key used to filter the crawler runs for a specified crawler. Valid values for each of the field names are:

- **CRAWL\_ID**: A string representing the UUID identifier for a crawl.
- **STATE**: A string representing the state of the crawl.
- **START\_TIME** and **END\_TIME**: The epoch timestamp in milliseconds.
- **DPU\_HOUR**: The number of data processing unit (DPU) hours used for the crawl.
- **FilterOperator** – UTF-8 string (valid values: GT | GE | LT | LE | EQ | NE).

A defined comparator that operates on the value. The available operators are:

- **GT**: Greater than.
- **GE**: Greater than or equal to.
- **LT**: Less than.
- **LE**: Less than or equal to.
- **EQ**: Equal to.
- **NE**: Not equal to.
- **FieldValue** – UTF-8 string.

The value provided for comparison on the crawl field.

## SchemaChangePolicy structure

A policy that specifies update and deletion behaviors for the crawler.

## Fields

- `UpdateBehavior` – UTF-8 string (valid values: LOG | UPDATE\_IN\_DATABASE).

The update behavior when the crawler finds a changed schema.

- `DeleteBehavior` – UTF-8 string (valid values: LOG | DELETE\_FROM\_DATABASE | DEPRECATE\_IN\_DATABASE).

The deletion behavior when the crawler finds a deleted object.

## LastCrawlInfo structure

Status and error information about the most recent crawl.

### Fields

- `Status` – UTF-8 string (valid values: SUCCEEDED | CANCELLED | FAILED).

Status of the last crawl.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

If an error occurred, the error information about the last crawl.

- `LogGroup` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log group string pattern](#).

The log group for the last crawl.

- `LogStream` – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log-stream string pattern](#).

The log stream for the last crawl.

- `MessagePrefix` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The prefix for a message about this crawl.

- `StartTime` – Timestamp.

The time at which the crawl started.

## RecrawlPolicy structure

When crawling an Amazon S3 data source after the first crawl is complete, specifies whether to crawl the entire dataset again or to crawl only folders that were added since the last crawler run. For more information, see [Incremental Crawls in AWS Glue](#) in the developer guide.

### Fields

- `RecrawlBehavior` – UTF-8 string (valid values: `CRAWL_EVERYTHING` | `CRAWL_NEW_FOLDERS_ONLY` | `CRAWL_EVENT_MODE`).

Specifies whether to crawl the entire dataset again or to crawl only folders that were added since the last crawler run.

A value of `CRAWL_EVERYTHING` specifies crawling the entire dataset again.

A value of `CRAWL_NEW_FOLDERS_ONLY` specifies crawling only folders that were added since the last crawler run.

A value of `CRAWL_EVENT_MODE` specifies crawling only the changes identified by Amazon S3 events.

## LineageConfiguration structure

Specifies data lineage configuration settings for the crawler.

### Fields

- `CrawlerLineageSettings` – UTF-8 string (valid values: `ENABLE` | `DISABLE`).

Specifies whether data lineage is enabled for the crawler. Valid values are:

- `ENABLE`: enables data lineage for the crawler
- `DISABLE`: disables data lineage for the crawler

## LakeFormationConfiguration structure

Specifies AWS Lake Formation configuration settings for the crawler.

## Fields

- `UseLakeFormationCredentials` – Boolean.

Specifies whether to use AWS Lake Formation credentials for the crawler instead of the IAM role credentials.

- `AccountId` – UTF-8 string, not more than 12 bytes long.

Required for cross account crawls. For same account crawls as the target data, this can be left as null.

## Operations

- [CreateCrawler action \(Python: `create\_crawler`\)](#)
- [DeleteCrawler action \(Python: `delete\_crawler`\)](#)
- [GetCrawler action \(Python: `get\_crawler`\)](#)
- [GetCrawlers action \(Python: `get\_crawlers`\)](#)
- [GetCrawlerMetrics action \(Python: `get\_crawler\_metrics`\)](#)
- [UpdateCrawler action \(Python: `update\_crawler`\)](#)
- [StartCrawler action \(Python: `start\_crawler`\)](#)
- [StopCrawler action \(Python: `stop\_crawler`\)](#)
- [BatchGetCrawlers action \(Python: `batch\_get\_crawlers`\)](#)
- [ListCrawlers action \(Python: `list\_crawlers`\)](#)
- [ListCrawls action \(Python: `list\_crawls`\)](#)

## CreateCrawler action (Python: `create_crawler`)

Creates a new crawler with specified targets, role, configuration, and optional schedule. At least one crawl target must be specified, in the `s3Targets` field, the `jdbcTargets` field, or the `DynamoDBTargets` field.

## Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the new crawler.

- Role – *Required*: UTF-8 string.

The IAM role or Amazon Resource Name (ARN) of an IAM role used by the new crawler to access customer resources.

- DatabaseName – UTF-8 string.

The AWS Glue database where results are written, such as: `arn:aws:daylight:us-east-1::database/sometable/*`.

- Description – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the new crawler.

- Targets – *Required*: A [CrawlerTargets](#) object.

A list of collection of targets to crawl.

- Schedule – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- Classifiers – An array of UTF-8 strings.

A list of custom classifiers that the user has registered. By default, all built-in classifiers are included in a crawl, but these custom classifiers always override the default classifiers for a given classification.

- TablePrefix – UTF-8 string, not more than 128 bytes long.

The table prefix used for catalog tables that are created.

- SchemaChangePolicy – A [SchemaChangePolicy](#) object.

The policy for the crawler's update and deletion behavior.

- RecrawlPolicy – A [RecrawlPolicy](#) object.

A policy that specifies whether to crawl the entire dataset again, or to crawl only folders that were added since the last crawler run.

- LineageConfiguration – A [LineageConfiguration](#) object.

Specifies data lineage configuration settings for the crawler.

- `LakeFormationConfiguration` – A [LakeFormationConfiguration](#) object.

Specifies AWS Lake Formation configuration settings for the crawler.

- `Configuration` – UTF-8 string.

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see [Setting crawler configuration options](#).

- `CrawlerSecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

The name of the `SecurityConfiguration` structure to be used by this crawler.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this crawler request. You may use tags to limit access to the crawler. For more information about tags in AWS Glue, see [AWS Tags in AWS Glue](#) in the developer guide.

## Response

- *No Response parameters.*

## Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`

## DeleteCrawler action (Python: `delete_crawler`)

Removes a specified crawler from the AWS Glue Data Catalog, unless the crawler state is `RUNNING`.

## Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to remove.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- CrawlerRunningException
- SchedulerTransitioningException
- OperationTimeoutException

## GetCrawler action (Python: `get_crawler`)

Retrieves metadata for a specified crawler.

## Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to retrieve metadata for.

## Response

- Crawler – A [Crawler](#) object.

The metadata for the specified crawler.

## Errors

- EntityNotFoundException

- `OperationTimeoutException`

## GetCrawlers action (Python: `get_crawlers`)

Retrieves metadata for all crawlers defined in the customer account.

### Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The number of crawlers to return on each call.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

### Response

- `Crawlers` – An array of [Crawler](#) objects.

A list of crawler metadata.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list has not reached the end of those defined in this customer account.

### Errors

- `OperationTimeoutException`

## GetCrawlerMetrics action (Python: `get_crawler_metrics`)

Retrieves metrics about specified crawlers.

### Request

- `CrawlerNameList` – An array of UTF-8 strings, not more than 100 strings.

A list of the names of crawlers about which to retrieve metrics.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- CrawlerMetricsList – An array of [CrawlerMetrics](#) objects.

A list of metrics for the specified crawler.

- NextToken – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

## Errors

- OperationTimeoutException

## UpdateCrawler action (Python: update\_crawler)

Updates a crawler. If a crawler is running, you must stop it using StopCrawler before updating it.

## Request

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the new crawler.

- Role – UTF-8 string.

The IAM role or Amazon Resource Name (ARN) of an IAM role that is used by the new crawler to access customer resources.

- DatabaseName – UTF-8 string.

The AWS Glue database where results are stored, such as: arn:aws:daylight:us-east-1::database/sometable/\*.

- **Description** – UTF-8 string, not more than 2048 bytes long, matching the [URI address multiline string pattern](#).

A description of the new crawler.

- **Targets** – A [CrawlerTargets](#) object.

A list of targets to crawl.

- **Schedule** – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- **Classifiers** – An array of UTF-8 strings.

A list of custom classifiers that the user has registered. By default, all built-in classifiers are included in a crawl, but these custom classifiers always override the default classifiers for a given classification.

- **TablePrefix** – UTF-8 string, not more than 128 bytes long.

The table prefix used for catalog tables that are created.

- **SchemaChangePolicy** – A [SchemaChangePolicy](#) object.

The policy for the crawler's update and deletion behavior.

- **RecrawlPolicy** – A [RecrawlPolicy](#) object.

A policy that specifies whether to crawl the entire dataset again, or to crawl only folders that were added since the last crawler run.

- **LineageConfiguration** – A [LineageConfiguration](#) object.

Specifies data lineage configuration settings for the crawler.

- **LakeFormationConfiguration** – A [LakeFormationConfiguration](#) object.

Specifies AWS Lake Formation configuration settings for the crawler.

- **Configuration** – UTF-8 string.

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see [Setting crawler configuration options](#).

- **CrawlerSecurityConfiguration** – UTF-8 string, not more than 128 bytes long.

The name of the `SecurityConfiguration` structure to be used by this crawler.

## Response

- *No Response parameters.*

## Errors

- `InvalidInputException`
- `VersionMismatchException`
- `EntityNotFoundException`
- `CrawlerRunningException`
- `OperationTimeoutException`

## StartCrawler action (Python: `start_crawler`)

Starts a crawl using the specified crawler, regardless of what is scheduled. If the crawler is already running, returns a [CrawlerRunningException](#).

## Request

- Name – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler to start.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `CrawlerRunningException`
- `OperationTimeoutException`

## StopCrawler action (Python: stop\_crawler)

If the specified crawler is running, stops the crawl.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler to stop.

### Response

- *No Response parameters.*

### Errors

- EntityNotFoundException
- CrawlerNotRunningException
- CrawlerStoppingException
- OperationTimeoutException

## BatchGetCrawlers action (Python: batch\_get\_crawlers)

Returns a list of resource metadata for a given list of crawler names. After calling the `ListCrawlers` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

### Request

- CrawlerNames – *Required*: An array of UTF-8 strings, not more than 100 strings.

A list of crawler names, which might be the names returned from the `ListCrawlers` operation.

### Response

- Crawlers – An array of [Crawler](#) objects.

A list of crawler definitions.

- `CrawlersNotFound` – An array of UTF-8 strings, not more than 100 strings.

A list of names of crawlers that were not found.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`

## ListCrawlers action (Python: `list_crawlers`)

Retrieves the names of all crawler resources in this AWS account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

## Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

## Response

- `CrawlerNames` – An array of UTF-8 strings, not more than 100 strings.

The names of all crawlers in the account, or the crawlers with the specified tags.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

## Errors

- `OperationTimeoutException`

## ListCrawls action (Python: `list_crawls`)

Returns all the crawls of a specified crawler. Returns only the crawls that have occurred since the launch date of the crawler history feature, and only retains up to 12 months of crawls. Older crawls will not be returned.

You may use this API to:

- Retrieve all the crawls of a specified crawler.
- Retrieve all the crawls of a specified crawler within a limited count.
- Retrieve all the crawls of a specified crawler in a specific time range.
- Retrieve all the crawls of a specified crawler with a particular state, crawl ID, or DPU hour value.

## Request

- `CrawlerName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler whose runs you want to retrieve.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return. The default is 20, and maximum is 100.

- `Filters` – An array of [CrawlsFilter](#) objects.

Filters the crawls by the criteria you specify in a list of `CrawlsFilter` objects.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- Crawls – An array of [CrawlerHistory](#) objects.

A list of CrawlerHistory objects representing the crawl runs that meet your criteria.

- NextToken – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

## Errors

- EntityNotFoundException
- OperationTimeoutException
- InvalidInputException

## Column statistics API

The column statistics API describes AWS Glue APIs for returning statistics on columns in a table.

## Data types

- [ColumnStatisticsTaskRun structure](#)
- [ColumnStatisticsTaskRunningException structure](#)
- [ColumnStatisticsTaskNotRunningException structure](#)
- [ColumnStatisticsTaskStoppingException structure](#)

## ColumnStatisticsTaskRun structure

The object that shows the details of the column stats run.

## Fields

- `CustomerId` – UTF-8 string, not more than 12 bytes long.

The AWS account ID.

- `ColumnStatisticsTaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The identifier for the particular column statistics task run.

- `DatabaseName` – UTF-8 string.

The database where the table resides.

- `TableName` – UTF-8 string.

The name of the table for which column statistics is generated.

- `ColumnNameList` – An array of UTF-8 strings.

A list of the column names. If none is supplied, all column names for the table will be used by default.

- `CatalogID` – Catalog id string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table resides. If none is supplied, the AWS account ID is used by default.

- `Role` – UTF-8 string.

The IAM role that the service assumes to generate statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of rows used to generate statistics. If none is supplied, the entire table will be used to generate stats.

- `SecurityConfiguration` – UTF-8 string, not more than 128 bytes long.

Name of the security configuration that is used to encrypt CloudWatch logs for the column stats task run.

- `NumberOfWorkers` – Number (integer), at least 1.

The number of workers used to generate column statistics. The job is preconfigured to autoscale up to 25 instances.

- `WorkerType` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The type of workers being used for generating stats. The default is `g.1x`.

- `Status` – UTF-8 string (valid values: `STARTING` | `RUNNING` | `SUCCEEDED` | `FAILED` | `STOPPED`).

The status of the task run.

- `CreationTime` – Timestamp.

The time that this task was created.

- `LastUpdated` – Timestamp.

The last point in time when this task was modified.

- `StartTime` – Timestamp.

The start time of the task.

- `EndTime` – Timestamp.

The end time of the task.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The error message for the job.

- `DPUSeconds` – Number (double), not more than None.

The calculated DPU usage in seconds for all autoscaled workers.

## ColumnStatisticsTaskRunningException structure

An exception thrown when you try to start another job while running a column stats generation job.

### Fields

- `Message` – UTF-8 string.

A message describing the problem.

## ColumnStatisticsTaskNotRunningException structure

An exception thrown when you try to stop a task run when there is no task running.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## ColumnStatisticsTaskStoppingException structure

An exception thrown when you try to stop a task run.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## Operations

- [StartColumnStatisticsTaskRun action \(Python: start\\_column\\_statistics\\_task\\_run\)](#)
- [GetColumnStatisticsTaskRun action \(Python: get\\_column\\_statistics\\_task\\_run\)](#)
- [GetColumnStatisticsTaskRuns action \(Python: get\\_column\\_statistics\\_task\\_runs\)](#)
- [ListColumnStatisticsTaskRuns action \(Python: list\\_column\\_statistics\\_task\\_runs\)](#)
- [StopColumnStatisticsTaskRun action \(Python: stop\\_column\\_statistics\\_task\\_run\)](#)

## StartColumnStatisticsTaskRun action (Python: start\_column\_statistics\_task\_run)

Starts a column statistics task run, for a specified table and columns.

### Request

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table to generate statistics.

- `ColumnNameList` – An array of UTF-8 strings.

A list of the column names to generate statistics. If none is supplied, all column names for the table will be used by default.

- `Role` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The IAM role that the service assumes to generate statistics.

- `SampleSize` – Number (double), not more than 100.

The percentage of rows used to generate statistics. If none is supplied, the entire table will be used to generate stats.

- `CatalogID` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the Data Catalog where the table reside. If none is supplied, the AWS account ID is used by default.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the security configuration that is used to encrypt CloudWatch logs for the column stats task run.

## Response

- `ColumnStatisticsTaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The identifier for the column statistics task run.

## Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `ColumnStatisticsTaskRunningException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `InvalidInputException`

## GetColumnStatisticsTaskRun action (Python: `get_column_statistics_task_run`)

Get the associated metadata/information for a task run, given a task run ID.

### Request

- `ColumnStatisticsTaskRunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The identifier for the particular column statistics task run.

### Response

- `ColumnStatisticsTaskRun` – A [ColumnStatisticsTaskRun](#) object.

A `ColumnStatisticsTaskRun` object representing the details of the column stats run.

## Errors

- `EntityNotFoundException`
- `OperationTimeoutException`
- `InvalidInputException`

## GetColumnStatisticsTaskRuns action (Python: `get_column_statistics_task_runs`)

Retrieves information about all runs associated with the specified table.

## Request

- `DatabaseName` – *Required*: UTF-8 string.

The name of the database where the table resides.

- `TableName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of the response.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- `ColumnStatisticsTaskRuns` – An array of [ColumnStatisticsTaskRun](#) objects.

A list of column statistics task runs.

- `NextToken` – UTF-8 string.

A continuation token, if not all task runs have yet been returned.

## Errors

- `OperationTimeoutException`

## ListColumnStatisticsTaskRuns action (Python: `list_column_statistics_task_runs`)

List all task runs for a particular account.

## Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of the response.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- `ColumnStatisticsTaskRunIds` – An array of UTF-8 strings, not more than 100 strings.

A list of column statistics task run IDs.

- `NextToken` – UTF-8 string.

A continuation token, if not all task run IDs have yet been returned.

## Errors

- `OperationTimeoutException`

## StopColumnStatisticsTaskRun action (Python: `stop_column_statistics_task_run`)

Stops a task run for the specified table.

## Request

- `DatabaseName` – *Required:* UTF-8 string.

The name of the database where the table resides.

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `ColumnStatisticsTaskNotRunningException`

- `ColumnStatisticsTaskStoppingException`
- `OperationTimeoutException`

## Crawler scheduler API

The Crawler scheduler API describes AWS Glue crawler data types, along with the API for creating, deleting, updating, and listing crawlers.

### Data types

- [Schedule structure](#)

### Schedule structure

A scheduling object using a `cron` statement to schedule an event.

#### Fields

- `ScheduleExpression` – UTF-8 string.

A `cron` expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- `State` – UTF-8 string (valid values: `SCHEDULED` | `NOT_SCHEDULED` | `TRANSITIONING`).

The state of the schedule.

### Operations

- [UpdateCrawlerSchedule action \(Python: `update\_crawler\_schedule`\)](#)
- [StartCrawlerSchedule action \(Python: `start\_crawler\_schedule`\)](#)
- [StopCrawlerSchedule action \(Python: `stop\_crawler\_schedule`\)](#)

### UpdateCrawlerSchedule action (Python: `update_crawler_schedule`)

Updates the schedule of a crawler using a `cron` expression.

## Request

- `CrawlerName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler whose schedule to update.

- `Schedule` – UTF-8 string.

The updated cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `VersionMismatchException`
- `SchedulerTransitioningException`
- `OperationTimeoutException`

## StartCrawlerSchedule action (Python: `start_crawler_schedule`)

Changes the schedule state of the specified crawler to SCHEDULED, unless the crawler is already running or the schedule state is already SCHEDULED.

## Request

- `CrawlerName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler to schedule.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- SchedulerRunningException
- SchedulerTransitioningException
- NoScheduleException
- OperationTimeoutException

## StopCrawlerSchedule action (Python: stop\_crawler\_schedule)

Sets the schedule state of the specified crawler to NOT\_SCHEDULED, but does not stop the crawler if it is already running.

## Request

- CrawlerName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the crawler whose schedule state to set.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- SchedulerNotRunningException
- SchedulerTransitioningException
- OperationTimeoutException

# Autogenerating ETL Scripts API

The ETL script-generation API describes the datatypes and API for generating ETL scripts in AWS Glue.

## Data types

- [CodeGenNode structure](#)
- [CodeGenNodeArg structure](#)
- [CodeGenEdge structure](#)
- [Location structure](#)
- [CatalogEntry structure](#)
- [MappingEntry structure](#)

## CodeGenNode structure

Represents a node in a directed acyclic graph (DAG)

### Fields

- **Id** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Identifier string pattern](#).

A node identifier that is unique within the node's graph.

- **NodeType** – *Required*: UTF-8 string.

The type of node that this is.

- **Args** – *Required*: An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

Properties of the node, in the form of name-value pairs.

- **LineNumber** – Number (integer).

The line number of the node.

## CodeGenNodeArg structure

An argument or property of a node.

## Fields

- Name – *Required:* UTF-8 string.

The name of the argument or property.

- Value – *Required:* UTF-8 string.

The value of the argument or property.

- Param – Boolean.

True if the value is used as a parameter.

## CodeGenEdge structure

Represents a directional edge in a directed acyclic graph (DAG).

### Fields

- Source – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Identifier string pattern](#).

The ID of the node at which the edge starts.

- Target – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Identifier string pattern](#).

The ID of the node at which the edge ends.

- TargetParameter – UTF-8 string.

The target of the edge.

## Location structure

The location of resources.

### Fields

- Jdbc – An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

A JDBC location.

- S3 – An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

An Amazon Simple Storage Service (Amazon S3) location.

- DynamoDB – An array of [CodeGenNodeArg](#) objects, not more than 50 structures.

An Amazon DynamoDB table location.

## CatalogEntry structure

Specifies a table definition in the AWS Glue Data Catalog.

### Fields

- DatabaseName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The database in which the table metadata resides.

- TableName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the table in question.

## MappingEntry structure

Defines a mapping.

### Fields

- SourceTable – UTF-8 string.

The name of the source table.

- SourcePath – UTF-8 string.

The source path.

- SourceType – UTF-8 string.

The source type.

- TargetTable – UTF-8 string.

The target table.

- `TargetPath` – UTF-8 string.

The target path.

- `TargetType` – UTF-8 string.

The target type.

## Operations

- [CreateScript action \(Python: `create\_script`\)](#)
- [GetDataflowGraph action \(Python: `get\_dataflow\_graph`\)](#)
- [GetMapping action \(Python: `get\_mapping`\)](#)
- [GetPlan action \(Python: `get\_plan`\)](#)

## CreateScript action (Python: `create_script`)

Transforms a directed acyclic graph (DAG) into code.

### Request

- `DagNodes` – An array of [CodeGenNode](#) objects.

A list of the nodes in the DAG.

- `DagEdges` – An array of [CodeGenEdge](#) objects.

A list of the edges in the DAG.

- `Language` – UTF-8 string (valid values: PYTHON | SCALA).

The programming language of the resulting code from the DAG.

### Response

- `PythonScript` – UTF-8 string.

The Python script generated from the DAG.

- `ScalaCode` – UTF-8 string.

The Scala code generated from the DAG.

## Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetDataflowGraph action (Python: `get_dataflow_graph`)

Transforms a Python script into a directed acyclic graph (DAG).

### Request

- `PythonScript` – UTF-8 string.

The Python script to transform.

### Response

- `DagNodes` – An array of [CodeGenNode](#) objects.

A list of the nodes in the resulting DAG.

- `DagEdges` – An array of [CodeGenEdge](#) objects.

A list of the edges in the resulting DAG.

## Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetMapping action (Python: get\_mapping)

Creates mappings.

### Request

- Source – *Required:* A [CatalogEntry](#) object.

Specifies the source table.

- Sinks – An array of [CatalogEntry](#) objects.

A list of target tables.

- Location – A [Location](#) object.

Parameters for the mapping.

### Response

- Mapping – *Required:* An array of [MappingEntry](#) objects.

A list of mappings to the specified targets.

### Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `EntityNotFoundException`

## GetPlan action (Python: get\_plan)

Gets code to perform a specified mapping.

### Request

- Mapping – *Required:* An array of [MappingEntry](#) objects.

The list of mappings from a source table to target tables.

- **Source** – *Required:* A [CatalogEntry](#) object.

The source table.

- **Sinks** – An array of [CatalogEntry](#) objects.

The target tables.

- **Location** – A [Location](#) object.

The parameters for the mapping.

- **Language** – UTF-8 string (valid values: PYTHON | SCALA).

The programming language of the code to perform the mapping.

- **AdditionalPlanOptionsMap** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map to hold additional optional key-value parameters.

Currently, these key-value pairs are supported:

- **inferSchema** — Specifies whether to set `inferSchema` to true or false for the default script generated by an AWS Glue job. For example, to set `inferSchema` to true, pass the following key value pair:

```
--additional-plan-options-map '{"inferSchema":"true"}
```

## Response

- **PythonScript** – UTF-8 string.

A Python script to perform the mapping.

- **ScalaCode** – UTF-8 string.

The Scala code to perform the mapping.

## Errors

- **InvalidInputException**

- `InternalServiceException`
- `OperationTimeoutException`

## Visual job API

The Visual job API allows you to create data integration jobs by using the AWS Glue API from a JSON object that represents a visual configuration of a AWS Glue job.

A list of `CodeGenConfigurationNodes` are provided to a create or update job API to register a DAG in AWS Glue Studio for the created job and generate the associated code.

## Data types

- [CodeGenConfigurationNode structure](#)
- [JDBCConnectorOptions structure](#)
- [StreamingDataPreviewOptions structure](#)
- [AthenaConnectorSource structure](#)

## CodeGenConfigurationNode structure

CodeGenConfigurationNode enumerates all valid Node types. One and only one of its member variables can be populated.

### Fields

- AthenaConnectorSource – An [AthenaConnectorSource](#) object.

Specifies a connector to an Amazon Athena data source.

- `JDBCConnectorSource` – A [JDBCConnectorSource](#) object.

Specifies a connector to a JDBC data source.

- `SparkConnectorSource` – A [SparkConnectorSource](#) object.

Specifies a connector to an Apache Spark data source.

- `CatalogSource` – A [CatalogSource](#) object.

Specifies a data store in the AWS Glue Data Catalog.

- `RedshiftSource` – A [RedshiftSource](#) object.

Specifies an Amazon Redshift data store.

- `S3CatalogSource` – A [S3CatalogSource](#) object.

Specifies an Amazon S3 data store in the AWS Glue Data Catalog.

- `S3CsvSource` – A [S3CsvSource](#) object.

Specifies a command-separated value (CSV) data store stored in Amazon S3.

- `S3JsonSource` – A [S3JsonSource](#) object.

Specifies a JSON data store stored in Amazon S3.

- `S3ParquetSource` – A [S3ParquetSource](#) object.

Specifies an Apache Parquet data store stored in Amazon S3.

- `RelationalCatalogSource` – A [RelationalCatalogSource](#) object.

Specifies a relational catalog data store in the AWS Glue Data Catalog.

- `DynamoDBCatalogSource` – A [DynamoDBCatalogSource](#) object.

Specifies a DynamoDBC Catalog data store in the AWS Glue Data Catalog.

- `JDBCConnectorTarget` – A [JDBCConnectorTarget](#) object.

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

- `SparkConnectorTarget` – A [SparkConnectorTarget](#) object.

Specifies a target that uses an Apache Spark connector.

- `CatalogTarget` – A [BasicCatalogTarget](#) object.

Specifies a target that uses a AWS Glue Data Catalog table.

- `RedshiftTarget` – A [RedshiftTarget](#) object.

Specifies a target that uses Amazon Redshift.

- `S3CatalogTarget` – A [S3CatalogTarget](#) object.

Specifies a data target that writes to Amazon S3 using the AWS Glue Data Catalog.

- `S3GlueParquetTarget` – A [S3GlueParquetTarget](#) object.

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

- `S3DirectTarget` – A [S3DirectTarget](#) object.

Specifies a data target that writes to Amazon S3.

- `ApplyMapping` – An [ApplyMapping](#) object.

Specifies a transform that maps data property keys in the data source to data property keys in the data target. You can rename keys, modify the data types for keys, and choose which keys to drop from the dataset.

- `SelectFields` – A [SelectFields](#) object.

Specifies a transform that chooses the data property keys that you want to keep.

- `DropFields` – A [DropFields](#) object.

Specifies a transform that chooses the data property keys that you want to drop.

- `RenameField` – A [RenameField](#) object.

Specifies a transform that renames a single data property key.

- `Spigot` – A [Spigot](#) object.

Specifies a transform that writes samples of the data to an Amazon S3 bucket.

- `Join` – A [Join](#) object.

Specifies a transform that joins two datasets into one dataset using a comparison phrase on the specified data property keys. You can use inner, outer, left, right, left semi, and left anti joins.

- `SplitFields` – A [SplitFields](#) object.

Specifies a transform that splits data property keys into two `DynamicFrames`. The output is a collection of `DynamicFrames`: one with selected data property keys, and one with the remaining data property keys.

- `SelectFromCollection` – A [SelectFromCollection](#) object.

Specifies a transform that chooses one `DynamicFrame` from a collection of `DynamicFrames`. The output is the selected `DynamicFrame`.

- `FillMissingValues` – A [FillMissingValues](#) object.

Specifies a transform that locates records in the dataset that have missing values and adds a new field with a value determined by imputation. The input data set is used to train the machine learning model that determines what the missing value should be.

- `Filter` – A [Filter](#) object.

Specifies a transform that splits a dataset into two, based on a filter condition.

- `CustomCode` – A [CustomCode](#) object.

Specifies a transform that uses custom code you provide to perform the data transformation. The output is a collection of `DynamicFrames`.

- `SparkSQL` – A [SparkSQL](#) object.

Specifies a transform where you enter a SQL query using Spark SQL syntax to transform the data. The output is a single `DynamicFrame`.

- `DirectKinesisSource` – A [DirectKinesisSource](#) object.

Specifies a direct Amazon Kinesis data source.

- `DirectKafkaSource` – A [DirectKafkaSource](#) object.

Specifies an Apache Kafka data store.

- `CatalogKinesisSource` – A [CatalogKinesisSource](#) object.

Specifies a Kinesis data source in the AWS Glue Data Catalog.

- `CatalogKafkaSource` – A [CatalogKafkaSource](#) object.

Specifies an Apache Kafka data store in the Data Catalog.

- `DropNullFields` – A [DropNullFields](#) object.

Specifies a transform that removes columns from the dataset if all values in the column are 'null'. By default, AWS Glue Studio will recognize null objects, but some values such as empty strings, strings that are "null", -1 integers or other placeholders such as zeros, are not automatically recognized as nulls.

- Merge – A [Merge](#) object.

Specifies a transform that merges a DynamicFrame with a staging DynamicFrame based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated.

- Union – An [Union](#) object.

Specifies a transform that combines the rows from two or more datasets into a single result.

- PII Detection – A [PIIDetection](#) object.

Specifies a transform that identifies, removes or masks PII data.

- Aggregate – An [Aggregate](#) object.

Specifies a transform that groups rows by chosen fields and computes the aggregated value by specified function.

- DropDuplicates – A [DropDuplicates](#) object.

Specifies a transform that removes rows of repeating data from a data set.

- GovernedCatalogTarget – A [GovernedCatalogTarget](#) object.

Specifies a data target that writes to a governed catalog.

- GovernedCatalogSource – A [GovernedCatalogSource](#) object.

Specifies a data source in a governed Data Catalog.

- MicrosoftSQLServerCatalogSource – A [MicrosoftSQLServerCatalogSource](#) object.

Specifies a Microsoft SQL server data source in the AWS Glue Data Catalog.

- MySQLCatalogSource – A [MySQLCatalogSource](#) object.

Specifies a MySQL data source in the AWS Glue Data Catalog.

- OracleSQLCatalogSource – An [OracleSQLCatalogSource](#) object.

Specifies an Oracle data source in the AWS Glue Data Catalog.

- `PostgreSQLCatalogSource` – A [PostgreSQLCatalogSource](#) object.  
Specifies a PostgreSQL data source in the AWS Glue Data Catalog.
- `MicrosoftSQLServerCatalogTarget` – A [MicrosoftSQLServerCatalogTarget](#) object.  
Specifies a target that uses Microsoft SQL.
- `MySQLCatalogTarget` – A [MySQLCatalogTarget](#) object.  
Specifies a target that uses MySQL.
- `OracleSQLCatalogTarget` – An [OracleSQLCatalogTarget](#) object.  
Specifies a target that uses Oracle SQL.
- `PostgreSQLCatalogTarget` – A [PostgreSQLCatalogTarget](#) object.  
Specifies a target that uses Postgres SQL.
- `DynamicTransform` – A [DynamicTransform](#) object.  
Specifies a custom visual transform created by a user.
- `EvaluateDataQuality` – An [EvaluateDataQuality](#) object.  
Specifies your data quality evaluation criteria.
- `S3CatalogHudiSource` – A [S3CatalogHudiSource](#) object.  
Specifies a Hudi data source that is registered in the AWS Glue Data Catalog. The data source must be stored in Amazon S3.
- `CatalogHudiSource` – A [CatalogHudiSource](#) object.  
Specifies a Hudi data source that is registered in the AWS Glue Data Catalog.
- `S3HudiSource` – A [S3HudiSource](#) object.  
Specifies a Hudi data source stored in Amazon S3.
- `S3HudiCatalogTarget` – A [S3HudiCatalogTarget](#) object.  
Specifies a target that writes to a Hudi data source in the AWS Glue Data Catalog.
- `S3HudiDirectTarget` – A [S3HudiDirectTarget](#) object.  
Specifies a target that writes to a Hudi data source in Amazon S3.
- `S3CatalogDeltaSource` – A [S3CatalogDeltaSource](#) object.

Specifies a Delta Lake data source that is registered in the AWS Glue Data Catalog. The data source must be stored in Amazon S3.

- `CatalogDeltaSource` – A [CatalogDeltaSource](#) object.

Specifies a Delta Lake data source that is registered in the AWS Glue Data Catalog.

- `S3DeltaSource` – A [S3DeltaSource](#) object.

Specifies a Delta Lake data source stored in Amazon S3.

- `S3DeltaCatalogTarget` – A [S3DeltaCatalogTarget](#) object.

Specifies a target that writes to a Delta Lake data source in the AWS Glue Data Catalog.

- `S3DeltaDirectTarget` – A [S3DeltaDirectTarget](#) object.

Specifies a target that writes to a Delta Lake data source in Amazon S3.

- `AmazonRedshiftSource` – An [AmazonRedshiftSource](#) object.

Specifies a target that writes to a data source in Amazon Redshift.

- `AmazonRedshiftTarget` – An [AmazonRedshiftTarget](#) object.

Specifies a target that writes to a data target in Amazon Redshift.

- `EvaluateDataQualityMultiFrame` – An [EvaluateDataQualityMultiFrame](#) object.

Specifies your data quality evaluation criteria. Allows multiple input data and returns a collection of Dynamic Frames.

- `Recipe` – A [Recipe](#) object.

Specifies a AWS Glue DataBrew recipe node.

- `SnowflakeSource` – A [SnowflakeSource](#) object.

Specifies a Snowflake data source.

- `SnowflakeTarget` – A [SnowflakeTarget](#) object.

Specifies a target that writes to a Snowflake data source.

- `ConnectorDataSource` – A [ConnectorDataSource](#) object.

Specifies a source generated with standard connection options.

- `ConnectorDataTarget` – A [ConnectorDataTarget](#) object.

Specifies a target generated with standard connection options.

## JDBCCredentialsOptions structure

Additional connection options for the connector.

### Fields

- `FilterPredicate` – UTF-8 string, matching the [Custom string pattern #39](#).

Extra condition clause to filter data from source. For example:

```
BillingCity='Mountain View'
```

When using a query instead of a table name, you should validate that the query works with the specified `filterPredicate`.

- `PartitionColumn` – UTF-8 string, matching the [Custom string pattern #39](#).

The name of an integer column that is used for partitioning. This option works only when it's included with `lowerBound`, `upperBound`, and `numPartitions`. This option works the same way as in the Spark SQL JDBC reader.

- `LowerBound` – Number (long), not more than None.

The minimum value of `partitionColumn` that is used to decide partition stride.

- `UpperBound` – Number (long), not more than None.

The maximum value of `partitionColumn` that is used to decide partition stride.

- `NumPartitions` – Number (long), not more than None.

The number of partitions. This value, along with `lowerBound` (inclusive) and `upperBound` (exclusive), form partition strides for generated WHERE clause expressions that are used to split the `partitionColumn`.

- `JobBookmarkKeys` – An array of UTF-8 strings.

The name of the job bookmark keys on which to sort.

- `JobBookmarkKeysSortOrder` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies an ascending or descending sort order.

- `DataTypeMapping` – A map array of key-value pairs.

Each key is a UTF-8 string (valid values: ARRAY | BIGINT | BINARY | BIT | BLOB | BOOLEAN | CHAR | CLOB | DATALINK | DATE | DECIMAL | DISTINCT | DOUBLE | FLOAT | INTEGER | JAVA\_OBJECT | LONGNVARCHAR | LONGVARBINARY | LONGVARCHAR | NCHAR | NCLOB | NULL | NUMERIC | NVARCHAR | OTHER | REAL | REF | REF\_CURSOR | ROWID | SMALLINT | SQLXML | STRUCT | TIME | TIME\_WITH\_TIMEZONE | TIMESTAMP | TIMESTAMP\_WITH\_TIMEZONE | TINYINT | VARBINARY | VARCHAR).

Each value is a UTF-8 string (valid values: DATE | STRING | TIMESTAMP | INT | FLOAT | LONG | BIGDECIMAL | BYTE | SHORT | DOUBLE).

Custom data type mapping that builds a mapping from a JDBC data type to an AWS Glue data type. For example, the option `"dataTypeMapping": {"FLOAT": "STRING"}` maps data fields of JDBC type `FLOAT` into the Java `String` type by calling the `ResultSet.getString()` method of the driver, and uses it to build the AWS Glue record. The `ResultSet` object is implemented by each driver, so the behavior is specific to the driver you use. Refer to the documentation for your JDBC driver to understand how the driver performs the conversions.

## StreamingDataPreviewOptions structure

Specifies options related to data preview for viewing a sample of your data.

### Fields

- `PollingTime` – Number (long), at least 10.

The polling time in milliseconds.

- `RecordPollingLimit` – Number (long), at least 1.

The limit to the number of records polled.

## AthenaConnectorSource structure

Specifies a connector to an Amazon Athena data source.

### Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the connection that is associated with the connector.

- `ConnectorName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of a connector that assists with accessing the data store in AWS Glue Studio.

- `ConnectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The type of connection, such as `marketplace.athena` or `custom.athena`, designating a connection to an Amazon Athena data store.

- `ConnectionTable` – UTF-8 string, matching the [Custom string pattern #40](#).

The name of the table in the data source.

- `SchemaName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the Cloudwatch log group to read from. For example, `/aws-glue/jobs/output`.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom Athena source.

## JDBCConectorSource structure

Specifies a connector to a JDBC data source.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the connection that is associated with the connector.

- `ConnectorName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of a connector that assists with accessing the data store in AWS Glue Studio.

- `ConnectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The type of connection, such as `marketplace.jdbc` or `custom.jdbc`, designating a connection to a JDBC data store.

- `AdditionalOptions` – A [JDBCConnectorOptions](#) object.

Additional connection options for the connector.

- `ConnectionTable` – UTF-8 string, matching the [Custom string pattern #40](#).

The name of the table in the data source.

- `Query` – UTF-8 string, matching the [Custom string pattern #41](#).

The table or SQL query to get the data from. You can specify either `ConnectionTable` or `query`, but not both.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom JDBC source.

## SparkConnectorSource structure

Specifies a connector to an Apache Spark data source.

### Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- `ConnectionName` – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the connection that is associated with the connector.

- `ConnectorName` – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of a connector that assists with accessing the data store in AWS Glue Studio.

- `ConnectionType` – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The type of connection, such as `marketplace.spark` or `custom.spark`, designating a connection to an Apache Spark data store.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Additional connection options for the connector.

- OutputSchemas – An array of [GlueSchema](#) objects.

Specifies data schema for the custom spark source.

## CatalogSource structure

Specifies a data store in the AWS Glue Data Catalog.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- Table – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## MySQLCatalogSource structure

Specifies a MySQL data source in the AWS Glue Data Catalog.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- Table – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## PostgreSQLCatalogSource structure

Specifies a PostgreSQL data source in the AWS Glue Data Catalog.

### Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- Database – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- Table – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## OracleSQLCatalogSource structure

Specifies an Oracle data source in the AWS Glue Data Catalog.

### Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- Database – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- Table – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## MicrosoftSQLServerCatalogSource structure

Specifies a Microsoft SQL server data source in the AWS Glue Data Catalog.

### Fields

- Name – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- Table – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## CatalogKinesisSource structure

Specifies a Kinesis data source in the AWS Glue Data Catalog.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- WindowSize – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- DetectSchema – Boolean.

Whether to automatically determine the schema from the incoming data.

- Table – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- StreamingOptions – A [KinesisStreamingSourceOptions](#) object.

Additional options for the Kinesis streaming data source.

- DataPreviewOptions – A [StreamingDataPreviewOptions](#) object.

Additional options for data preview.

## DirectKinesisSource structure

Specifies a direct Amazon Kinesis data source.

### Fields

- **Name** – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- **WindowSize** – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- **DetectSchema** – Boolean.

Whether to automatically determine the schema from the incoming data.

- **StreamingOptions** – A [KinesisStreamingSourceOptions](#) object.

Additional options for the Kinesis streaming data source.

- **DataPreviewOptions** – A [StreamingDataPreviewOptions](#) object.

Additional options for data preview.

## KinesisStreamingSourceOptions structure

Additional options for the Amazon Kinesis streaming data source.

### Fields

- **EndpointUrl** – UTF-8 string, matching the [Custom string pattern #39](#).

The URL of the Kinesis endpoint.

- **StreamName** – UTF-8 string, matching the [Custom string pattern #39](#).

The name of the Kinesis data stream.

- **Classification** – UTF-8 string, matching the [Custom string pattern #39](#).

An optional classification.

- **Delimiter** – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the delimiter character.

- `StartingPosition` – UTF-8 string (valid values: `latest="LATEST"` | `trim_horizon="TRIM_HORIZON"` | `earliest="EARLIEST"` | `timestamp="TIMESTAMP"`).

The starting position in the Kinesis data stream to read data from. The possible values are `"latest"`, `"trim_horizon"`, `"earliest"`, or a timestamp string in UTC format in the pattern `yyyy-mm-ddTHH:MM:SSZ` (where `Z` represents a UTC timezone offset with a `+/-`). For example: `"2023-04-04T08:00:00-04:00"`. The default value is `"latest"`.

Note: Using a value that is a timestamp string in UTC format for `"startingPosition"` is supported only for AWS Glue version 4.0 or later.

- `MaxFetchTimeInMs` – Number (long), not more than None.

The maximum time spent for the job executor to read records for the current batch from the Kinesis data stream, specified in milliseconds (ms). Multiple `GetRecords` API calls may be made within this time. The default value is `1000`.

- `MaxFetchRecordsPerShard` – Number (long), not more than None.

The maximum number of records to fetch per shard in the Kinesis data stream per microbatch.

Note: The client can exceed this limit if the streaming job has already read extra records from Kinesis (in the same `get-records` call). If `MaxFetchRecordsPerShard` needs to be strict then it needs to be a multiple of `MaxRecordPerRead`. The default value is `100000`.

- `MaxRecordPerRead` – Number (long), not more than None.

The maximum number of records to fetch from the Kinesis data stream in each `getRecords` operation. The default value is `10000`.

- `AddIdleTimeBetweenReads` – Boolean.

Adds a time delay between two consecutive `getRecords` operations. The default value is `"False"`. This option is only configurable for Glue version 2.0 and above.

- `IdleTimeBetweenReadsInMs` – Number (long), not more than None.

The minimum time delay between two consecutive `getRecords` operations, specified in ms. The default value is `1000`. This option is only configurable for Glue version 2.0 and above.

- `DescribeShardInterval` – Number (long), not more than None.

The minimum time interval between two ListShards API calls for your script to consider resharding. The default value is 1s.

- NumRetries – Number (integer), not more than None.

The maximum number of retries for Kinesis Data Streams API requests. The default value is 3.

- RetryIntervalMs – Number (long), not more than None.

The cool-off time period (specified in ms) before retrying the Kinesis Data Streams API call. The default value is 1000.

- MaxRetryIntervalMs – Number (long), not more than None.

The maximum cool-off time period (specified in ms) between two retries of a Kinesis Data Streams API call. The default value is 10000.

- AvoidEmptyBatches – Boolean.

Avoids creating an empty microbatch job by checking for unread data in the Kinesis data stream before the batch is started. The default value is "False".

- StreamArn – UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon Resource Name (ARN) of the Kinesis data stream.

- RoleArn – UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon Resource Name (ARN) of the role to assume using AWS Security Token Service (AWS STS). This role must have permissions for describe or read record operations for the Kinesis data stream. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSSessionName".

- RoleSessionName – UTF-8 string, matching the [Custom string pattern #39](#).

An identifier for the session assuming the role using AWS STS. You must use this parameter when accessing a data stream in a different account. Used in conjunction with "awsSTSRoleARN".

- AddRecordTimestamp – UTF-8 string, matching the [Custom string pattern #39](#).

When this option is set to 'true', the data output will contain an additional column named "\_\_src\_timestamp" that indicates the time when the corresponding record received by the stream. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

- `EmitConsumerLagMetrics` – UTF-8 string, matching the [Custom string pattern #39](#).

When this option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the stream and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

- `StartingTimestamp` – UTF-8 string.

The timestamp of the record in the Kinesis data stream to start reading data from. The possible values are a timestamp string in UTC format of the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: "2023-04-04T08:00:00+08:00".

## CatalogKafkaSource structure

Specifies an Apache Kafka data store in the Data Catalog.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- `WindowSize` – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- `DetectSchema` – Boolean.

Whether to automatically determine the schema from the incoming data.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- `StreamingOptions` – A [KafkaStreamingSourceOptions](#) object.

Specifies the streaming options.

- `DataPreviewOptions` – A [StreamingDataPreviewOptions](#) object.

Specifies options related to data preview for viewing a sample of your data.

## DirectKafkaSource structure

Specifies an Apache Kafka data store.

### Fields

- **Name** – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- **StreamingOptions** – A [KafkaStreamingSourceOptions](#) object.

Specifies the streaming options.

- **WindowSize** – Number (integer), not more than None.

The amount of time to spend processing each micro batch.

- **DetectSchema** – Boolean.

Whether to automatically determine the schema from the incoming data.

- **DataPreviewOptions** – A [StreamingDataPreviewOptions](#) object.

Specifies options related to data preview for viewing a sample of your data.

## KafkaStreamingSourceOptions structure

Additional options for streaming.

### Fields

- **BootstrapServers** – UTF-8 string, matching the [Custom string pattern #39](#).

A list of bootstrap server URLs, for example, as `b-1.vpc-test-2.o4q88o.c6.kafka.us-east-1.amazonaws.com:9094`. This option must be specified in the API call or defined in the table metadata in the Data Catalog.

- **SecurityProtocol** – UTF-8 string, matching the [Custom string pattern #39](#).

The protocol used to communicate with brokers. The possible values are "SSL" or "PLAINTEXT".

- **ConnectionName** – UTF-8 string, matching the [Custom string pattern #39](#).

The name of the connection.

- `TopicName` – UTF-8 string, matching the [Custom string pattern #39](#).

The topic name as specified in Apache Kafka. You must specify at least one of "topicName", "assign" or "subscribePattern".

- `Assign` – UTF-8 string, matching the [Custom string pattern #39](#).

The specific TopicPartitions to consume. You must specify at least one of "topicName", "assign" or "subscribePattern".

- `SubscribePattern` – UTF-8 string, matching the [Custom string pattern #39](#).

A Java regex string that identifies the topic list to subscribe to. You must specify at least one of "topicName", "assign" or "subscribePattern".

- `Classification` – UTF-8 string, matching the [Custom string pattern #39](#).

An optional classification.

- `Delimiter` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the delimiter character.

- `StartingOffsets` – UTF-8 string, matching the [Custom string pattern #39](#).

The starting position in the Kafka topic to read data from. The possible values are "earliest" or "latest". The default value is "latest".

- `EndingOffsets` – UTF-8 string, matching the [Custom string pattern #39](#).

The end point when a batch query is ended. Possible values are either "latest" or a JSON string that specifies an ending offset for each TopicPartition.

- `PollTimeoutMs` – Number (long), not more than None.

The timeout in milliseconds to poll data from Kafka in Spark job executors. The default value is 512.

- `NumRetries` – Number (integer), not more than None.

The number of times to retry before failing to fetch Kafka offsets. The default value is 3.

- `RetryIntervalMs` – Number (long), not more than None.

The time in milliseconds to wait before retrying to fetch Kafka offsets. The default value is 10.

- `MaxOffsetsPerTrigger` – Number (long), not more than None.

The rate limit on the maximum number of offsets that are processed per trigger interval. The specified total number of offsets is proportionally split across `topicPartitions` of different volumes. The default value is null, which means that the consumer reads all offsets until the known latest offset.

- `MinPartitions` – Number (integer), not more than None.

The desired minimum number of partitions to read from Kafka. The default value is null, which means that the number of spark partitions is equal to the number of Kafka partitions.

- `IncludeHeaders` – Boolean.

Whether to include the Kafka headers. When the option is set to "true", the data output will contain an additional column named "glue\_streaming\_kafka\_headers" with type `Array[Struct(key: String, value: String)]`. The default value is "false". This option is available in AWS Glue version 3.0 or later only.

- `AddRecordTimestamp` – UTF-8 string, matching the [Custom string pattern #39](#).

When this option is set to 'true', the data output will contain an additional column named "`__src_timestamp`" that indicates the time when the corresponding record received by the topic. The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

- `EmitConsumerLagMetrics` – UTF-8 string, matching the [Custom string pattern #39](#).

When this option is set to 'true', for each batch, it will emit the metrics for the duration between the oldest record received by the topic and the time it arrives in AWS Glue to CloudWatch. The metric's name is "glue.driver.streaming.maxConsumerLagInMs". The default value is 'false'. This option is supported in AWS Glue version 4.0 or later.

- `StartingTimestamp` – UTF-8 string.

The timestamp of the record in the Kafka topic to start reading data from. The possible values are a timestamp string in UTC format of the pattern `yyyy-mm-ddTHH:MM:SSZ` (where Z represents a UTC timezone offset with a +/-). For example: "2023-04-04T08:00:00+08:00").

Only one of `StartingTimestamp` or `StartingOffsets` must be set.

## RedshiftSource structure

Specifies an Amazon Redshift data store.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Amazon Redshift data store.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database table to read from.

- **RedshiftTmpDir** – UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 path where temporary data can be staged when copying out of the database.

- **TmpDirIAMRole** – UTF-8 string, matching the [Custom string pattern #39](#).

The IAM role with permissions.

## AmazonRedshiftSource structure

Specifies an Amazon Redshift source.

### Fields

- **Name** – UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Amazon Redshift source.

- **Data** – An [AmazonRedshiftNodeData](#) object.

Specifies the data of the Amazon Reshift source node.

## AmazonRedshiftNodeData structure

Specifies an Amazon Redshift node.

## Fields

- `AccessType` – UTF-8 string, matching the [Custom string pattern #38](#).

The access type for the Redshift connection. Can be a direct connection or catalog connections.

- `SourceType` – UTF-8 string, matching the [Custom string pattern #38](#).

The source type to specify whether a specific table is the source or a custom query.

- `Connection` – An [Option](#) object.

The AWS Glue connection to the Redshift cluster.

- `Schema` – An [Option](#) object.

The Redshift schema name when working with a direct connection.

- `Table` – An [Option](#) object.

The Redshift table name when working with a direct connection.

- `CatalogDatabase` – An [Option](#) object.

The name of the AWS Glue Data Catalog database when working with a data catalog.

- `CatalogTable` – An [Option](#) object.

The AWS Glue Data Catalog table name when working with a data catalog.

- `CatalogRedshiftSchema` – UTF-8 string.

The Redshift schema name when working with a data catalog.

- `CatalogRedshiftTable` – UTF-8 string.

The database table to read from.

- `TempDir` – UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 path where temporary data can be staged when copying out of the database.

- `IamRole` – An [Option](#) object.

Optional. The role name use when connection to S3. The IAM role ill default to the role on the job when left blank.

- `AdvancedOptions` – An array of [AmazonRedshiftAdvancedOption](#) objects.

Optional values when connecting to the Redshift cluster.

- `SampleQuery` – UTF-8 string.

The SQL used to fetch the data from a Redshift sources when the `SourceType` is 'query'.

- `PreAction` – UTF-8 string.

The SQL used before a MERGE or APPEND with upsert is run.

- `PostAction` – UTF-8 string.

The SQL used before a MERGE or APPEND with upsert is run.

- `Action` – UTF-8 string.

Specifies how writing to a Redshift cluster will occur.

- `TablePrefix` – UTF-8 string, matching the [Custom string pattern #38](#).

Specifies the prefix to a table.

- `Upsert` – Boolean.

The action used on Redshift sinks when doing an APPEND.

- `MergeAction` – UTF-8 string, matching the [Custom string pattern #38](#).

The action used when to determine how a MERGE in a Redshift sink will be handled.

- `MergeWhenMatched` – UTF-8 string, matching the [Custom string pattern #38](#).

The action used when to determine how a MERGE in a Redshift sink will be handled when an existing record matches a new record.

- `MergeWhenNotMatched` – UTF-8 string, matching the [Custom string pattern #38](#).

The action used when to determine how a MERGE in a Redshift sink will be handled when an existing record doesn't match a new record.

- `MergeClause` – UTF-8 string.

The SQL used in a custom merge to deal with matching records.

- `CrawlerConnection` – UTF-8 string.

Specifies the name of the connection that is associated with the catalog table used.

- `TableSchema` – An array of [Option](#) objects.

The array of schema output for a given node.

- `StagingTable` – UTF-8 string.

The name of the temporary staging table that is used when doing a MERGE or APPEND with upsert.

- `SelectedColumns` – An array of [Option](#) objects.

The list of column names used to determine a matching record when doing a MERGE or APPEND with upsert.

## AmazonRedshiftAdvancedOption structure

Specifies an optional value when connecting to the Redshift cluster.

### Fields

- `Key` – UTF-8 string.

The key for the additional connection option.

- `Value` – UTF-8 string.

The value for the additional connection option.

## Option structure

Specifies an option value.

### Fields

- `Value` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the value of the option.

- `Label` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the label of the option.

- `Description` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the description of the option.

## S3CatalogSource structure

Specifies an Amazon S3 data store in the AWS Glue Data Catalog.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database table to read from.

- **PartitionPredicate** – UTF-8 string, matching the [Custom string pattern #39](#).

Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to "" – empty by default.

- **AdditionalOptions** – A [S3SourceAdditionalOptions](#) object.

Specifies additional connection options.

## S3SourceAdditionalOptions structure

Specifies additional connection options for the Amazon S3 data store.

### Fields

- **BoundedSize** – Number (long).

Sets the upper limit for the target size of the dataset in bytes that will be processed.

- **BoundedFiles** – Number (long).

Sets the upper limit for the target number of files that will be processed.

## S3CsvSource structure

Specifies a command-separated value (CSV) data store stored in Amazon S3.

## Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- **Paths** – *Required:* An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- **CompressionType** – UTF-8 string (valid values: gzip="GZIP" | bzip2="BZIP2").

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **Exclusions** – An array of UTF-8 strings.

A string containing a JSON list of Unix-style glob patterns to exclude. For example, "[\ "\*\*.pdf\ "] excludes all PDF files.

- **GroupSize** – UTF-8 string, matching the [Custom string pattern #39](#).

The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, "groupFiles" must be set to "inPartition" for this to take effect.

- **GroupFiles** – UTF-8 string, matching the [Custom string pattern #39](#).

Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to "inPartition". To disable grouping when there are more than 50,000 files, set this parameter to "none".

- **Recurse** – Boolean.

If set to true, recursively reads files in all subdirectories under the specified paths.

- **MaxBand** – Number (integer), not more than None.

This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last maxBand milliseconds are tracked specially when using JobBookmarks to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- **MaxFilesInBand** – Number (integer), not more than None.

This option specifies the maximum number of files to save from the last maxBand seconds. If this number is exceeded, extra files are skipped and only processed in the next job run.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional connection options.

- `Separator` – *Required*: UTF-8 string (valid values: `comma="COMMA" | ctrlA="CTRLA" | pipe="PIPE" | semicolon="SEMICOLON" | tab="TAB"`).

Specifies the delimiter character. The default is a comma: `,`, but any other character can be specified.

- `Escaper` – UTF-8 string, matching the [Custom string pattern #40](#).

Specifies a character to use for escaping. This option is used only when reading CSV files. The default value is none. If enabled, the character which immediately follows is used as-is, except for a small set of well-known escapes (`\n`, `\r`, `\t`, and `\0`).

- `QuoteChar` – *Required*: UTF-8 string (valid values: `quote="QUOTE" | quillemet="QUILLET" | single_quote="SINGLE_QUOTE" | disabled="DISABLED"`).

Specifies the character to use for quoting. The default is a double quote: `'"`. Set this to `-1` to turn off quoting entirely.

- `Multiline` – Boolean.

A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to `True` if any record spans multiple lines. The default value is `False`, which allows for more aggressive file-splitting during parsing.

- `WithHeader` – Boolean.

A Boolean value that specifies whether to treat the first line as a header. The default value is `False`.

- `WriteHeader` – Boolean.

A Boolean value that specifies whether to write the header to output. The default value is `True`.

- `SkipFirst` – Boolean.

A Boolean value that specifies whether to skip the first data line. The default value is `False`.

- `OptimizePerformance` – Boolean.

A Boolean value that specifies whether to use the advanced SIMD CSV reader along with Apache Arrow based columnar memory formats. Only available in AWS Glue version 3.0.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 CSV source.

## DirectJDBCSource structure

Specifies the direct JDBC source connection.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the JDBC source connection.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database of the JDBC source connection.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The table of the JDBC source connection.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The connection name of the JDBC source.

- `ConnectionType` – *Required:* UTF-8 string (valid values: `sqlserver` | `mysql` | `oracle` | `postgresql` | `redshift`).

The connection type of the JDBC source.

- `RedshiftTmpDir` – UTF-8 string, matching the [Custom string pattern #39](#).

The temp directory of the JDBC Redshift source.

## S3DirectSourceAdditionalOptions structure

Specifies additional connection options for the Amazon S3 data store.

## Fields

- **BoundedSize** – Number (long).  
Sets the upper limit for the target size of the dataset in bytes that will be processed.
- **BoundedFiles** – Number (long).  
Sets the upper limit for the target number of files that will be processed.
- **EnableSamplePath** – Boolean.  
Sets option to enable a sample path.
- **SamplePath** – UTF-8 string, matching the [Custom string pattern #39](#).  
If enabled, specifies the sample path.

## S3JsonSource structure

Specifies a JSON data store stored in Amazon S3.

### Fields

- **Name** – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).  
The name of the data store.
- **Paths** – *Required*: An array of UTF-8 strings.  
A list of the Amazon S3 paths to read from.
- **CompressionType** – UTF-8 string (valid values: `gzip="GZIP" | bzip2="BZIP2"`).  
Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").
- **Exclusions** – An array of UTF-8 strings.  
A string containing a JSON list of Unix-style glob patterns to exclude. For example, "[\ "\*\*.pdf\""]" excludes all PDF files.
- **GroupSize** – UTF-8 string, matching the [Custom string pattern #39](#).

The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, "groupFiles" must be set to "inPartition" for this to take effect.

- `GroupFiles` – UTF-8 string, matching the [Custom string pattern #39](#).

Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to "inPartition". To disable grouping when there are more than 50,000 files, set this parameter to "none".

- `Recurse` – Boolean.

If set to true, recursively reads files in all subdirectories under the specified paths.

- `MaxBand` – Number (integer), not more than None.

This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last maxBand milliseconds are tracked specially when using JobBookmarks to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- `MaxFilesInBand` – Number (integer), not more than None.

This option specifies the maximum number of files to save from the last maxBand seconds. If this number is exceeded, extra files are skipped and only processed in the next job run.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional connection options.

- `JsonPath` – UTF-8 string, matching the [Custom string pattern #39](#).

A JsonPath string defining the JSON data.

- `Multiline` – Boolean.

A Boolean value that specifies whether a single record can span multiple lines. This can occur when a field contains a quoted new-line character. You must set this option to True if any record spans multiple lines. The default value is False, which allows for more aggressive file-splitting during parsing.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 JSON source.

## S3ParquetSource structure

Specifies an Apache Parquet data store stored in Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- **Paths** – *Required:* An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- **CompressionType** – UTF-8 string (valid values: snappy="SNAPPY" | lzo="LZO" | gzip="GZIP" | uncompressed="UNCOMPRESSED" | none="NONE").

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **Exclusions** – An array of UTF-8 strings.

A string containing a JSON list of Unix-style glob patterns to exclude. For example, "[\ "\*\*.pdf\ "] excludes all PDF files.

- **GroupSize** – UTF-8 string, matching the [Custom string pattern #39](#).

The target group size in bytes. The default is computed based on the input data size and the size of your cluster. When there are fewer than 50,000 input files, "groupFiles" must be set to "inPartition" for this to take effect.

- **GroupFiles** – UTF-8 string, matching the [Custom string pattern #39](#).

Grouping files is turned on by default when the input contains more than 50,000 files. To turn on grouping with fewer than 50,000 files, set this parameter to "inPartition". To disable grouping when there are more than 50,000 files, set this parameter to "none".

- **Recurse** – Boolean.

If set to true, recursively reads files in all subdirectories under the specified paths.

- **MaxBand** – Number (integer), not more than None.

This option controls the duration in milliseconds after which the s3 listing is likely to be consistent. Files with modification timestamps falling within the last maxBand milliseconds are

tracked specially when using JobBookmarks to account for Amazon S3 eventual consistency. Most users don't need to set this option. The default is 900000 milliseconds, or 15 minutes.

- `MaxFilesInBand` – Number (integer), not more than None.

This option specifies the maximum number of files to save from the last `maxBand` seconds. If this number is exceeded, extra files are skipped and only processed in the next job run.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional connection options.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the S3 Parquet source.

## S3DeltaSource structure

Specifies a Delta Lake data source stored in Amazon S3.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Delta Lake source.

- `Paths` – *Required:* An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- `AdditionalDeltaOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options.

- `AdditionalOptions` – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional options for the connector.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the Delta Lake source.

## S3CatalogDeltaSource structure

Specifies a Delta Lake data source that is registered in the AWS Glue Data Catalog. The data source must be stored in Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Delta Lake data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

- **AdditionalDeltaOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the Delta Lake source.

## CatalogDeltaSource structure

Specifies a Delta Lake data source that is registered in the AWS Glue Data Catalog.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Delta Lake data source.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

- **AdditionalDeltaOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the Delta Lake source.

## S3HudiSource structure

Specifies a Hudi data source stored in Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Hudi source.

- **Paths** – *Required:* An array of UTF-8 strings.

A list of the Amazon S3 paths to read from.

- **AdditionalHudiOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options.

- **AdditionalOptions** – A [S3DirectSourceAdditionalOptions](#) object.

Specifies additional options for the connector.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the Hudi source.

## S3CatalogHudiSource structure

Specifies a Hudi data source that is registered in the AWS Glue Data Catalog. The Hudi data source must be stored in Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).  
The name of the Hudi data source.
- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).  
The name of the database to read from.
- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).  
The name of the table in the database to read from.
- **AdditionalHudiOptions** – A map array of key-value pairs.  
Each key is a UTF-8 string, matching the [Custom string pattern #39](#).  
Each value is a UTF-8 string, matching the [Custom string pattern #39](#).  
Specifies additional connection options.
- **OutputSchemas** – An array of [GlueSchema](#) objects.  
Specifies the data schema for the Hudi source.

## CatalogHudiSource structure

Specifies a Hudi data source that is registered in the AWS Glue Data Catalog.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).  
The name of the Hudi data source.
- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).  
The name of the database to read from.
- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

- `AdditionalHudiOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the Hudi source.

## DynamoDBCatalogSource structure

Specifies a DynamoDB data source in the AWS Glue Data Catalog.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## RelationalCatalogSource structure

Specifies a Relational database data source in the AWS Glue Data Catalog.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data source.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to read from.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to read from.

## JDBCConnectorTarget structure

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `ConnectionName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the connection that is associated with the connector.

- `ConnectionTable` – *Required:* UTF-8 string, matching the [Custom string pattern #40](#).

The name of the table in the data target.

- `ConnectorName` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of a connector that will be used.

- `ConnectionType` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The type of connection, such as `marketplace.jdbc` or `custom.jdbc`, designating a connection to a JDBC data target.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Additional connection options for the connector.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies the data schema for the JDBC target.

## SparkConnectorTarget structure

Specifies a target that uses an Apache Spark connector.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **ConnectionName** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of a connection for an Apache Spark connector.

- **ConnectorName** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of an Apache Spark connector.

- **ConnectionType** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The type of connection, such as marketplace.spark or custom.spark, designating a connection to an Apache Spark data store.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Additional connection options for the connector.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom spark target.

## BasicCatalogTarget structure

Specifies a target that uses a AWS Glue Data Catalog table.

## Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of your data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database that contains the table you want to use as the target. This database must already exist in the Data Catalog.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The table that defines the schema of your output data. This table must already exist in the Data Catalog.

## MySQLCatalogTarget structure

Specifies a target that uses MySQL.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

## PostgreSQLCatalogTarget structure

Specifies a target that uses Postgres SQL.

## Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

## OracleSQLCatalogTarget structure

Specifies a target that uses Oracle SQL.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

## MicrosoftSQLServerCatalogTarget structure

Specifies a target that uses Microsoft SQL.

## Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

## RedshiftTarget structure

Specifies a target that uses Amazon Redshift.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

- **RedshiftTmpDir** – UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 path where temporary data can be staged when copying out of the database.

- **TmpDirIAMRole** – UTF-8 string, matching the [Custom string pattern #39](#).

The IAM role with permissions.

- UpsertRedshiftOptions – An [UpsertRedshiftTargetOptions](#) object.

The set of options to configure an upsert operation when writing to a Redshift target.

## AmazonRedshiftTarget structure

Specifies an Amazon Redshift target.

### Fields

- Name – UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Amazon Redshift target.

- Data – An [AmazonRedshiftNodeData](#) object.

Specifies the data of the Amazon Redshift target node.

- Inputs – An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

## UpsertRedshiftTargetOptions structure

The options to configure an upsert operation when writing to a Redshift target .

### Fields

- TableLocation – UTF-8 string, matching the [Custom string pattern #39](#).

The physical location of the Redshift table.

- ConnectionName – UTF-8 string, matching the [Custom string pattern #39](#).

The name of the connection to use to write to Redshift.

- UpsertKeys – An array of UTF-8 strings.

The keys used to determine whether to perform an update or insert.

## S3CatalogTarget structure

Specifies a data target that writes to Amazon S3 using the AWS Glue Data Catalog.

## Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **SchemaChangePolicy** – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## S3GlueParquetTarget structure

Specifies a data target that writes to Amazon S3 in Apache Parquet columnar storage.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

A single Amazon S3 path to write to.

- **Compression** – UTF-8 string (valid values: `snappy="SNAPPY" | lzo="LZO" | gzip="GZIP" | uncompressed="UNCOMPRESSED" | none="NONE"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## CatalogSchemaChangePolicy structure

A policy that specifies update behavior for the crawler.

### Fields

- **EnableUpdateCatalog** – Boolean.

Whether to use the specified update behavior when the crawler finds a changed schema.

- **UpdateBehavior** – UTF-8 string (valid values: `UPDATE_IN_DATABASE | LOG`).

The update behavior when the crawler finds a changed schema.

## S3DirectTarget structure

Specifies a data target that writes to Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

A single Amazon S3 path to write to.

- **Compression** – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **Format** – *Required*: UTF-8 string (valid values: json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA").

Specifies the data output format for the target.

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## S3HudiCatalogTarget structure

Specifies a target that writes to a Hudi data source in the AWS Glue Data Catalog.

### Fields

- **Name** – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

- **Database** – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **AdditionalOptions** – *Required*: A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options for the connector.

- `SchemaChangePolicy` – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## S3HudiDirectTarget structure

Specifies a target that writes to a Hudi data source in Amazon S3.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `Path` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 path of your Hudi data source to write to.

- `Compression` – *Required:* UTF-8 string (valid values: `gzip="GZIP" | lzo="LZO" | uncompressed="UNCOMPRESSED" | snappy="SNAPPY"`).

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- `PartitionKeys` – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- `Format` – *Required:* UTF-8 string (valid values: `json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA"`).

Specifies the data output format for the target.

- `AdditionalOptions` – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options for the connector.

- `SchemaChangePolicy` – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## S3DeltaCatalogTarget structure

Specifies a target that writes to a Delta Lake data source in the AWS Glue Data Catalog.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- `PartitionKeys` – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- `Table` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

- `Database` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options for the connector.

- `SchemaChangePolicy` – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## S3DeltaDirectTarget structure

Specifies a target that writes to a Delta Lake data source in Amazon S3.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Path** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 path of your Delta Lake data source to write to.

- **Compression** – *Required:* UTF-8 string (valid values: uncompressed="UNCOMPRESSED" | snappy="SNAPPY").

Specifies how the data is compressed. This is generally not necessary if the data has a standard file extension. Possible values are "gzip" and "bzip").

- **Format** – *Required:* UTF-8 string (valid values: json="JSON" | csv="CSV" | avro="AVRO" | orc="ORC" | parquet="PARQUET" | hudi="HUDI" | delta="DELTA").

Specifies the data output format for the target.

- **AdditionalOptions** – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional connection options for the connector.

- **SchemaChangePolicy** – A [DirectSchemaChangePolicy](#) object.

A policy that specifies update behavior for the crawler.

## DirectSchemaChangePolicy structure

A policy that specifies update behavior for the crawler.

### Fields

- `EnableUpdateCatalog` – Boolean.

Whether to use the specified update behavior when the crawler finds a changed schema.

- `UpdateBehavior` – UTF-8 string (valid values: `UPDATE_IN_DATABASE` | `LOG`).

The update behavior when the crawler finds a changed schema.

- `Table` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the table in the database that the schema change policy applies to.

- `Database` – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the database that the schema change policy applies to.

## ApplyMapping structure

Specifies a transform that maps data property keys in the data source to data property keys in the data target. You can rename keys, modify the data types for keys, and choose which keys to drop from the dataset.

### Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- `Inputs` – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- `Mapping` – *Required*: An array of [Mapping](#) objects.

Specifies the mapping of data property keys in the data source to data property keys in the data target.

## Mapping structure

Specifies the mapping of data property keys.

### Fields

- **ToKey** – UTF-8 string, matching the [Custom string pattern #39](#).

After the apply mapping, what the name of the column should be. Can be the same as `FromPath`.

- **FromPath** – An array of UTF-8 strings.

The table or column to be modified.

- **FromType** – UTF-8 string, matching the [Custom string pattern #39](#).

The type of the data to be modified.

- **ToType** – UTF-8 string, matching the [Custom string pattern #39](#).

The data type that the data is to be modified to.

- **Dropped** – Boolean.

If true, then the column is removed.

- **Children** – An array of [Mapping](#) objects.

Only applicable to nested data structures. If you want to change the parent structure, but also one of its children, you can fill out this data structure. It is also [Mapping](#), but its `FromPath` will be the parent's `FromPath` plus the `FromPath` from this structure.

For the children part, suppose you have the structure:

```
{ "FromPath": "OuterStructure", "ToKey": "OuterStructure", "ToType":  
"Struct", "Dropped": false, "Children": [{ "FromPath": "inner", "ToKey":  
"inner", "ToType": "Double", "Dropped": false, }] }
```

You can specify a [Mapping](#) that looks like:

```
{ "FromPath": "OuterStructure", "ToKey": "OuterStructure", "ToType":  
"Struct", "Dropped": false, "Children": [{ "FromPath": "inner", "ToKey":  
"inner", "ToType": "Double", "Dropped": false, }] }
```

## SelectFields structure

Specifies a transform that chooses the data property keys that you want to keep.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Paths – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure.

## DropFields structure

Specifies a transform that chooses the data property keys that you want to drop.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Paths – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure.

## RenameField structure

Specifies a transform that renames a single data property key.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- SourcePath – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure for the source data.

- TargetPath – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure for the target data.

## Spigot structure

Specifies a transform that writes samples of the data to an Amazon S3 bucket.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Path – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

A path in Amazon S3 where the transform will write a subset of records from the dataset to a JSON file in an Amazon S3 bucket.

- Topk – Number (integer), not more than 100.

Specifies a number of records to write starting from the beginning of the dataset.

- Prob – Number (double), not more than 1.

The probability (a decimal value with a maximum value of 1) of picking any given record. A value of 1 indicates that each row read from the dataset should be included in the sample output.

## Join structure

Specifies a transform that joins two datasets into one dataset using a comparison phrase on the specified data property keys. You can use inner, outer, left, right, left semi, and left anti joins.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).  
The name of the transform node.
- **Inputs** – *Required:* An array of UTF-8 strings, not less than 2 or more than 2 strings.  
The data inputs identified by their node names.
- **JoinType** – *Required:* UTF-8 string (valid values: `equijoin="EQUIJOIN" | left="LEFT" | right="RIGHT" | outer="OUTER" | leftsemi="LEFT_SEMI" | leftanti="LEFT_ANTI"`).  
Specifies the type of join to be performed on the datasets.
- **Columns** – *Required:* An array of [JoinColumn](#) objects, not less than 2 or more than 2 structures.  
A list of the two columns to be joined.

## JoinColumn structure

Specifies a column to be joined.

### Fields

- **From** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).  
The column to be joined.
- **Keys** – *Required:* An array of UTF-8 strings.  
The key of the column to be joined.

## SplitFields structure

Specifies a transform that splits data property keys into two `DynamicFrames`. The output is a collection of `DynamicFrames`: one with selected data property keys, and one with the remaining data property keys.

## Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Paths – *Required:* An array of UTF-8 strings.

A JSON path to a variable in the data structure.

## SelectFromCollection structure

Specifies a transform that chooses one `DynamicFrame` from a collection of `DynamicFrames`. The output is the selected `DynamicFrame`

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- Index – *Required:* Number (integer), not more than None.

The index for the `DynamicFrame` to be selected.

## FillMissingValues structure

Specifies a transform that locates records in the dataset that have missing values and adds a new field with a value determined by imputation. The input data set is used to train the machine learning model that determines what the missing value should be.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **ImputedPath** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

A JSON path to a variable in the data structure for the dataset that is imputed.

- **FilledPath** – UTF-8 string, matching the [Custom string pattern #39](#).

A JSON path to a variable in the data structure for the dataset that is filled.

## Filter structure

Specifies a transform that splits a dataset into two, based on a filter condition.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **LogicalOperator** – *Required:* UTF-8 string (valid values: AND | OR).

The operator used to filter rows by comparing the key value to a specified value.

- **Filters** – *Required:* An array of [FilterExpression](#) objects.

Specifies a filter expression.

## FilterExpression structure

Specifies a filter expression.

### Fields

- **Operation** – *Required:* UTF-8 string (valid values: EQ | LT | GT | LTE | GTE | REGEX | ISNULL).

The type of operation to perform in the expression.

- **Negated** – Boolean.

Whether the expression is to be negated.

- **Values** – *Required*: An array of [FilterValue](#) objects.

A list of filter values.

## FilterValue structure

Represents a single entry in the list of values for a `FilterExpression`.

### Fields

- **Type** – *Required*: UTF-8 string (valid values: COLUMNEXTRACTED | CONSTANT).

The type of filter value.

- **Value** – *Required*: An array of UTF-8 strings.

The value to be associated.

## CustomCode structure

Specifies a transform that uses custom code you provide to perform the data transformation. The output is a collection of `DynamicFrames`.

### Fields

- **Name** – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required*: An array of UTF-8 strings, at least 1 string.

The data inputs identified by their node names.

- **Code** – *Required*: UTF-8 string, matching the [Custom string pattern #34](#).

The custom code that is used to perform the data transformation.

- **ClassName** – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The name defined for the custom code node class.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the custom code transform.

## SparkSQL structure

Specifies a transform where you enter a SQL query using Spark SQL syntax to transform the data. The output is a single `DynamicFrame`.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, at least 1 string.

The data inputs identified by their node names. You can associate a table name with each input node to use in the SQL query. The name you choose must meet the Spark SQL naming restrictions.

- **SqlQuery** – *Required:* UTF-8 string, matching the [Custom string pattern #41](#).

A SQL query that must use Spark SQL syntax and return a single data set.

- **SqlAliases** – *Required:* An array of [SqlAlias](#) objects.

A list of aliases. An alias allows you to specify what name to use in the SQL for a given input. For example, you have a datasource named "MyDataSource". If you specify `From` as `MyDataSource`, and `Alias` as `SqlName`, then in your SQL you can do:

```
select * from SqlName
```

and that gets data from `MyDataSource`.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the SparkSQL transform.

## SqlAlias structure

Represents a single entry in the list of values for `SqlAliases`.

### Fields

- `From` – *Required*: UTF-8 string, matching the [Custom string pattern #38](#).

A table, or a column in a table.

- `Alias` – *Required*: UTF-8 string, matching the [Custom string pattern #40](#).

A temporary name given to a table, or a column in a table.

## DropNullFields structure

Specifies a transform that removes columns from the dataset if all values in the column are 'null'. By default, AWS Glue Studio will recognize null objects, but some values such as empty strings, strings that are "null", -1 integers or other placeholders such as zeros, are not automatically recognized as nulls.

### Fields

- `Name` – *Required*: UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- `Inputs` – *Required*: An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- `NullCheckBoxList` – A [NullCheckBoxList](#) object.

A structure that represents whether certain values are recognized as null values for removal.

- `NullTextList` – An array of [NullValueField](#) objects, not more than 50 structures.

A structure that specifies a list of `NullValueField` structures that represent a custom null value such as zero or other value being used as a null placeholder unique to the dataset.

The `DropNullFields` transform removes custom null values only if both the value of the null placeholder and the datatype match the data.

## NullCheckBoxList structure

Represents whether certain values are recognized as null values for removal.

### Fields

- `IsEmpty` – Boolean.

Specifies that an empty string is considered as a null value.

- `IsNullString` – Boolean.

Specifies that a value spelling out the word 'null' is considered as a null value.

- `IsNegOne` – Boolean.

Specifies that an integer value of -1 is considered as a null value.

## NullValueField structure

Represents a custom null value such as a zeros or other value being used as a null placeholder unique to the dataset.

### Fields

- `Value` – *Required*: UTF-8 string, matching the [Custom string pattern #39](#).

The value of the null placeholder.

- `Datatype` – *Required*: A [Datatype](#) object.

The datatype of the value.

## Datatype structure

A structure representing the datatype of the value.

### Fields

- `Id` – *Required*: UTF-8 string, matching the [Custom string pattern #38](#).

The datatype of the value.

- **Label** – *Required:* UTF-8 string, matching the [Custom string pattern #38](#).

A label assigned to the datatype.

## Merge structure

Specifies a transform that merges a `DynamicFrame` with a staging `DynamicFrame` based on the specified primary keys to identify records. Duplicate records (records with the same primary keys) are not de-duplicated.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 2 or more than 2 strings.

The data inputs identified by their node names.

- **Source** – *Required:* UTF-8 string, matching the [Custom string pattern #38](#).

The source `DynamicFrame` that will be merged with a staging `DynamicFrame`.

- **PrimaryKeys** – *Required:* An array of UTF-8 strings.

The list of primary key fields to match records from the source and staging dynamic frames.

## Union structure

Specifies a transform that combines the rows from two or more datasets into a single result.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 2 or more than 2 strings.

The node ID inputs to the transform.

- **UnionType** – *Required:* UTF-8 string (valid values: ALL | DISTINCT).

Indicates the type of Union transform.

Specify ALL to join all rows from data sources to the resulting DynamicFrame. The resulting union does not remove duplicate rows.

Specify DISTINCT to remove duplicate rows in the resulting DynamicFrame.

## PIIDetection structure

Specifies a transform that identifies, removes or masks PII data.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The node ID inputs to the transform.

- PiiType – *Required:* UTF-8 string (valid values: RowAudit | RowMasking | ColumnAudit | ColumnMasking).

Indicates the type of PIIDetection transform.

- EntityTypesToDetect – *Required:* An array of UTF-8 strings.

Indicates the types of entities the PIIDetection transform will identify as PII data.

PII type entities include: PERSON\_NAME, DATE, USA\_SNN, EMAIL, USA\_ITIN, USA\_PASSPORT\_NUMBER, PHONE\_NUMBER, BANK\_ACCOUNT, IP\_ADDRESS, MAC\_ADDRESS, USA\_CPT\_CODE, USA\_HCPCS\_CODE, USA\_NATIONAL\_DRUG\_CODE, USA\_MEDICARE\_BENEFICIARY\_IDENTIFIER, USA\_HEALTH\_INSURANCE\_CLAIM\_NUMBER, CREDIT\_CARD, USA\_NATIONAL\_PROVIDER\_IDENTIFIER, USA...

- OutputColumnName – UTF-8 string, matching the [Custom string pattern #39](#).

Indicates the output column name that will contain any entity type detected in that row.

- SampleFraction – Number (double), not more than 1.

Indicates the fraction of the data to sample when scanning for PII entities.

- `ThresholdFraction` – Number (double), not more than 1.

Indicates the fraction of the data that must be met in order for a column to be identified as PII data.

- `MaskValue` – UTF-8 string, not more than 256 bytes long, matching the [Custom string pattern #36](#).

Indicates the value that will replace the detected entity.

## Aggregate structure

Specifies a transform that groups rows by chosen fields and computes the aggregated value by specified function.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

Specifies the fields and rows to use as inputs for the aggregate transform.

- `Groups` – *Required:* An array of UTF-8 strings.

Specifies the fields to group by.

- `Aggs` – *Required:* An array of [AggregateOperation](#) objects, not less than 1 or more than 30 structures.

Specifies the aggregate functions to be performed on specified fields.

## DropDuplicates structure

Specifies a transform that removes rows of repeating data from a data set.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the transform node.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The data inputs identified by their node names.

- **Columns** – An array of UTF-8 strings.

The name of the columns to be merged or removed if repeating.

## GovernedCatalogTarget structure

Specifies a data target that writes to Amazon S3 using the AWS Glue Data Catalog.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data target.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

- **PartitionKeys** – An array of UTF-8 strings.

Specifies native partitioning using a sequence of keys.

- **Table** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the table in the database to write to.

- **Database** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The name of the database to write to.

- **SchemaChangePolicy** – A [CatalogSchemaChangePolicy](#) object.

A policy that specifies update behavior for the governed catalog.

## GovernedCatalogSource structure

Specifies the data store in the governed AWS Glue Data Catalog.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data store.

- Database – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database to read from.

- Table – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The database table to read from.

- PartitionPredicate – UTF-8 string, matching the [Custom string pattern #39](#).

Partitions satisfying this predicate are deleted. Files within the retention period in these partitions are not deleted. Set to "" – empty by default.

- AdditionalOptions – A [S3SourceAdditionalOptions](#) object.

Specifies additional connection options.

## AggregateOperation structure

Specifies the set of parameters needed to perform aggregation in the aggregate transform.

### Fields

- Column – *Required:* An array of UTF-8 strings.

Specifies the column on the data set on which the aggregation function will be applied.

- AggFunc – *Required:* UTF-8 string (valid values: avg | countDistinct | count | first | last | kurtosis | max | min | skewness | stddev\_samp | stddev\_pop | sum | sumDistinct | var\_samp | var\_pop).

Specifies the aggregation function to apply.

Possible aggregation functions include: avg, countDistinct, count, first, last, kurtosis, max, min, skewness, stddev\_samp, stddev\_pop, sum, sumDistinct, var\_samp, var\_pop

## GlueSchema structure

Specifies a user-defined schema when a schema cannot be determined by AWS Glue.

## Fields

- `Columns` – An array of [GlueStudioSchemaColumn](#) objects.

Specifies the column definitions that make up a AWS Glue schema.

## GlueStudioSchemaColumn structure

Specifies a single column in a AWS Glue schema definition.

### Fields

- `Name` – *Required:* UTF-8 string, not more than 1024 bytes long, matching the [Single-line string pattern](#).

The name of the column in the AWS Glue Studio schema.

- `Type` – UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The hive type for this column in the AWS Glue Studio schema.

## GlueStudioColumn structure

Specifies a single column in AWS GlueStudio.

### Fields

- `Key` – *Required:* UTF-8 string, matching the [Custom string pattern #40](#).

The key of the column in AWS Glue Studio.

- `FullPath` – *Required:* An array of UTF-8 strings.

The full URL of the column in AWS Glue Studio.

- `Type` – *Required:* UTF-8 string (valid values: `array="ARRAY" | bigint="BIGINT" | bigint array="BIGINT_ARRAY" | binary="BINARY" | binary array="BINARY_ARRAY" | boolean="BOOLEAN" | boolean array="BOOLEAN_ARRAY" | byte="BYTE" | byte array="BYTE_ARRAY" | char="CHAR" | char array="CHAR_ARRAY" | choice="CHOICE" | choice array="CHOICE_ARRAY" | date="DATE" | date array="DATE_ARRAY" | decimal="DECIMAL" | decimal array="DECIMAL_ARRAY" | double="DOUBLE" | double array="DOUBLE_ARRAY" | enum="ENUM" | enum array="ENUM_ARRAY" |`

```
float="FLOAT" | float array="FLOAT_ARRAY" | int="INT" | int array="INT_ARRAY"
| interval="INTERVAL" | interval array="INTERVAL_ARRAY" | long="LONG"
| long array="LONG_ARRAY" | object="OBJECT" | short="SHORT" | short
array="SHORT_ARRAY" | smallint="SMALLINT" | smallint array="SMALLINT_ARRAY"
| string="STRING" | string array="STRING_ARRAY" | timestamp="TIMESTAMP"
| timestamp array="TIMESTAMP_ARRAY" | tinyint="TINYINT" | tinyint
array="TINYINT_ARRAY" | varchar="VARCHAR" | varchar array="VARCHAR_ARRAY" |
null="NULL" | unknown="UNKNOWN" | unknown array="UNKNOWN_ARRAY").
```

The type of the column in AWS Glue Studio.

- Children – An array of a structures.

The children of the parent column in AWS Glue Studio.

## DynamicTransform structure

Specifies the set of parameters needed to perform the dynamic transform.

### Fields

- Name – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the name of the dynamic transform.

- TransformName – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the name of the dynamic transform as it appears in the AWS Glue Studio visual editor.

- Inputs – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

Specifies the inputs for the dynamic transform that are required.

- Parameters – An array of [TransformConfigParameter](#) objects.

Specifies the parameters of the dynamic transform.

- FunctionName – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the name of the function of the dynamic transform.

- Path – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the path of the dynamic transform source and config files.

- **Version** – UTF-8 string, matching the [Custom string pattern #39](#).

This field is not used and will be deprecated in future release.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for the dynamic transform.

## TransformConfigParameter structure

Specifies the parameters in the config file of the dynamic transform.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the name of the parameter in the config file of the dynamic transform.

- **Type** – *Required:* UTF-8 string (valid values: `str="STR" | int="INT" | float="FLOAT" | complex="COMPLEX" | bool="BOOL" | list="LIST" | null="NULL"`).

Specifies the parameter type in the config file of the dynamic transform.

- **ValidationRule** – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the validation rule in the config file of the dynamic transform.

- **ValidationMessage** – UTF-8 string, matching the [Custom string pattern #39](#).

Specifies the validation message in the config file of the dynamic transform.

- **Value** – An array of UTF-8 strings.

Specifies the value of the parameter in the config file of the dynamic transform.

- **ListType** – UTF-8 string (valid values: `str="STR" | int="INT" | float="FLOAT" | complex="COMPLEX" | bool="BOOL" | list="LIST" | null="NULL"`).

Specifies the list type of the parameter in the config file of the dynamic transform.

- **IsOptional** – Boolean.

Specifies whether the parameter is optional or not in the config file of the dynamic transform.

## EvaluateDataQuality structure

Specifies your data quality evaluation criteria.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data quality evaluation.

- **Inputs** – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The inputs of your data quality evaluation.

- **Ruleset** – *Required:* UTF-8 string, not less than 1 or more than 65536 bytes long, matching the [Custom string pattern #37](#).

The ruleset for your data quality evaluation.

- **Output** – UTF-8 string (valid values: PrimaryInput | EvaluationResults).

The output of your data quality evaluation.

- **PublishingOptions** – A [DQResultsPublishingOptions](#) object.

Options to configure how your results are published.

- **StopJobOnFailureOptions** – A [DQStopJobOnFailureOptions](#) object.

Options to configure how your job will stop if your data quality evaluation fails.

## DQResultsPublishingOptions structure

Options to configure how your data quality evaluation results are published.

### Fields

- **EvaluationContext** – UTF-8 string, matching the [Custom string pattern #38](#).

The context of the evaluation.

- **ResultsS3Prefix** – UTF-8 string, matching the [Custom string pattern #39](#).

The Amazon S3 prefix prepended to the results.

- **CloudWatchMetricsEnabled** – Boolean.

Enable metrics for your data quality results.

- `ResultsPublishingEnabled` – Boolean.

Enable publishing for your data quality results.

## DQStopJobOnFailureOptions structure

Options to configure how your job will stop if your data quality evaluation fails.

### Fields

- `StopJobOnFailureTiming` – UTF-8 string (valid values: `Immediate` | `AfterDataLoad`).

When to stop job if your data quality evaluation fails. Options are `Immediate` or `AfterDataLoad`.

## EvaluateDataQualityMultiFrame structure

Specifies your data quality evaluation criteria.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the data quality evaluation.

- `Inputs` – *Required:* An array of UTF-8 strings, at least 1 string.

The inputs of your data quality evaluation. The first input in this list is the primary data source.

- `AdditionalDataSources` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #42](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

The aliases of all data sources except primary.

- `Ruleset` – *Required:* UTF-8 string, not less than 1 or more than 65536 bytes long, matching the [Custom string pattern #37](#).

The ruleset for your data quality evaluation.

- `PublishingOptions` – A [DQResultsPublishingOptions](#) object.

Options to configure how your results are published.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string (valid values: `performanceTuning.caching="CacheOption" | observations.scope="ObservationsOption"`).

Each value is a UTF-8 string.

Options to configure runtime behavior of the transform.

- `StopJobOnFailureOptions` – A [DQStopJobOnFailureOptions](#) object.

Options to configure how your job will stop if your data quality evaluation fails.

## Recipe structure

A AWS Glue Studio node that uses a AWS Glue DataBrew recipe in AWS Glue jobs.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the AWS Glue Studio node.

- `Inputs` – *Required:* An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the recipe node, identified by id.

- `RecipeReference` – *Required:* A [RecipeReference](#) object.

A reference to the DataBrew recipe used by the node.

## RecipeReference structure

A reference to a AWS Glue DataBrew recipe.

### Fields

- `RecipeArn` – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The ARN of the DataBrew recipe.

- `RecipeVersion` – *Required*: UTF-8 string, not less than 1 or more than 16 bytes long.

The `RecipeVersion` of the DataBrew recipe.

## SnowflakeNodeData structure

Specifies configuration for Snowflake nodes in AWS Glue Studio.

### Fields

- `SourceType` – UTF-8 string, matching the [Custom string pattern #38](#).

Specifies how retrieved data is specified. Valid values: "table", "query".

- `Connection` – An [Option](#) object.

Specifies a AWS Glue Data Catalog Connection to a Snowflake endpoint.

- `Schema` – UTF-8 string.

Specifies a Snowflake database schema for your node to use.

- `Table` – UTF-8 string.

Specifies a Snowflake table for your node to use.

- `Database` – UTF-8 string.

Specifies a Snowflake database for your node to use.

- `TempDir` – UTF-8 string, matching the [Custom string pattern #39](#).

Not currently used.

- `IamRole` – An [Option](#) object.

Not currently used.

- `AdditionalOptions` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #39](#).

Each value is a UTF-8 string, matching the [Custom string pattern #39](#).

Specifies additional options passed to the Snowflake connector. If options are specified elsewhere in this node, this will take precedence.

- `SampleQuery` – UTF-8 string.

A SQL string used to retrieve data with the `query` sourcetype.

- `PreAction` – UTF-8 string.

A SQL string run before the Snowflake connector performs its standard actions.

- `PostAction` – UTF-8 string.

A SQL string run after the Snowflake connector performs its standard actions.

- `Action` – UTF-8 string.

Specifies what action to take when writing to a table with preexisting data. Valid values: `append`, `merge`, `truncate`, `drop`.

- `Upsert` – Boolean.

Used when `Action` is `append`. Specifies the resolution behavior when a row already exists. If true, preexisting rows will be updated. If false, those rows will be inserted.

- `MergeAction` – UTF-8 string, matching the [Custom string pattern #38](#).

Specifies a merge action. Valid values: `simple`, `custom`. If `simple`, merge behavior is defined by `MergeWhenMatched` and `MergeWhenNotMatched`. If `custom`, defined by `MergeClause`.

- `MergeWhenMatched` – UTF-8 string, matching the [Custom string pattern #38](#).

Specifies how to resolve records that match preexisting data when merging. Valid values: `update`, `delete`.

- `MergeWhenNotMatched` – UTF-8 string, matching the [Custom string pattern #38](#).

Specifies how to process records that do not match preexisting data when merging. Valid values: `insert`, `none`.

- `MergeClause` – UTF-8 string.

A SQL statement that specifies a custom merge behavior.

- `StagingTable` – UTF-8 string.

The name of a staging table used when performing merge or upsert append actions. Data is written to this table, then moved to `table` by a generated postaction.

- `SelectedColumns` – An array of [Option](#) objects.

Specifies the columns combined to identify a record when detecting matches for merges and upserts. A list of structures with `value`, `label` and `description` keys. Each structure describes a column.

- `AutoPushdown` – Boolean.

Specifies whether automatic query pushdown is enabled. If pushdown is enabled, then when a query is run on Spark, if part of the query can be "pushed down" to the Snowflake server, it is pushed down. This improves performance of some queries.

- `TableSchema` – An array of [Option](#) objects.

Manually defines the target schema for the node. A list of structures with `value`, `label` and `description` keys. Each structure defines a column.

## SnowflakeSource structure

Specifies a Snowflake data source.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Snowflake data source.

- `Data` – *Required:* A [SnowflakeNodeData](#) object.

Configuration for the Snowflake data source.

- `OutputSchemas` – An array of [GlueSchema](#) objects.

Specifies user-defined schemas for your output data.

## SnowflakeTarget structure

Specifies a Snowflake target.

### Fields

- `Name` – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of the Snowflake target.

- **Data** – *Required:* A [SnowflakeNodeData](#) object.

Specifies the data of the Snowflake target node.

- **Inputs** – An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

## ConnectorDataSource structure

Specifies a source generated with standard connection options.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of this source node.

- **connectionType** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The `connectionType`, as provided to the underlying AWS Glue library. This node type supports the following connection types:

- `opensearch`
- `azuresql`
- `azurecosmos`
- `bigquery`
- `saphana`
- `teradata`
- `vertica`
- **Data** – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map specifying connection options for the node. You can find standard connection options for the corresponding connection type in the [Connection parameters](#) section of the AWS Glue documentation.

- **OutputSchemas** – An array of [GlueSchema](#) objects.

Specifies the data schema for this source.

## ConnectorDataTarget structure

Specifies a target generated with standard connection options.

### Fields

- **Name** – *Required:* UTF-8 string, matching the [Custom string pattern #42](#).

The name of this target node.

- **ConnectionType** – *Required:* UTF-8 string, matching the [Custom string pattern #39](#).

The `connectionType`, as provided to the underlying AWS Glue library. This node type supports the following connection types:

- `opensearch`
- `azuresql`
- `azurecosmos`
- `bigquery`
- `saphana`
- `teradata`
- `vertica`
- **Data** – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map specifying connection options for the node. You can find standard connection options for the corresponding connection type in the [Connection parameters](#) section of the AWS Glue documentation.

- **Inputs** – An array of UTF-8 strings, not less than 1 or more than 1 strings.

The nodes that are inputs to the data target.

# Jobs API

The Jobs API describes jobs data types and contains APIs for working with jobs, job runs, and triggers in AWS Glue.

## Topics

- [Jobs](#)
- [Job runs](#)
- [Triggers](#)

## Jobs

The Jobs API describes the data types and API related to creating, updating, deleting, or viewing jobs in AWS Glue.

## Data types

- [Job structure](#)
- [ExecutionProperty structure](#)
- [NotificationProperty structure](#)
- [JobCommand structure](#)
- [ConnectionsList structure](#)
- [JobUpdate structure](#)
- [SourceControlDetails structure](#)

## Job structure

Specifies a job definition.

### Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name you assign to this job definition.

- **JobMode** – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- **SCRIPT** - The job was created using the AWS Glue Studio script editor.
- **VISUAL** - The job was created using the AWS Glue Studio visual editor.
- **NOTEBOOK** - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the job.

- **LogUri** – UTF-8 string.

This field is reserved for future use.

- **Role** – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role associated with this job.

- **CreatedOn** – Timestamp.

The time and date that this job definition was created.

- **LastModifiedOn** – Timestamp.

The last point in time when this job definition was modified.

- **ExecutionProperty** – An [ExecutionProperty](#) object.

An ExecutionProperty specifying the maximum number of concurrent runs allowed for this job.

- **Command** – A [JobCommand](#) object.

The JobCommand that runs this job.

- **DefaultArguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The default arguments for every run of this job, specified as name-value pairs.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a AWS Glue Connection, AWS Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling AWS Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by AWS Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `NonOverridableArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

Arguments for this job that are not overridden when providing job arguments in a job run, specified as name-value pairs.

- `Connections` – A [ConnectionsList](#) object.

The connections used for this job.

- `MaxRetries` – Number (integer).

The maximum number of times to retry this job after a JobRun fails.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of AWS Glue data processing units (DPUs) allocated to runs of this job. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The job timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status. The default is 2,880 minutes (48 hours) for batch jobs.

Streaming jobs must have timeout values less than 7 days or 10080 minutes. When the value is left blank, the job will be restarted after 7 days based if you have not setup a maintenance window. If you have setup maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

For Glue version 2.0 or later jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, `G.8X` or `G.025X` for Spark jobs. Accepts the value `Z.2X` for Ray jobs.

- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.

- For the G.2X worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.4X worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).
- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk (approximately 120GB free), and provides up to 8 Ray workers based on the autoscaler.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job notification.

- `Running` – Boolean.

This field is reserved for future use.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that AWS Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `CodeGenConfigurationNodes` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #38](#).

Each value is a [CodeGenConfigurationNode](#) object.

The representation of a directed acyclic graph on which both the Glue Studio visual component and Glue Studio code generation is based.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with AWS Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to `FLEX`. The flexible execution class is available for Spark jobs.

- `SourceControlDetails` – A [SourceControlDetails](#) object.

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #30](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. AWS Glue periodically performs maintenance activities. During these maintenance windows, AWS Glue will need to restart your streaming jobs.

AWS Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

## ExecutionProperty structure

An execution property of a job.

### Fields

- `MaxConcurrentRuns` – Number (integer).

The maximum number of concurrent runs allowed for the job. The default is 1. An error is returned when this threshold is reached. The maximum value you can specify is controlled by a service limit.

## NotificationProperty structure

Specifies configuration properties of a notification.

### Fields

- `NotifyDelayAfter` – Number (integer), at least 1.

After a job run starts, the number of minutes to wait before sending a job run delay notification.

## JobCommand structure

Specifies code that runs when a job is run.

### Fields

- `Name` – UTF-8 string.

The name of the job command. For an Apache Spark ETL job, this must be `glueetl`. For a Python shell job, it must be `pythonshell`. For an Apache Spark streaming ETL job, this must be `gluestreaming`. For a Ray job, this must be `glueray`.

- `ScriptLocation` – UTF-8 string, not more than 400000 bytes long.

Specifies the Amazon Simple Storage Service (Amazon S3) path to a script that runs a job.

- `PythonVersion` – UTF-8 string, matching the [Custom string pattern #21](#).

The Python version being used to run a Python shell job. Allowed values are 2 or 3.

- `Runtime` – UTF-8 string, not more than 64 bytes long, matching the [Custom string pattern #29](#).

In Ray jobs, `Runtime` is used to specify the versions of Ray, Python and additional libraries available in your environment. This field is not used in other job types. For supported runtime environment values, see [Supported Ray runtime environments](#) in the AWS Glue Developer Guide.

## ConnectionsList structure

Specifies the connections used by a job.

### Fields

- `Connections` – An array of UTF-8 strings.

A list of connections used by the job.

## JobUpdate structure

Specifies information used to update an existing job definition. The previous job definition is completely overwritten by this information.

### Fields

- `JobMode` – UTF-8 string (valid values: `SCRIPT=""` | `VISUAL=""` | `NOTEBOOK=""`).

A mode that describes how a job was created. Valid values are:

- `SCRIPT` - The job was created using the AWS Glue Studio script editor.
- `VISUAL` - The job was created using the AWS Glue Studio visual editor.
- `NOTEBOOK` - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- Description – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Description of the job being defined.

- LogUri – UTF-8 string.

This field is reserved for future use.

- Role – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role associated with this job (required).

- ExecutionProperty – An [ExecutionProperty](#) object.

An ExecutionProperty specifying the maximum number of concurrent runs allowed for this job.

- Command – A [JobCommand](#) object.

The JobCommand that runs this job (required).

- DefaultArguments – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The default arguments for every run of this job, specified as name-value pairs.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a AWS Glue Connection, AWS Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling AWS Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by AWS Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `NonOverridableArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

Arguments for this job that are not overridden when providing job arguments in a job run, specified as name-value pairs.

- `Connections` – A [ConnectionsList](#) object.

The connections used for this job.

- `MaxRetries` – Number (integer).

The maximum number of times to retry this job if it fails.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of AWS Glue data processing units (DPUs) to allocate to this job. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The job timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters `TIMEOUT` status. The default is 2,880 minutes (48 hours) for batch jobs.

Streaming jobs must have timeout values less than 7 days or 10080 minutes. When the value is left blank, the job will be restarted after 7 days based if you have not setup a maintenance window. If you have setup maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative

measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `MaximumCapacity`. Instead, you should specify a `WorkerType` and the `NumberOfWorkers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, `G.8X` or `G.025X` for Spark jobs. Accepts the value `Z.2X` for Ray jobs.

- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the `G.2X` worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the `G.4X` worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).

- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk (approximately 120GB free), and provides up to 8 Ray workers based on the autoscaler.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies the configuration properties of a job notification.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that AWS Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `CodeGenConfigurationNodes` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #38](#).

Each value is a [CodeGenConfigurationNode](#) object.

The representation of a directed acyclic graph on which both the Glue Studio visual component and Glue Studio code generation is based.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with AWS Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to `FLEX`. The flexible execution class is available for Spark jobs.

- `SourceControlDetails` – A [SourceControlDetails](#) object.

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #30](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. AWS Glue periodically performs maintenance activities. During these maintenance windows, AWS Glue will need to restart your streaming jobs.

AWS Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

## SourceControlDetails structure

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

## Fields

- `Provider` – UTF-8 string.

The provider for the remote repository.

- `Repository` – UTF-8 string, not less than 1 or more than 512 bytes long.

The name of the remote repository that contains the job artifacts.

- `Owner` – UTF-8 string, not less than 1 or more than 512 bytes long.

The owner of the remote repository that contains the job artifacts.

- `Branch` – UTF-8 string, not less than 1 or more than 512 bytes long.

An optional branch in the remote repository.

- `Folder` – UTF-8 string, not less than 1 or more than 512 bytes long.

An optional folder in the remote repository.

- `LastCommitId` – UTF-8 string, not less than 1 or more than 512 bytes long.

The last commit ID for a commit in the remote repository.

- `LastSyncTimestamp` – UTF-8 string, not less than 1 or more than 512 bytes long.

The date and time that the last job synchronization was performed.

- `AuthStrategy` – UTF-8 string.

The type of authentication, which can be an authentication token stored in AWS Secrets Manager, or a personal access token.

- `AuthToken` – UTF-8 string, not less than 1 or more than 512 bytes long.

The value of an authorization token.

## Operations

- [CreateJob action \(Python: `create\_job`\)](#)
- [UpdateJob action \(Python: `update\_job`\)](#)
- [GetJob action \(Python: `get\_job`\)](#)
- [GetJobs action \(Python: `get\_jobs`\)](#)

- [DeleteJob action \(Python: delete\\_job\)](#)
- [ListJobs action \(Python: list\\_jobs\)](#)
- [BatchGetJobs action \(Python: batch\\_get\\_jobs\)](#)

## CreateJob action (Python: create\_job)

Creates a new job definition.

### Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name you assign to this job definition. It must be unique in your account.

- **JobMode** – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- SCRIPT - The job was created using the AWS Glue Studio script editor.
- VISUAL - The job was created using the AWS Glue Studio visual editor.
- NOTEBOOK - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Description of the job being defined.

- **LogUri** – UTF-8 string.

This field is reserved for future use.

- **Role** – *Required:* UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role associated with this job.

- **ExecutionProperty** – An [ExecutionProperty](#) object.

An ExecutionProperty specifying the maximum number of concurrent runs allowed for this job.

- **Command** – *Required:* A [JobCommand](#) object.

The JobCommand that runs this job.

- `DefaultArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The default arguments for every run of this job, specified as name-value pairs.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a AWS Glue Connection, AWS Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling AWS Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by AWS Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `NonOverridableArguments` – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

Arguments for this job that are not overridden when providing job arguments in a job run, specified as name-value pairs.

- `Connections` – A [ConnectionsList](#) object.

The connections used for this job.

- `MaxRetries` – Number (integer).

The maximum number of times to retry this job if it fails.

- `AllocatedCapacity` – Number (integer).

This parameter is deprecated. Use `MaxCapacity` instead.

The number of AWS Glue data processing units (DPUs) to allocate to this Job. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

- `Timeout` – Number (integer), at least 1.

The job timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters `TIMEOUT` status. The default is 2,880 minutes (48 hours) for batch jobs.

Streaming jobs must have timeout values less than 7 days or 10080 minutes. When the value is left blank, the job will be restarted after 7 days based if you have not setup a maintenance window. If you have setup maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this job. You may use tags to limit access to the job. For more information about tags in AWS Glue, see [AWS Tags in AWS Glue](#) in the developer guide.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job notification.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that AWS Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of G.1X, G.2X, G.4X, G.8X or G.025X for Spark jobs. Accepts the value Z.2X for Ray jobs.

- For the G.1X worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this

worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.

- For the G.2X worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.4X worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).
- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk (approximately 120GB free), and provides up to 8 Ray workers based on the autoscaler.
- `CodeGenConfigurationNodes` – A map array of key-value pairs.

Each key is a UTF-8 string, matching the [Custom string pattern #38](#).

Each value is a A [CodeGenConfigurationNode](#) object.

The representation of a directed acyclic graph on which both the Glue Studio visual component and Glue Studio code generation is based.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with AWS Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to FLEX. The flexible execution class is available for Spark jobs.

- `SourceControlDetails` – A [SourceControlDetails](#) object.

The details for a source control configuration for a job, allowing synchronization of job artifacts to or from a remote repository.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #30](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. AWS Glue periodically performs maintenance activities. During these maintenance windows, AWS Glue will need to restart your streaming jobs.

AWS Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

## Response

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique name that was provided for this job definition.

## Errors

- `InvalidInputException`
- `IdempotentParameterMismatchException`
- `AlreadyExistsException`
- `InternalServiceException`

- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`

## UpdateJob action (Python: `update_job`)

Updates an existing job definition. The previous job definition is completely overwritten by this information.

### Request

- `JobName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to update.

- `JobUpdate` – *Required:* A [JobUpdate](#) object.

Specifies the values with which to update the job definition. Unspecified configuration is removed or reset to default values.

### Response

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the name of the updated job definition.

### Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## GetJob action (Python: `get_job`)

Retrieves an existing job definition.

### Request

- `JobName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to retrieve.

### Response

- `Job` – A [Job](#) object.

The requested job definition.

### Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetJobs action (Python: `get_jobs`)

Retrieves all current job definitions.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of the response.

## Response

- Jobs – An array of [Job](#) objects.

A list of job definitions.

- NextToken – UTF-8 string.

A continuation token, if not all job definitions have yet been returned.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## DeleteJob action (Python: `delete_job`)

Deletes a specified job definition. If the job definition is not found, no exception is thrown.

### Request

- `JobName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to delete.

### Response

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition that was deleted.

## Errors

- `InvalidInputException`
- `InternalServiceException`

- `OperationTimeoutException`

## ListJobs action (Python: `list_jobs`)

Retrieves the names of all job resources in this AWS account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

### Response

- `JobNames` – An array of UTF-8 strings.

The names of all jobs in the account, or the jobs with the specified tags.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## BatchGetJobs action (Python: `batch_get_jobs`)

Returns a list of resource metadata for a given list of job names. After calling the `ListJobs` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

### Request

- `JobNames` – *Required*: An array of UTF-8 strings.

A list of job names, which might be the names returned from the `ListJobs` operation.

### Response

- `Jobs` – An array of [Job](#) objects.

A list of job definitions.

- `JobsNotFound` – An array of UTF-8 strings.

A list of names of jobs not found.

## Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## Job runs

The Jobs Runs API describes the data types and API related to starting, stopping, or viewing job runs, and resetting job bookmarks, in AWS Glue. Job run history is accessible for 90 days for your workflow and job run.

### Data types

- [JobRun structure](#)
- [Predecessor structure](#)
- [JobBookmarkEntry structure](#)
- [BatchStopJobRunSuccessfulSubmission structure](#)
- [BatchStopJobRunError structure](#)
- [NotificationProperty structure](#)

### JobRun structure

Contains information about a job run.

#### Fields

- **Id** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of this job run.

- **Attempt** – Number (integer).

The number of the attempt to run this job.

- **PreviousRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the previous run of this job. For example, the JobRunId specified in the StartJobRun action.

- **TriggerName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that started this job run.

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition being used in this run.

- **JobMode** – UTF-8 string (valid values: SCRIPT="" | VISUAL="" | NOTEBOOK="").

A mode that describes how a job was created. Valid values are:

- **SCRIPT** - The job was created using the AWS Glue Studio script editor.
- **VISUAL** - The job was created using the AWS Glue Studio visual editor.
- **NOTEBOOK** - The job was created using an interactive sessions notebook.

When the JobMode field is missing or null, SCRIPT is assigned as the default value.

- **StartedOn** – Timestamp.

The date and time at which this job run was started.

- **LastModifiedOn** – Timestamp.

The last time that this job run was modified.

- **CompletedOn** – Timestamp.

The date and time that this job run completed.

- **JobRunState** – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT | ERROR | WAITING | EXPIRED).

The current state of the job run. For more information about the statuses of jobs that have terminated abnormally, see [AWS Glue Job Run Statuses](#).

- **Arguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The job arguments associated with this run. For this job run, they replace the default arguments set in the job definition itself.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a AWS Glue Connection, AWS Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling AWS Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by AWS Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- `ErrorMessage` – UTF-8 string.

An error message associated with this job run.

- `PredecessorRuns` – An array of [Predecessor](#) objects.

A list of predecessors to this job run.

- `AllocatedCapacity` – Number (integer).

This field is deprecated. Use `MaxCapacity` instead.

The number of AWS Glue data processing units (DPUs) allocated to this JobRun. From 2 to 100 DPUs can be allocated; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

- `ExecutionTime` – Number (integer).

The amount of time (in seconds) that the job run consumed resources.

- `Timeout` – Number (integer), at least 1.

The JobRun timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status. This value overrides the timeout value set in the parent job.

Streaming jobs must have timeout values less than 7 days or 10080 minutes. When the value is left blank, the job will be restarted after 7 days based if you have not setup a maintenance

window. If you have setup maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, `G.8X` or `G.025X` for Spark jobs. Accepts the value `Z.2X` for Ray jobs.

- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the `G.2X` worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the `G.4X` worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms,

aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).

- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk (approximately 120GB free), and provides up to 8 Ray workers based on the autoscaler.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job run.

- `LogGroupName` – UTF-8 string.

The name of the log group for secure logging that can be server-side encrypted in Amazon CloudWatch using AWS KMS. This name can be `/aws-glue/jobs/`, in which case the default encryption is NONE. If you add a role name and `SecurityConfiguration` name (in other words, `/aws-glue/jobs-yourRoleName-yourSecurityConfigurationName/`), then that security configuration is used to encrypt the log group.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job run notification.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

In Spark jobs, `GlueVersion` determines the versions of Apache Spark and Python that AWS Glue available in a job. The Python version indicates the version supported for jobs of type Spark.

Ray jobs should set `GlueVersion` to 4.0 or greater. However, the versions of Ray, Python and additional libraries available in your Ray job are determined by the `Runtime` parameter of the Job command.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Jobs that are created without specifying a Glue version default to Glue 0.9.

- `DPUSeconds` – Number (double).

This field can be set for either job runs with execution class FLEX or when Auto Scaling is enabled, and represents the total time each executor ran during the lifecycle of a job run in seconds, multiplied by a DPU factor (1 for G.1X, 2 for G.2X, or 0.25 for G.025X workers). This value may be different than the `executionEngineRuntime * MaxCapacity` as in the case of Auto Scaling jobs, as the number of executors running at a given time may be less than the `MaxCapacity`. Therefore, it is possible that the value of `DPUSeconds` is less than `executionEngineRuntime * MaxCapacity`.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: FLEX="" | STANDARD="").

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with AWS Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to FLEX. The flexible execution class is available for Spark jobs.

- `MaintenanceWindow` – UTF-8 string, matching the [Custom string pattern #30](#).

This field specifies a day of the week and hour for a maintenance window for streaming jobs. AWS Glue periodically performs maintenance activities. During these maintenance windows, AWS Glue will need to restart your streaming jobs.

AWS Glue will restart the job within 3 hours of the specified maintenance window. For instance, if you set up the maintenance window for Monday at 10:00AM GMT, your jobs will be restarted between 10:00AM GMT to 1:00PM GMT.

## Predecessor structure

A job run that was used in the predicate of a conditional trigger that triggered this job run.

### Fields

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition used by the predecessor job run.

- **RunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job-run ID of the predecessor job run.

## JobBookmarkEntry structure

Defines a point that a job can resume processing.

### Fields

- **JobName** – UTF-8 string.

The name of the job in question.

- **Version** – Number (integer).

The version of the job.

- **Run** – Number (integer).

The run ID number.

- **Attempt** – Number (integer).

The attempt ID number.

- **PreviousRunId** – UTF-8 string.

The unique run identifier associated with the previous job run.

- `RunId` – UTF-8 string.

The run ID number.

- `JobBookmark` – UTF-8 string.

The bookmark itself.

## BatchStopJobRunSuccessfulSubmission structure

Records a successful request to stop a specified JobRun.

### Fields

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition used in the job run that was stopped.

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The JobRunId of the job run that was stopped.

## BatchStopJobRunError structure

Records an error that occurred when attempting to stop a specified job run.

### Fields

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition that is used in the job run in question.

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The JobRunId of the job run in question.

- `ErrorDetail` – An [ErrorDetail](#) object.

Specifies details about the error that was encountered.

## NotificationProperty structure

Specifies configuration properties of a notification.

### Fields

- `NotifyDelayAfter` – Number (integer), at least 1.

After a job run starts, the number of minutes to wait before sending a job run delay notification.

## Operations

- [StartJobRun action \(Python: `start\_job\_run`\)](#)
- [BatchStopJobRun action \(Python: `batch\_stop\_job\_run`\)](#)
- [GetJobRun action \(Python: `get\_job\_run`\)](#)
- [GetJobRuns action \(Python: `get\_job\_runs`\)](#)
- [GetJobBookmark action \(Python: `get\_job\_bookmark`\)](#)
- [GetJobBookmarks action \(Python: `get\_job\_bookmarks`\)](#)
- [ResetJobBookmark action \(Python: `reset\_job\_bookmark`\)](#)

## StartJobRun action (Python: `start_job_run`)

Starts a job run using a job definition.

### Request

- `JobName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition to use.

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of a previous JobRun to retry.

- **Arguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The job arguments associated with this run. For this job run, they replace the default arguments set in the job definition itself.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes.

Job arguments may be logged. Do not pass plaintext secrets as arguments. Retrieve secrets from a AWS Glue Connection, AWS Secrets Manager or other secret management mechanism if you intend to keep them within the Job.

For information about how to specify and consume your own Job arguments, see the [Calling AWS Glue APIs in Python](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Spark jobs, see the [Special Parameters Used by AWS Glue](#) topic in the developer guide.

For information about the arguments you can provide to this field when configuring Ray jobs, see [Using job parameters in Ray jobs](#) in the developer guide.

- **AllocatedCapacity** – Number (integer).

This field is deprecated. Use **MaxCapacity** instead.

The number of AWS Glue data processing units (DPUs) to allocate to this JobRun. You can allocate a minimum of 2 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

- **Timeout** – Number (integer), at least 1.

The JobRun timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status. This value overrides the timeout value set in the parent job.

Streaming jobs must have timeout values less than 7 days or 10080 minutes. When the value is left blank, the job will be restarted after 7 days based if you have not setup a maintenance

window. If you have setup maintenance window, it will be restarted during the maintenance window after 7 days.

- `MaxCapacity` – Number (double).

For Glue version 1.0 or earlier jobs, using the standard worker type, the number of AWS Glue data processing units (DPUs) that can be allocated when this job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

For Glue version 2.0+ jobs, you cannot specify a `Maximum capacity`. Instead, you should specify a `Worker type` and the `Number of workers`.

Do not set `MaxCapacity` if using `WorkerType` and `NumberOfWorkers`.

The value that can be allocated for `MaxCapacity` depends on whether you are running a Python shell job, an Apache Spark ETL job, or an Apache Spark streaming ETL job:

- When you specify a Python shell job (`JobCommand.Name="pythonshell"`), you can allocate either 0.0625 or 1 DPU. The default is 0.0625 DPU.
- When you specify an Apache Spark ETL job (`JobCommand.Name="glueetl"`) or Apache Spark streaming ETL job (`JobCommand.Name="gluestreaming"`), you can allocate from 2 to 100 DPUs. The default is 10 DPUs. This job type cannot have a fractional DPU allocation.
- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this job run.

- `NotificationProperty` – A [NotificationProperty](#) object.

Specifies configuration properties of a job run notification.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, `G.8X` or `G.025X` for Spark jobs. Accepts the value `Z.2X` for Ray jobs.

- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.

- For the G.2X worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the G.4X worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).
- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- For the G.025X worker type, each worker maps to 0.25 DPU (2 vCPUs, 4 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for low volume streaming jobs. This worker type is only available for AWS Glue version 3.0 streaming jobs.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk (approximately 120GB free), and provides up to 8 Ray workers based on the autoscaler.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when a job runs.

- `ExecutionClass` – UTF-8 string, not more than 16 bytes long (valid values: `FLEX=""` | `STANDARD=""`).

Indicates whether the job is run with a standard or flexible execution class. The standard execution-class is ideal for time-sensitive workloads that require fast job startup and dedicated resources.

The flexible execution class is appropriate for time-insensitive jobs whose start and completion times may vary.

Only jobs with AWS Glue version 3.0 and above and command type `glueetl` will be allowed to set `ExecutionClass` to `FLEX`. The flexible execution class is available for Spark jobs.

## Response

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID assigned to this job run.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentRunsExceededException`

## BatchStopJobRun action (Python: `batch_stop_job_run`)

Stops one or more job runs for a specified job definition.

### Request

- `JobName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition for which to stop job runs.

- `JobRunIds` – *Required*: An array of UTF-8 strings, not less than 1 or more than 25 strings.

A list of the `JobRunIds` that should be stopped for that job definition.

### Response

- `SuccessfulSubmissions` – An array of [BatchStopJobRunSuccessfulSubmission](#) objects.

A list of the JobRuns that were successfully submitted for stopping.

- **Errors** – An array of [BatchStopJobRunError](#) objects.

A list of the errors that were encountered in trying to stop JobRuns, including the JobRunId for which each error was encountered and details about the error.

## Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetJobRun action (Python: `get_job_run`)

Retrieves the metadata for a given job run. Job run history is accessible for 90 days for your workflow and job run.

### Request

- **JobName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the job definition being run.

- **RunId** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the job run.

- **PredecessorsIncluded** – Boolean.

True if a list of predecessor runs should be returned.

### Response

- **JobRun** – A [JobRun](#) object.

The requested job-run metadata.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetJobRuns action (Python: `get_job_runs`)

Retrieves metadata for all runs of a given job definition.

### Request

- `JobName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job definition for which to retrieve all job runs.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `MaxResults` – Number (integer), not less than 1 or more than 200.

The maximum size of the response.

### Response

- `JobRuns` – An array of [JobRun](#) objects.

A list of job-run metadata objects.

- `NextToken` – UTF-8 string.

A continuation token, if not all requested job runs have been returned.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`

- `InternalServiceException`
- `OperationTimeoutException`

## GetJobBookmark action (Python: `get_job_bookmark`)

Returns information on a job bookmark entry.

For more information about enabling and using job bookmarks, see:

- [Tracking processed data using job bookmarks](#)
- [Job parameters used by AWS Glue](#)
- [Job structure](#)

### Request

- `JobName` – *Required*: UTF-8 string.

The name of the job in question.

- `Version` – Number (integer).

The version of the job.

- `RunId` – UTF-8 string.

The unique run identifier associated with this job run.

### Response

- `JobBookmarkEntry` – A [JobBookmarkEntry](#) object.

A structure that defines a point that a job can resume processing.

### Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

- `ValidationException`

## GetJobBookmarks action (Python: `get_job_bookmarks`)

Returns information on the job bookmark entries. The list is ordered on decreasing version numbers.

For more information about enabling and using job bookmarks, see:

- [Tracking processed data using job bookmarks](#)
- [Job parameters used by AWS Glue](#)
- [Job structure](#)

### Request

- `JobName` – *Required*: UTF-8 string.

The name of the job in question.

- `MaxResults` – Number (integer).

The maximum size of the response.

- `NextToken` – Number (integer).

A continuation token, if this is a continuation call.

### Response

- `JobBookmarkEntries` – An array of [JobBookmarkEntry](#) objects.

A list of job bookmark entries that defines a point that a job can resume processing.

- `NextToken` – Number (integer).

A continuation token, which has a value of 1 if all the entries are returned, or > 1 if not all requested job runs have been returned.

### Errors

- `InvalidInputException`

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## ResetJobBookmark action (Python: `reset_job_bookmark`)

Resets a bookmark entry.

For more information about enabling and using job bookmarks, see:

- [Tracking processed data using job bookmarks](#)
- [Job parameters used by AWS Glue](#)
- [Job structure](#)

### Request

- `JobName` – *Required*: UTF-8 string.

The name of the job in question.

- `RunId` – UTF-8 string.

The unique run identifier associated with this job run.

### Response

- `JobBookmarkEntry` – A [JobBookmarkEntry](#) object.

The reset bookmark entry.

### Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

# Triggers

The Triggers API describes the data types and API related to creating, updating, or deleting, and starting and stopping job triggers in AWS Glue.

## Data types

- [Trigger structure](#)
- [TriggerUpdate structure](#)
- [Predicate structure](#)
- [Condition structure](#)
- [Action structure](#)
- [EventBatchingCondition structure](#)

## Trigger structure

Information about a specific trigger.

### Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger.

- WorkflowName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow associated with the trigger.

- Id – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Reserved for future use.

- Type – UTF-8 string (valid values: SCHEDULED | CONDITIONAL | ON\_DEMAND | EVENT).

The type of trigger that this is.

- State – UTF-8 string (valid values: CREATING | CREATED | ACTIVATING | ACTIVATED | DEACTIVATING | DEACTIVATED | DELETING | UPDATING).

The current state of the trigger.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of this trigger.

- **Schedule** – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`).

- **Actions** – An array of [Action](#) objects.

The actions initiated by this trigger.

- **Predicate** – A [Predicate](#) object.

The predicate of this trigger, which defines when it will fire.

- **EventBatchingCondition** – An [EventBatchingCondition](#) object.

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

## TriggerUpdate structure

A structure used to provide information used to update a trigger. This object updates the previous trigger definition by overwriting it completely.

### Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Reserved for future use.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of this trigger.

- **Schedule** – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

- **Actions** – An array of [Action](#) objects.

The actions initiated by this trigger.

- **Predicate** – A [Predicate](#) object.

The predicate of this trigger, which defines when it will fire.

- **EventBatchingCondition** – An [EventBatchingCondition](#) object.

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

## Predicate structure

Defines the predicate of the trigger, which determines when it fires.

### Fields

- **Logical** – UTF-8 string (valid values: AND | ANY).

An optional field if only one condition is listed. If multiple conditions are listed, then this field is required.

- **Conditions** – An array of [Condition](#) objects.

A list of the conditions that determine when the trigger will fire.

## Condition structure

Defines a condition under which a trigger fires.

### Fields

- **LogicalOperator** – UTF-8 string (valid values: EQUALS).

A logical operator.

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job whose JobRuns this condition applies to, and on which this trigger waits.

- **State** – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT | ERROR | WAITING | EXPIRED).

The condition state. Currently, the only job states that a trigger can listen for are SUCCEEDED, STOPPED, FAILED, and TIMEOUT. The only crawler states that a trigger can listen for are SUCCEEDED, FAILED, and CANCELLED.

- **CrawlerName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to which this condition applies.

- **CrawlState** – UTF-8 string (valid values: RUNNING | CANCELLING | CANCELLED | SUCCEEDED | FAILED | ERROR).

The state of the crawler to which this condition applies.

## Action structure

Defines an action to be initiated by a trigger.

### Fields

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of a job to be run.

- **Arguments** – A map array of key-value pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The job arguments used when this trigger fires. For this job run, they replace the default arguments set in the job definition itself.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes.

For information about how to specify and consume your own Job arguments, see the [Calling AWS Glue APIs in Python](#) topic in the developer guide.

For information about the key-value pairs that AWS Glue consumes to set up your job, see the [Special Parameters Used by AWS Glue](#) topic in the developer guide.

- **Timeout** – Number (integer), at least 1.

The JobRun timeout in minutes. This is the maximum time that a job run can consume resources before it is terminated and enters TIMEOUT status. The default is 2,880 minutes (48 hours). This overrides the timeout value set in the parent job.

- **SecurityConfiguration** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the SecurityConfiguration structure to be used with this action.

- **NotificationProperty** – A [NotificationProperty](#) object.

Specifies configuration properties of a job run notification.

- **CrawlerName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the crawler to be used with this action.

## EventBatchingCondition structure

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

### Fields

- **BatchSize** – *Required:* Number (integer), not less than 1 or more than 100.

Number of events that must be received from Amazon EventBridge before EventBridge event trigger fires.

- **BatchWindow** – Number (integer), not less than 1 or more than 900.

Window of time in seconds after which EventBridge event trigger fires. Window starts when first event is received.

## Operations

- [CreateTrigger action \(Python: create\\_trigger\)](#)
- [StartTrigger action \(Python: start\\_trigger\)](#)
- [GetTrigger action \(Python: get\\_trigger\)](#)
- [GetTriggers action \(Python: get\\_triggers\)](#)
- [UpdateTrigger action \(Python: update\\_trigger\)](#)
- [StopTrigger action \(Python: stop\\_trigger\)](#)
- [DeleteTrigger action \(Python: delete\\_trigger\)](#)
- [ListTriggers action \(Python: list\\_triggers\)](#)
- [BatchGetTriggers action \(Python: batch\\_get\\_triggers\)](#)

## CreateTrigger action (Python: create\_trigger)

Creates a new trigger.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger.

- WorkflowName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow associated with the trigger.

- Type – *Required*: UTF-8 string (valid values: SCHEDULED | CONDITIONAL | ON\_DEMAND | EVENT).

The type of the new trigger.

- Schedule – UTF-8 string.

A cron expression used to specify the schedule (see [Time-Based Schedules for Jobs and Crawlers](#)). For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

This field is required when the trigger type is SCHEDULED.

- **Predicate** – A [Predicate](#) object.

A predicate to specify when the new trigger should fire.

This field is required when the trigger type is CONDITIONAL.

- **Actions** – *Required:* An array of [Action](#) objects.

The actions initiated by this trigger when it fires.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the new trigger.

- **StartOnCreation** – Boolean.

Set to `true` to start SCHEDULED and CONDITIONAL triggers when created. True is not supported for ON\_DEMAND triggers.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this trigger. You may use tags to limit access to the trigger. For more information about tags in AWS Glue, see [AWS Tags in AWS Glue](#) in the developer guide.

- **EventBatchingCondition** – An [EventBatchingCondition](#) object.

Batch condition that must be met (specified number of events received or batch time window expired) before EventBridge event trigger fires.

## Response

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger.

## Errors

- `AlreadyExistsException`
- `EntityNotFoundException`
- `InvalidInputException`
- `IdempotentParameterMismatchException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`

## StartTrigger action (Python: `start_trigger`)

Starts an existing trigger. See [Triggering Jobs](#) for information about how different types of trigger are started.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to start.

### Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that was started.

## Errors

- `InvalidInputException`

- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentRunsExceededException`

## GetTrigger action (Python: `get_trigger`)

Retrieves the definition of a trigger.

### Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to retrieve.

### Response

- `Trigger` – A [Trigger](#) object.

The requested trigger definition.

### Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetTriggers action (Python: `get_triggers`)

Gets all the triggers associated with a job.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

- `DependentJobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job to retrieve triggers for. The trigger that can start this job is returned, and if there is no such trigger, all triggers are returned.

- `MaxResults` – Number (integer), not less than 1 or more than 200.

The maximum size of the response.

## Response

- `Triggers` – An array of [Trigger](#) objects.

A list of triggers for the specified job.

- `NextToken` – UTF-8 string.

A continuation token, if not all the requested triggers have yet been returned.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## UpdateTrigger action (Python: `update_trigger`)

Updates a trigger definition.

### Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to update.

- `TriggerUpdate` – *Required:* A [TriggerUpdate](#) object.

The new values with which to update the trigger.

## Response

- `Trigger` – A [Trigger](#) object.

The resulting trigger definition.

## Errors

- `InvalidInputException`
- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## StopTrigger action (Python: `stop_trigger`)

Stops a specified trigger.

### Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to stop.

### Response

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that was stopped.

## Errors

- `InvalidInputException`

- `InternalServiceException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## DeleteTrigger action (Python: `delete_trigger`)

Deletes a specified trigger. If the trigger is not found, no exception is thrown.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger to delete.

### Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the trigger that was deleted.

### Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## ListTriggers action (Python: `list_triggers`)

Retrieves the names of all trigger resources in this AWS account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

## Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `DependentJobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the job for which to retrieve triggers. The trigger that can start this job is returned. If there is no such trigger, all triggers are returned.

- `MaxResults` – Number (integer), not less than 1 or more than 200.

The maximum size of a list to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

## Response

- `TriggerNames` – An array of UTF-8 strings.

The names of all triggers in the account, or the triggers with the specified tags.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`

- `OperationTimeoutException`

## BatchGetTriggers action (Python: `batch_get_triggers`)

Returns a list of resource metadata for a given list of trigger names. After calling the `ListTriggers` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

### Request

- `TriggerNames` – *Required*: An array of UTF-8 strings.

A list of trigger names, which may be the names returned from the `ListTriggers` operation.

### Response

- `Triggers` – An array of [Trigger](#) objects.

A list of trigger definitions.

- `TriggersNotFound` – An array of UTF-8 strings.

A list of names of triggers not found.

### Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## Interactive sessions API

The interactive sessions API describes the AWS Glue API related to using AWS Glue interactive sessions to build and test extract, transform, and load (ETL) scripts for data integration.

### Data types

- [Session structure](#)

- [SessionCommand structure](#)
- [Statement structure](#)
- [StatementOutput structure](#)
- [StatementOutputData structure](#)
- [ConnectionsList structure](#)

## Session structure

The period in which a remote Spark runtime environment is running.

### Fields

- **Id** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the session.

- **CreatedOn** – Timestamp.

The time and date when the session was created.

- **Status** – UTF-8 string (valid values: PROVISIONING | READY | FAILED | TIMEOUT | STOPPING | STOPPED).

The session status.

- **ErrorMessage** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The error message displayed during the session.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the session.

- **Role** – UTF-8 string, not less than 20 or more than 2048 bytes long, matching the [Custom string pattern #26](#).

The name or Amazon Resource Name (ARN) of the IAM role associated with the Session.

- **Command** – A [SessionCommand](#) object.

The command object. See `SessionCommand`.

- `DefaultArguments` – A map array of key-value pairs, not more than 75 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

Each value is a UTF-8 string, not more than 4096 bytes long, matching the [URI address multi-line string pattern](#).

A map array of key-value pairs. Max is 75 pairs.

- `Connections` – A [ConnectionsList](#) object.

The number of connections used for the session.

- `Progress` – Number (double).

The code execution progress of the session.

- `MaxCapacity` – Number (double).

The number of AWS Glue data processing units (DPUs) that can be allocated when the job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB memory.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with the session.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

The AWS Glue version determines the versions of Apache Spark and Python that AWS Glue supports. The `GlueVersion` must be greater than 2.0.

- `DataAccessId` – UTF-8 string, not less than 1 or more than 36 bytes long.

The data access ID of the session.

- `PartitionId` – UTF-8 string, not less than 1 or more than 36 bytes long.

The partition ID of the session.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `WorkerType` to use for the session.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a session runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, or `G.8X` for Spark sessions. Accepts the value `Z.2X` for Ray sessions.

- `CompletedOn` – Timestamp.

The date and time that this session is completed.

- `ExecutionTime` – Number (double).

The total time the session ran for.

- `DPUSeconds` – Number (double).

The DPUs consumed by the session (formula: `ExecutionTime * MaxCapacity`).

- `IdleTimeout` – Number (integer).

The number of minutes when idle before the session times out.

## SessionCommand structure

The `SessionCommand` that runs the job.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Specifies the name of the `SessionCommand`. Can be 'glueetl' or 'gluestreaming'.

- `PythonVersion` – UTF-8 string, matching the [Custom string pattern #21](#).

Specifies the Python version. The Python version indicates the version supported for jobs of type Spark.

## Statement structure

The statement or request for a particular action to occur in a session.

## Fields

- **Id** – Number (integer).  
The ID of the statement.
- **Code** – UTF-8 string.  
The execution code of the statement.
- **State** – UTF-8 string (valid values: WAITING | RUNNING | AVAILABLE | CANCELLING | CANCELLED | ERROR).  
The state while request is actioned.
- **Output** – A [StatementOutput](#) object.  
The output in JSON.
- **Progress** – Number (double).  
The code execution progress.
- **StartedOn** – Number (long).  
The unix time and date that the job definition was started.
- **CompletedOn** – Number (long).  
The unix time and date that the job definition was completed.

## StatementOutput structure

The code execution output in JSON format.

### Fields

- **Data** – A [StatementOutputData](#) object.  
The code execution output.
- **ExecutionCount** – Number (integer).  
The execution count of the output.
- **Status** – UTF-8 string (valid values: WAITING | RUNNING | AVAILABLE | CANCELLING | CANCELLED | ERROR).

The status of the code execution output.

- `ErrorName` – UTF-8 string.

The name of the error in the output.

- `ErrorValue` – UTF-8 string.

The error value of the output.

- `Traceback` – An array of UTF-8 strings.

The traceback of the output.

## StatementOutputData structure

The code execution output in JSON format.

### Fields

- `TextPlain` – UTF-8 string.

The code execution output in text format.

## ConnectionsList structure

Specifies the connections used by a job.

### Fields

- `Connections` – An array of UTF-8 strings.

A list of connections used by the job.

## Operations

- [CreateSession action \(Python: `create\_session`\)](#)
- [StopSession action \(Python: `stop\_session`\)](#)
- [DeleteSession action \(Python: `delete\_session`\)](#)
- [GetSession action \(Python: `get\_session`\)](#)

- [ListSessions action \(Python: list\\_sessions\)](#)
- [RunStatement action \(Python: run\\_statement\)](#)
- [CancelStatement action \(Python: cancel\\_statement\)](#)
- [GetStatement action \(Python: get\\_statement\)](#)
- [ListStatements action \(Python: list\\_statements\)](#)

## CreateSession action (Python: create\_session)

Creates a new session.

### Request

Request to create a new session.

- **Id** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the session request.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the session.

- **Role** – *Required:* UTF-8 string, not less than 20 or more than 2048 bytes long, matching the [Custom string pattern #26](#).

The IAM Role ARN

- **Command** – *Required:* A [SessionCommand](#) object.

The SessionCommand that runs the job.

- **Timeout** – Number (integer), at least 1.

The number of minutes before session times out. Default for Spark ETL jobs is 48 hours (2880 minutes), the maximum session lifetime for this job type. Consult the documentation for other job types.

- **IdleTimeout** – Number (integer), at least 1.

The number of minutes when idle before session times out. Default for Spark ETL jobs is value of Timeout. Consult the documentation for other job types.

- `DefaultArguments` – A map array of key-value pairs, not more than 75 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

Each value is a UTF-8 string, not more than 4096 bytes long, matching the [URI address multi-line string pattern](#).

A map array of key-value pairs. Max is 75 pairs.

- `Connections` – A [ConnectionsList](#) object.

The number of connections to use for the session.

- `MaxCapacity` – Number (double).

The number of AWS Glue data processing units (DPUs) that can be allocated when the job runs. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB memory.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `WorkerType` to use for the session.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when a job runs. Accepts a value of `G.1X`, `G.2X`, `G.4X`, or `G.8X` for Spark jobs. Accepts the value `Z.2X` for Ray notebooks.

- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPUs, 16 GB of memory) with 84GB disk (approximately 34GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the `G.2X` worker type, each worker maps to 2 DPU (8 vCPUs, 32 GB of memory) with 128GB disk (approximately 77GB free), and provides 1 executor per worker. We recommend this worker type for workloads such as data transforms, joins, and queries, to offers a scalable and cost effective way to run most jobs.
- For the `G.4X` worker type, each worker maps to 4 DPU (16 vCPUs, 64 GB of memory) with 256GB disk (approximately 235GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0

or later Spark ETL jobs in the following AWS Regions: US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), and Europe (Stockholm).

- For the G.8X worker type, each worker maps to 8 DPU (32 vCPUs, 128 GB of memory) with 512GB disk (approximately 487GB free), and provides 1 executor per worker. We recommend this worker type for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. This worker type is available only for AWS Glue version 3.0 or later Spark ETL jobs, in the same AWS Regions as supported for the G.4X worker type.
- For the Z.2X worker type, each worker maps to 2 M-DPU (8vCPUs, 64 GB of memory) with 128 GB disk (approximately 120GB free), and provides up to 8 Ray workers based on the autoscaler.
- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with the session

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

The AWS Glue version determines the versions of Apache Spark and Python that AWS Glue supports. The `GlueVersion` must be greater than 2.0.

- `DataAccessId` – UTF-8 string, not less than 1 or more than 36 bytes long.

The data access ID of the session.

- `PartitionId` – UTF-8 string, not less than 1 or more than 36 bytes long.

The partition ID of the session.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The map of key value pairs (tags) belonging to the session.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request.

## Response

- Session – A [Session](#) object.

Returns the session object in the response.

## Errors

- AccessDeniedException
- IdempotentParameterMismatchException
- InternalServiceException
- OperationTimeoutException
- InvalidInputException
- ValidationException
- AlreadyExistsException
- ResourceNumberLimitExceededException

## StopSession action (Python: stop\_session)

Stops the session.

### Request

- Id – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the session to be stopped.

- RequestOrigin – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request.

### Response

- Id – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the Id of the stopped session.

## Errors

- `AccessDeniedException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `IllegalSessionStateException`
- `ConcurrentModificationException`

## DeleteSession action (Python: `delete_session`)

Deletes the session.

### Request

- `Id` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the session to be deleted.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the origin of the delete session request.

### Response

- `Id` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the ID of the deleted session.

## Errors

- `AccessDeniedException`

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `IllegalSessionStateException`
- `ConcurrentModificationException`

## GetSession action (Python: `get_session`)

Retrieves the session.

### Request

- `Id` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the session.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request.

### Response

- `Session` – A [Session](#) object.

The session object is returned in the response.

### Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## ListSessions action (Python: list\_sessions)

Retrieve a list of sessions.

### Request

- `NextToken` – UTF-8 string, not more than 400000 bytes long.

The token for the next set of results, or null if there are no more result.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Tags belonging to the session.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request.

### Response

- `Ids` – An array of UTF-8 strings.

Returns the ID of the session.

- `Sessions` – An array of [Session](#) objects.

Returns the session object.

- `NextToken` – UTF-8 string, not more than 400000 bytes long.

The token for the next set of results, or null if there are no more result.

### Errors

- `AccessDeniedException`

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## RunStatement action (Python: `run_statement`)

Executes the statement.

### Request

- `SessionId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Session Id of the statement to be run.

- `Code` – *Required*: UTF-8 string, not more than 68000 bytes long.

The statement code to be run.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request.

### Response

- `Id` – Number (integer).

Returns the Id of the statement that was run.

### Errors

- `EntityNotFoundException`
- `AccessDeniedException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `ValidationException`

- ResourceNumberLimitExceededException
- IllegalSessionStateException

## CancelStatement action (Python: cancel\_statement)

Cancels the statement.

### Request

- SessionId – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Session ID of the statement to be cancelled.

- Id – *Required:* Number (integer).

The ID of the statement to be cancelled.

- RequestOrigin – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request to cancel the statement.

### Response

- *No Response parameters.*

### Errors

- AccessDeniedException
- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException
- InvalidInputException
- IllegalSessionStateException

## GetStatement action (Python: `get_statement`)

Retrieves the statement.

### Request

- `SessionId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Session ID of the statement.

- `Id` – *Required*: Number (integer).

The Id of the statement.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request.

### Response

- `Statement` – A [Statement](#) object.

Returns the statement.

### Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `IllegalSessionStateException`

## ListStatements action (Python: `list_statements`)

Lists statements for the session.

## Request

- `SessionId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The Session ID of the statements.

- `RequestOrigin` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The origin of the request to list statements.

- `NextToken` – UTF-8 string, not more than 400000 bytes long.

A continuation token, if this is a continuation call.

## Response

- `Statements` – An array of [Statement](#) objects.

Returns the list of statements.

- `NextToken` – UTF-8 string, not more than 400000 bytes long.

A continuation token, if not all statements have yet been returned.

## Errors

- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `IllegalSessionStateException`

## Development endpoints API

The Development endpoints API describes the AWS Glue API related to testing using a custom `DevEndpoint`.

## Data types

- [DevEndpoint structure](#)
- [DevEndpointCustomLibraries structure](#)

### DevEndpoint structure

A development endpoint where a developer can remotely debug extract, transform, and load (ETL) scripts.

#### Fields

- `EndpointName` – UTF-8 string.

The name of the DevEndpoint.

- `RoleArn` – UTF-8 string, matching the [AWS IAM ARN string pattern](#).

The Amazon Resource Name (ARN) of the IAM role used in this DevEndpoint.

- `SecurityGroupIds` – An array of UTF-8 strings.

A list of security group identifiers used in this DevEndpoint.

- `SubnetId` – UTF-8 string.

The subnet ID for this DevEndpoint.

- `YarnEndpointAddress` – UTF-8 string.

The YARN endpoint address used by this DevEndpoint.

- `PrivateAddress` – UTF-8 string.

A private IP address to access the DevEndpoint within a VPC if the DevEndpoint is created within one. The `PrivateAddress` field is present only when you create the DevEndpoint within your VPC.

- `ZeppelinRemoteSparkInterpreterPort` – Number (integer).

The Apache Zeppelin port for the remote Apache Spark interpreter.

- `PublicAddress` – UTF-8 string.

The public IP address used by this DevEndpoint. The `PublicAddress` field is present only when you create a non-virtual private cloud (VPC) DevEndpoint.

- `Status` – UTF-8 string.

The current status of this DevEndpoint.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated to the development endpoint. Accepts a value of `Standard`, `G.1X`, or `G.2X`.

- For the `Standard` worker type, each worker provides 4 vCPU, 16 GB of memory and a 50GB disk, and 2 executors per worker.
- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPU, 16 GB of memory, 64 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs.
- For the `G.2X` worker type, each worker maps to 2 DPU (8 vCPU, 32 GB of memory, 128 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs.

Known issue: when a development endpoint is created with the `G.2X WorkerType` configuration, the Spark drivers for the development endpoint will run on 4 vCPU, 16 GB of memory, and a 64 GB disk.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

Glue version determines the versions of Apache Spark and Python that AWS Glue supports. The Python version indicates the version supported for running your ETL scripts on development endpoints.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Development endpoints that are created without specifying a Glue version default to Glue 0.9.

You can specify a version of Python support for development endpoints by using the `Arguments` parameter in the `CreateDevEndpoint` or `UpdateDevEndpoint` APIs. If no arguments are provided, the version defaults to Python 2.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated to the development endpoint.

The maximum number of workers you can define are 299 for G.1X, and 149 for G.2X.

- `NumberOfNodes` – Number (integer).

The number of AWS Glue Data Processing Units (DPUs) allocated to this `DevEndpoint`.

- `AvailabilityZone` – UTF-8 string.

The AWS Availability Zone where this `DevEndpoint` is located.

- `VpcId` – UTF-8 string.

The ID of the virtual private cloud (VPC) used by this `DevEndpoint`.

- `ExtraPythonLibsS3Path` – UTF-8 string.

The paths to one or more Python libraries in an Amazon S3 bucket that should be loaded in your `DevEndpoint`. Multiple values must be complete paths separated by a comma.

 **Note**

You can only use pure Python libraries with a `DevEndpoint`. Libraries that rely on C extensions, such as the [pandas](#) Python data analysis library, are not currently supported.

- `ExtraJarsS3Path` – UTF-8 string.

The path to one or more Java `.jar` files in an S3 bucket that should be loaded in your `DevEndpoint`.

 **Note**

You can only use pure Java/Scala libraries with a `DevEndpoint`.

- `FailureReason` – UTF-8 string.

The reason for a current failure in this `DevEndpoint`.

- `LastUpdateStatus` – UTF-8 string.

The status of the last update.

- `CreatedTimestamp` – Timestamp.

The point in time at which this `DevEndpoint` was created.

- `LastModifiedTimestamp` – Timestamp.

The point in time at which this `DevEndpoint` was last modified.

- `PublicKey` – UTF-8 string.

The public key to be used by this `DevEndpoint` for authentication. This attribute is provided for backward compatibility because the recommended attribute to use is public keys.

- `PublicKeys` – An array of UTF-8 strings, not more than 5 strings.

A list of public keys to be used by the `DevEndpoints` for authentication. Using this attribute is preferred over a single public key because the public keys allow you to have a different private key per client.

 **Note**

If you previously created an endpoint with a public key, you must remove that key to be able to set a list of public keys. Call the `UpdateDevEndpoint` API operation with the public key content in the `deletePublicKeys` attribute, and the list of new keys in the `addPublicKeys` attribute.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this `DevEndpoint`.

- `Arguments` – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map of arguments used to configure the `DevEndpoint`.

Valid arguments are:

- `--enable-glue-datacatalog`: ""

You can specify a version of Python support for development endpoints by using the `Arguments` parameter in the `CreateDevEndpoint` or `UpdateDevEndpoint` APIs. If no arguments are provided, the version defaults to Python 2.

## DevEndpointCustomLibraries structure

Custom libraries to be loaded into a development endpoint.

### Fields

- `ExtraPythonLibsS3Path` – UTF-8 string.

The paths to one or more Python libraries in an Amazon Simple Storage Service (Amazon S3) bucket that should be loaded in your `DevEndpoint`. Multiple values must be complete paths separated by a comma.

#### Note

You can only use pure Python libraries with a `DevEndpoint`. Libraries that rely on C extensions, such as the [pandas](#) Python data analysis library, are not currently supported.

- `ExtraJarsS3Path` – UTF-8 string.

The path to one or more Java `.jar` files in an S3 bucket that should be loaded in your `DevEndpoint`.

#### Note

You can only use pure Java/Scala libraries with a `DevEndpoint`.

## Operations

- [CreateDevEndpoint action \(Python: `create\_dev\_endpoint`\)](#)
- [UpdateDevEndpoint action \(Python: `update\_dev\_endpoint`\)](#)
- [DeleteDevEndpoint action \(Python: `delete\_dev\_endpoint`\)](#)
- [GetDevEndpoint action \(Python: `get\_dev\_endpoint`\)](#)

- [GetDevEndpoints action \(Python: `get\_dev\_endpoints`\)](#)
- [BatchGetDevEndpoints action \(Python: `batch\_get\_dev\_endpoints`\)](#)
- [ListDevEndpoints action \(Python: `list\_dev\_endpoints`\)](#)

## CreateDevEndpoint action (Python: `create_dev_endpoint`)

Creates a new development endpoint.

### Request

- `EndpointName` – *Required:* UTF-8 string.

The name to be assigned to the new DevEndpoint.

- `RoleArn` – *Required:* UTF-8 string, matching the [AWS IAM ARN string pattern](#).

The IAM role for the DevEndpoint.

- `SecurityGroupIds` – An array of UTF-8 strings.

Security group IDs for the security groups to be used by the new DevEndpoint.

- `SubnetId` – UTF-8 string.

The subnet ID for the new DevEndpoint to use.

- `PublicKey` – UTF-8 string.

The public key to be used by this DevEndpoint for authentication. This attribute is provided for backward compatibility because the recommended attribute to use is public keys.

- `PublicKeys` – An array of UTF-8 strings, not more than 5 strings.

A list of public keys to be used by the development endpoints for authentication. The use of this attribute is preferred over a single public key because the public keys allow you to have a different private key per client.

#### Note

If you previously created an endpoint with a public key, you must remove that key to be able to set a list of public keys. Call the `UpdateDevEndpoint` API with the public

key content in the `deletePublicKeys` attribute, and the list of new keys in the `addPublicKeys` attribute.

- `NumberOfNodes` – Number (integer).

The number of AWS Glue Data Processing Units (DPUs) to allocate to this `DevEndpoint`.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated to the development endpoint. Accepts a value of `Standard`, `G.1X`, or `G.2X`.

- For the `Standard` worker type, each worker provides 4 vCPU, 16 GB of memory and a 50GB disk, and 2 executors per worker.
- For the `G.1X` worker type, each worker maps to 1 DPU (4 vCPU, 16 GB of memory, 64 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs.
- For the `G.2X` worker type, each worker maps to 2 DPU (8 vCPU, 32 GB of memory, 128 GB disk), and provides 1 executor per worker. We recommend this worker type for memory-intensive jobs.

Known issue: when a development endpoint is created with the `G.2X` `WorkerType` configuration, the Spark drivers for the development endpoint will run on 4 vCPU, 16 GB of memory, and a 64 GB disk.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

Glue version determines the versions of Apache Spark and Python that AWS Glue supports. The Python version indicates the version supported for running your ETL scripts on development endpoints.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

Development endpoints that are created without specifying a Glue version default to Glue 0.9.

You can specify a version of Python support for development endpoints by using the `Arguments` parameter in the `CreateDevEndpoint` or `UpdateDevEndpoint` APIs. If no arguments are provided, the version defaults to Python 2.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated to the development endpoint.

The maximum number of workers you can define are 299 for G.1X, and 149 for G.2X.

- `ExtraPythonLibsS3Path` – UTF-8 string.

The paths to one or more Python libraries in an Amazon S3 bucket that should be loaded in your `DevEndpoint`. Multiple values must be complete paths separated by a comma.

 **Note**

You can only use pure Python libraries with a `DevEndpoint`. Libraries that rely on C extensions, such as the [pandas](#) Python data analysis library, are not yet supported.

- `ExtraJarsS3Path` – UTF-8 string.

The path to one or more Java `.jar` files in an S3 bucket that should be loaded in your `DevEndpoint`.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure to be used with this `DevEndpoint`.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this `DevEndpoint`. You may use tags to limit access to the `DevEndpoint`. For more information about tags in AWS Glue, see [AWS Tags in AWS Glue](#) in the developer guide.

- `Arguments` – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

A map of arguments used to configure the `DevEndpoint`.

## Response

- `EndpointName` – UTF-8 string.

The name assigned to the new `DevEndpoint`.

- `Status` – UTF-8 string.

The current status of the new `DevEndpoint`.

- `SecurityGroupIds` – An array of UTF-8 strings.

The security groups assigned to the new `DevEndpoint`.

- `SubnetId` – UTF-8 string.

The subnet ID assigned to the new `DevEndpoint`.

- `RoleArn` – UTF-8 string, matching the [AWS IAM ARN string pattern](#).

The Amazon Resource Name (ARN) of the role assigned to the new `DevEndpoint`.

- `YarnEndpointAddress` – UTF-8 string.

The address of the YARN endpoint used by this `DevEndpoint`.

- `ZeppelinRemoteSparkInterpreterPort` – Number (integer).

The Apache Zeppelin port for the remote Apache Spark interpreter.

- `NumberOfNodes` – Number (integer).

The number of AWS Glue Data Processing Units (DPUs) allocated to this `DevEndpoint`.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated to the development endpoint. May be a value of `Standard`, `G.1X`, or `G.2X`.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

Glue version determines the versions of Apache Spark and Python that AWS Glue supports. The Python version indicates the version supported for running your ETL scripts on development endpoints.

For more information about the available AWS Glue versions and corresponding Spark and Python versions, see [Glue version](#) in the developer guide.

- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated to the development endpoint.

- `AvailabilityZone` – UTF-8 string.

The AWS Availability Zone where this `DevEndpoint` is located.

- `VpcId` – UTF-8 string.

The ID of the virtual private cloud (VPC) used by this `DevEndpoint`.

- `ExtraPythonLibsS3Path` – UTF-8 string.

The paths to one or more Python libraries in an S3 bucket that will be loaded in your `DevEndpoint`.

- `ExtraJarsS3Path` – UTF-8 string.

Path to one or more Java `.jar` files in an S3 bucket that will be loaded in your `DevEndpoint`.

- `FailureReason` – UTF-8 string.

The reason for a current failure in this `DevEndpoint`.

- `SecurityConfiguration` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the `SecurityConfiguration` structure being used with this `DevEndpoint`.

- `CreatedTimestamp` – Timestamp.

The point in time at which this `DevEndpoint` was created.

- `Arguments` – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The map of arguments used to configure this `DevEndpoint`.

Valid arguments are:

- `--enable-glue-datacatalog`: ""

You can specify a version of Python support for development endpoints by using the `Arguments` parameter in the `CreateDevEndpoint` or `UpdateDevEndpoint` APIs. If no arguments are provided, the version defaults to Python 2.

## Errors

- `AccessDeniedException`
- `AlreadyExistsException`
- `IdempotentParameterMismatchException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `ValidationException`
- `ResourceNumberLimitExceededException`

## UpdateDevEndpoint action (Python: update\_dev\_endpoint)

Updates a specified development endpoint.

### Request

- `EndpointName` – *Required*: UTF-8 string.

The name of the `DevEndpoint` to be updated.

- `PublicKey` – UTF-8 string.

The public key for the `DevEndpoint` to use.

- `AddPublicKeys` – An array of UTF-8 strings, not more than 5 strings.

The list of public keys for the `DevEndpoint` to use.

- `DeletePublicKeys` – An array of UTF-8 strings, not more than 5 strings.

The list of public keys to be deleted from the `DevEndpoint`.

- `CustomLibraries` – A [DevEndpointCustomLibraries](#) object.

Custom Python or Java libraries to be loaded in the DevEndpoint.

- `UpdateEtlLibraries` – Boolean.

`True` if the list of custom libraries to be loaded in the development endpoint needs to be updated, or `False` if otherwise.

- `DeleteArguments` – An array of UTF-8 strings.

The list of argument keys to be deleted from the map of arguments used to configure the DevEndpoint.

- `AddArguments` – A map array of key-value pairs, not more than 100 pairs.

Each key is a UTF-8 string.

Each value is a UTF-8 string.

The map of arguments to add the map of arguments used to configure the DevEndpoint.

Valid arguments are:

- `--enable-glue-datacatalog`: `""`

You can specify a version of Python support for development endpoints by using the `Arguments` parameter in the `CreateDevEndpoint` or `UpdateDevEndpoint` APIs. If no arguments are provided, the version defaults to Python 2.

## Response

- *No Response parameters.*

## Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`
- `ValidationException`

## DeleteDevEndpoint action (Python: delete\_dev\_endpoint)

Deletes a specified development endpoint.

### Request

- `EndpointName` – *Required:* UTF-8 string.

The name of the DevEndpoint.

### Response

- *No Response parameters.*

### Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## GetDevEndpoint action (Python: get\_dev\_endpoint)

Retrieves information about a specified development endpoint.

### Note

When you create a development endpoint in a virtual private cloud (VPC), AWS Glue returns only a private IP address, and the public IP address field is not populated. When you create a non-VPC development endpoint, AWS Glue returns only a public IP address.

### Request

- `EndpointName` – *Required:* UTF-8 string.

Name of the DevEndpoint to retrieve information for.

## Response

- `DevEndpoint` – A [DevEndpoint](#) object.

A `DevEndpoint` definition.

## Errors

- `EntityNotFoundException`
- `InternalServerErrorException`
- `OperationTimeoutException`
- `InvalidInputException`

## GetDevEndpoints action (Python: `get_dev_endpoints`)

Retrieves all the development endpoints in this AWS account.

### Note

When you create a development endpoint in a virtual private cloud (VPC), AWS Glue returns only a private IP address and the public IP address field is not populated. When you create a non-VPC development endpoint, AWS Glue returns only a public IP address.

## Request

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of information to return.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- `DevEndpoints` – An array of [DevEndpoint](#) objects.

A list of `DevEndpoint` definitions.

- NextToken – UTF-8 string.

A continuation token, if not all DevEndpoint definitions have yet been returned.

## Errors

- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException
- InvalidInputException

## BatchGetDevEndpoints action (Python: batch\_get\_dev\_endpoints)

Returns a list of resource metadata for a given list of development endpoint names. After calling the ListDevEndpoints operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

### Request

- customerAccountId – UTF-8 string.

The AWS account ID.

- DevEndpointNames – *Required*: An array of UTF-8 strings, not less than 1 or more than 25 strings.

The list of DevEndpoint names, which might be the names returned from the ListDevEndpoint operation.

### Response

- DevEndpoints – An array of [DevEndpoint](#) objects.

A list of DevEndpoint definitions.

- DevEndpointsNotFound – An array of UTF-8 strings, not less than 1 or more than 25 strings.

A list of DevEndpoints not found.

## Errors

- `AccessDeniedException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## ListDevEndpoints action (Python: `list_dev_endpoints`)

Retrieves the names of all `DevEndpoint` resources in this AWS account, or the resources with the specified tag. This operation allows you to see which resources are available in your account, and their names.

This operation takes the optional `Tags` field, which you can use as a filter on the response so that tagged resources can be retrieved as a group. If you choose to use tags filtering, only resources with the tag are retrieved.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

### Response

- `DevEndpointNames` – An array of UTF-8 strings.

The names of all the `DevEndpoints` in the account, or the `DevEndpoints` with the specified tags.

- NextToken – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

## Errors

- InvalidInputException
- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException

## Schema registry

The Schema registry API describes the data types and API related to working with schemas in AWS Glue.

## Data types

- [RegistryId structure](#)
- [RegistryListItem structure](#)
- [MetadataInfo structure](#)
- [OtherMetadataValueListItem structure](#)
- [SchemaListItem structure](#)
- [SchemaVersionListItem structure](#)
- [MetadataKeyValuePair structure](#)
- [SchemaVersionErrorItem structure](#)
- [ErrorDetails structure](#)
- [SchemaVersionNumber structure](#)
- [SchemaId structure](#)

## RegistryId structure

A wrapper structure that may contain the registry name and Amazon Resource Name (ARN).

## Fields

- **RegistryName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

Name of the registry. Used only for lookup. One of **RegistryArn** or **RegistryName** has to be provided.

- **RegistryArn** – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

Arn of the registry to be updated. One of **RegistryArn** or **RegistryName** has to be provided.

## RegistryListItem structure

A structure containing the details for a registry.

### Fields

- **RegistryName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry.

- **RegistryArn** – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the registry.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the registry.

- **Status** – UTF-8 string (valid values: AVAILABLE | DELETING).

The status of the registry.

- **CreatedTime** – UTF-8 string.

The data the registry was created.

- **UpdatedTime** – UTF-8 string.

The date the registry was updated.

## MetadataInfo structure

A structure containing metadata information for a schema version.

### Fields

- `MetadataValue` – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #32](#).

The metadata key's corresponding value.

- `CreateTime` – UTF-8 string.

The time at which the entry was created.

- `OtherMetadataValueList` – An array of [OtherMetadataValueListItem](#) objects.

Other metadata belonging to the same metadata key.

## OtherMetadataValueListItem structure

A structure containing other metadata for a schema version belonging to the same metadata key.

### Fields

- `MetadataValue` – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #32](#).

The metadata key's corresponding value for the other metadata belonging to the same metadata key.

- `CreateTime` – UTF-8 string.

The time at which the entry was created.

## SchemaListItem structure

An object that contains minimal details for a schema.

### Fields

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

the name of the registry where the schema resides.

- `SchemaName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema.

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) for the schema.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description for the schema.

- `SchemaStatus` – UTF-8 string (valid values: AVAILABLE | PENDING | DELETING).

The status of the schema.

- `CreatedTime` – UTF-8 string.

The date and time that a schema was created.

- `UpdatedTime` – UTF-8 string.

The date and time that a schema was updated.

## SchemaVersionListItem structure

An object containing the details about a schema version.

### Fields

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique identifier of the schema version.

- `VersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

- `Status` – UTF-8 string (valid values: AVAILABLE | PENDING | FAILURE | DELETING).

The status of the schema version.

- `CreatedTime` – UTF-8 string.

The date and time the schema version was created.

## MetadataKeyValuePair structure

A structure containing a key value pair for metadata.

### Fields

- `MetadataKey` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #32](#).

A metadata key.

- `MetadataValue` – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #32](#).

A metadata key's corresponding value.

## SchemaVersionErrorItem structure

An object that contains the error details for an operation on a schema version.

### Fields

- `VersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

- `ErrorDetails` – An [ErrorDetails](#) object.

The details of the error for the schema version.

## ErrorDetails structure

An object containing error details.

### Fields

- `ErrorCode` – UTF-8 string.  
The error code for an error.
- `ErrorMessage` – UTF-8 string.  
The error message for an error.

## SchemaVersionNumber structure

A structure containing the schema version information.

### Fields

- `LatestVersion` – Boolean.  
The latest version available for the schema.
- `VersionNumber` – Number (long), not less than 1 or more than 100000.  
The version number of the schema.

## SchemaId structure

The unique ID of the schema in the AWS Glue schema registry.

### Fields

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).  
The Amazon Resource Name (ARN) of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `SchemaName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema. One of SchemaArn or SchemaName has to be provided.

- RegistryName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema registry that contains the schema.

## Operations

- [CreateRegistry action \(Python: create\\_registry\)](#)
- [CreateSchema action \(Python: create\\_schema\)](#)
- [GetSchema action \(Python: get\\_schema\)](#)
- [ListSchemaVersions action \(Python: list\\_schema\\_versions\)](#)
- [GetSchemaVersion action \(Python: get\\_schema\\_version\)](#)
- [GetSchemaVersionsDiff action \(Python: get\\_schema\\_versions\\_diff\)](#)
- [ListRegistries action \(Python: list\\_registries\)](#)
- [ListSchemas action \(Python: list\\_schemas\)](#)
- [RegisterSchemaVersion action \(Python: register\\_schema\\_version\)](#)
- [UpdateSchema action \(Python: update\\_schema\)](#)
- [CheckSchemaVersionValidity action \(Python: check\\_schema\\_version\\_validity\)](#)
- [UpdateRegistry action \(Python: update\\_registry\)](#)
- [GetSchemaByDefinition action \(Python: get\\_schema\\_by\\_definition\)](#)
- [GetRegistry action \(Python: get\\_registry\)](#)
- [PutSchemaVersionMetadata action \(Python: put\\_schema\\_version\\_metadata\)](#)
- [QuerySchemaVersionMetadata action \(Python: query\\_schema\\_version\\_metadata\)](#)
- [RemoveSchemaVersionMetadata action \(Python: remove\\_schema\\_version\\_metadata\)](#)
- [DeleteRegistry action \(Python: delete\\_registry\)](#)
- [DeleteSchema action \(Python: delete\\_schema\)](#)
- [DeleteSchemaVersions action \(Python: delete\\_schema\\_versions\)](#)

## CreateRegistry action (Python: create\_registry)

Creates a new registry which may be used to hold a collection of schemas.

## Request

- **RegistryName** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

Name of the registry to be created of max length of 255, and may only contain letters, numbers, hyphen, underscore, dollar sign, or hash mark. No whitespace.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the registry. If description is not provided, there will not be any default value for this.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

AWS tags that contain a key value pair and may be searched by console, command line, or API.

## Response

- **RegistryArn** – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the newly created registry.

- **RegistryName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the registry.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags for the registry.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`
- `InternalServiceException`

## CreateSchema action (Python: `create_schema`)

Creates a new schema set and registers the schema definition. Returns an error if the schema set already exists without actually registering the version.

When the schema set is created, a version checkpoint will be set to the first version. Compatibility mode "DISABLED" restricts any additional schema versions from being added after the first schema version. For all other compatibility modes, validation of compatibility settings will be applied only from the second version onwards when the `RegisterSchemaVersion` API is used.

When this API is called without a `RegistryId`, this will create an entry for a "default-registry" in the registry database tables, if it is not already present.

## Request

- `RegistryId` – A [RegistryId](#) object.

This is a wrapper shape to contain the registry identity fields. If this is not provided, the default registry will be used. The ARN format for the same will be: `arn:aws:glue:us-east-2:<customer id>:registry/default-registry:random-5-letter-id`.

- `SchemaName` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

Name of the schema to be created of max length of 255, and may only contain letters, numbers, hyphen, underscore, dollar sign, or hash mark. No whitespace.

- **DataFormat** – *Required*: UTF-8 string (valid values: AVRO | JSON | PROTOBUF).

The data format of the schema definition. Currently AVRO, JSON and PROTOBUF are supported.

- **Compatibility** – UTF-8 string (valid values: NONE | DISABLED | BACKWARD | BACKWARD\_ALL | FORWARD | FORWARD\_ALL | FULL | FULL\_ALL).

The compatibility mode of the schema. The possible values are:

- **NONE**: No compatibility mode applies. You can use this choice in development scenarios or if you do not know the compatibility mode that you want to apply to schemas. Any new version added will be accepted without undergoing a compatibility check.
- **DISABLED**: This compatibility choice prevents versioning for a particular schema. You can use this choice to prevent future versioning of a schema.
- **BACKWARD**: This compatibility choice is recommended as it allows data receivers to read both the current and one previous schema version. This means that for instance, a new schema version cannot drop data fields or change the type of these fields, so they can't be read by readers using the previous version.
- **BACKWARD\_ALL**: This compatibility choice allows data receivers to read both the current and all previous schema versions. You can use this choice when you need to delete fields or add optional fields, and check compatibility against all previous schema versions.
- **FORWARD**: This compatibility choice allows data receivers to read both the current and one next schema version, but not necessarily later versions. You can use this choice when you need to add fields or delete optional fields, but only check compatibility against the last schema version.
- **FORWARD\_ALL**: This compatibility choice allows data receivers to read written by producers of any new registered schema. You can use this choice when you need to add fields or delete optional fields, and check compatibility against all previous schema versions.
- **FULL**: This compatibility choice allows data receivers to read data written by producers using the previous or next version of the schema, but not necessarily earlier or later versions. You can use this choice when you need to add or remove optional fields, but only check compatibility against the last schema version.
- **FULL\_ALL**: This compatibility choice allows data receivers to read data written by producers using all previous schema versions. You can use this choice when you need to add or remove optional fields, and check compatibility against all previous schema versions.
- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

An optional description of the schema. If description is not provided, there will not be any automatic default value for this.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

AWS tags that contain a key value pair and may be searched by console, command line, or API. If specified, follows the AWS tags-on-create pattern.

- **SchemaDefinition** – UTF-8 string, not less than 1 or more than 170000 bytes long, matching the [Custom string pattern #31](#).

The schema definition using the DataFormat setting for SchemaName.

## Response

- **RegistryName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry.

- **RegistryArn** – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the registry.

- **SchemaName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema.

- **SchemaArn** – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the schema if specified when created.

- **DataFormat** – UTF-8 string (valid values: AVRO | JSON | PROTOBUF).

The data format of the schema definition. Currently AVRO, JSON and PROTOBUF are supported.

- **Compatibility** – UTF-8 string (valid values: NONE | DISABLED | BACKWARD | BACKWARD\_ALL | FORWARD | FORWARD\_ALL | FULL | FULL\_ALL).

The schema compatibility mode.

- **SchemaCheckpoint** – Number (long), not less than 1 or more than 100000.

The version number of the checkpoint (the last time the compatibility mode was changed).

- **LatestSchemaVersion** – Number (long), not less than 1 or more than 100000.

The latest version of the schema associated with the returned schema definition.

- **NextSchemaVersion** – Number (long), not less than 1 or more than 100000.

The next version of the schema associated with the returned schema definition.

- **SchemaStatus** – UTF-8 string (valid values: AVAILABLE | PENDING | DELETING).

The status of the schema.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags for the schema.

- **SchemaVersionId** – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique identifier of the first schema version.

- **SchemaVersionStatus** – UTF-8 string (valid values: AVAILABLE | PENDING | FAILURE | DELETING).

The status of the first schema version created.

## Errors

- **InvalidInputException**

CreateSchema (create\_schema)

- `AccessDeniedException`
- `EntityNotFoundException`
- `AlreadyExistsException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`
- `InternalServiceException`

## GetSchema action (Python: `get_schema`)

Describes the specified schema in detail.

### Request

- `SchemaId` – *Required:* A [Schemald](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- `Schemald$SchemaArn`: The Amazon Resource Name (ARN) of the schema. Either `SchemaArn` or `SchemaName` and `RegistryName` has to be provided.
- `Schemald$SchemaName`: The name of the schema. Either `SchemaArn` or `SchemaName` and `RegistryName` has to be provided.

### Response

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry.

- `RegistryArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the registry.

- `SchemaName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema.

- **SchemaArn** – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of schema if specified when created

- **DataFormat** – UTF-8 string (valid values: AVRO | JSON | PROTOBUF).

The data format of the schema definition. Currently AVRO, JSON and PROTOBUF are supported.

- **Compatibility** – UTF-8 string (valid values: NONE | DISABLED | BACKWARD | BACKWARD\_ALL | FORWARD | FORWARD\_ALL | FULL | FULL\_ALL).

The compatibility mode of the schema.

- **SchemaCheckpoint** – Number (long), not less than 1 or more than 100000.

The version number of the checkpoint (the last time the compatibility mode was changed).

- **LatestSchemaVersion** – Number (long), not less than 1 or more than 100000.

The latest version of the schema associated with the returned schema definition.

- **NextSchemaVersion** – Number (long), not less than 1 or more than 100000.

The next version of the schema associated with the returned schema definition.

- **SchemaStatus** – UTF-8 string (valid values: AVAILABLE | PENDING | DELETING).

The status of the schema.

- **CreatedTime** – UTF-8 string.

The date and time the schema was created.

- **UpdatedTime** – UTF-8 string.

The date and time the schema was updated.

## Errors

- `InvalidInputException`
- `AccessDeniedException`

- EntityNotFoundException
- InternalServiceException

## ListSchemaVersions action (Python: list\_schema\_versions)

Returns a list of schema versions that you have created, with minimal information. Schema versions in Deleted status will not be included in the results. Empty results will be returned if there are no schema versions available.

### Request

- SchemaId – *Required:* A [Schemald](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- Schemald\$SchemaArn: The Amazon Resource Name (ARN) of the schema. Either SchemaArn or SchemaName and RegistryName has to be provided.
- Schemald\$SchemaName: The name of the schema. Either SchemaArn or SchemaName and RegistryName has to be provided.
- MaxResults – Number (integer), not less than 1 or more than 100.

Maximum number of results required per page. If the value is not supplied, this will be defaulted to 25 per page.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

### Response

- Schemas – An array of [SchemaVersionListItem](#) objects.

An array of SchemaVersionList objects containing details of each schema version.

- NextToken – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`

## GetSchemaVersion action (Python: `get_schema_version`)

Get the specified schema by its unique ID assigned when a version of the schema is created or registered. Schema versions in Deleted status will not be included in the results.

### Request

- `SchemaId` – A [SchemaId](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- `SchemaId$SchemaArn`: The Amazon Resource Name (ARN) of the schema. Either `SchemaArn` or `SchemaName` and `RegistryName` has to be provided.
- `SchemaId$SchemaName`: The name of the schema. Either `SchemaArn` or `SchemaName` and `RegistryName` has to be provided.
- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The `SchemaVersionId` of the schema version. This field is required for fetching by schema ID. Either this or the `SchemaId` wrapper has to be provided.

- `SchemaVersionNumber` – A [SchemaVersionNumber](#) object.

The version number of the schema.

### Response

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The `SchemaVersionId` of the schema version.

- `SchemaDefinition` – UTF-8 string, not less than 1 or more than 170000 bytes long, matching the [Custom string pattern #31](#).

The schema definition for the schema ID.

- `DataFormat` – UTF-8 string (valid values: AVRO | JSON | PROTOBUF).

The data format of the schema definition. Currently AVRO, JSON and PROTOBUF are supported.

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- `VersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

- `Status` – UTF-8 string (valid values: AVAILABLE | PENDING | FAILURE | DELETING).

The status of the schema version.

- `CreatedTime` – UTF-8 string.

The date and time the schema version was created.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`

## GetSchemaVersionsDiff action (Python: `get_schema_versions_diff`)

Fetches the schema version difference in the specified difference type between two stored schema versions in the Schema Registry.

This API allows you to compare two schema versions between two schema definitions under the same schema.

## Request

- `SchemaId` – *Required:* A [SchemaId](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- `SchemaId$SchemaArn`: The Amazon Resource Name (ARN) of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `SchemaId$SchemaName`: The name of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `FirstSchemaVersionNumber` – *Required:* A [SchemaVersionNumber](#) object.

The first of the two schema versions to be compared.

- `SecondSchemaVersionNumber` – *Required:* A [SchemaVersionNumber](#) object.

The second of the two schema versions to be compared.

- `SchemaDiffType` – *Required:* UTF-8 string (valid values: SYNTAX\_DIFF).

Refers to SYNTAX\_DIFF, which is the currently supported diff type.

## Response

- `Diff` – UTF-8 string, not less than 1 or more than 340000 bytes long, matching the [Custom string pattern #31](#).

The difference between schemas as a string in JsonPatch format.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `AccessDeniedException`
- `InternalServiceException`

## ListRegistries action (Python: list\_registries)

Returns a list of registries that you have created, with minimal registry information. Registries in the Deleting status will not be included in the results. Empty results will be returned if there are no registries available.

### Request

- `MaxResults` – Number (integer), not less than 1 or more than 100.

Maximum number of results required per page. If the value is not supplied, this will be defaulted to 25 per page.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

### Response

- `Registries` – An array of [RegistryListItem](#) objects.

An array of `RegistryDetailedListItem` objects containing minimal details of each registry.

- `NextToken` – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

### Errors

- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`

## ListSchemas action (Python: list\_schemas)

Returns a list of schemas with minimal details. Schemas in Deleting status will not be included in the results. Empty results will be returned if there are no schemas available.

When the `RegistryId` is not provided, all the schemas across registries will be part of the API response.

## Request

- `RegistryId` – A [RegistryId](#) object.

A wrapper structure that may contain the registry name and Amazon Resource Name (ARN).

- `MaxResults` – Number (integer), not less than 1 or more than 100.

Maximum number of results required per page. If the value is not supplied, this will be defaulted to 25 per page.

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation call.

## Response

- `Schemas` – An array of [SchemaListItem](#) objects.

An array of `SchemaListItem` objects containing details of each schema.

- `NextToken` – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`

## RegisterSchemaVersion action (Python: register\_schema\_version)

Adds a new version to the existing schema. Returns an error if new version of schema does not meet the compatibility requirements of the schema set. This API will not create a new schema set and will return a 404 error if the schema set is not already present in the Schema Registry.

If this is the first schema definition to be registered in the Schema Registry, this API will store the schema version and return immediately. Otherwise, this call has the potential to run longer than other operations due to compatibility modes. You can call the `GetSchemaVersion` API with the `SchemaVersionId` to check compatibility modes.

If the same schema definition is already stored in Schema Registry as a version, the schema ID of the existing schema is returned to the caller.

### Request

- `SchemaId` – *Required:* A [Schemald](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- `Schemald$SchemaArn`: The Amazon Resource Name (ARN) of the schema. Either `SchemaArn` or `SchemaName` and `RegistryName` has to be provided.
- `Schemald$SchemaName`: The name of the schema. Either `SchemaArn` or `SchemaName` and `RegistryName` has to be provided.
- `SchemaDefinition` – *Required:* UTF-8 string, not less than 1 or more than 170000 bytes long, matching the [Custom string pattern #31](#).

The schema definition using the `DataFormat` setting for the `SchemaName`.

### Response

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique ID that represents the version of this schema.

- `VersionNumber` – Number (long), not less than 1 or more than 100000.

The version of this schema (for sync flow only, in case this is the first version).

- `Status` – UTF-8 string (valid values: AVAILABLE | PENDING | FAILURE | DELETING).

The status of the schema version.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`
- `InternalServiceException`

## UpdateSchema action (Python: `update_schema`)

Updates the description, compatibility setting, or version checkpoint for a schema set.

For updating the compatibility setting, the call will not validate compatibility for the entire set of schema versions with the new compatibility setting. If the value for `Compatibility` is provided, the `VersionNumber` (a checkpoint) is also required. The API will validate the checkpoint version number for consistency.

If the value for the `VersionNumber` (checkpoint) is provided, `Compatibility` is optional and this can be used to set/reset a checkpoint for the schema.

This update will happen only if the schema is in the `AVAILABLE` state.

## Request

- `SchemaId` – *Required:* A [SchemaId](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- `SchemaId$SchemaArn`: The Amazon Resource Name (ARN) of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `SchemaId$SchemaName`: The name of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `SchemaVersionNumber` – A [SchemaVersionNumber](#) object.

Version number required for check pointing. One of `VersionNumber` or `Compatibility` has to be provided.

- `Compatibility` – UTF-8 string (valid values: NONE | DISABLED | BACKWARD | BACKWARD\_ALL | FORWARD | FORWARD\_ALL | FULL | FULL\_ALL).

The new compatibility setting for the schema.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The new description for the schema.

## Response

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- `SchemaName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema.

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry that contains the schema.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `ConcurrentModificationException`
- `InternalServiceException`

## CheckSchemaVersionValidity action (Python: `check_schema_version_validity`)

Validates the supplied schema. This call has no side effects, it simply validates using the supplied schema using `DataFormat` as the format. Since it does not take a schema set name, no compatibility checks are performed.

### Request

- `DataFormat` – *Required*: UTF-8 string (valid values: AVRO | JSON | PROTOBUF).

The data format of the schema definition. Currently AVRO, JSON and PROTOBUF are supported.

- `SchemaDefinition` – *Required*: UTF-8 string, not less than 1 or more than 170000 bytes long, matching the [Custom string pattern #31](#).

The definition of the schema that has to be validated.

### Response

- `Valid` – Boolean.

Return true, if the schema is valid and false otherwise.

- `Error` – UTF-8 string, not less than 1 or more than 5000 bytes long.

A validation failure error message.

### Errors

- `InvalidInputException`
- `AccessDeniedException`
- `InternalServiceException`

## UpdateRegistry action (Python: `update_registry`)

Updates an existing registry which is used to hold a collection of schemas. The updated properties relate to the registry, and do not modify any of the schemas within the registry.

## Request

- `RegistryId` – *Required:* A [RegistryId](#) object.

This is a wrapper structure that may contain the registry name and Amazon Resource Name (ARN).

- `Description` – *Required:* Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the registry. If description is not provided, this field will not be updated.

## Response

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the updated registry.

- `RegistryArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource name (ARN) of the updated registry.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `ConcurrentModificationException`
- `InternalServiceException`

## GetSchemaByDefinition action (Python: `get_schema_by_definition`)

Retrieves a schema by the `SchemaDefinition`. The schema definition is sent to the Schema Registry, canonicalized, and hashed. If the hash is matched within the scope of the `SchemaName` or ARN (or the default registry, if none is supplied), that schema's metadata is returned. Otherwise, a 404 or `NotFound` error is returned. Schema versions in `Deleted` statuses will not be included in the results.

## Request

- `SchemaId` – *Required*: A [Schemald](#) object.

This is a wrapper structure to contain schema identity fields. The structure contains:

- `Schemald$SchemaArn`: The Amazon Resource Name (ARN) of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `Schemald$SchemaName`: The name of the schema. One of `SchemaArn` or `SchemaName` has to be provided.
- `SchemaDefinition` – *Required*: UTF-8 string, not less than 1 or more than 170000 bytes long, matching the [Custom string pattern #31](#).

The definition of the schema for which schema details are required.

## Response

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The schema ID of the schema version.

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- `DataFormat` – UTF-8 string (valid values: AVRO | JSON | PROTOBUF).

The data format of the schema definition. Currently AVRO, JSON and PROTOBUF are supported.

- `Status` – UTF-8 string (valid values: AVAILABLE | PENDING | FAILURE | DELETING).

The status of the schema version.

- `CreatedTime` – UTF-8 string.

The date and time the schema was created.

## Errors

- `InvalidInputException`

- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`

## GetRegistry action (Python: `get_registry`)

Describes the specified registry in detail.

### Request

- `RegistryId` – *Required:* A [RegistryId](#) object.

This is a wrapper structure that may contain the registry name and Amazon Resource Name (ARN).

### Response

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry.

- `RegistryArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the registry.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the registry.

- `Status` – UTF-8 string (valid values: AVAILABLE | DELETING).

The status of the registry.

- `CreatedTime` – UTF-8 string.

The date and time the registry was created.

- `UpdatedTime` – UTF-8 string.

The date and time the registry was updated.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`
- `InternalServiceException`

## PutSchemaVersionMetadata action (Python: `put_schema_version_metadata`)

Puts the metadata key value pair for a specified schema version ID. A maximum of 10 key value pairs will be allowed per schema version. They can be added over one or more calls.

### Request

- `SchemaId` – A [SchemaId](#) object.

The unique ID for the schema.

- `SchemaVersionNumber` – A [SchemaVersionNumber](#) object.

The version number of the schema.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique version ID of the schema version.

- `MetadataKey` – *Required:* A [MetadataKeyValuePair](#) object.

The metadata key's corresponding value.

### Response

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) for the schema.

- `SchemaName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name for the schema.

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name for the registry.

- `LatestVersion` – Boolean.

The latest version of the schema.

- `VersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique version ID of the schema version.

- `MetadataKey` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #32](#).

The metadata key.

- `MetadataValue` – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #32](#).

The value of the metadata key.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `AlreadyExistsException`
- `EntityNotFoundException`
- `ResourceNumberLimitExceededException`

## QuerySchemaVersionMetadata action (Python: query\_schema\_version\_metadata)

Queries for the schema version metadata information.

### Request

- SchemaId – A [SchemaId](#) object.

A wrapper structure that may contain the schema name and Amazon Resource Name (ARN).

- SchemaVersionNumber – A [SchemaVersionNumber](#) object.

The version number of the schema.

- SchemaVersionId – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique version ID of the schema version.

- MetadataList – An array of [MetadataKeyValuePair](#) objects.

Search key-value pairs for metadata, if they are not provided all the metadata information will be fetched.

- MaxResults – Number (integer), not less than 1 or more than 50.

Maximum number of results required per page. If the value is not supplied, this will be defaulted to 25 per page.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation call.

### Response

- MetadataInfoMap – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #32](#).

Each value is a A [MetadataInfo](#) object.

A map of a metadata key and associated values.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique version ID of the schema version.

- `NextToken` – UTF-8 string.

A continuation token for paginating the returned list of tokens, returned if the current segment of the list is not the last.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`

## RemoveSchemaVersionMetadata action (Python: `remove_schema_version_metadata`)

Removes a key value pair from the schema version metadata for the specified schema version ID.

### Request

- `SchemaId` – A [SchemaId](#) object.

A wrapper structure that may contain the schema name and Amazon Resource Name (ARN).

- `SchemaVersionNumber` – A [SchemaVersionNumber](#) object.

The version number of the schema.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The unique version ID of the schema version.

- `MetadataKeyValue` – *Required:* A [MetadataKeyValuePair](#) object.

The value of the metadata key.

## Response

- `SchemaArn` – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema.

- `SchemaName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema.

- `RegistryName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry.

- `LatestVersion` – Boolean.

The latest version of the schema.

- `VersionNumber` – Number (long), not less than 1 or more than 100000.

The version number of the schema.

- `SchemaVersionId` – UTF-8 string, not less than 36 or more than 36 bytes long, matching the [Custom string pattern #17](#).

The version ID for the schema version.

- `MetadataKey` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #32](#).

The metadata key.

- `MetadataValue` – UTF-8 string, not less than 1 or more than 256 bytes long, matching the [Custom string pattern #32](#).

The value of the metadata key.

## Errors

- `InvalidInputException`
- `AccessDeniedException`
- `EntityNotFoundException`

## DeleteRegistry action (Python: delete\_registry)

Delete the entire registry including schema and all of its versions. To get the status of the delete operation, you can call the GetRegistry API after the asynchronous call. Deleting a registry will deactivate all online operations for the registry such as the UpdateRegistry, CreateSchema, UpdateSchema, and RegisterSchemaVersion APIs.

### Request

- RegistryId – *Required:* A [RegistryId](#) object.

This is a wrapper structure that may contain the registry name and Amazon Resource Name (ARN).

### Response

- RegistryName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the registry being deleted.

- RegistryArn – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the registry being deleted.

- Status – UTF-8 string (valid values: AVAILABLE | DELETING).

The status of the registry. A successful operation will return the Deleting status.

### Errors

- InvalidInputException
- EntityNotFoundException
- AccessDeniedException
- ConcurrentModificationException

## DeleteSchema action (Python: delete\_schema)

Deletes the entire schema set, including the schema set and all of its versions. To get the status of the delete operation, you can call GetSchema API after the asynchronous call. Deleting a registry will deactivate all online operations for the schema, such as the GetSchemaByDefinition, and RegisterSchemaVersion APIs.

### Request

- SchemaId – *Required:* A [Schemald](#) object.

This is a wrapper structure that may contain the schema name and Amazon Resource Name (ARN).

### Response

- SchemaArn – UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the schema being deleted.

- SchemaName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #18](#).

The name of the schema being deleted.

- Status – UTF-8 string (valid values: AVAILABLE | PENDING | DELETING).

The status of the schema.

### Errors

- InvalidInputException
- EntityNotFoundException
- AccessDeniedException
- ConcurrentModificationException

## DeleteSchemaVersions action (Python: delete\_schema\_versions)

Remove versions from the specified schema. A version number or range may be supplied. If the compatibility mode forbids deleting of a version that is necessary, such as BACKWARDS\_FULL, an error is returned. Calling the GetSchemaVersions API after this call will list the status of the deleted versions.

When the range of version numbers contain check pointed version, the API will return a 409 conflict and will not proceed with the deletion. You have to remove the checkpoint first using the DeleteSchemaCheckpoint API before using this API.

You cannot use the DeleteSchemaVersions API to delete the first schema version in the schema set. The first schema version can only be deleted by the DeleteSchema API. This operation will also delete the attached SchemaVersionMetadata under the schema versions. Hard deletes will be enforced on the database.

If the compatibility mode forbids deleting of a version that is necessary, such as BACKWARDS\_FULL, an error is returned.

### Request

- **SchemaId** – *Required:* A [Schemald](#) object.

This is a wrapper structure that may contain the schema name and Amazon Resource Name (ARN).

- **Versions** – *Required:* UTF-8 string, not less than 1 or more than 100000 bytes long, matching the [Custom string pattern #33](#).

A version range may be supplied which may be of the format:

- a single version number, 5
- a range, 5-8 : deletes versions 5, 6, 7, 8

### Response

- **SchemaVersionErrors** – An array of [SchemaVersionErrorItem](#) objects.

A list of SchemaVersionErrorItem objects, each containing an error and schema version.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `AccessDeniedException`
- `ConcurrentModificationException`

## Workflows

The Workflows API describes the data types and API related to creating, updating, or viewing workflows in AWS Glue. Job run history is accessible for 90 days for your workflow and job run.

## Data types

- [JobNodeDetails structure](#)
- [CrawlerNodeDetails structure](#)
- [TriggerNodeDetails structure](#)
- [Crawl structure](#)
- [Node structure](#)
- [Edge structure](#)
- [Workflow structure](#)
- [WorkflowGraph structure](#)
- [WorkflowRun structure](#)
- [WorkflowRunStatistics structure](#)
- [StartingEventBatchCondition structure](#)
- [Blueprint structure](#)
- [BlueprintDetails structure](#)
- [LastActiveDefinition structure](#)
- [BlueprintRun structure](#)

## JobNodeDetails structure

The details of a Job node present in the workflow.

## Fields

- JobRuns – An array of [JobRun](#) objects.

The information for the job runs represented by the job node.

## CrawlerNodeDetails structure

The details of a Crawler node present in the workflow.

### Fields

- Crawls – An array of [Crawl](#) objects.

A list of crawls represented by the crawl node.

## TriggerNodeDetails structure

The details of a Trigger node present in the workflow.

### Fields

- Trigger – A [Trigger](#) object.

The information of the trigger represented by the trigger node.

## Crawl structure

The details of a crawl in the workflow.

### Fields

- State – UTF-8 string (valid values: RUNNING | CANCELLING | CANCELLED | SUCCEEDED | FAILED | ERROR).

The state of the crawler.

- StartedOn – Timestamp.

The date and time on which the crawl started.

- CompletedOn – Timestamp.

The date and time on which the crawl completed.

- **ErrorMessage** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The error message associated with the crawl.

- **LogGroup** – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log group string pattern](#).

The log group associated with the crawl.

- **LogStream** – UTF-8 string, not less than 1 or more than 512 bytes long, matching the [Log-stream string pattern](#).

The log stream associated with the crawl.

## Node structure

A node represents an AWS Glue component (trigger, crawler, or job) on a workflow graph.

### Fields

- **Type** – UTF-8 string (valid values: CRAWLER | JOB | TRIGGER).

The type of AWS Glue component represented by the node.

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the AWS Glue component represented by the node.

- **UniqueId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique Id assigned to the node within the workflow.

- **TriggerDetails** – A [TriggerNodeDetails](#) object.

Details of the Trigger when the node represents a Trigger.

- **JobDetails** – A [JobNodeDetails](#) object.

Details of the Job when the node represents a Job.

- `CrawlerDetails` – A [CrawlerNodeDetails](#) object.

Details of the crawler when the node represents a crawler.

## Edge structure

An edge represents a directed connection between two AWS Glue components that are part of the workflow the edge belongs to.

### Fields

- `SourceId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique of the node within the workflow where the edge starts.

- `DestinationId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique of the node within the workflow where the edge ends.

## Workflow structure

A workflow is a collection of multiple dependent AWS Glue jobs and crawlers that are run to complete a complex ETL task. A workflow manages the execution and monitoring of all its jobs and crawlers.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow.

- `Description` – UTF-8 string.

A description of the workflow.

- `DefaultRunProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

A collection of properties to be used as part of each execution of the workflow. The run properties are made available to each job in the workflow. A job can modify the properties for the next jobs in the flow.

- `CreatedOn` – Timestamp.

The date and time when the workflow was created.

- `LastModifiedOn` – Timestamp.

The date and time when the workflow was last modified.

- `LastRun` – A [WorkflowRun](#) object.

The information about the last execution of the workflow.

- `Graph` – A [WorkflowGraph](#) object.

The graph representing all the AWS Glue components that belong to the workflow as nodes and directed connections between them as edges.

- `CreationStatus` – UTF-8 string (valid values: `CREATING` | `CREATED` | `CREATION_FAILED`).

The creation status of the workflow.

- `MaxConcurrentRuns` – Number (integer).

You can use this parameter to prevent unwanted multiple updates to data, to control costs, or in some cases, to prevent exceeding the maximum number of concurrent runs of any of the component jobs. If you leave this parameter blank, there is no limit to the number of concurrent workflow runs.

- `BlueprintDetails` – A [BlueprintDetails](#) object.

This structure indicates the details of the blueprint that this particular workflow is created from.

## WorkflowGraph structure

A workflow graph represents the complete workflow containing all the AWS Glue components present in the workflow and all the directed connections between them.

## Fields

- Nodes – An array of [Node](#) objects.

A list of the the AWS Glue components belong to the workflow represented as nodes.

- Edges – An array of [Edge](#) objects.

A list of all the directed connections between the nodes belonging to the workflow.

## WorkflowRun structure

A workflow run is an execution of a workflow providing all the runtime information.

### Fields

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow that was run.

- WorkflowRunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of this workflow run.

- PreviousRunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the previous workflow run.

- WorkflowRunProperties – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

The workflow run properties which were set during the run.

- StartedOn – Timestamp.

The date and time when the workflow run was started.

- CompletedOn – Timestamp.

The date and time when the workflow run completed.

- `Status` – UTF-8 string (valid values: `RUNNING` | `COMPLETED` | `STOPPING` | `STOPPED` | `ERROR`).

The status of the workflow run.

- `ErrorMessage` – UTF-8 string.

This error message describes any error that may have occurred in starting the workflow run. Currently the only error message is "Concurrent runs exceeded for workflow: foo."

- `Statistics` – A [WorkflowRunStatistics](#) object.

The statistics of the run.

- `Graph` – A [WorkflowGraph](#) object.

The graph representing all the AWS Glue components that belong to the workflow as nodes and directed connections between them as edges.

- `StartingEventBatchCondition` – A [StartingEventBatchCondition](#) object.

The batch condition that started the workflow run.

## WorkflowRunStatistics structure

Workflow run statistics provides statistics about the workflow run.

### Fields

- `TotalActions` – Number (integer).

Total number of Actions in the workflow run.

- `TimeoutActions` – Number (integer).

Total number of Actions that timed out.

- `FailedActions` – Number (integer).

Total number of Actions that have failed.

- `StoppedActions` – Number (integer).

Total number of Actions that have stopped.

- **SucceededActions** – Number (integer).

Total number of Actions that have succeeded.

- **RunningActions** – Number (integer).

Total number Actions in running state.

- **ErroredActions** – Number (integer).

Indicates the count of job runs in the ERROR state in the workflow run.

- **WaitingActions** – Number (integer).

Indicates the count of job runs in WAITING state in the workflow run.

## StartingEventBatchCondition structure

The batch condition that started the workflow run. Either the number of events in the batch size arrived, in which case the **BatchSize** member is non-zero, or the batch window expired, in which case the **BatchWindow** member is non-zero.

### Fields

- **BatchSize** – Number (integer).

Number of events in the batch.

- **BatchWindow** – Number (integer).

Duration of the batch window in seconds.

## Blueprint structure

The details of a blueprint.

### Fields

- **Name** – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- **Description** – UTF-8 string, not less than 1 or more than 512 bytes long.

The description of the blueprint.

- `CreatedOn` – Timestamp.

The date and time the blueprint was registered.

- `LastModifiedOn` – Timestamp.

The date and time the blueprint was last modified.

- `ParameterSpec` – UTF-8 string, not less than 1 or more than 131072 bytes long.

A JSON string that indicates the list of parameter specifications for the blueprint.

- `BlueprintLocation` – UTF-8 string.

Specifies the path in Amazon S3 where the blueprint is published.

- `BlueprintServiceLocation` – UTF-8 string.

Specifies a path in Amazon S3 where the blueprint is copied when you call `CreateBlueprint/UpdateBlueprint` to register the blueprint in AWS Glue.

- `Status` – UTF-8 string (valid values: `CREATING` | `ACTIVE` | `UPDATING` | `FAILED`).

The status of the blueprint registration.

- `Creating` — The blueprint registration is in progress.
- `Active` — The blueprint has been successfully registered.
- `Updating` — An update to the blueprint registration is in progress.
- `Failed` — The blueprint registration failed.
- `ErrorMessage` – UTF-8 string.

An error message.

- `LastActiveDefinition` – A [LastActiveDefinition](#) object.

When there are multiple versions of a blueprint and the latest version has some errors, this attribute indicates the last successful blueprint definition that is available with the service.

## BlueprintDetails structure

The details of a blueprint.

## Fields

- `BlueprintName` – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The run ID for this blueprint.

## LastActiveDefinition structure

When there are multiple versions of a blueprint and the latest version has some errors, this attribute indicates the last successful blueprint definition that is available with the service.

### Fields

- `Description` – UTF-8 string, not less than 1 or more than 512 bytes long.

The description of the blueprint.

- `LastModifiedOn` – Timestamp.

The date and time the blueprint was last modified.

- `ParameterSpec` – UTF-8 string, not less than 1 or more than 131072 bytes long.

A JSON string specifying the parameters for the blueprint.

- `BlueprintLocation` – UTF-8 string.

Specifies a path in Amazon S3 where the blueprint is published by the AWS Glue developer.

- `BlueprintServiceLocation` – UTF-8 string.

Specifies a path in Amazon S3 where the blueprint is copied when you create or update the blueprint.

## BlueprintRun structure

The details of a blueprint run.

## Fields

- **BlueprintName** – UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- **RunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The run ID for this blueprint run.

- **WorkflowName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of a workflow that is created as a result of a successful blueprint run. If a blueprint run has an error, there will not be a workflow created.

- **State** – UTF-8 string (valid values: RUNNING | SUCCEEDED | FAILED | ROLLING\_BACK).

The state of the blueprint run. Possible values are:

- **Running** — The blueprint run is in progress.
  - **Succeeded** — The blueprint run completed successfully.
  - **Failed** — The blueprint run failed and rollback is complete.
  - **Rolling Back** — The blueprint run failed and rollback is in progress.
- **StartedOn** – Timestamp.

The date and time that the blueprint run started.

- **CompletedOn** – Timestamp.

The date and time that the blueprint run completed.

- **ErrorMessage** – UTF-8 string.

Indicates any errors that are seen while running the blueprint.

- **RollbackErrorMessage** – UTF-8 string.

If there are any errors while creating the entities of a workflow, we try to roll back the created entities until that point and delete them. This attribute indicates the errors seen while trying to delete the entities that are created.

- **Parameters** – UTF-8 string, not less than 1 or more than 131072 bytes long.

The blueprint parameters as a string. You will have to provide a value for each key that is required from the parameter spec that is defined in the `Blueprint$ParameterSpec`.

- `RoleArn` – UTF-8 string, not less than 1 or more than 1024 bytes long, matching the [Custom string pattern #26](#).

The role ARN. This role will be assumed by the AWS Glue service and will be used to create the workflow and other entities of a workflow.

## Operations

- [CreateWorkflow action \(Python: create\\_workflow\)](#)
- [UpdateWorkflow action \(Python: update\\_workflow\)](#)
- [DeleteWorkflow action \(Python: delete\\_workflow\)](#)
- [GetWorkflow action \(Python: get\\_workflow\)](#)
- [ListWorkflows action \(Python: list\\_workflows\)](#)
- [BatchGetWorkflows action \(Python: batch\\_get\\_workflows\)](#)
- [GetWorkflowRun action \(Python: get\\_workflow\\_run\)](#)
- [GetWorkflowRuns action \(Python: get\\_workflow\\_runs\)](#)
- [GetWorkflowRunProperties action \(Python: get\\_workflow\\_run\\_properties\)](#)

- [StopWorkflowRun action \(Python: stop\\_workflow\\_run\)](#)
- [ResumeWorkflowRun action \(Python: resume\\_workflow\\_run\)](#)

## CreateWorkflow action (Python: create\_workflow)

Creates a new workflow.

### Request

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name to be assigned to the workflow. It should be unique within your account.

- **Description** – UTF-8 string.

A description of the workflow.

- **DefaultRunProperties** – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

A collection of properties to be used as part of each execution of the workflow.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to be used with this workflow.

- **MaxConcurrentRuns** – Number (integer).

You can use this parameter to prevent unwanted multiple updates to data, to control costs, or in some cases, to prevent exceeding the maximum number of concurrent runs of any of the component jobs. If you leave this parameter blank, there is no limit to the number of concurrent workflow runs.

### Response

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow which was provided as part of the request.

## Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`

## UpdateWorkflow action (Python: `update_workflow`)

Updates an existing workflow.

### Request

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow to be updated.

- **Description** – UTF-8 string.

The description of the workflow.

- **DefaultRunProperties** – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

A collection of properties to be used as part of each execution of the workflow.

- **MaxConcurrentRuns** – Number (integer).

You can use this parameter to prevent unwanted multiple updates to data, to control costs, or in some cases, to prevent exceeding the maximum number of concurrent runs of any of the

component jobs. If you leave this parameter blank, there is no limit to the number of concurrent workflow runs.

## Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow which was specified in input.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## DeleteWorkflow action (Python: `delete_workflow`)

Deletes a workflow.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow to be deleted.

### Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow specified in input.

## Errors

- `InvalidInputException`
- `InternalServerErrorException`
- `OperationTimeoutException`
- `ConcurrentModificationException`

## GetWorkflow action (Python: `get_workflow`)

Retrieves resource metadata for a workflow.

### Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow to retrieve.

- `IncludeGraph` – Boolean.

Specifies whether to include a graph when returning the workflow resource metadata.

### Response

- `Workflow` – A [Workflow](#) object.

The resource metadata for the workflow.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServerErrorException`
- `OperationTimeoutException`

## ListWorkflows action (Python: `list_workflows`)

Lists names of workflows created in the account.

## Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 25.

The maximum size of a list to return.

## Response

- `Workflows` – An array of UTF-8 strings, not less than 1 or more than 25 strings.

List of names of workflows in the account.

- `NextToken` – UTF-8 string.

A continuation token, if not all workflow names have been returned.

## Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## BatchGetWorkflows action (Python: `batch_get_workflows`)

Returns a list of resource metadata for a given list of workflow names. After calling the `ListWorkflows` operation, you can call this operation to access the data to which you have been granted permissions. This operation supports all IAM permissions, including permission conditions that uses tags.

## Request

- `Names` – *Required*: An array of UTF-8 strings, not less than 1 or more than 25 strings.

A list of workflow names, which may be the names returned from the `ListWorkflows` operation.

- `IncludeGraph` – Boolean.

Specifies whether to include a graph when returning the workflow resource metadata.

## Response

- **Workflows** – An array of [Workflow](#) objects, not less than 1 or more than 25 structures.

A list of workflow resource metadata.

- **MissingWorkflows** – An array of UTF-8 strings, not less than 1 or more than 25 strings.

A list of names of workflows not found.

## Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## GetWorkflowRun action (Python: `get_workflow_run`)

Retrieves the metadata for a given workflow run. Job run history is accessible for 90 days for your workflow and job run.

### Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow being run.

- **RunId** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the workflow run.

- **IncludeGraph** – Boolean.

Specifies whether to include the workflow graph in response or not.

## Response

- Run – A [WorkflowRun](#) object.

The requested workflow run metadata.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetWorkflowRuns action (Python: `get_workflow_runs`)

Retrieves metadata for all runs of a given workflow.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow whose metadata of runs should be returned.

- IncludeGraph – Boolean.

Specifies whether to include the workflow graph in response or not.

- NextToken – UTF-8 string.

The maximum size of the response.

- MaxResults – Number (integer), not less than 1 or more than 1000.

The maximum number of workflow runs to be included in the response.

### Response

- Runs – An array of [WorkflowRun](#) objects, not less than 1 or more than 1000 structures.

A list of workflow run metadata objects.

- `NextToken` – UTF-8 string.

A continuation token, if not all requested workflow runs have been returned.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## GetWorkflowRunProperties action (Python: `get_workflow_run_properties`)

Retrieves the workflow run properties which were set during the run.

### Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow which was run.

- `RunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the workflow run whose run properties should be returned.

### Response

- `RunProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

The workflow run properties which were set during the specified run.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

## PutWorkflowRunProperties action (Python: `put_workflow_run_properties`)

Puts the specified workflow run properties for the given workflow run. If a property already exists for the specified run, then it overrides the value otherwise adds the property to existing properties.

### Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of the workflow which was run.

- `RunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the workflow run for which the run properties should be updated.

- `RunProperties` – *Required:* A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

The properties to put for the specified run.

### Response

- *No Response parameters.*

## Errors

- `AlreadyExistsException`
- `EntityNotFoundException`
- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentModificationException`

## CreateBlueprint action (Python: `create_blueprint`)

Registers a blueprint with AWS Glue.

### Request

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- **Description** – UTF-8 string, not less than 1 or more than 512 bytes long.

A description of the blueprint.

- **BlueprintLocation** – *Required*: UTF-8 string, not less than 1 or more than 8192 bytes long, matching the [Custom string pattern #28](#).

Specifies a path in Amazon S3 where the blueprint is published.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to be applied to this blueprint.

## Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the name of the blueprint that was registered.

## Errors

- AlreadyExistsException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException
- ResourceNumberLimitExceededException

## UpdateBlueprint action (Python: update\_blueprint)

Updates a registered blueprint.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- Description – UTF-8 string, not less than 1 or more than 512 bytes long.

A description of the blueprint.

- BlueprintLocation – *Required*: UTF-8 string, not less than 1 or more than 8192 bytes long, matching the [Custom string pattern #28](#).

Specifies a path in Amazon S3 where the blueprint is published.

## Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the name of the blueprint that was updated.

## Errors

- `EntityNotFoundException`
- `ConcurrentModificationException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `IllegalBlueprintStateException`

## DeleteBlueprint action (Python: `delete_blueprint`)

Deletes an existing blueprint.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the blueprint to delete.

### Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Returns the name of the blueprint that was deleted.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## ListBlueprints action (Python: list\_blueprints)

Lists all the blueprint names in an account.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 25.

The maximum size of a list to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Filters the list by an AWS resource tag.

### Response

- `Blueprints` – An array of UTF-8 strings.

List of names of blueprints in the account.

- `NextToken` – UTF-8 string.

A continuation token, if not all blueprint names have been returned.

### Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`

## BatchGetBlueprints action (Python: batch\_get\_blueprints)

Retrieves information about a list of blueprints.

## Request

- **Names** – *Required*: An array of UTF-8 strings, not less than 1 or more than 25 strings.

A list of blueprint names.

- **IncludeBlueprint** – Boolean.

Specifies whether or not to include the blueprint in the response.

- **IncludeParameterSpec** – Boolean.

Specifies whether or not to include the parameters, as a JSON string, for the blueprint in the response.

## Response

- **Blueprints** – An array of [Blueprint](#) objects.

Returns a list of blueprint as a Blueprints object.

- **MissingBlueprints** – An array of UTF-8 strings.

Returns a list of BlueprintNames that were not found.

## Errors

- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## StartBlueprintRun action (Python: `start_blueprint_run`)

Starts a new run of the specified blueprint.

### Request

- **BlueprintName** – *Required*: UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- **Parameters** – UTF-8 string, not less than 1 or more than 131072 bytes long.

Specifies the parameters as a `BlueprintParameters` object.

- **RoleArn** – *Required:* UTF-8 string, not less than 1 or more than 1024 bytes long, matching the [Custom string pattern #26](#).

Specifies the IAM role used to create the workflow.

## Response

- **RunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The run ID for this blueprint run.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `ResourceNumberLimitExceededException`
- `EntityNotFoundException`
- `IllegalBlueprintStateException`

## GetBlueprintRun action (Python: `get_blueprint_run`)

Retrieves the details of a blueprint run.

### Request

- **BlueprintName** – *Required:* UTF-8 string, not less than 1 or more than 128 bytes long, matching the [Custom string pattern #27](#).

The name of the blueprint.

- **RunId** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The run ID for the blueprint run you want to retrieve.

## Response

- BlueprintRun – A [BlueprintRun](#) object.

Returns a BlueprintRun object.

## Errors

- EntityNotFoundException
- InternalServiceException
- OperationTimeoutException

## GetBlueprintRuns action (Python: `get_blueprint_runs`)

Retrieves the details of blueprint runs for a specified blueprint.

### Request

- BlueprintName – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the blueprint.

- NextToken – UTF-8 string.

A continuation token, if this is a continuation request.

- MaxResults – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

### Response

- BlueprintRuns – An array of [BlueprintRun](#) objects.

Returns a list of BlueprintRun objects.

- NextToken – UTF-8 string.

A continuation token, if not all blueprint runs have been returned.

## Errors

- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `InvalidInputException`

## StartWorkflowRun action (Python: `start_workflow_run`)

Starts a new run of the specified workflow.

### Request

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow to start.

- `RunProperties` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a UTF-8 string.

The workflow run properties for the new workflow run.

### Response

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

An Id for the new run.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`
- `ConcurrentRunsExceededException`

## StopWorkflowRun action (Python: `stop_workflow_run`)

Stops the execution of the specified workflow run.

### Request

- `Name` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow to stop.

- `RunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the workflow run to stop.

### Response

- *No Response parameters.*

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`
- `IllegalWorkflowStateException`

## ResumeWorkflowRun action (Python: `resume_workflow_run`)

Restarts selected nodes of a previous partially completed workflow run and resumes the workflow run. The selected nodes and all nodes that are downstream from the selected nodes are run.

### Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the workflow to resume.

- **RunId** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the workflow run to resume.

- **NodeIds** – *Required:* An array of UTF-8 strings.

A list of the node IDs for the nodes you want to restart. The nodes that are to be restarted must have a run attempt in the original run.

### Response

- **RunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The new ID assigned to the resumed workflow run. Each resume of a workflow run will have a new run ID.

- **NodeIds** – An array of UTF-8 strings.

A list of the node IDs for the nodes that were actually restarted.

### Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `InternalServiceException`
- `OperationTimeoutException`

- `ConcurrentRunsExceededException`
- `IllegalWorkflowStateException`

## Machine learning API

The Machine learning API describes the machine learning data types, and includes the API for creating, deleting, or updating a transform, or starting a machine learning task run.

### Data types

- [TransformParameters structure](#)
- [EvaluationMetrics structure](#)
- [MLTransform structure](#)
- [FindMatchesParameters structure](#)
- [FindMatchesMetrics structure](#)
- [ConfusionMatrix structure](#)
- [GlueTable structure](#)
- [TaskRun structure](#)
- [TransformFilterCriteria structure](#)
- [TransformSortCriteria structure](#)
- [TaskRunFilterCriteria structure](#)
- [TaskRunSortCriteria structure](#)
- [TaskRunProperties structure](#)
- [FindMatchesTaskRunProperties structure](#)
- [ImportLabelsTaskRunProperties structure](#)
- [ExportLabelsTaskRunProperties structure](#)
- [LabelingSetGenerationTaskRunProperties structure](#)
- [SchemaColumn structure](#)
- [TransformEncryption structure](#)
- [MLUserDataEncryption structure](#)

- [ColumnImportance structure](#)

## TransformParameters structure

The algorithm-specific parameters that are associated with the machine learning transform.

### Fields

- `TransformType` – *Required:* UTF-8 string (valid values: FIND\_MATCHES).

The type of machine learning transform.

For information about the types of machine learning transforms, see [Creating Machine Learning Transforms](#).

- `FindMatchesParameters` – A [FindMatchesParameters](#) object.

The parameters for the find matches algorithm.

## EvaluationMetrics structure

Evaluation metrics provide an estimate of the quality of your machine learning transform.

### Fields

- `TransformType` – *Required:* UTF-8 string (valid values: FIND\_MATCHES).

The type of machine learning transform.

- `FindMatchesMetrics` – A [FindMatchesMetrics](#) object.

The evaluation metrics for the find matches algorithm.

## MLTransform structure

A structure for a machine learning transform.

### Fields

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique transform ID that is generated for the machine learning transform. The ID is guaranteed to be unique and does not change.

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A user-defined name for the machine learning transform. Names are not guaranteed unique and can be changed at any time.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A user-defined, long-form description text for the machine learning transform. Descriptions are not guaranteed to be unique and can be changed at any time.

- **Status** – UTF-8 string (valid values: NOT\_READY | READY | DELETING).

The current status of the machine learning transform.

- **CreatedOn** – Timestamp.

A timestamp. The time and date that this machine learning transform was created.

- **LastModifiedOn** – Timestamp.

A timestamp. The last point in time when this machine learning transform was modified.

- **InputRecordTables** – An array of [GlueTable](#) objects, not more than 10 structures.

A list of AWS Glue table definitions used by the transform.

- **Parameters** – A [TransformParameters](#) object.

A `TransformParameters` object. You can use parameters to tune (customize) the behavior of the machine learning transform by specifying what data it learns from and your preference on various tradeoffs (such as precision vs. recall, or accuracy vs. cost).

- **EvaluationMetrics** – An [EvaluationMetrics](#) object.

An `EvaluationMetrics` object. Evaluation metrics provide an estimate of the quality of your machine learning transform.

- **LabelCount** – Number (integer).

A count identifier for the labeling files generated by AWS Glue for this transform. As you create a better transform, you can iteratively download, label, and upload the labeling file.

- Schema – An array of [SchemaColumn](#) objects, not more than 100 structures.

A map of key-value pairs representing the columns and data types that this transform can run against. Has an upper bound of 100 columns.

- Role – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role with the required permissions. The required permissions include both AWS Glue service role permissions to AWS Glue resources, and Amazon S3 permissions required by the transform.

- This role needs AWS Glue service role permissions to allow access to resources in AWS Glue. See [Attach a Policy to IAM Users That Access AWS Glue](#).
- This role needs permission to your Amazon Simple Storage Service (Amazon S3) sources, targets, temporary directory, scripts, and any libraries used by the task run for this transform.
- GlueVersion – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

This value determines which version of AWS Glue this machine learning transform is compatible with. Glue 1.0 is recommended for most customers. If the value is not set, the Glue compatibility defaults to Glue 0.9. For more information, see [AWS Glue Versions](#) in the developer guide.

- MaxCapacity – Number (double).

The number of AWS Glue data processing units (DPUs) that are allocated to task runs for this transform. You can allocate from 2 to 100 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

MaxCapacity is a mutually exclusive option with NumberOfWorkers and WorkerType.

- If either NumberOfWorkers or WorkerType is set, then MaxCapacity cannot be set.
- If MaxCapacity is set then neither NumberOfWorkers or WorkerType can be set.
- If WorkerType is set, then NumberOfWorkers is required (and vice versa).
- MaxCapacity and NumberOfWorkers must both be at least 1.

When the WorkerType field is set to a value other than Standard, the MaxCapacity field is set automatically and becomes read-only.

- WorkerType – UTF-8 string (valid values: Standard="" | G.1X="" | G.2X="" | G.025X="" | G.4X="" | G.8X="" | Z.2X="").

The type of predefined worker that is allocated when a task of this transform runs. Accepts a value of Standard, G.1X, or G.2X.

- For the Standard worker type, each worker provides 4 vCPU, 16 GB of memory and a 50GB disk, and 2 executors per worker.
- For the G.1X worker type, each worker provides 4 vCPU, 16 GB of memory and a 64GB disk, and 1 executor per worker.
- For the G.2X worker type, each worker provides 8 vCPU, 32 GB of memory and a 128GB disk, and 1 executor per worker.

MaxCapacity is a mutually exclusive option with NumberOfWorkers and WorkerType.

- If either NumberOfWorkers or WorkerType is set, then MaxCapacity cannot be set.
- If MaxCapacity is set then neither NumberOfWorkers or WorkerType can be set.
- If WorkerType is set, then NumberOfWorkers is required (and vice versa).
- MaxCapacity and NumberOfWorkers must both be at least 1.
- NumberOfWorkers – Number (integer).

The number of workers of a defined workerType that are allocated when a task of the transform runs.

If WorkerType is set, then NumberOfWorkers is required (and vice versa).

- Timeout – Number (integer), at least 1.

The timeout in minutes of the machine learning transform.

- MaxRetries – Number (integer).

The maximum number of times to retry after an MLTaskRun of the machine learning transform fails.

- TransformEncryption – A [TransformEncryption](#) object.

The encryption-at-rest settings of the transform that apply to accessing user data. Machine learning transforms can access user data encrypted in Amazon S3 using KMS.

## FindMatchesParameters structure

The parameters to configure the find matches transform.

## Fields

- `PrimaryKeyColumnName` – UTF-8 string, not less than 1 or more than 1024 bytes long, matching the [Single-line string pattern](#).

The name of a column that uniquely identifies rows in the source table. Used to help identify matching records.

- `PrecisionRecallTradeoff` – Number (double), not more than 1.0.

The value selected when tuning your transform for a balance between precision and recall. A value of 0.5 means no preference; a value of 1.0 means a bias purely for precision, and a value of 0.0 means a bias for recall. Because this is a tradeoff, choosing values close to 1.0 means very low recall, and choosing values close to 0.0 results in very low precision.

The precision metric indicates how often your model is correct when it predicts a match.

The recall metric indicates that for an actual match, how often your model predicts the match.

- `AccuracyCostTradeoff` – Number (double), not more than 1.0.

The value that is selected when tuning your transform for a balance between accuracy and cost. A value of 0.5 means that the system balances accuracy and cost concerns. A value of 1.0 means a bias purely for accuracy, which typically results in a higher cost, sometimes substantially higher. A value of 0.0 means a bias purely for cost, which results in a less accurate `FindMatches` transform, sometimes with unacceptable accuracy.

Accuracy measures how well the transform finds true positives and true negatives. Increasing accuracy requires more machine resources and cost. But it also results in increased recall.

Cost measures how many compute resources, and thus money, are consumed to run the transform.

- `EnforceProvidedLabels` – Boolean.

The value to switch on or off to force the output to match the provided labels from users. If the value is `True`, the `find matches` transform forces the output to match the provided labels. The results override the normal conflation results. If the value is `False`, the `find matches` transform does not ensure all the labels provided are respected, and the results rely on the trained model.

Note that setting this value to true may increase the conflation execution time.

## FindMatchesMetrics structure

The evaluation metrics for the find matches algorithm. The quality of your machine learning transform is measured by getting your transform to predict some matches and comparing the results to known matches from the same dataset. The quality metrics are based on a subset of your data, so they are not precise.

### Fields

- `AreaUnderPRCurve` – Number (double), not more than 1.0.

The area under the precision/recall curve (AUPRC) is a single number measuring the overall quality of the transform, that is independent of the choice made for precision vs. recall. Higher values indicate that you have a more attractive precision vs. recall tradeoff.

For more information, see [Precision and recall](#) in Wikipedia.

- `Precision` – Number (double), not more than 1.0.

The precision metric indicates when often your transform is correct when it predicts a match. Specifically, it measures how well the transform finds true positives from the total true positives possible.

For more information, see [Precision and recall](#) in Wikipedia.

- `Recall` – Number (double), not more than 1.0.

The recall metric indicates that for an actual match, how often your transform predicts the match. Specifically, it measures how well the transform finds true positives from the total records in the source data.

For more information, see [Precision and recall](#) in Wikipedia.

- `F1` – Number (double), not more than 1.0.

The maximum F1 metric indicates the transform's accuracy between 0 and 1, where 1 is the best accuracy.

For more information, see [F1 score](#) in Wikipedia.

- `ConfusionMatrix` – A [ConfusionMatrix](#) object.

The confusion matrix shows you what your transform is predicting accurately and what types of errors it is making.

For more information, see [Confusion matrix](#) in Wikipedia.

- `ColumnImportances` – An array of [ColumnImportance](#) objects, not more than 100 structures.

A list of `ColumnImportance` structures containing column importance metrics, sorted in order of descending importance.

## ConfusionMatrix structure

The confusion matrix shows you what your transform is predicting accurately and what types of errors it is making.

For more information, see [Confusion matrix](#) in Wikipedia.

### Fields

- `NumTruePositives` – Number (long).

The number of matches in the data that the transform correctly found, in the confusion matrix for your transform.

- `NumFalsePositives` – Number (long).

The number of nonmatches in the data that the transform incorrectly classified as a match, in the confusion matrix for your transform.

- `NumTrueNegatives` – Number (long).

The number of nonmatches in the data that the transform correctly rejected, in the confusion matrix for your transform.

- `NumFalseNegatives` – Number (long).

The number of matches in the data that the transform didn't find, in the confusion matrix for your transform.

## GlueTable structure

The database and table in the AWS Glue Data Catalog that is used for input or output data.

## Fields

- **DatabaseName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A database name in the AWS Glue Data Catalog.

- **TableName** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A table name in the AWS Glue Data Catalog.

- **CatalogId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the AWS Glue Data Catalog.

- **ConnectionName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the connection to the AWS Glue Data Catalog.

- **AdditionalOptions** – A map array of key-value pairs, not less than 1 or more than 10 pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

Additional options for the table. Currently there are two keys supported:

- **pushDownPredicate**: to filter on partitions without having to list and read all the files in your dataset.
- **catalogPartitionPredicate**: to use server-side partition pruning using partition indexes in the AWS Glue Data Catalog.

## TaskRun structure

The sampling parameters that are associated with the machine learning transform.

## Fields

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the transform.

- `TaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for this task run.

- `Status` – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT).

The current status of the requested task run.

- `LogGroupName` – UTF-8 string.

The names of the log group for secure logging, associated with this task run.

- `Properties` – A [TaskRunProperties](#) object.

Specifies configuration properties associated with this task run.

- `ErrorString` – UTF-8 string.

The list of error strings associated with this task run.

- `StartedOn` – Timestamp.

The date and time that this task run started.

- `LastModifiedOn` – Timestamp.

The last point in time that the requested task run was updated.

- `CompletedOn` – Timestamp.

The last point in time that the requested task run was completed.

- `ExecutionTime` – Number (integer).

The amount of time (in seconds) that the task run consumed resources.

## TransformFilterCriteria structure

The criteria used to filter the machine learning transforms.

### Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique transform name that is used to filter the machine learning transforms.

- **TransformType** – UTF-8 string (valid values: FIND\_MATCHES).

The type of machine learning transform that is used to filter the machine learning transforms.

- **Status** – UTF-8 string (valid values: NOT\_READY | READY | DELETING).

Filters the list of machine learning transforms by the last known status of the transforms (to indicate whether a transform can be used or not). One of "NOT\_READY", "READY", or "DELETING".

- **GlueVersion** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

This value determines which version of AWS Glue this machine learning transform is compatible with. Glue 1.0 is recommended for most customers. If the value is not set, the Glue compatibility defaults to Glue 0.9. For more information, see [AWS Glue Versions](#) in the developer guide.

- **CreatedBefore** – Timestamp.

The time and date before which the transforms were created.

- **CreatedAfter** – Timestamp.

The time and date after which the transforms were created.

- **LastModifiedBefore** – Timestamp.

Filter on transforms last modified before this date.

- **LastModifiedAfter** – Timestamp.

Filter on transforms last modified after this date.

- **Schema** – An array of [SchemaColumn](#) objects, not more than 100 structures.

Filters on datasets with a specific schema. The Map<Column, Type> object is an array of key-value pairs representing the schema this transform accepts, where Column is the name of a

column, and Type is the type of the data such as an integer or string. Has an upper bound of 100 columns.

## TransformSortCriteria structure

The sorting criteria that are associated with the machine learning transform.

### Fields

- **Column** – *Required:* UTF-8 string (valid values: NAME | TRANSFORM\_TYPE | STATUS | CREATED | LAST\_MODIFIED).

The column to be used in the sorting criteria that are associated with the machine learning transform.

- **SortDirection** – *Required:* UTF-8 string (valid values: DESCENDING | ASCENDING).

The sort direction to be used in the sorting criteria that are associated with the machine learning transform.

## TaskRunFilterCriteria structure

The criteria that are used to filter the task runs for the machine learning transform.

### Fields

- **TaskRunType** – UTF-8 string (valid values: EVALUATION | LABELING\_SET\_GENERATION | IMPORT\_LABELS | EXPORT\_LABELS | FIND\_MATCHES).

The type of task run.

- **Status** – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT).

The current status of the task run.

- **StartedBefore** – Timestamp.

Filter on task runs started before this date.

- **StartedAfter** – Timestamp.

Filter on task runs started after this date.

## TaskRunSortCriteria structure

The sorting criteria that are used to sort the list of task runs for the machine learning transform.

### Fields

- **Column** – *Required:* UTF-8 string (valid values: TASK\_RUN\_TYPE | STATUS | STARTED).

The column to be used to sort the list of task runs for the machine learning transform.

- **SortDirection** – *Required:* UTF-8 string (valid values: DESCENDING | ASCENDING).

The sort direction to be used to sort the list of task runs for the machine learning transform.

## TaskRunProperties structure

The configuration properties for the task run.

### Fields

- **TaskType** – UTF-8 string (valid values: EVALUATION | LABELING\_SET\_GENERATION | IMPORT\_LABELS | EXPORT\_LABELS | FIND\_MATCHES).

The type of task run.

- **ImportLabelsTaskRunProperties** – An [ImportLabelsTaskRunProperties](#) object.

The configuration properties for an importing labels task run.

- **ExportLabelsTaskRunProperties** – An [ExportLabelsTaskRunProperties](#) object.

The configuration properties for an exporting labels task run.

- **LabelingSetGenerationTaskRunProperties** – A [LabelingSetGenerationTaskRunProperties](#) object.

The configuration properties for a labeling set generation task run.

- **FindMatchesTaskRunProperties** – A [FindMatchesTaskRunProperties](#) object.

The configuration properties for a find matches task run.

## FindMatchesTaskRunProperties structure

Specifies configuration properties for a Find Matches task run.

### Fields

- JobId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job ID for the Find Matches task run.

- JobName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name assigned to the job for the Find Matches task run.

- JobRunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job run ID for the Find Matches task run.

## ImportLabelsTaskRunProperties structure

Specifies configuration properties for an importing labels task run.

### Fields

- InputS3Path – UTF-8 string.

The Amazon Simple Storage Service (Amazon S3) path from where you will import the labels.

- Replace – Boolean.

Indicates whether to overwrite your existing labels.

## ExportLabelsTaskRunProperties structure

Specifies configuration properties for an exporting labels task run.

### Fields

- OutputS3Path – UTF-8 string.

The Amazon Simple Storage Service (Amazon S3) path where you will export the labels.

## LabelingSetGenerationTaskRunProperties structure

Specifies configuration properties for a labeling set generation task run.

### Fields

- `OutputS3Path` – UTF-8 string.

The Amazon Simple Storage Service (Amazon S3) path where you will generate the labeling set.

## SchemaColumn structure

A key-value pair representing a column and data type that this transform can run against. The `Schema` parameter of the `MLTransform` may contain up to 100 of these structures.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 1024 bytes long, matching the [Single-line string pattern](#).

The name of the column.

- `DataType` – UTF-8 string, not more than 131072 bytes long, matching the [Single-line string pattern](#).

The type of data in the column.

## TransformEncryption structure

The encryption-at-rest settings of the transform that apply to accessing user data. Machine learning transforms can access user data encrypted in Amazon S3 using KMS.

Additionally, imported labels and trained transforms can now be encrypted using a customer provided KMS key.

### Fields

- `MLUserDataEncryption` – A [MLUserDataEncryption](#) object.

An `MLUserDataEncryption` object containing the encryption mode and customer-provided KMS key ID.

- `TaskRunSecurityConfigurationName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the security configuration.

## MLUserDataEncryption structure

The encryption-at-rest settings of the transform that apply to accessing user data.

### Fields

- `MLUserDataEncryptionMode` – *Required*: UTF-8 string (valid values: DISABLED | SSE-KMS="SSEKMS").

The encryption mode applied to user data. Valid values are:

- `DISABLED`: encryption is disabled
- `SSEKMS`: use of server-side encryption with AWS Key Management Service (SSE-KMS) for user data stored in Amazon S3.
- `KmsKeyId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID for the customer-provided KMS key.

## ColumnImportance structure

A structure containing the column name and column importance score for a column.

Column importance helps you understand how columns contribute to your model, by identifying which columns in your records are more important than others.

### Fields

- `ColumnName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of a column.

- Importance – Number (double), not more than 1.0.

The column importance score for the column, as a decimal.

## Operations

- [CreateMLTransform action \(Python: create\\_ml\\_transform\)](#)
- [UpdateMLTransform action \(Python: update\\_ml\\_transform\)](#)
- [DeleteMLTransform action \(Python: delete\\_ml\\_transform\)](#)
- [GetMLTransform action \(Python: get\\_ml\\_transform\)](#)
- [GetMLTransforms action \(Python: get\\_ml\\_transforms\)](#)
- [ListMLTransforms action \(Python: list\\_ml\\_transforms\)](#)
- [StartMLEvaluationTaskRun action \(Python: start\\_ml\\_evaluation\\_task\\_run\)](#)
- [StartMLLabelingSetGenerationTaskRun action \(Python: start\\_ml\\_labeling\\_set\\_generation\\_task\\_run\)](#)
- [GetMLTaskRun action \(Python: get\\_ml\\_task\\_run\)](#)
- [GetMLTaskRuns action \(Python: get\\_ml\\_task\\_runs\)](#)
- [CancelMLTaskRun action \(Python: cancel\\_ml\\_task\\_run\)](#)
- [StartExportLabelsTaskRun action \(Python: start\\_export\\_labels\\_task\\_run\)](#)
- [StartImportLabelsTaskRun action \(Python: start\\_import\\_labels\\_task\\_run\)](#)

## CreateMLTransform action (Python: create\_ml\_transform)

Creates an AWS Glue machine learning transform. This operation creates the transform and all the necessary parameters to train it.

Call this operation as the first step in the process of using a machine learning transform (such as the FindMatches transform) for deduplicating data. You can provide an optional Description, in addition to the parameters that you want to use for your algorithm.

You must also specify certain parameters for the tasks that AWS Glue runs on your behalf as part of learning from your data and creating a high-quality machine learning transform. These parameters include Role, and optionally, AllocatedCapacity, Timeout, and MaxRetries. For more information, see [Jobs](#).

## Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique name that you give the transform when you create it.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the machine learning transform that is being defined. The default is an empty string.

- **InputRecordTables** – *Required:* An array of [GlueTable](#) objects, not more than 10 structures.

A list of AWS Glue table definitions used by the transform.

- **Parameters** – *Required:* A [TransformParameters](#) object.

The algorithmic parameters that are specific to the transform type used. Conditionally dependent on the transform type.

- **Role** – *Required:* UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role with the required permissions. The required permissions include both AWS Glue service role permissions to AWS Glue resources, and Amazon S3 permissions required by the transform.

- This role needs AWS Glue service role permissions to allow access to resources in AWS Glue. See [Attach a Policy to IAM Users That Access AWS Glue](#).
- This role needs permission to your Amazon Simple Storage Service (Amazon S3) sources, targets, temporary directory, scripts, and any libraries used by the task run for this transform.
- **GlueVersion** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

This value determines which version of AWS Glue this machine learning transform is compatible with. Glue 1.0 is recommended for most customers. If the value is not set, the Glue compatibility defaults to Glue 0.9. For more information, see [AWS Glue Versions](#) in the developer guide.

- **MaxCapacity** – Number (double).

The number of AWS Glue data processing units (DPUs) that are allocated to task runs for this transform. You can allocate from 2 to 100 DPUs; the default is 10. A DPU is a relative measure of

processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

`MaxCapacity` is a mutually exclusive option with `NumberOfWorkers` and `WorkerType`.

- If either `NumberOfWorkers` or `WorkerType` is set, then `MaxCapacity` cannot be set.
- If `MaxCapacity` is set then neither `NumberOfWorkers` or `WorkerType` can be set.
- If `WorkerType` is set, then `NumberOfWorkers` is required (and vice versa).
- `MaxCapacity` and `NumberOfWorkers` must both be at least 1.

When the `WorkerType` field is set to a value other than `Standard`, the `MaxCapacity` field is set automatically and becomes read-only.

When the `WorkerType` field is set to a value other than `Standard`, the `MaxCapacity` field is set automatically and becomes read-only.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when this task runs. Accepts a value of `Standard`, `G.1X`, or `G.2X`.

- For the `Standard` worker type, each worker provides 4 vCPU, 16 GB of memory and a 50GB disk, and 2 executors per worker.
- For the `G.1X` worker type, each worker provides 4 vCPU, 16 GB of memory and a 64GB disk, and 1 executor per worker.
- For the `G.2X` worker type, each worker provides 8 vCPU, 32 GB of memory and a 128GB disk, and 1 executor per worker.

`MaxCapacity` is a mutually exclusive option with `NumberOfWorkers` and `WorkerType`.

- If either `NumberOfWorkers` or `WorkerType` is set, then `MaxCapacity` cannot be set.
- If `MaxCapacity` is set then neither `NumberOfWorkers` or `WorkerType` can be set.
- If `WorkerType` is set, then `NumberOfWorkers` is required (and vice versa).
- `MaxCapacity` and `NumberOfWorkers` must both be at least 1.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when this task runs.

- **Timeout** – Number (integer), at least 1.

The timeout of the task run for this transform in minutes. This is the maximum time that a task run for this transform can consume resources before it is terminated and enters TIMEOUT status. The default is 2,880 minutes (48 hours).

- **MaxRetries** – Number (integer).

The maximum number of times to retry a task for this transform after a task run fails.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The tags to use with this machine learning transform. You may use tags to limit access to the machine learning transform. For more information about tags in AWS Glue, see [AWS Tags in AWS Glue](#) in the developer guide.

- **TransformEncryption** – A [TransformEncryption](#) object.

The encryption-at-rest settings of the transform that apply to accessing user data. Machine learning transforms can access user data encrypted in Amazon S3 using KMS.

## Response

- **TransformId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique identifier that is generated for the transform.

## Errors

- `AlreadyExistsException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `AccessDeniedException`
- `ResourceNumberLimitExceededException`

- `IdempotentParameterMismatchException`

## UpdateMLTransform action (Python: `update_ml_transform`)

Updates an existing machine learning transform. Call this operation to tune the algorithm parameters to achieve better results.

After calling this operation, you can call the `StartMLEvaluationTaskRun` operation to assess how well your new parameters achieved your goals (such as improving the quality of your machine learning transform, or making it more cost-effective).

### Request

- `TransformId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique identifier that was generated when the transform was created.

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique name that you gave the transform when you created it.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the transform. The default is an empty string.

- `Parameters` – A [TransformParameters](#) object.

The configuration parameters that are specific to the transform type (algorithm) used. Conditionally dependent on the transform type.

- `Role` – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role with the required permissions.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

This value determines which version of AWS Glue this machine learning transform is compatible with. Glue 1.0 is recommended for most customers. If the value is not set, the Glue compatibility defaults to Glue 0.9. For more information, see [AWS Glue Versions](#) in the developer guide.

- `MaxCapacity` – Number (double).

The number of AWS Glue data processing units (DPUs) that are allocated to task runs for this transform. You can allocate from 2 to 100 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

When the `WorkerType` field is set to a value other than `Standard`, the `MaxCapacity` field is set automatically and becomes read-only.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when this task runs. Accepts a value of `Standard`, `G.1X`, or `G.2X`.

- For the `Standard` worker type, each worker provides 4 vCPU, 16 GB of memory and a 50GB disk, and 2 executors per worker.
- For the `G.1X` worker type, each worker provides 4 vCPU, 16 GB of memory and a 64GB disk, and 1 executor per worker.
- For the `G.2X` worker type, each worker provides 8 vCPU, 32 GB of memory and a 128GB disk, and 1 executor per worker.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when this task runs.

- `Timeout` – Number (integer), at least 1.

The timeout for a task run for this transform in minutes. This is the maximum time that a task run for this transform can consume resources before it is terminated and enters `TIMEOUT` status. The default is 2,880 minutes (48 hours).

- `MaxRetries` – Number (integer).

The maximum number of times to retry a task for this transform after a task run fails.

## Response

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the transform that was updated.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `AccessDeniedException`

## DeleteMLTransform action (Python: `delete_ml_transform`)

Deletes an AWS Glue machine learning transform. Machine learning transforms are a special type of transform that use machine learning to learn the details of the transformation to be performed by learning from examples provided by humans. These transformations are then saved by AWS Glue. If you no longer need a transform, you can delete it by calling `DeleteMLTransforms`. However, any AWS Glue jobs that still reference the deleted transform will no longer succeed.

## Request

- `TransformId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the transform to delete.

## Response

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the transform that was deleted.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`

- `OperationTimeoutException`
- `InternalServiceException`

## GetMLTransform action (Python: `get_ml_transform`)

Gets an AWS Glue machine learning transform artifact and all its corresponding metadata. Machine learning transforms are a special type of transform that use machine learning to learn the details of the transformation to be performed by learning from examples provided by humans. These transformations are then saved by AWS Glue. You can retrieve their metadata by calling `GetMLTransform`.

### Request

- `TransformId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the transform, generated at the time that the transform was created.

### Response

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the transform, generated at the time that the transform was created.

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique name given to the transform when it was created.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the transform.

- `Status` – UTF-8 string (valid values: `NOT_READY` | `READY` | `DELETING`).

The last known status of the transform (to indicate whether it can be used or not). One of "NOT\_READY", "READY", or "DELETING".

- `CreatedOn` – Timestamp.

The date and time when the transform was created.

- `LastModifiedOn` – Timestamp.

The date and time when the transform was last modified.

- `InputRecordTables` – An array of [GlueTable](#) objects, not more than 10 structures.

A list of AWS Glue table definitions used by the transform.

- `Parameters` – A [TransformParameters](#) object.

The configuration parameters that are specific to the algorithm used.

- `EvaluationMetrics` – An [EvaluationMetrics](#) object.

The latest evaluation metrics.

- `LabelCount` – Number (integer).

The number of labels available for this transform.

- `Schema` – An array of [SchemaColumn](#) objects, not more than 100 structures.

The `Map<Column, Type>` object that represents the schema that this transform accepts. Has an upper bound of 100 columns.

- `Role` – UTF-8 string.

The name or Amazon Resource Name (ARN) of the IAM role with the required permissions.

- `GlueVersion` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Custom string pattern #20](#).

This value determines which version of AWS Glue this machine learning transform is compatible with. Glue 1.0 is recommended for most customers. If the value is not set, the Glue compatibility defaults to Glue 0.9. For more information, see [AWS Glue Versions](#) in the developer guide.

- `MaxCapacity` – Number (double).

The number of AWS Glue data processing units (DPUs) that are allocated to task runs for this transform. You can allocate from 2 to 100 DPUs; the default is 10. A DPU is a relative measure of processing power that consists of 4 vCPUs of compute capacity and 16 GB of memory. For more information, see the [AWS Glue pricing page](#).

When the `WorkerType` field is set to a value other than `Standard`, the `MaxCapacity` field is set automatically and becomes read-only.

- `WorkerType` – UTF-8 string (valid values: `Standard=""` | `G.1X=""` | `G.2X=""` | `G.025X=""` | `G.4X=""` | `G.8X=""` | `Z.2X=""`).

The type of predefined worker that is allocated when this task runs. Accepts a value of `Standard`, `G.1X`, or `G.2X`.

- For the `Standard` worker type, each worker provides 4 vCPU, 16 GB of memory and a 50GB disk, and 2 executors per worker.
- For the `G.1X` worker type, each worker provides 4 vCPU, 16 GB of memory and a 64GB disk, and 1 executor per worker.
- For the `G.2X` worker type, each worker provides 8 vCPU, 32 GB of memory and a 128GB disk, and 1 executor per worker.
- `NumberOfWorkers` – Number (integer).

The number of workers of a defined `workerType` that are allocated when this task runs.

- `Timeout` – Number (integer), at least 1.

The timeout for a task run for this transform in minutes. This is the maximum time that a task run for this transform can consume resources before it is terminated and enters `TIMEOUT` status. The default is 2,880 minutes (48 hours).

- `MaxRetries` – Number (integer).

The maximum number of times to retry a task for this transform after a task run fails.

- `TransformEncryption` – A [TransformEncryption](#) object.

The encryption-at-rest settings of the transform that apply to accessing user data. Machine learning transforms can access user data encrypted in Amazon S3 using KMS.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## GetMLTransforms action (Python: `get_ml_transforms`)

Gets a sortable, filterable list of existing AWS Glue machine learning transforms. Machine learning transforms are a special type of transform that use machine learning to learn the details of the transformation to be performed by learning from examples provided by humans. These transformations are then saved by AWS Glue, and you can retrieve their metadata by calling `GetMLTransforms`.

### Request

- `NextToken` – UTF-8 string.

A paginated token to offset the results.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `Filter` – A [TransformFilterCriteria](#) object.

The filter transformation criteria.

- `Sort` – A [TransformSortCriteria](#) object.

The sorting criteria.

### Response

- `Transforms` – *Required:* An array of [MLTransform](#) objects.

A list of machine learning transforms.

- `NextToken` – UTF-8 string.

A pagination token, if more results are available.

### Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## ListMLTransforms action (Python: list\_ml\_transforms)

Retrieves a sortable, filterable list of existing AWS Glue machine learning transforms in this AWS account, or the resources with the specified tag. This operation takes the optional Tags field, which you can use as a filter of the responses so that tagged resources can be retrieved as a group. If you choose to use tag filtering, only resources with the tags are retrieved.

### Request

- `NextToken` – UTF-8 string.

A continuation token, if this is a continuation request.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum size of a list to return.

- `Filter` – A [TransformFilterCriteria](#) object.

A `TransformFilterCriteria` used to filter the machine learning transforms.

- `Sort` – A [TransformSortCriteria](#) object.

A `TransformSortCriteria` used to sort the machine learning transforms.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Specifies to return only these tagged resources.

### Response

- `TransformIds` – *Required:* An array of UTF-8 strings.

The identifiers of all the machine learning transforms in the account, or the machine learning transforms with the specified tags.

- `NextToken` – UTF-8 string.

A continuation token, if the returned list does not contain the last metric available.

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException

## StartMLEvaluationTaskRun action (Python: start\_ml\_evaluation\_task\_run)

Starts a task to estimate the quality of the transform.

When you provide label sets as examples of truth, AWS Glue machine learning uses some of those examples to learn from them. The rest of the labels are used as a test to estimate quality.

Returns a unique identifier for the run. You can call GetMLTaskRun to get more information about the stats of the EvaluationTaskRun.

### Request

- TransformId – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

### Response

- TaskRunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier associated with this run.

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException

- `InternalServiceException`
- `ConcurrentRunsExceededException`
- `MLTransformNotReadyException`

## StartMLLabelingSetGenerationTaskRun action (Python: `start_ml_labeling_set_generation_task_run`)

Starts the active learning workflow for your machine learning transform to improve the transform's quality by generating label sets and adding labels.

When the `StartMLLabelingSetGenerationTaskRun` finishes, AWS Glue will have generated a "labeling set" or a set of questions for humans to answer.

In the case of the `FindMatches` transform, these questions are of the form, "What is the correct way to group these rows together into groups composed entirely of matching records?"

After the labeling process is finished, you can upload your labels with a call to `StartImportLabelsTaskRun`. After `StartImportLabelsTaskRun` finishes, all future runs of the machine learning transform will use the new and improved labels and perform a higher-quality transformation.

### Request

- `TransformId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `OutputS3Path` – *Required*: UTF-8 string.

The Amazon Simple Storage Service (Amazon S3) path where you generate the labeling set.

### Response

- `TaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier that is associated with this task run.

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException
- ConcurrentRunsExceededException

## GetMLTaskRun action (Python: `get_ml_task_run`)

Gets details for a specific task run on a machine learning transform. Machine learning task runs are asynchronous tasks that AWS Glue runs on your behalf as part of various machine learning workflows. You can check the stats of any task run by calling `GetMLTaskRun` with the `TaskRunID` and its parent transform's `TransformID`.

### Request

- `TransformId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `TaskRunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the task run.

### Response

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the task run.

- `TaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

- **Status** – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT).

The status for this task run.

- **LogGroupName** – UTF-8 string.

The names of the log groups that are associated with the task run.

- **Properties** – A [TaskRunProperties](#) object.

The list of properties that are associated with the task run.

- **ErrorString** – UTF-8 string.

The error strings that are associated with the task run.

- **StartedOn** – Timestamp.

The date and time when this task run started.

- **LastModifiedOn** – Timestamp.

The date and time when this task run was last modified.

- **CompletedOn** – Timestamp.

The date and time when this task run was completed.

- **ExecutionTime** – Number (integer).

The amount of time (in seconds) that the task run consumed resources.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## GetMLTaskRuns action (Python: `get_ml_task_runs`)

Gets a list of runs for a machine learning transform. Machine learning task runs are asynchronous tasks that AWS Glue runs on your behalf as part of various machine learning workflows. You can

get a sortable, filterable list of machine learning task runs by calling `GetMLTaskRuns` with their parent transform's `TransformID` and other optional parameters as documented in this section.

This operation returns a list of historic runs and must be paginated.

## Request

- `TransformId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `NextToken` – UTF-8 string.

A token for pagination of the results. The default is empty.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `Filter` – A [TaskRunFilterCriteria](#) object.

The filter criteria, in the `TaskRunFilterCriteria` structure, for the task run.

- `Sort` – A [TaskRunSortCriteria](#) object.

The sorting criteria, in the `TaskRunSortCriteria` structure, for the task run.

## Response

- `TaskRuns` – An array of [TaskRun](#) objects.

A list of task runs that are associated with the transform.

- `NextToken` – UTF-8 string.

A pagination token, if more results are available.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`

- `InternalServiceException`

## CancelMLTaskRun action (Python: `cancel_ml_task_run`)

Cancels (stops) a task run. Machine learning task runs are asynchronous tasks that AWS Glue runs on your behalf as part of various machine learning workflows. You can cancel a machine learning task run at any time by calling `CancelMLTaskRun` with a task run's parent transform's `TransformID` and the task run's `TaskRunId`.

### Request

- `TransformId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `TaskRunId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique identifier for the task run.

### Response

- `TransformId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `TaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the task run.

- `Status` – UTF-8 string (valid values: `STARTING` | `RUNNING` | `STOPPING` | `STOPPED` | `SUCCEEDED` | `FAILED` | `TIMEOUT`).

The status for this run.

### Errors

- `EntityNotFoundException`

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## StartExportLabelsTaskRun action (Python: `start_export_labels_task_run`)

Begins an asynchronous task to export all labeled data for a particular transform. This task is the only label-related API call that is not part of the typical active learning workflow. You typically use `StartExportLabelsTaskRun` when you want to work with all of your existing labels at the same time, such as when you want to remove or change labels that were previously submitted as truth. This API operation accepts the `TransformId` whose labels you want to export and an Amazon Simple Storage Service (Amazon S3) path to export the labels to. The operation returns a `TaskRunId`. You can check on the status of your task run by calling the `GetMLTaskRun` API.

### Request

- `TransformId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `OutputS3Path` – *Required:* UTF-8 string.

The Amazon S3 path where you export the labels.

### Response

- `TaskRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the task run.

### Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`

- `InternalServiceException`

## StartImportLabelsTaskRun action (Python: `start_import_labels_task_run`)

Enables you to provide additional labels (examples of truth) to be used to teach the machine learning transform and improve its quality. This API operation is generally used as part of the active learning workflow that starts with the `StartMLLabelingSetGenerationTaskRun` call and that ultimately results in improving the quality of your machine learning transform.

After the `StartMLLabelingSetGenerationTaskRun` finishes, AWS Glue machine learning will have generated a series of questions for humans to answer. (Answering these questions is often called 'labeling' in the machine learning workflows). In the case of the `FindMatches` transform, these questions are of the form, "What is the correct way to group these rows together into groups composed entirely of matching records?" After the labeling process is finished, users upload their answers/labels with a call to `StartImportLabelsTaskRun`. After `StartImportLabelsTaskRun` finishes, all future runs of the machine learning transform use the new and improved labels and perform a higher-quality transformation.

By default, `StartMLLabelingSetGenerationTaskRun` continually learns from and combines all labels that you upload unless you set `Replace` to true. If you set `Replace` to true, `StartImportLabelsTaskRun` deletes and forgets all previously uploaded labels and learns only from the exact set that you upload. Replacing labels can be helpful if you realize that you previously uploaded incorrect labels, and you believe that they are having a negative effect on your transform quality.

You can check on the status of your task run by calling the `GetMLTaskRun` operation.

### Request

- `TransformId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier of the machine learning transform.

- `InputS3Path` – *Required*: UTF-8 string.

The Amazon Simple Storage Service (Amazon S3) path from where you import the labels.

- `ReplaceAllLabels` – Boolean.

Indicates whether to overwrite your existing labels.

## Response

- TaskRunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique identifier for the task run.

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- ResourceNumberLimitExceededException
- InternalServiceException

# Data Quality API

The Data Quality API describes the data quality data types, and includes the API for creating, deleting, or updating data quality rulesets, runs and evaluations.

## Data types

- [DataSource structure](#)
- [DataQualityRulesetListDetails structure](#)
- [DataQualityTargetTable structure](#)
- [DataQualityRulesetEvaluationRunDescription structure](#)
- [DataQualityRulesetEvaluationRunFilter structure](#)
- [DataQualityEvaluationRunAdditionalRunOptions structure](#)
- [DataQualityRuleRecommendationRunDescription structure](#)
- [DataQualityRuleRecommendationRunFilter structure](#)
- [DataQualityResult structure](#)

- [DataQualityAnalyzerResult structure](#)
- [DataQualityObservation structure](#)
- [MetricBasedObservation structure](#)
- [DataQualityMetricValues structure](#)
- [DataQualityRuleResult structure](#)
- [DataQualityResultDescription structure](#)
- [DataQualityResultFilterCriteria structure](#)
- [DataQualityRulesetFilterCriteria structure](#)

## DataSource structure

A data source (an AWS Glue table) for which you want data quality results.

### Fields

- `GlueTable` – *Required:* A [GlueTable](#) object.

An AWS Glue table.

## DataQualityRulesetListDetails structure

Describes a data quality ruleset returned by `GetDataQualityRuleset`.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the data quality ruleset.

- `Description` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the data quality ruleset.

- `CreatedOn` – Timestamp.

The date and time the data quality ruleset was created.

- `LastModifiedOn` – Timestamp.

The date and time the data quality ruleset was last modified.

- `TargetTable` – A [DataQualityTargetTable](#) object.

An object representing an AWS Glue table.

- `RecommendationRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

When a ruleset was created from a recommendation run, this run ID is generated to link the two together.

- `RuleCount` – Number (integer).

The number of rules in the ruleset.

## DataQualityTargetTable structure

An object representing an AWS Glue table.

### Fields

- `TableName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the AWS Glue table.

- `DatabaseName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the database where the AWS Glue table exists.

- `CatalogId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The catalog id where the AWS Glue table exists.

## DataQualityRulesetEvaluationRunDescription structure

Describes the result of a data quality ruleset evaluation run.

## Fields

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

- `Status` – UTF-8 string (valid values: `STARTING` | `RUNNING` | `STOPPING` | `STOPPED` | `SUCCEEDED` | `FAILED` | `TIMEOUT`).

The status for this run.

- `StartedOn` – Timestamp.

The date and time when the run started.

- `DataSource` – A [DataSource](#) object.

The data source (an AWS Glue table) associated with the run.

## DataQualityRulesetEvaluationRunFilter structure

The filter criteria.

### Fields

- `DataSource` – *Required:* A [DataSource](#) object.

Filter based on a data source (an AWS Glue table) associated with the run.

- `StartedBefore` – Timestamp.

Filter results by runs that started before this time.

- `StartedAfter` – Timestamp.

Filter results by runs that started after this time.

## DataQualityEvaluationRunAdditionalRunOptions structure

Additional run options you can specify for an evaluation run.

## Fields

- `CloudWatchMetricsEnabled` – Boolean.  
Whether or not to enable CloudWatch metrics.
- `ResultsS3Prefix` – UTF-8 string.  
Prefix for Amazon S3 to store results.

## DataQualityRuleRecommendationRunDescription structure

Describes the result of a data quality rule recommendation run.

### Fields

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).  
The unique run identifier associated with this run.
- `Status` – UTF-8 string (valid values: `STARTING` | `RUNNING` | `STOPPING` | `STOPPED` | `SUCCEEDED` | `FAILED` | `TIMEOUT`).  
The status for this run.
- `StartedOn` – Timestamp.  
The date and time when this run started.
- `DataSource` – A [DataSource](#) object.  
The data source (AWS Glue table) associated with the recommendation run.

## DataQualityRuleRecommendationRunFilter structure

A filter for listing data quality recommendation runs.

### Fields

- `DataSource` – *Required:* A [DataSource](#) object.  
Filter based on a specified data source (AWS Glue table).

- `StartedBefore` – Timestamp.  
Filter based on time for results started before provided time.
- `StartedAfter` – Timestamp.  
Filter based on time for results started after provided time.

## DataQualityResult structure

Describes a data quality result.

### Fields

- `ResultId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).  
A unique result ID for the data quality result.
- `Score` – Number (double), not more than 1.0.  
An aggregate data quality score. Represents the ratio of rules that passed to the total number of rules.
- `DataSource` – A [DataSource](#) object.  
The table associated with the data quality result, if any.
- `RulesetName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).  
The name of the ruleset associated with the data quality result.
- `EvaluationContext` – UTF-8 string.  
In the context of a job in AWS Glue Studio, each node in the canvas is typically assigned some sort of name and data quality nodes will have names. In the case of multiple nodes, the `evaluationContext` can differentiate the nodes.
- `StartedOn` – Timestamp.  
The date and time when this data quality run started.
- `CompletedOn` – Timestamp.  
The date and time when this data quality run completed.

- **JobName** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job name associated with the data quality result, if any.

- **JobRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job run ID associated with the data quality result, if any.

- **RulesetEvaluationRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run ID for the ruleset evaluation for this data quality result.

- **RuleResults** – An array of [DataQualityRuleResult](#) objects, not more than 2000 structures.

A list of [DataQualityRuleResult](#) objects representing the results for each rule.

- **AnalyzerResults** – An array of [DataQualityAnalyzerResult](#) objects, not more than 2000 structures.

A list of [DataQualityAnalyzerResult](#) objects representing the results for each analyzer.

- **Observations** – An array of [DataQualityObservation](#) objects, not more than 50 structures.

A list of [DataQualityObservation](#) objects representing the observations generated after evaluating the rules and analyzers.

## DataQualityAnalyzerResult structure

Describes the result of the evaluation of a data quality analyzer.

### Fields

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the data quality analyzer.

- **Description** – UTF-8 string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the data quality analyzer.

- `EvaluationMessage` – UTF-8 string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

An evaluation message.

- `EvaluatedMetrics` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a Number (double).

A map of metrics associated with the evaluation of the analyzer.

## DataQualityObservation structure

Describes the observation generated after evaluating the rules and analyzers.

### Fields

- `Description` – UTF-8 string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the data quality observation.

- `MetricBasedObservation` – A [MetricBasedObservation](#) object.

An object of type `MetricBasedObservation` representing the observation that is based on evaluated data quality metrics.

## MetricBasedObservation structure

Describes the metric based observation generated based on evaluated data quality metrics.

### Fields

- `MetricName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the data quality metric used for generating the observation.

- `MetricValues` – A [DataQualityMetricValues](#) object.

An object of type `DataQualityMetricValues` representing the analysis of the data quality metric value.

- `NewRules` – An array of UTF-8 strings.

A list of new data quality rules generated as part of the observation based on the data quality metric value.

## DataQualityMetricValues structure

Describes the data quality metric value according to the analysis of historical data.

### Fields

- `ActualValue` – Number (double).

The actual value of the data quality metric.

- `ExpectedValue` – Number (double).

The expected value of the data quality metric according to the analysis of historical data.

- `LowerLimit` – Number (double).

The lower limit of the data quality metric value according to the analysis of historical data.

- `UpperLimit` – Number (double).

The upper limit of the data quality metric value according to the analysis of historical data.

## DataQualityRuleResult structure

Describes the result of the evaluation of a data quality rule.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the data quality rule.

- `Description` – UTF-8 string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the data quality rule.

- `EvaluationMessage` – UTF-8 string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

An evaluation message.

- `Result` – UTF-8 string (valid values: PASS | FAIL | ERROR).

A pass or fail status for the rule.

- `EvaluatedMetrics` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a Number (double).

A map of metrics associated with the evaluation of the rule.

## DataQualityResultDescription structure

Describes a data quality result.

### Fields

- `ResultId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique result ID for this data quality result.

- `DataSource` – A [DataSource](#) object.

The table name associated with the data quality result.

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job name associated with the data quality result.

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job run ID associated with the data quality result.

- `StartedOn` – Timestamp.

The time that the run started for this data quality result.

## DataQualityResultFilterCriteria structure

Criteria used to return data quality results.

### Fields

- `DataSource` – A [DataSource](#) object.

Filter results by the specified data source. For example, retrieving all results for an AWS Glue table.

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Filter results by the specified job name.

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Filter results by the specified job run ID.

- `StartedAfter` – Timestamp.

Filter results by runs that started after this time.

- `StartedBefore` – Timestamp.

Filter results by runs that started before this time.

## DataQualityRulesetFilterCriteria structure

The criteria used to filter data quality rulesets.

### Fields

- `Name` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the ruleset filter criteria.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

The description of the ruleset filter criteria.

- **CreatedBefore** – Timestamp.

Filter on rulesets created before this date.

- **CreatedAfter** – Timestamp.

Filter on rulesets created after this date.

- **LastModifiedBefore** – Timestamp.

Filter on rulesets last modified before this date.

- **LastModifiedAfter** – Timestamp.

Filter on rulesets last modified after this date.

- **TargetTable** – A [DataQualityTargetTable](#) object.

The name and database name of the target table.

## Operations

- [StartDataQualityRulesetEvaluationRun](#) action (Python: [start\\_data\\_quality\\_ruleset\\_evaluation\\_run](#))
- [CancelDataQualityRulesetEvaluationRun](#) action (Python: [cancel\\_data\\_quality\\_ruleset\\_evaluation\\_run](#))
- [GetDataQualityRulesetEvaluationRun](#) action (Python: [get\\_data\\_quality\\_ruleset\\_evaluation\\_run](#))
- [ListDataQualityRulesetEvaluationRuns](#) action (Python: [list\\_data\\_quality\\_ruleset\\_evaluation\\_runs](#))
- [StartDataQualityRuleRecommendationRun](#) action (Python: [start\\_data\\_quality\\_rule\\_recommendation\\_run](#))
- [CancelDataQualityRuleRecommendationRun](#) action (Python: [cancel\\_data\\_quality\\_rule\\_recommendation\\_run](#))
- [GetDataQualityRuleRecommendationRun](#) action (Python: [get\\_data\\_quality\\_rule\\_recommendation\\_run](#))
- [ListDataQualityRuleRecommendationRuns](#) action (Python: [list\\_data\\_quality\\_rule\\_recommendation\\_runs](#))

- [GetDataQualityResult](#) action (Python: `get_data_quality_result`)
- [BatchGetDataQualityResult](#) action (Python: `batch_get_data_quality_result`)
- [ListDataQualityResults](#) action (Python: `list_data_quality_results`)
- [CreateDataQualityRuleset](#) action (Python: `create_data_quality_ruleset`)
- [DeleteDataQualityRuleset](#) action (Python: `delete_data_quality_ruleset`)
- [GetDataQualityRuleset](#) action (Python: `get_data_quality_ruleset`)
- [ListDataQualityRulesets](#) action (Python: `list_data_quality_rulesets`)
- [UpdateDataQualityRuleset](#) action (Python: `update_data_quality_ruleset`)

## **StartDataQualityRulesetEvaluationRun** action (Python: `start_data_quality_ruleset_evaluation_run`)

Once you have a ruleset definition (either recommended or your own), you call this operation to evaluate the ruleset against a data source (AWS Glue table). The evaluation computes results which you can retrieve with the `GetDataQualityResult` API.

### **Request**

- `DataSource` – *Required:* A [DataSource](#) object.

The data source (AWS Glue table) associated with this run.

- `Role` – *Required:* UTF-8 string.

An IAM role supplied to encrypt the results of the run.

- `NumberOfWorkers` – Number (integer).

The number of G.1X workers to be used in the run. The default is 5.

- `Timeout` – Number (integer), at least 1.

The timeout for a run in minutes. This is the maximum time that a run can consume resources before it is terminated and enters `TIMEOUT` status. The default is 2,880 minutes (48 hours).

- `ClientToken` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Used for idempotency and is recommended to be set to a random ID (such as a UUID) to avoid creating or starting multiple instances of the same resource.

- `AdditionalRunOptions` – A [DataQualityEvaluationRunAdditionalRunOptions](#) object.

Additional run options you can specify for an evaluation run.

- `RulesetNames` – *Required*: An array of UTF-8 strings, not less than 1 or more than 10 strings.

A list of ruleset names.

- `AdditionalDataSources` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a [DataSource](#) object.

A map of reference strings to additional data sources you can specify for an evaluation run.

## Response

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

## Errors

- `InvalidInputException`
- `EntityNotFoundException`
- `OperationTimeoutException`
- `InternalServiceException`
- `ConflictException`

## CancelDataQualityRulesetEvaluationRun action (Python: `cancel_data_quality_ruleset_evaluation_run`)

Cancels a run where a ruleset is being evaluated against a data source.

## Request

- RunId – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException

## GetDataQualityRulesetEvaluationRun action (Python: `get_data_quality_ruleset_evaluation_run`)

Retrieves a specific run where a ruleset is evaluated against a data source.

## Request

- RunId – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

## Response

- RunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

- DataSource – A [DataSource](#) object.

The data source (an AWS Glue table) associated with this evaluation run.

- `Role` – UTF-8 string.

An IAM role supplied to encrypt the results of the run.

- `NumberOfWorkers` – Number (integer).

The number of G.1X workers to be used in the run. The default is 5.

- `Timeout` – Number (integer), at least 1.

The timeout for a run in minutes. This is the maximum time that a run can consume resources before it is terminated and enters `TIMEOUT` status. The default is 2,880 minutes (48 hours).

- `AdditionalRunOptions` – A [DataQualityEvaluationRunAdditionalRunOptions](#) object.

Additional run options you can specify for an evaluation run.

- `Status` – UTF-8 string (valid values: `STARTING` | `RUNNING` | `STOPPING` | `STOPPED` | `SUCCEEDED` | `FAILED` | `TIMEOUT`).

The status for this run.

- `ErrorString` – UTF-8 string.

The error strings that are associated with the run.

- `StartedOn` – Timestamp.

The date and time when this run started.

- `LastModifiedOn` – Timestamp.

A timestamp. The last point in time when this data quality rule recommendation run was modified.

- `CompletedOn` – Timestamp.

The date and time when this run was completed.

- `ExecutionTime` – Number (integer).

The amount of time (in seconds) that the run consumed resources.

- `RulesetNames` – An array of UTF-8 strings, not less than 1 or more than 10 strings.

A list of ruleset names for the run. Currently, this parameter takes only one Ruleset name.

- `ResultIds` – An array of UTF-8 strings, not less than 1 or more than 10 strings.

A list of result IDs for the data quality results for the run.

- `AdditionalDataSources` – A map array of key-value pairs.

Each key is a UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Each value is a A [DataSource](#) object.

A map of reference strings to additional data sources you can specify for an evaluation run.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## ListDataQualityRulesetEvaluationRuns action (Python: `list_data_quality_ruleset_evaluation_runs`)

Lists all the runs meeting the filter criteria, where a ruleset is evaluated against a data source.

### Request

- `Filter` – A [DataQualityRulesetEvaluationRunFilter](#) object.

The filter criteria.

- `NextToken` – UTF-8 string.

A paginated token to offset the results.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

## Response

- **Runs** – An array of [DataQualityRulesetEvaluationRunDescription](#) objects.

A list of `DataQualityRulesetEvaluationRunDescription` objects representing data quality ruleset runs.

- **NextToken** – UTF-8 string.

A pagination token, if more results are available.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## StartDataQualityRuleRecommendationRun action (Python: `start_data_quality_rule_recommendation_run`)

Starts a recommendation run that is used to generate rules when you don't know what rules to write. AWS Glue Data Quality analyzes the data and comes up with recommendations for a potential ruleset. You can then triage the ruleset and modify the generated ruleset to your liking.

Recommendation runs are automatically deleted after 90 days.

## Request

- **DataSource** – *Required:* A [DataSource](#) object.

The data source (AWS Glue table) associated with this run.

- **Role** – *Required:* UTF-8 string.

An IAM role supplied to encrypt the results of the run.

- **NumberOfWorkers** – Number (integer).

The number of G.1X workers to be used in the run. The default is 5.

- **Timeout** – Number (integer), at least 1.

The timeout for a run in minutes. This is the maximum time that a run can consume resources before it is terminated and enters TIMEOUT status. The default is 2,880 minutes (48 hours).

- `CreatedRulesetName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A name for the ruleset.

- `ClientToken` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Used for idempotency and is recommended to be set to a random ID (such as a UUID) to avoid creating or starting multiple instances of the same resource.

## Response

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `ConflictException`

## CancelDataQualityRuleRecommendationRun action (Python: `cancel_data_quality_rule_recommendation_run`)

Cancels the specified recommendation run that was being used to generate rules.

## Request

- `RunId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

## Response

- *No Response parameters.*

## Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException

## GetDataQualityRuleRecommendationRun action (Python: `get_data_quality_rule_recommendation_run`)

Gets the specified recommendation run that was used to generate rules.

## Request

- `RunId` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

## Response

- `RunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run identifier associated with this run.

- `DataSource` – A [DataSource](#) object.

The data source (an AWS Glue table) associated with this run.

- `Role` – UTF-8 string.

An IAM role supplied to encrypt the results of the run.

- `NumberOfWorkers` – Number (integer).

The number of G.1X workers to be used in the run. The default is 5.

- `Timeout` – Number (integer), at least 1.

The timeout for a run in minutes. This is the maximum time that a run can consume resources before it is terminated and enters TIMEOUT status. The default is 2,880 minutes (48 hours).

- `Status` – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT).

The status for this run.

- `ErrorString` – UTF-8 string.

The error strings that are associated with the run.

- `StartedOn` – Timestamp.

The date and time when this run started.

- `LastModifiedOn` – Timestamp.

A timestamp. The last point in time when this data quality rule recommendation run was modified.

- `CompletedOn` – Timestamp.

The date and time when this run was completed.

- `ExecutionTime` – Number (integer).

The amount of time (in seconds) that the run consumed resources.

- `RecommendedRuleset` – UTF-8 string, not less than 1 or more than 65536 bytes long.

When a start rule recommendation run completes, it creates a recommended ruleset (a set of rules). This member has those rules in Data Quality Definition Language (DQDL) format.

- `CreatedRulesetName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the ruleset that was created by the run.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## ListDataQualityRuleRecommendationRuns action (Python: `list_data_quality_rule_recommendation_runs`)

Lists the recommendation runs meeting the filter criteria.

### Request

- `Filter` – A [DataQualityRuleRecommendationRunFilter](#) object.

The filter criteria.

- `NextToken` – UTF-8 string.

A paginated token to offset the results.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

### Response

- `Runs` – An array of [DataQualityRuleRecommendationRunDescription](#) objects.

A list of `DataQualityRuleRecommendationRunDescription` objects.

- `NextToken` – UTF-8 string.

A pagination token, if more results are available.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`

- `InternalServiceException`

## GetDataQualityResult action (Python: `get_data_quality_result`)

Retrieves the result of a data quality rule evaluation.

### Request

- `ResultId` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique result ID for the data quality result.

### Response

- `ResultId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique result ID for the data quality result.

- `Score` – Number (double), not more than 1.0.

An aggregate data quality score. Represents the ratio of rules that passed to the total number of rules.

- `DataSource` – A [DataSource](#) object.

The table associated with the data quality result, if any.

- `RulesetName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the ruleset associated with the data quality result.

- `EvaluationContext` – UTF-8 string.

In the context of a job in AWS Glue Studio, each node in the canvas is typically assigned some sort of name and data quality nodes will have names. In the case of multiple nodes, the `evaluationContext` can differentiate the nodes.

- `StartedOn` – Timestamp.

The date and time when the run for this data quality result started.

- `CompletedOn` – Timestamp.

The date and time when the run for this data quality result was completed.

- `JobName` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job name associated with the data quality result, if any.

- `JobRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The job run ID associated with the data quality result, if any.

- `RulesetEvaluationRunId` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The unique run ID associated with the ruleset evaluation.

- `RuleResults` – An array of [DataQualityRuleResult](#) objects, not more than 2000 structures.

A list of `DataQualityRuleResult` objects representing the results for each rule.

- `AnalyzerResults` – An array of [DataQualityAnalyzerResult](#) objects, not more than 2000 structures.

A list of `DataQualityAnalyzerResult` objects representing the results for each analyzer.

- `Observations` – An array of [DataQualityObservation](#) objects, not more than 50 structures.

A list of `DataQualityObservation` objects representing the observations generated after evaluating the rules and analyzers.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `EntityNotFoundException`

## BatchGetDataQualityResult action (Python: `batch_get_data_quality_result`)

Retrieves a list of data quality results for the specified result IDs.

### Request

- `ResultIds` – *Required:* An array of UTF-8 strings, not less than 1 or more than 100 strings.

A list of unique result IDs for the data quality results.

### Response

- `Results` – *Required:* An array of [DataQualityResult](#) objects.

A list of `DataQualityResult` objects representing the data quality results.

- `ResultsNotFound` – An array of UTF-8 strings, not less than 1 or more than 100 strings.

A list of result IDs for which results were not found.

### Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## ListDataQualityResults action (Python: `list_data_quality_results`)

Returns all data quality execution results for your account.

### Request

- `Filter` – A [DataQualityResultFilterCriteria](#) object.

The filter criteria.

- `NextToken` – UTF-8 string.

A paginated token to offset the results.

- **MaxResults** – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

## Response

- **Results** – *Required*: An array of [DataQualityResultDescription](#) objects.

A list of `DataQualityResultDescription` objects.

- **NextToken** – UTF-8 string.

A pagination token, if more results are available.

## Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## CreateDataQualityRuleset action (Python: `create_data_quality_ruleset`)

Creates a data quality ruleset with DQDL rules applied to a specified AWS Glue table.

You create the ruleset using the Data Quality Definition Language (DQDL). For more information, see the AWS Glue developer guide.

## Request

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique name for the data quality ruleset.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the data quality ruleset.

- **Ruleset** – *Required*: UTF-8 string, not less than 1 or more than 65536 bytes long.

A Data Quality Definition Language (DQDL) ruleset. For more information, see the AWS Glue developer guide.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

A list of tags applied to the data quality ruleset.

- **TargetTable** – A [DataQualityTargetTable](#) object.

A target table associated with the data quality ruleset.

- **RecommendationRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique run ID for the recommendation run.

- **ClientToken** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Used for idempotency and is recommended to be set to a random ID (such as a UUID) to avoid creating or starting multiple instances of the same resource.

## Response

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A unique name for the data quality ruleset.

## Errors

- `InvalidInputException`
- `AlreadyExistsException`
- `OperationTimeoutException`
- `InternalServiceException`
- `ResourceNumberLimitExceededException`

## DeleteDataQualityRuleset action (Python: delete\_data\_quality\_ruleset)

Deletes a data quality ruleset.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A name for the data quality ruleset.

### Response

- *No Response parameters.*

### Errors

- EntityNotFoundException
- InvalidInputException
- OperationTimeoutException
- InternalServiceException

## GetDataQualityRuleset action (Python: get\_data\_quality\_ruleset)

Returns an existing ruleset by identifier or name.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the ruleset.

### Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the ruleset.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the ruleset.

- **Ruleset** – UTF-8 string, not less than 1 or more than 65536 bytes long.

A Data Quality Definition Language (DQDL) ruleset. For more information, see the AWS Glue developer guide.

- **TargetTable** – A [DataQualityTargetTable](#) object.

The name and database name of the target table.

- **CreatedOn** – Timestamp.

A timestamp. The time and date that this data quality ruleset was created.

- **LastModifiedOn** – Timestamp.

A timestamp. The last point in time when this data quality ruleset was modified.

- **RecommendationRunId** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

When a ruleset was created from a recommendation run, this run ID is generated to link the two together.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## ListDataQualityRulesets action (Python: `list_data_quality_rulesets`)

Returns a paginated list of rulesets for the specified list of AWS Glue tables.

## Request

- `NextToken` – UTF-8 string.

A paginated token to offset the results.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `Filter` – A [DataQualityRulesetFilterCriteria](#) object.

The filter criteria.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

A list of key-value pair tags.

## Response

- `Rulesets` – An array of [DataQualityRulesetListDetails](#) objects.

A paginated list of rulesets for the specified list of AWS Glue tables.

- `NextToken` – UTF-8 string.

A pagination token, if more results are available.

## Errors

- `EntityNotFoundException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`

## UpdateDataQualityRuleset action (Python: update\_data\_quality\_ruleset)

Updates the specified data quality ruleset.

### Request

- **Name** – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the data quality ruleset.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the ruleset.

- **Ruleset** – UTF-8 string, not less than 1 or more than 65536 bytes long.

A Data Quality Definition Language (DQDL) ruleset. For more information, see the AWS Glue developer guide.

### Response

- **Name** – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the data quality ruleset.

- **Description** – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A description of the ruleset.

- **Ruleset** – UTF-8 string, not less than 1 or more than 65536 bytes long.

A Data Quality Definition Language (DQDL) ruleset. For more information, see the AWS Glue developer guide.

### Errors

- `EntityNotFoundException`

- `AlreadyExistsException`
- `IdempotentParameterMismatchException`
- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServiceException`
- `ResourceNumberLimitExceededException`

## Sensitive data detection API

The Sensitive data detection API describes the APIs used to detect sensitive data across the columns and rows of your structured data.

### Data types

- [CustomEntityType structure](#)

### CustomEntityType structure

An object representing a custom pattern for detecting sensitive data across the columns and rows of your structured data.

#### Fields

- `Name` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A name for the custom pattern that allows it to be retrieved or deleted later. This name must be unique per AWS account.

- `RegexString` – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A regular expression string that is used for detecting sensitive data in a custom pattern.

- `ContextWords` – An array of UTF-8 strings, not less than 1 or more than 20 strings.

A list of context words. If none of these context words are found within the vicinity of the regular expression the data will not be detected as sensitive data.

If no context words are passed only a regular expression is checked.

## Operations

- [CreateCustomEntityType action \(Python: create\\_custom\\_entity\\_type\)](#)
- [DeleteCustomEntityType action \(Python: delete\\_custom\\_entity\\_type\)](#)
- [GetCustomEntityType action \(Python: get\\_custom\\_entity\\_type\)](#)
- [BatchGetCustomEntityTypes action \(Python: batch\\_get\\_custom\\_entity\\_types\)](#)
- [ListCustomEntityTypes action \(Python: list\\_custom\\_entity\\_types\)](#)

### CreateCustomEntityType action (Python: create\_custom\_entity\_type)

Creates a custom pattern that is used to detect sensitive data across the columns and rows of your structured data.

Each custom pattern you create specifies a regular expression and an optional list of context words. If no context words are passed only a regular expression is checked.

#### Request

- **Name** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A name for the custom pattern that allows it to be retrieved or deleted later. This name must be unique per AWS account.

- **RegexString** – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A regular expression string that is used for detecting sensitive data in a custom pattern.

- **ContextWords** – An array of UTF-8 strings, not less than 1 or more than 20 strings.

A list of context words. If none of these context words are found within the vicinity of the regular expression the data will not be detected as sensitive data.

If no context words are passed only a regular expression is checked.

- **Tags** – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

A list of tags applied to the custom entity type.

## Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the custom pattern you created.

## Errors

- `AccessDeniedException`
- `AlreadyExistsException`
- `IdempotentParameterMismatchException`
- `InternalServiceException`
- `InvalidInputException`
- `OperationTimeoutException`
- `ResourceNumberLimitExceededException`

## DeleteCustomEntityType action (Python: `delete_custom_entity_type`)

Deletes a custom pattern by specifying its name.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the custom pattern that you want to delete.

## Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the custom pattern you deleted.

## Errors

- EntityNotFoundException
- AccessDeniedException
- InternalServiceException
- InvalidInputException
- OperationTimeoutException

## GetCustomEntityType action (Python: `get_custom_entity_type`)

Retrieves the details of a custom pattern by specifying its name.

### Request

- Name – *Required*: UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the custom pattern that you want to retrieve.

### Response

- Name – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the custom pattern that you retrieved.

- `RegexString` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

A regular expression string that is used for detecting sensitive data in a custom pattern.

- `ContextWords` – An array of UTF-8 strings, not less than 1 or more than 20 strings.

A list of context words if specified when you created the custom pattern. If none of these context words are found within the vicinity of the regular expression the data will not be detected as sensitive data.

## Errors

- `EntityNotFoundException`
- `AccessDeniedException`
- `InternalServiceException`
- `InvalidInputException`
- `OperationTimeoutException`

## BatchGetCustomEntityTypes action (Python: `batch_get_custom_entity_types`)

Retrieves the details for the custom patterns specified by a list of names.

### Request

- `Names` – *Required*: An array of UTF-8 strings, not less than 1 or more than 50 strings.

A list of names of the custom patterns that you want to retrieve.

### Response

- `CustomEntityTypes` – An array of [CustomEntityType](#) objects.

A list of `CustomEntityType` objects representing the custom patterns that have been created.

- `CustomEntityTypesNotFound` – An array of UTF-8 strings, not less than 1 or more than 50 strings.

A list of the names of custom patterns that were not found.

## Errors

- `InvalidInputException`

- `InternalServerErrorException`
- `OperationTimeoutException`

## ListCustomEntityTypes action (Python: `list_custom_entity_types`)

Lists all the custom patterns that have been created.

### Request

- `NextToken` – UTF-8 string.

A paginated token to offset the results.

- `MaxResults` – Number (integer), not less than 1 or more than 1000.

The maximum number of results to return.

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

A list of key-value pair tags.

### Response

- `CustomEntityTypes` – An array of [CustomEntityType](#) objects.

A list of `CustomEntityType` objects representing custom patterns.

- `NextToken` – UTF-8 string.

A pagination token, if more results are available.

### Errors

- `InvalidInputException`
- `OperationTimeoutException`
- `InternalServerErrorException`

# Tagging APIs in AWS Glue

## Data types

- [Tag structure](#)

## Tag structure

The Tag object represents a label that you can assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

For more information about tags, and controlling access to resources in AWS Glue, see [AWS Tags in AWS Glue](#) and [Specifying AWS Glue Resource ARNs](#) in the developer guide.

## Fields

- `key` – UTF-8 string, not less than 1 or more than 128 bytes long.

The tag key. The key is required when you create a tag on an object. The key is case-sensitive, and must not contain the prefix `aws`.

- `value` – UTF-8 string, not more than 256 bytes long.

The tag value. The value is optional when you create a tag on an object. The value is case-sensitive, and must not contain the prefix `aws`.

## Operations

- [TagResource action \(Python: `tag\_resource`\)](#)
- [UntagResource action \(Python: `untag\_resource`\)](#)
- [GetTags action \(Python: `get\_tags`\)](#)

## TagResource action (Python: `tag_resource`)

Adds tags to a resource. A tag is a label you can assign to an AWS resource. In AWS Glue, you can tag only certain resources. For information about what resources you can tag, see [AWS Tags in AWS Glue](#).

In addition to the tagging permissions to call tag related APIs, you also need the `glue:GetConnection` permission to call tagging APIs on connections, and the `glue:GetDatabase` permission to call tagging APIs on databases.

### Request

- `ResourceArn` – *Required:* UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The ARN of the AWS Glue resource to which to add the tags. For more information about AWS Glue resource ARNs, see the [AWS Glue ARN string pattern](#).

- `TagsToAdd` – *Required:* A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

Tags to add to this resource.

### Response

- *No Response parameters.*

### Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `EntityNotFoundException`

## UntagResource action (Python: `untag_resource`)

Removes tags from a resource.

### Request

- `ResourceArn` – *Required:* UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the resource from which to remove the tags.

- `TagsToRemove` – *Required*: An array of UTF-8 strings, not more than 50 strings.

Tags to remove from this resource.

## Response

- *No Response parameters.*

## Errors

- `InvalidInputException`
- `InternalServerErrorException`
- `OperationTimeoutException`
- `EntityNotFoundException`

## GetTags action (Python: `get_tags`)

Retrieves a list of tags associated with a resource.

### Request

- `ResourceArn` – *Required*: UTF-8 string, not less than 1 or more than 10240 bytes long, matching the [Custom string pattern #22](#).

The Amazon Resource Name (ARN) of the resource for which to retrieve tags.

### Response

- `Tags` – A map array of key-value pairs, not more than 50 pairs.

Each key is a UTF-8 string, not less than 1 or more than 128 bytes long.

Each value is a UTF-8 string, not more than 256 bytes long.

The requested tags.

## Errors

- `InvalidInputException`
- `InternalServiceException`
- `OperationTimeoutException`
- `EntityNotFoundException`

## Common data types

The Common data types describes miscellaneous common data types in AWS Glue.

### Tag structure

The Tag object represents a label that you can assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

For more information about tags, and controlling access to resources in AWS Glue, see [AWS Tags in AWS Glue](#) and [Specifying AWS Glue Resource ARNs](#) in the developer guide.

### Fields

- `key` – UTF-8 string, not less than 1 or more than 128 bytes long.

The tag key. The key is required when you create a tag on an object. The key is case-sensitive, and must not contain the prefix `aws`.

- `value` – UTF-8 string, not more than 256 bytes long.

The tag value. The value is optional when you create a tag on an object. The value is case-sensitive, and must not contain the prefix `aws`.

## DecimalNumber structure

Contains a numeric value in decimal format.

### Fields

- `UnscaledValue` – *Required:* Blob.

The unscaled numeric value.

- `Scale` – *Required*: Number (integer).

The scale that determines where the decimal point falls in the unscaled value.

## ErrorDetail structure

Contains details about an error.

### Fields

- `ErrorCode` – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The code associated with this error.

- `ErrorMessage` – Description string, not more than 2048 bytes long, matching the [URI address multi-line string pattern](#).

A message describing the error.

## PropertyPredicate structure

Defines a property predicate.

### Fields

- `Key` – Value string, not more than 1024 bytes long.

The key of the property.

- `Value` – Value string, not more than 1024 bytes long.

The value of the property.

- `Comparator` – UTF-8 string (valid values: EQUALS | GREATER\_THAN | LESS\_THAN | GREATER\_THAN\_EQUALS | LESS\_THAN\_EQUALS).

The comparator used to compare this property to others.

## ResourceUri structure

The URIs for function resources.

## Fields

- `ResourceType` – UTF-8 string (valid values: JAR | FILE | ARCHIVE).

The type of the resource.

- `Uri` – Uniform resource identifier (uri), not less than 1 or more than 1024 bytes long, matching the [URI address multi-line string pattern](#).

The URI for accessing the resource.

## ColumnStatistics structure

Represents the generated column-level statistics for a table or partition.

### Fields

- `ColumnName` – *Required:* UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

Name of column which statistics belong to.

- `ColumnType` – *Required:* Type name, not more than 20000 bytes long, matching the [Single-line string pattern](#).

The data type of the column.

- `AnalyzedTime` – *Required:* Timestamp.

The timestamp of when column statistics were generated.

- `StatisticsData` – *Required:* A [ColumnStatisticsData](#) object.

A `ColumnStatisticData` object that contains the statistics data values.

## ColumnStatisticsError structure

Encapsulates a `ColumnStatistics` object that failed and the reason for failure.

### Fields

- `ColumnStatistics` – A [ColumnStatistics](#) object.

The ColumnStatistics of the column.

- Error – An [ErrorDetail](#) object.

An error message with the reason for the failure of an operation.

## ColumnError structure

Encapsulates a column name that failed and the reason for failure.

### Fields

- ColumnName – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The name of the column that failed.

- Error – An [ErrorDetail](#) object.

An error message with the reason for the failure of an operation.

## ColumnStatisticsData structure

Contains the individual types of column statistics data. Only one data object should be set and indicated by the Type attribute.

### Fields

- Type – *Required*: UTF-8 string (valid values: BOOLEAN | DATE | DECIMAL | DOUBLE | LONG | STRING | BINARY).

The type of column statistics data.

- BooleanColumnStatisticsData – A [BooleanColumnStatisticsData](#) object.

Boolean column statistics data.

- DateColumnStatisticsData – A [DateColumnStatisticsData](#) object.

Date column statistics data.

- DecimalColumnStatisticsData – A [DecimalColumnStatisticsData](#) object.

Decimal column statistics data. UnscaledValues within are Base64-encoded binary objects storing big-endian, two's complement representations of the decimal's unscaled value.

- `DoubleColumnStatisticsData` – A [DoubleColumnStatisticsData](#) object.

Double column statistics data.

- `LongColumnStatisticsData` – A [LongColumnStatisticsData](#) object.

Long column statistics data.

- `StringColumnStatisticsData` – A [StringColumnStatisticsData](#) object.

String column statistics data.

- `BinaryColumnStatisticsData` – A [BinaryColumnStatisticsData](#) object.

Binary column statistics data.

## BooleanColumnStatisticsData structure

Defines column statistics supported for Boolean data columns.

### Fields

- `NumberOfTrues` – *Required:* Number (long), not more than None.

The number of true values in the column.

- `NumberOfFalses` – *Required:* Number (long), not more than None.

The number of false values in the column.

- `NumberOfNulls` – *Required:* Number (long), not more than None.

The number of null values in the column.

## DateColumnStatisticsData structure

Defines column statistics supported for timestamp data columns.

### Fields

- `MinimumValue` – Timestamp.

The lowest value in the column.

- `MaximumValue – Timestamp`.

The highest value in the column.

- `NumberOfNulls – Required: Number (long), not more than None`.

The number of null values in the column.

- `NumberOfDistinctValues – Required: Number (long), not more than None`.

The number of distinct values in a column.

## DecimalColumnStatisticsData structure

Defines column statistics supported for fixed-point number data columns.

### Fields

- `MinimumValue` – A [DecimalNumber](#) object.

The lowest value in the column.

- `MaximumValue` – A [DecimalNumber](#) object.

The highest value in the column.

- `NumberOfNulls – Required: Number (long), not more than None`.

The number of null values in the column.

- `NumberOfDistinctValues – Required: Number (long), not more than None`.

The number of distinct values in a column.

## DoubleColumnStatisticsData structure

Defines column statistics supported for floating-point number data columns.

### Fields

- `MinimumValue` – Number (double).

The lowest value in the column.

- `MaximumValue` – Number (double).

The highest value in the column.

- `NumberOfNulls` – *Required:* Number (long), not more than None.

The number of null values in the column.

- `NumberOfDistinctValues` – *Required:* Number (long), not more than None.

The number of distinct values in a column.

## LongColumnStatisticsData structure

Defines column statistics supported for integer data columns.

### Fields

- `MinimumValue` – Number (long).

The lowest value in the column.

- `MaximumValue` – Number (long).

The highest value in the column.

- `NumberOfNulls` – *Required:* Number (long), not more than None.

The number of null values in the column.

- `NumberOfDistinctValues` – *Required:* Number (long), not more than None.

The number of distinct values in a column.

## StringColumnStatisticsData structure

Defines column statistics supported for character sequence data values.

### Fields

- `MaxLength` – *Required:* Number (long), not more than None.

The size of the longest string in the column.

- `AverageLength` – *Required:* Number (double), not more than None.

The average string length in the column.

- `NumberOfNulls` – *Required:* Number (long), not more than None.

The number of null values in the column.

- `NumberOfDistinctValues` – *Required:* Number (long), not more than None.

The number of distinct values in a column.

## BinaryColumnStatisticsData structure

Defines column statistics supported for bit sequence data values.

### Fields

- `MaxLength` – *Required:* Number (long), not more than None.

The size of the longest bit sequence in the column.

- `AverageLength` – *Required:* Number (double), not more than None.

The average bit sequence length in the column.

- `NumberOfNulls` – *Required:* Number (long), not more than None.

The number of null values in the column.

## String patterns

The API uses the following regular expressions to define what is valid content for various string parameters and members:

- Single-line string pattern – `"[\u0020-\uD7FF\uE000-\uFFFF\uD800\uDC00-\uDBFF\uDFFF\t]*"`
- URI address multi-line string pattern – `"[\u0020-\uD7FF\uE000-\uFFFF\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*"`

- A Logstash Grok string pattern – "[\u0020-\u007F\uE000-\uFFFF\uD800\uDC00-\uDBFF\uDFFF\x\t]\*"
- Identifier string pattern – "[A-Za-z\_][A-Za-z0-9\_]\*"
- AWS IAM ARN string pattern – "arn:aws:iam::\d{12}:role/.\*"
- Version string pattern – "^[a-zA-Z0-9-\_]+\$"
- Log group string pattern – "[\.\-\_/#A-Za-z0-9]+"
- Log-stream string pattern – "[^:]\*"
- Custom string pattern #10 – "[^\r\n]"
- Custom string pattern #11 – "^arn:aws(-(cn|us-gov|iso(-[bef]))?)?:secretsmanager:.\*\$"
- Custom string pattern #12 – "^(https?)://[-a-zA-Z0-9+&@#/%?~\_!|:,.;]\*[-a-zA-Z0-9+&@#/%?~\_]"
- Custom string pattern #13 – "\S+"
- Custom string pattern #14 – "^(https?):\s+[\s/\$.?!#].[\s]\*\$"
- Custom string pattern #15 – "^subnet-[a-z0-9]+\$"
- Custom string pattern #16 – "[\p{L}\p{N}\p{P}]\*"
- Custom string pattern #17 – "[a-f0-9]{8}-[a-f0-9]{4}-[a-f0-9]{4}-[a-f0-9]{4}-[a-f0-9]{12}"

## Exceptions

This section describes AWS Glue exceptions that you can use to find the source of problems and fix them. For more information on HTTP error codes and strings for exceptions related to machine learning, see [the section called "AWS Glue machine learning exceptions"](#).

### AccessDeniedException structure

Access to a resource was denied.

#### Fields

- Message – UTF-8 string.

A message describing the problem.

## **AlreadyExistsException structure**

A resource to be created or added already exists.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **ConcurrentModificationException structure**

Two processes are trying to modify a resource simultaneously.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **ConcurrentRunsExceededException structure**

Too many jobs are being run concurrently.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **CrawlerNotRunningException structure**

The specified crawler is not running.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **CrawlerRunningException structure**

The operation cannot be performed because the crawler is already running.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **CrawlerStoppingException structure**

The specified crawler is stopping.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **EntityNotFoundException structure**

A specified entity does not exist

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

- `FromFederationSource` – Boolean.

Indicates whether or not the exception relates to a federated source.

## **FederationSourceException structure**

A federation source failed.

## Fields

- `FederationSourceErrorCode` – UTF-8 string (valid values: `AccessDeniedException` | `EntityNotFoundException` | `InvalidCredentialsException` | `InvalidInputException` | `InvalidResponseException` | `OperationTimeoutException` | `OperationNotSupportedException` | `InternalServiceException` | `PartialFailureException` | `ThrottlingException`).

The error code of the problem.

- `Message` – UTF-8 string.

The message describing the problem.

## FederationSourceRetryableException structure

A federation source failed, but the operation may be retried.

### Fields

- `Message` – UTF-8 string.

A message describing the problem.

## GlueEncryptionException structure

An encryption operation failed.

### Fields

- `Message` – UTF-8 string.

The message describing the problem.

## IdempotentParameterMismatchException structure

The same unique identifier was associated with two different records.

### Fields

- `Message` – UTF-8 string.

A message describing the problem.

## **IllegalWorkflowStateException structure**

The workflow is in an invalid state to perform a requested operation.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **InternalServiceException structure**

An internal service error occurred.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

## **InvalidExecutionEngineException structure**

An unknown or invalid execution engine was specified.

### **Fields**

- message – UTF-8 string.

A message describing the problem.

## **InvalidInputException structure**

The input provided was not valid.

### **Fields**

- Message – UTF-8 string.

A message describing the problem.

- `FromFederationSource` – Boolean.

Indicates whether or not the exception relates to a federated source.

## **InvalidStateException structure**

An error that indicates your data is in an invalid state.

### **Fields**

- `Message` – UTF-8 string.

A message describing the problem.

## **InvalidTaskStatusTransitionException structure**

Proper transition from one task to the next failed.

### **Fields**

- `message` – UTF-8 string.

A message describing the problem.

## **JobDefinitionErrorException structure**

A job definition is not valid.

### **Fields**

- `message` – UTF-8 string.

A message describing the problem.

## **JobRunInTerminalStateException structure**

The terminal state of a job run signals a failure.

## Fields

- message – UTF-8 string.

A message describing the problem.

## JobRunInvalidStateTransitionException structure

A job run encountered an invalid transition from source state to target state.

### Fields

- jobRunId – UTF-8 string, not less than 1 or more than 255 bytes long, matching the [Single-line string pattern](#).

The ID of the job run in question.

- message – UTF-8 string.

A message describing the problem.

- sourceState – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT | ERROR | WAITING | EXPIRED).

The source state.

- targetState – UTF-8 string (valid values: STARTING | RUNNING | STOPPING | STOPPED | SUCCEEDED | FAILED | TIMEOUT | ERROR | WAITING | EXPIRED).

The target state.

## JobRunNotInTerminalStateException structure

A job run is not in a terminal state.

### Fields

- message – UTF-8 string.

A message describing the problem.

## LateRunnerException structure

A job runner is late.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## NoScheduleException structure

There is no applicable schedule.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## OperationTimeoutException structure

The operation timed out.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## ResourceNotReadyException structure

A resource was not ready for a transaction.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## ResourceNumberLimitExceededException structure

A resource numerical limit was exceeded.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## SchedulerNotRunningException structure

The specified scheduler is not running.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## SchedulerRunningException structure

The specified scheduler is already running.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## SchedulerTransitioningException structure

The specified scheduler is transitioning.

### Fields

- Message – UTF-8 string.

A message describing the problem.

## UnrecognizedRunnerException structure

The job runner was not recognized.

### Fields

- Message – UTF-8 string.  
A message describing the problem.

## ValidationException structure

A value could not be validated.

### Fields

- Message – UTF-8 string.  
A message describing the problem.

## VersionMismatchException structure

There was a version conflict.

### Fields

- Message – UTF-8 string.  
A message describing the problem.

# AWS Glue API code examples using AWS SDKs

The following code examples show how to use AWS Glue with an AWS software development kit (SDK).

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Get started

### Hello AWS Glue

The following code examples show how to get started using AWS Glue.

.NET

#### AWS SDK for .NET

##### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
namespace GlueActions;

public class HelloGlue
{
    private static ILogger logger = null!;

    static async Task Main(string[] args)
    {
        // Set up dependency injection for AWS Glue.
```

```
using var host = Host.CreateDefaultBuilder(args)
    .ConfigureLogging(logging =>
        logging.AddFilter("System", LogLevel.Debug)
            .AddFilter<DebugLoggerProvider>("Microsoft",
                LogLevel.Information)
            .AddFilter<ConsoleLoggerProvider>("Microsoft",
                LogLevel.Trace))
    .ConfigureServices((_, services) =>
        services.AddAWSService<IAmazonGlue>()
            .AddTransient<GlueWrapper>()
    )
    .Build();

logger = LoggerFactory.Create(builder => { builder.AddConsole(); })
    .CreateLogger<HelloGlue>();
var glueClient = host.Services.GetRequiredService<IAmazonGlue>();

var request = new ListJobsRequest();

var jobNames = new List<string>();

do
{
    var response = await glueClient.ListJobsAsync(request);
    jobNames.AddRange(response.JobNames);
    request.NextToken = response.NextToken;
}
while (request.NextToken is not null);

Console.Clear();
Console.WriteLine("Hello, Glue. Let's list your existing Glue Jobs:");
if (jobNames.Count == 0)
{
    Console.WriteLine("You don't have any AWS Glue jobs.");
}
else
{
    jobNames.ForEach(Console.WriteLine);
}
}
```

- For API details, see [ListJobs](#) in *AWS SDK for .NET API Reference*.

## C++

### SDK for C++

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS glue)

# Set this project's name.
project("hello_glue")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
  libraries for the AWS SDK.
  string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
    "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
  list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif ()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD AND AWSSDK_INSTALL_AS_SHARED_LIBS)
```

```

    # Copy relevant AWS SDK for C++ libraries into the current binary directory
    for running and debugging.

    # set(BIN_SUB_DIR "/Debug") # if you are building from the command line you
    may need to uncomment this
                                # and set the proper subdirectory to the
    executables' location.

    AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""
    ${CMAKE_CURRENT_BINARY_DIR}${BIN_SUB_DIR})
endif ()

add_executable(${PROJECT_NAME}
    hello_glue.cpp)

target_link_libraries(${PROJECT_NAME}
    ${AWSSDK_LINK_LIBRARIES})

```

### Code for the hello\_glue.cpp source file.

```

#include <aws/core/Aws.h>
#include <aws/glue/GlueClient.h>
#include <aws/glue/model/ListJobsRequest.h>
#include <iostream>

/*
 * A "Hello Glue" starter application which initializes an AWS Glue client and
 * lists the
 * AWS Glue job definitions.
 *
 * main function
 *
 * Usage: 'hello_glue'
 *
 */

int main(int argc, char **argv) {
    Aws::SDKOptions options;
    // Optionally change the log level for debugging.
    // options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.
    int result = 0;
}

```

```
{
    Aws::Client::ClientConfiguration clientConfig;
    // Optional: Set to the AWS Region (overrides config file).
    // clientConfig.region = "us-east-1";

    Aws::Glue::GlueClient glueClient(clientConfig);

    std::vector<Aws::String> jobs;

    Aws::String nextToken; // Used for pagination.
    do {
        Aws::Glue::Model::ListJobsRequest listJobsRequest;
        if (!nextToken.empty()) {
            listJobsRequest.SetNextToken(nextToken);
        }

        Aws::Glue::Model::ListJobsOutcome listRunsOutcome =
glueClient.ListJobs(
            listJobsRequest);

        if (listRunsOutcome.IsSuccess()) {
            const std::vector<Aws::String> &jobNames =
listRunsOutcome.GetResult().GetJobNames();
            jobs.insert(jobs.end(), jobNames.begin(), jobNames.end());

            nextToken = listRunsOutcome.GetResult().GetNextToken();
        } else {
            std::cerr << "Error listing jobs. "
                << listRunsOutcome.GetError().GetMessage()
                << std::endl;

            result = 1;
            break;
        }
    } while (!nextToken.empty());

    std::cout << "Your account has " << jobs.size() << " jobs."
        << std::endl;
    for (size_t i = 0; i < jobs.size(); ++i) {
        std::cout << "    " << i + 1 << ". " << jobs[i] << std::endl;
    }
}
Aws::ShutdownAPI(options); // Should only be called once.
return result;
}
```

- For API details, see [ListJobs](#) in *AWS SDK for C++ API Reference*.

## Java

### SDK for Java 2.x

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
package com.example.glue;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.ListJobsRequest;
import software.amazon.awssdk.services.glue.model.ListJobsResponse;
import java.util.List;

public class HelloGlue {
    public static void main(String[] args) {
        GlueClient glueClient = GlueClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listJobs(glueClient);
    }

    public static void listJobs(GlueClient glueClient) {
        ListJobsRequest request = ListJobsRequest.builder()
            .maxResults(10)
            .build();
        ListJobsResponse response = glueClient.listJobs(request);
        List<String> jobList = response.jobNames();
        jobList.forEach(job -> {
            System.out.println("Job Name: " + job);
        });
    }
}
```

- For API details, see [ListJobs](#) in *AWS SDK for Java 2.x API Reference*.

## JavaScript

### SDK for JavaScript (v3)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import { ListJobsCommand, GlueClient } from "@aws-sdk/client-glue";

const client = new GlueClient({});

export const main = async () => {
  const command = new ListJobsCommand({});

  const { JobNames } = await client.send(command);
  const formattedJobNames = JobNames.join("\n");
  console.log("Job names: ");
  console.log(formattedJobNames);
  return JobNames;
};
```

- For API details, see [ListJobs](#) in *AWS SDK for JavaScript API Reference*.

## Rust

### SDK for Rust

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
let mut list_jobs = glue.list_jobs().into_paginator().send();
while let Some(list_jobs_output) = list_jobs.next().await {
    match list_jobs_output {
        Ok(list_jobs) => {
            let names = list_jobs.job_names();
            info!(?names, "Found these jobs")
        }
        Err(err) => return Err(GlueMvpError::from_glue_sdk(err)),
    }
}
```

## Actions for AWS Glue using AWS SDKs

The following code examples demonstrate how to perform individual AWS Glue actions with AWS SDKs. These excerpts call the AWS Glue API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the [AWS Glue API Reference](#).

### Examples

- [Use CreateCrawler with an AWS SDK or CLI](#)
- [Use CreateJob with an AWS SDK or CLI](#)
- [Use DeleteCrawler with an AWS SDK or CLI](#)
- [Use DeleteDatabase with an AWS SDK or CLI](#)
- [Use DeleteJob with an AWS SDK or CLI](#)
- [Use DeleteTable with an AWS SDK or CLI](#)
- [Use GetCrawler with an AWS SDK or CLI](#)
- [Use GetDatabase with an AWS SDK or CLI](#)
- [Use GetDatabases with an AWS SDK or CLI](#)
- [Use GetJob with an AWS SDK or CLI](#)
- [Use GetJobRun with an AWS SDK or CLI](#)
- [Use GetJobRuns with an AWS SDK or CLI](#)
- [Use GetTables with an AWS SDK or CLI](#)
- [Use ListJobs with an AWS SDK or CLI](#)
- [Use StartCrawler with an AWS SDK or CLI](#)
- [Use StartJobRun with an AWS SDK or CLI](#)

### Use CreateCrawler with an AWS SDK or CLI

The following code examples show how to use `CreateCrawler`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with crawlers and jobs](#)

.NET

## CLI

### AWS CLI

#### To create a job to transform data

The following `create-job` example creates a streaming job that runs a script stored in S3.

```

aws glue create-job \
    --name my-testing-job \

```

```

--role AWSGlueServiceRoleDefault \
--command '{ \
  "Name": "gluestreaming", \
  "ScriptLocation": "s3://DOC-EXAMPLE-BUCKET/folder/" \
}' \
--region us-east-1 \
--output json \
--default-arguments '{ \
  "--job-language":"scala", \
  "--class":"GlueApp" \
}' \
--profile my-profile \
--endpoint https://glue.us-east-1.amazonaws.com

```

### Contents of test\_script.scala:

```

import com.amazonaws.services.glue.ChoiceOption
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.ResolveSpec
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueApp {
  def main(sysArgs: Array[String]) {
    val spark: SparkContext = new SparkContext()
    val glueContext: GlueContext = new GlueContext(spark)
    // @params: [JOB_NAME]
    val args = GlueArgParser.getResolvedOptions(sysArgs,
Seq("JOB_NAME").toArray)
    Job.init(args("JOB_NAME"), glueContext, args.asJava)
    // @type: DataSource
    // @args: [database = "tempdb", table_name = "s3-source",

    ]);
}
```

- For API details, see [CreateJob](#) in *AWS SDK for PHP API Reference*.

## PowerShell

### Tools for PowerShell

**Example 1:** This example creates a new job in AWS Glue. The command name value is always `glueetl`. AWS Glue supports running job scripts written in Python or Scala. In this example, the job script (`MyTestGlueJob.py`) is written in Python. Python parameters are specified in the `$DefArgs` variable, and then passed to the PowerShell command in the `DefaultArguments` parameter, which accepts a hashtable. The parameters in the `$JobParams` variable come from the `CreateJob` API, documented in the `Jobs` (<https://docs.aws.amazon.com/glue/latest/dg/aws-glue-api-jobs-job.html>) topic of the **AWS Glue API reference**.

```
$Command = New-Object Amazon.Glue.Model.JobCommand
$Command.Name = 'glueetl'
$Command.ScriptLocation = 's3://aws-glue-scripts-000000000000-us-west-2/admin/MyTestGlueJob.py'
$Command

$Source = "source_test_table"
$Target = "target_test_table"
$Connections = $Source, $Target

$DefArgs = @{
    '--TempDir' = 's3://aws-glue-temporary-000000000000-us-west-2/admin'
    '--job-bookmark-option' = 'job-bookmark-disable'
    '--job-language' = 'python'
}
$DefArgs

$ExecutionProp = New-Object Amazon.Glue.Model.ExecutionProperty
$ExecutionProp.MaxConcurrentRuns = 1
$ExecutionProp

$JobParams = @{
    "AllocatedCapacity" = "5"
    "Command" = $Command
    "Connections_Connection" = $Connections
    "DefaultArguments" = $DefArgs
    "Description" = "This is a test"
    "ExecutionProperty" = $ExecutionProp
    "MaxRetries" = "1"
```

```

    "Name"           = "MyOregonTestGlueJob"
    "Role"           = "Amazon-GlueServiceRoleForSSM"
    "Timeout"       = "20"
  }

```

New-GlueJob @JobParams

- For API details, see [CreateJob](#) in *AWS Tools for PowerShell Cmdlet Reference*.

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region in which the bucket was created
(overrides config file).
// clientConfig.region = "us-east-1";

Aws::Glue::GlueClient client(clientConfig);

Aws::Glue::Model::DeleteJobRequest request;
request.SetJobName(job);

Aws::Glue::Model::DeleteJobOutcome outcome = client.DeleteJob(request);

if (outcome.IsSuccess()) {
    std::cout << "Successfully deleted the job." << std::endl;
}
else {
    std::cerr << "Error deleting the job. " <<
outcome.GetError().GetMessage()
        << std::endl;
    result = false;
}
```

- For API details, see [DeleteJob](#) in *AWS SDK for C++ API Reference*.

## CLI

## AWS CLI

## To delete a job

The following `delete-job` example deletes a job that is no longer needed.

```
aws glue delete-job \  
  --job-name my-testing-job
```

Output:

```
{  
  "JobName": "my-testing-job"  
}
```

For more information, see [Working with Jobs on the AWS Glue Console](#) in the *AWS Glue Developer Guide*.

- For API details, see [DeleteJob](#) in *AWS CLI Command Reference*.

## Use GetDatabases with an AWS SDK or CLI

The following code examples show how to use GetDatabases.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with crawlers and jobs](#)

### CLI

#### AWS CLI

##### To list the definitions of some or all of the databases in the AWS Glue Data Catalog

The following `get-databases` example returns information about the databases in the Data Catalog.

```
aws glue get-databases
```

Output:

```
{
  "DatabaseList": [
    {
      "Name": "default",
```

```
"Description": "Default Hive database",
"LocationUri": "file:/spark-warehouse",
"CreateTime": 1602084052.0,
"CreateTableDefaultPermissions": [
  {
    "Principal": {
      "DataLakePrincipalIdentifier": "IAM_ALLOWED_PRINCIPALS"
    },
    "Permissions": [
      "ALL"
    ]
  }
],
"CatalogId": "111122223333"
},
{
  "Name": "flights-db",
  "CreateTime": 1587072847.0,
  "CreateTableDefaultPermissions": [
    {
      "Principal": {
        "DataLakePrincipalIdentifier": "IAM_ALLOWED_PRINCIPALS"
      },
      "Permissions": [
        "ALL"
      ]
    }
  ],
  "CatalogId": "111122223333"
},
{
  "Name": "legislators",
  "CreateTime": 1601415625.0,
  "CreateTableDefaultPermissions": [
    {
      "Principal": {
        "DataLakePrincipalIdentifier": "IAM_ALLOWED_PRINCIPALS"
      },
      "Permissions": [
        "ALL"
      ]
    }
  ],
  "CatalogId": "111122223333"
```

```
    },
    {
      "Name": "tempdb",
      "CreateTime": 1601498566.0,
      "CreateTableDefaultPermissions": [
        {
          "Principal": {
            "DataLakePrincipalIdentifier": "IAM_ALLOWED_PRINCIPALS"
          },
          "Permissions": [
            "ALL"
          ]
        }
      ],
      "CatalogId": "111122223333"
    }
  ]
}
```

## Use GetJob with an AWS SDK or CLI

The following code examples show how to use GetJob.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with crawlers and jobs](#)

### CLI

#### AWS CLI

##### To retrieve information about a job

The following `get-job` example retrieves information about a job.

```
aws glue get-job \  
  --job-name my-testing-job
```

Output:

```
{  
  "Job": {  
    "Name": "my-testing-job",  
    "Role": "Glue_DefaultRole",  
    "CreatedOn": 1602805698.167,  
    "LastModifiedOn": 1602805698.167,  
    "ExecutionProperty": {  
      "MaxConcurrentRuns": 1  
    },  
    "Command": {
```

```
        "Name": "gluestreaming",
        "ScriptLocation": "s3://janetst-bucket-01/Scripts/test_script.scala",
        "PythonVersion": "2"
    },
    "DefaultArguments": {
        "--class": "GlueApp",
        "--job-language": "scala"
    },
    "MaxRetries": 0,
    "AllocatedCapacity": 10,
    "MaxCapacity": 10.0,
    "GlueVersion": "1.0"
}
}
```

## Scenarios for AWS Glue using AWS SDKs

The following code examples show you how to implement common scenarios in AWS Glue with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within AWS Glue. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

### Examples

- [Get started running AWS Glue crawlers and jobs using an AWS SDK](#)

## Get started running AWS Glue crawlers and jobs using an AWS SDK

The following code examples show how to:

- Create a crawler that crawls a public Amazon S3 bucket and generates a database of CSV-formatted metadata.
- List information about databases and tables in your AWS Glue Data Catalog.
- Create a job to extract CSV data from the S3 bucket, transform the data, and load JSON-formatted output into another S3 bucket.
- List information about job runs, view transformed data, and clean up resources.

For more information, see [Tutorial: Getting started with AWS Glue Studio](#).

## .NET

### AWS SDK for .NET

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a class that wraps AWS Glue functions that are used in the scenario.

```
using System.Net;

namespace GlueActions;

public class GlueWrapper
{
    private readonly IAmazonGlue _amazonGlue;

    /// <summary>
    /// Constructor for the AWS Glue actions wrapper.
    /// </summary>
    /// <param name="amazonGlue"></param>
    public GlueWrapper(IAmazonGlue amazonGlue)
    {
        _amazonGlue = amazonGlue;
    }

    /// <summary>
    /// Create an AWS Glue crawler.
    /// </summary>
    /// <param name="crawlerName">The name for the crawler.</param>
    /// <param name="crawlerDescription">A description of the crawler.</param>
    /// <param name="role">The AWS Identity and Access Management (IAM) role to
    /// be assumed by the crawler.</param>

## Java

## SDK for Java 2.x

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
 *
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
 * started.html
 *
 * To set up the resources, see this documentation topic:
 *
 * https://docs.aws.amazon.com/glue/latest/ug/tutorial-add-crawler.html
 *
 * This example performs the following tasks:
 *
 * 1. Create a database.
 * 2. Create a crawler.
 * 3. Get a crawler.
 * 4. Start a crawler.
 * 5. Get a database.
 * 6. Get tables.
 * 7. Create a job.
 * 8. Start a job run.
 * 9. List all jobs.
 * 10. Get job runs.
 * 11. Delete a job.
 * 12. Delete a database.
 * 13. Delete a crawler.
 */

## JavaScript

### SDK for JavaScript (v3)

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create and run a crawler that crawls a public Amazon Simple Storage Service (Amazon S3) bucket and generates a metadata database that describes the CSV-formatted data it finds.

```
const createCrawler = (name, role, dbName, tablePrefix, s3TargetPath) => {
  const client = new GlueClient({});

  const command = new CreateCrawlerCommand({
    Name: name,
    Role: role,
    DatabaseName: dbName,
    TablePrefix: tablePrefix,
    Targets: {
      S3Targets: [{ Path: s3TargetPath }],
    },
  });

  return client.send(command);
};

const getCrawler = (name) => {
  const client = new GlueClient({});

  const command = new GetCrawlerCommand({
    Name: name,
  });

  return client.send(command);
};

const startCrawler = (name) => {
  const client = new GlueClient({});

  const command = new StartCrawlerCommand({
    Name: name,
  });

  return client.send(command);
};

const crawlerExists = async ({ getCrawler }, crawlerName) => {
  try {
    await getCrawler(crawlerName);
    return true;
  }
};
```

```
    } catch {
      return false;
    }
  };

/**
 * @param {{ createCrawler: import('../..../actions/create-crawler.js').createCrawler}} actions
 */
const makeCreateCrawlerStep = (actions) => async (context) => {
  if (await crawlerExists(actions, process.env.CRAWLER_NAME)) {
    log("Crawler already exists. Skipping creation.");
  } else {
    await actions.createCrawler(
      process.env.CRAWLER_NAME,
      process.env.ROLE_NAME,
      process.env.DATABASE_NAME,
      process.env.TABLE_PREFIX,
      process.env.S3_TARGET_PATH,
    );

    log("Crawler created successfully.", { type: "success" });
  }

  return { ...context };
};

/**
 * @param {(name: string) => Promise<import('@aws-sdk/client-glue').GetCrawlerCommandOutput>} getCrawler
 * @param {string} crawlerName
 */
const waitForCrawler = async (getCrawler, crawlerName) => {
  const waitTimeInSeconds = 30;
  const { Crawler } = await getCrawler(crawlerName);

  if (!Crawler) {
    throw new Error(`Crawler with name ${crawlerName} not found.`);
  }

  if (Crawler.State === "READY") {
    return;
  }
}
```

```

log(`Crawler is ${Crawler.State}. Waiting ${waitTimeInSeconds} seconds...`);
await wait(waitTimeInSeconds);
return waitForCrawler(getCrawler, crawlerName);
};

const makeStartCrawlerStep =
({ startCrawler, getCrawler }) =>
async (context) => {
  log("Starting crawler.");
  await startCrawler(process.env.CRAWLER_NAME);
  log("Crawler started.", { type: "success" });

  log("Waiting for crawler to finish running. This can take a while.");
  await waitForCrawler(getCrawler, process.env.CRAWLER_NAME);
  log("Crawler ready.", { type: "success" });

  return { ...context };
};

```

List information about databases and tables in your AWS Glue Data Catalog.

```

const getDatabase = (name) => {
  const client = new GlueClient({});

  const command = new GetDatabaseCommand({
    Name: name,
  });

  return client.send(command);

## Ruby

### SDK for Ruby

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a class that wraps AWS Glue functions used in the scenario.

```
# The `GlueWrapper` class serves as a wrapper around the AWS Glue API, providing
# a simplified interface for common operations.
# It encapsulates the functionality of the AWS SDK for Glue and provides methods
# for interacting with Glue crawlers, databases, tables, jobs, and S3 resources.
# The class initializes with a Glue client and a logger, allowing it to make API
# calls and log any errors or informational messages.
class GlueWrapper
  def initialize(glue_client, logger)
    @glue_client = glue_client
    @logger = logger
  end

  # Retrieves information about a specific crawler.
  #
  # @param name [String] The name of the crawler to retrieve information about.
  # @return [Aws::Glue::Types::Crawler, nil] The crawler object if found, or nil
  # if not found.
  def get_crawler(name)
    @glue_client.get_crawler(name: name)
  rescue Aws::Glue::Errors::EntityNotFoundException
    @logger.info("Crawler #{name} doesn't exist.")
    false
  rescue Aws::Glue::Errors::GlueException => e
    @logger.error("Glue could not get crawler #{name}: \n#{e.message}")
    raise
  end

  # Creates a new crawler with the specified configuration.
  #
  # @param name [String] The name of the crawler.
```

```
# @param role_arn [String] The ARN of the IAM role to be used by the crawler.
# @param db_name [String] The name of the database where the crawler stores its
metadata.
# @param db_prefix [String] The prefix to be added to the names of tables that
the crawler creates.
# @param s3_target [String] The S3 path that the crawler will crawl.
# @return [void]

## Rust

### SDK for Rust

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create and run a crawler that crawls a public Amazon Simple Storage Service (Amazon S3) bucket and generates a metadata database that describes the CSV-formatted data it finds.

```
let create_crawler = glue
    .create_crawler()
    .name(self.crawler())
    .database_name(self.database())
    .role(self.iam_role.expose_secret())
    .targets(
        CrawlerTargets::builder()
            .s3_targets(S3Target::builder().path(CRAWLER_TARGET).build())
```

```

        .build(),
    )
    .send()
    .await;

match create_crawler {
    Err(err) => {
        let glue_err: aws_sdk_glue::Error = err.into();
        match glue_err {
            aws_sdk_glue::Error::AlreadyExistsException(_) => {
                info!("Using existing crawler");
                Ok(())
            }
            _ => Err(GlueMvpError::GlueSdk(glue_err)),
        }
    }
    Ok(_) => Ok(()),
}?:

let start_crawler =
glue.start_crawler().name(self.crawler()).send().await;

match start_crawler {
    Ok(_) => Ok(()),
    Err(err) => {
        let glue_err: aws_sdk_glue::Error = err.into();
        match glue_err {
            aws_sdk_glue::Error::CrawlerRunningException(_) => Ok(()),
            _ => Err(GlueMvpError::GlueSdk(glue_err)),
        }
    }
}?:

```

List information about databases and tables in your AWS Glue Data Catalog.

```

let database = glue
    .get_database()
    .name(self.database())
    .send()
    .await
    .map_err(GlueMvpError::from_glue_sdk)?
    .to_owned();

```

```

    let database = database

# Security in AWS Glue

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to AWS Glue, see [AWS Services in Scope by Compliance Program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using AWS Glue. The following topics show you how to configure AWS Glue to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your AWS Glue resources.

## Topics

- [Data protection in AWS Glue](#)
- [Identity and access management for AWS Glue](#)
- [Logging and monitoring in AWS Glue](#)
- [Compliance validation for AWS Glue](#)
- [Resilience in AWS Glue](#)
- [Infrastructure security in AWS Glue](#)

## Data protection in AWS Glue

AWS Glue offers several features that are designed to help protect your data.

## Topics

- [Encryption at rest](#)
- [Encryption in transit](#)
- [FIPS compliance](#)
- [Key management](#)

- [Development endpoints](#)

## Encryption at rest

AWS Glue supports data encryption at rest for [Building visual ETL jobs with AWS Glue Studio](#) and [Developing scripts using development endpoints](#). You can configure extract, transform, and load (ETL) jobs and development endpoints to use [AWS Key Management Service \(AWS KMS\)](#) keys to write encrypted data at rest. You can also encrypt the metadata stored in the [AWS Glue Data Catalog](#) using keys that you manage with AWS KMS. Additionally, you can use AWS KMS keys to encrypt job bookmarks and the logs generated by [crawlers](#) and ETL jobs.

You can encrypt metadata objects in your AWS Glue Data Catalog in addition to the data written to Amazon Simple Storage Service (Amazon S3) and Amazon CloudWatch Logs by jobs, crawlers, and development endpoints. When you create jobs, crawlers, and development endpoints in AWS Glue, you can provide encryption settings by attaching a security configuration. Security configurations contain Amazon S3-managed server-side encryption keys (SSE-S3) or customer master keys (CMKs) stored in AWS KMS (SSE-KMS). You can create security configurations using the AWS Glue console.

You can also turn on encryption of the entire Data Catalog in your account. You do so by specifying CMKs stored in AWS KMS.

### Important

AWS Glue supports only symmetric customer managed keys. For more information, see [Customer Managed Keys \(CMKs\)](#) in the *AWS Key Management Service Developer Guide*.

With encryption turned on, when you add Data Catalog objects, run crawlers, run jobs, or start development endpoints, SSE-S3 or SSE-KMS keys are used to write data at rest. In addition, you

can configure AWS Glue to only access Java Database Connectivity (JDBC) data stores through a trusted Transport Layer Security (TLS) protocol.

In AWS Glue, you control encryption settings in the following places:

- The settings of your Data Catalog.
- The security configurations that you create.
- The server-side encryption setting (SSE-S3 or SSE-KMS) that is passed as a parameter to your AWS Glue ETL (extract, transform, and load) job.

For more information about how to set up encryption, see [Setting up encryption in AWS Glue](#).

## Topics

- [Encrypting your Data Catalog](#)
- [Encrypting connection passwords](#)
- [Encrypting data written by AWS Glue](#)

## Encrypting your Data Catalog

AWS Glue Data Catalog encryption provides enhanced security for your sensitive data. AWS Glue integrates with AWS Key Management Service (AWS KMS) to encrypt metadata that's stored in the Data Catalog. You can enable or disable encryption settings for resources in the Data Catalog using the AWS Glue console or the AWS CLI.

When you enable encryption for your Data Catalog, all new objects that you create will be encrypted. When you disable encryption, the new objects you create will not be encrypted, but existing encrypted objects will remain encrypted.

You can reencrypt your entire Data Catalog using AWS managed encryption keys or customer managed encryption keys. For more information on key types and states, see [AWS Key Management Service concepts](#) in the AWS Key Management Service Developer Guide.

### AWS managed keys

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that's integrated with AWS KMS. You can view the AWS managed keys in your account, view their key policies, and audit their use in AWS CloudTrail logs. However, you can't manage these keys or change their permissions.

Encryption at rest automatically integrates with AWS KMS for managing the AWS managed keys for AWS Glue that are used to encrypt your metadata. If an AWS managed key doesn't exist when you enable metadata encryption, AWS KMS automatically creates a new key for you.

For more information, see [AWS managed keys](#).

## Customer managed keys

Customer managed keys are KMS keys in your AWS account that you create, own, and manage. You have full control over these KMS keys. You can:

- Establish and maintain their key policies, IAM policies, and grants
- Enable and disable them
- Rotate their cryptographic material
- Add tags
- Create aliases that refer to them
- Schedule them for deletion

For more information about managing the permissions of a customer managed key, see [Customer managed keys](#).

### Important

AWS Glue supports only symmetric customer managed keys. The KMS key list displays only symmetric keys. However, if you select **Choose a KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

To create a symmetric customer managed key, follow the steps for [creating symmetric customer managed keys](#) in the AWS Key Management Service Developer Guide.

When you enable Data Catalog encryption at rest, the following resource types are encrypted using KMS keys:

- Databases
- Tables
- Partitions

- Table versions
- Column statistics
- User-defined functions
- Data Catalog views

## AWS Glue encryption context

An [encryption context](#) is an optional set of key-value pairs that contain additional contextual information about the data. AWS KMS uses the encryption context as [additional authenticated data](#) to support [authenticated encryption](#). When you include an encryption context in a request to encrypt data, AWS KMS binds the encryption context to the encrypted data. To decrypt data, you include the same encryption context in the request. AWS Glue uses the same encryption context in all AWS KMS cryptographic operations, where the key is `glue_catalog_id` and the value is the `catalogId`.

```
"encryptionContext": {  
  "glue_catalog_id": "111122223333"  
}
```

When you use an AWS managed key or a symmetric customer managed key to encrypt your Data Catalog, you can also use the encryption context in audit records and logs to identify how the key is being used. The encryption context also appears in logs that are generated by AWS CloudTrail or Amazon CloudWatch logs.

## Enabling encryption

You can enable encryption for your AWS Glue Data Catalog objects in the **Data Catalog settings** in the AWS Glue console or by using the AWS CLI.

### Console

#### To enable encryption using the console

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose **Data Catalog** in the navigation pane.
3. On the **Data Catalog settings** page, select the **Metadata encryption** check box, and choose an AWS KMS key.

When you enable encryption, if you don't specify a customer managed key, the encryption settings use an AWS managed KMS key.

4. (Optional) When you use a customer managed key to encrypt your Data Catalog, the Data Catalog provides an option to register an IAM role to encrypt and decrypt resources. You need to grant your IAM role permissions that AWS Glue can assume on your behalf. This includes AWS KMS permissions to encrypt and decrypt data.

When you create a new resource in the Data Catalog, AWS Glue assumes the IAM role that's provided to encrypt the data. Similarly, when a consumer accesses the resource, AWS Glue assumes the IAM role to decrypt data. If you register an IAM role with the required permissions, the calling principal no longer requires permissions to access the key and decrypt the data.

 **Important**

You can delegate KMS operations to an IAM role only when you use a customer managed key to encrypt the Data Catalog resources. KMS role delegation feature doesn't support using AWS managed keys for encrypting Data Catalog resources at this time.

 **Warning**

When you enable an IAM role to delegate KMS operations, you can no longer access the Data Catalog resources that were encrypted previously with an AWS managed key.

- a. To enable an IAM role that AWS Glue can assume to encrypt and decrypt data on your behalf, select the **Delegate KMS operations to an IAM role** option.
- b. Next, choose an IAM role.

To create an IAM role, see [Create an IAM role for AWS Glue](#).

The IAM role that AWS Glue assumes to access the Data Catalog must have the permissions to encrypt and decrypt metadata in the Data Catalog. You can create an IAM role, and attach the following inline policies:

- Add the following policy to include AWS KMS permissions to encrypt and decrypt the Data Catalog.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "kms:Encrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": "arn:aws:kms:<region>:<account-id>:key/<key-id>"
    }
  ]
}
```

- Next, add the following trust policy to the role for AWS Glue service to assume the IAM role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "glue.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- Next, add the iam:PassRole permission to the IAM role.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": [
        "arn:aws:iam::<account-id>:role/<encryption-role-name>"
      ]
    }
  ]
}

```

When you enable encryption, if you haven't specified an IAM role for AWS Glue to assume, the principal accessing the Data Catalog must have permissions to perform the following API operations:

- kms:Decrypt
- kms:Encrypt
- kms:GenerateDataKey

## AWS CLI

### To enable encryption using the SDK or AWS CLI

- Use the PutDataCatalogEncryptionSettings API operation. If no key is specified, AWS Glue uses AWS managed encryption key for the customer account to encrypt the Data Catalog.

```

aws glue put-data-catalog-encryption-settings \
  --data-catalog-encryption-settings '{
    "EncryptionAtRest": {
      "CatalogEncryptionMode": "SSE-KMS-WITH-SERVICE-ROLE",
      "SseAwsKmsKeyId": "arn:aws:kms:<region>:<account-id>:key/<key-id>",
      "CatalogEncryptionServiceRole": "arn:aws:iam::<account-
id>:role/<encryption-role-name>"
    }
  }'

```

When you enable encryption, all objects that you create in the Data Catalog objects are encrypted. If you clear this setting, the objects you create in the Data Catalog are no longer encrypted. You can continue to access the existing encrypted objects in the Data Catalog with the required KMS permissions.

### Important

The AWS KMS key must remain available in the AWS KMS key store for any objects that are encrypted with it in the Data Catalog. If you remove the key, the objects can no longer be decrypted. You might want this in some scenarios to prevent access to Data Catalog metadata.

## Monitoring your KMS keys for AWS Glue

When you use KMS keys with your Data Catalog resources, you can use AWS CloudTrail or Amazon CloudWatch Logs to track requests that AWS Glue sends to AWS KMS. AWS CloudTrail monitors and records KMS operations that AWS Glue calls to access data that's encrypted by your KMS keys.

The following examples are AWS CloudTrail events for the Decrypt and GenerateDataKey operations.

### Decrypt

```
{
  "eventVersion": "1.08",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROAXPHTESTANDEXAMPLE:Sampleuser01",
    "arn": "arn:aws:sts::111122223333:assumed-role/Admin/Sampleuser01",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AROAXPHTESTANDEXAMPLE",
        "arn": "arn:aws:iam::111122223333:role/Admin",
```

```

        "accountId": "111122223333",
        "userName": "Admin"
    },
    "webIdFederationData": {},
    "attributes": {

  }
],
"eventType": "AwsApiCall",
"managementEvent": true,
"recipientAccountId": "111122223333",
"eventCategory": "Management"
}
```

## Encrypting connection passwords

You can retrieve connection passwords in the AWS Glue Data Catalog by using the `GetConnection` and `GetConnections` API operations. These passwords are stored in the Data Catalog connection and are used when AWS Glue connects to a Java Database Connectivity (JDBC) data store. When the connection was created or updated, an option in the Data Catalog settings determined whether the password was encrypted, and if so, what AWS Key Management Service (AWS KMS) key was specified.

On the AWS Glue console, you can turn on this option on the **Data catalog settings** page.

### To encrypt connection passwords

1. Sign in to the AWS Management Console and open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. Choose **Settings** in the navigation pane.
3. On the **Data catalog settings** page, select **Encrypt connection passwords**, and choose an AWS KMS key.

**⚠ Important**

AWS Glue supports only symmetric customer master keys (CMKs). The **AWS KMS key** list displays only symmetric keys. However, if you select **Choose a AWS KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

For more information, see [Data Catalog settings](#).

## Encrypting data written by AWS Glue

A *security configuration* is a set of security properties that can be used by AWS Glue. You can use a security configuration to encrypt data at rest. The following scenarios show some of the ways that you can use a security configuration.

- Attach a security configuration to an AWS Glue crawler to write encrypted Amazon CloudWatch Logs. For more information about attaching security configurations to crawlers, see [the section called “Step 3: Configure security settings”](#).
- Attach a security configuration to an extract, transform, and load (ETL) job to write encrypted Amazon Simple Storage Service (Amazon S3) targets and encrypted CloudWatch Logs.
- Attach a security configuration to an ETL job to write its jobs bookmarks as encrypted Amazon S3 data.
- Attach a security configuration to a development endpoint to write encrypted Amazon S3 targets.

**⚠ Important**

Currently, a security configuration overrides any server-side encryption (SSE-S3) setting that is passed as an ETL job parameter. Thus, if both a security configuration and an SSE-S3 parameter are associated with a job, the SSE-S3 parameter is ignored.

For more information about security configurations, see [Working with security configurations on the AWS Glue console](#).

## Topics

- [Setting Up AWS Glue to use security configurations](#)
- [Creating a route to AWS KMS for VPC jobs and crawlers](#)
- [Working with security configurations on the AWS Glue console](#)

## Setting Up AWS Glue to use security configurations

Follow these steps to set up your AWS Glue environment to use security configurations.

1. Create or update your AWS Key Management Service (AWS KMS) keys to grant AWS KMS permissions to the IAM roles that are passed to AWS Glue crawlers and jobs to encrypt CloudWatch Logs. For more information, see [Encrypt Log Data in CloudWatch Logs Using AWS KMS](#) in the *Amazon CloudWatch Logs User Guide*.

In the following example, *"role1"*, *"role2"*, and *"role3"* are IAM roles that are passed to crawlers and jobs.

```
{
  "Effect": "Allow",
  "Principal": { "Service": "logs.region.amazonaws.com" },
  "AWS": [
    "role1",
    "role2",
    "role3"
  ] },
  "Action": [
    "kms:Encrypt*",
    "kms:Decrypt*",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:Describe*"
  ],
  "Resource": "*"
}
```

The Service statement, shown as "Service": "logs.*region*.amazonaws.com", is required if you use the key to encrypt CloudWatch Logs.

2. Ensure that the AWS KMS key is ENABLED before it is used.

**Note**

If you are using Iceberg as your data lake framework, Iceberg tables have their own mechanisms to enable server-side encryption. You should enable these configuration in addition to AWS Glue's security configurations. To enable server-side encryption on Iceberg tables, review the guidance from [Iceberg documentation](#).

## Creating a route to AWS KMS for VPC jobs and crawlers

You can connect directly to AWS KMS through a private endpoint in your virtual private cloud (VPC) instead of connecting over the internet. When you use a VPC endpoint, communication between your VPC and AWS KMS is conducted entirely within the AWS network.

You can create an AWS KMS VPC endpoint within a VPC. Without this step, your jobs or crawlers might fail with a `kms timeout` on jobs or an `internal service exception` on crawlers. For detailed instructions, see [Connecting to AWS KMS Through a VPC Endpoint](#) in the *AWS Key Management Service Developer Guide*.

As you follow these instructions, on the [VPC console](#), you must do the following:

- Select **Enable Private DNS name**.
- Choose the **Security group** (with self-referencing rule) that you use for your job or crawler that accesses Java Database Connectivity (JDBC). For more information about AWS Glue connections, see [Connecting to data](#).

When you add a security configuration to a crawler or job that accesses JDBC data stores, AWS Glue must have a route to the AWS KMS endpoint. You can provide the route with a network address translation (NAT) gateway or with an AWS KMS VPC endpoint. To create a NAT gateway, see [NAT Gateways](#) in the *Amazon VPC User Guide*.

## Working with security configurations on the AWS Glue console

**Warning**

AWS Glue security configurations are not currently supported in Ray jobs.

A *security configuration* in AWS Glue contains the properties that are needed when you write encrypted data. You create security configurations on the AWS Glue console to provide the encryption properties that are used by crawlers, jobs, and development endpoints.

To see a list of all the security configurations that you have created, open the AWS Glue console at <https://console.aws.amazon.com/glue/> and choose **Security configurations** in the navigation pane.

The **Security configurations** list displays the following properties about each configuration:

### **Name**

The unique name you provided when you created the configuration. The name may contain letters (A-Z), numbers (0-9), hypens (-), or underscores (\_), and be up to 255 characters long.

### **Enable Amazon S3 encryption**

If turned on, the Amazon Simple Storage Service (Amazon S3) encryption mode such as SSE-KMS or SSE-S3 is enabled for metadata store in the data catalog.

### **Enable Amazon CloudWatch logs encryption**

If turned on, the Amazon S3 encryption mode such as SSE-KMS is enabled when writing logs to Amazon CloudWatch.

### **Advanced settings: Enable job bookmark encryption**

If turned on, the Amazon S3 encryption mode such as SSE-KMS is enabled when jobs are bookmarked.

You can add or delete configurations in the **Security configurations** section on the console. To see more details for a configuration, choose the configuration name in the list. Details include the information that you defined when you created the configuration.

### **Adding a security configuration**

To add a security configuration using the AWS Glue console, on the **Security configurations** page, choose **Add security configuration**.

## Add security configuration

Choose encryption and permission options for your accounts data catalog.

### Security configuration properties

Name

*Enter a unique security configuration name*

Name may contain letters (A-Z), numbers (0-9), hyphens (-), or underscores (\_), and can be up to 255 characters long.

### Encryption settings

Enable and choose options for at-rest encryption.

- Enable S3 encryption**  
Enable at-rest encryption for metadata stored in the data catalog.
- Enable CloudWatch logs encryption**  
Enable at-rest encryption when writing logs to Amazon CloudWatch.

#### ▼ Advanced settings

- Enable job bookmark encryption**  
Enable at-rest encryption of job bookmark.

Cancel

Save

### Security configuration properties

Enter a unique security configuration name. The name may contain letters (A-Z), numbers (0-9), hyphens (-), or underscores (\_), and can be up to 255 characters long.

### Encryption settings

You can enable at-rest encryption for metadata stored in the Data Catalog in Amazon S3 and logs in Amazon CloudWatch. To set up encryption of data and metadata with AWS Key Management Service (AWS KMS) keys on the AWS Glue console, add a policy to the console user. This policy must specify the allowed resources as key Amazon Resource Names (ARNs) that are used to encrypt Amazon S3 data stores, as in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:GenerateDataKey",
      "kms:Decrypt",
      "kms:Encrypt"],
    "Resource": "arn:aws:kms:region:account-id:key/key-id"}
}
```

### Important

When a security configuration is attached to a crawler or job, the IAM role that is passed must have AWS KMS permissions. For more information, see [Encrypting data written by AWS Glue](#).

When you define a configuration, you can provide values for the following properties:

### Enable S3 encryption

When you are writing Amazon S3 data, you use either server-side encryption with Amazon S3 managed keys (SSE-S3) or server-side encryption with AWS KMS managed keys (SSE-KMS). This field is optional. To allow access to Amazon S3, choose an AWS KMS key, or choose **Enter a key ARN** and provide the ARN for the key. Enter the ARN in the form `arn:aws:kms:region:account-id:key/key-id`. You can also provide the ARN as a key alias, such as `arn:aws:kms:region:account-id:alias/alias-name`.

If you enable Spark UI for your job, the Spark UI log file uploaded to Amazon S3 will be applied with the same encryption.

### Important

AWS Glue supports only symmetric customer master keys (CMKs). The **AWS KMS key** list displays only symmetric keys. However, if you select **Choose a AWS KMS key ARN**, the console lets you enter an ARN for any key type. Ensure that you enter only ARNs for symmetric keys.

## Enable CloudWatch Logs encryption

Server-side (SSE-KMS) encryption is used to encrypt CloudWatch Logs. This field is optional. To turn it on, choose an AWS KMS key, or choose **Enter a key ARN** and provide the ARN for the key. Enter the ARN in the form `arn:aws:kms:region:account-id:key/key-id`. You can also provide the ARN as a key alias, such as `arn:aws:kms:region:account-id:alias/alias-name`.

## Advanced settings: Job bookmark encryption

Client-side (CSE-KMS) encryption is used to encrypt job bookmarks. This field is optional. The bookmark data is encrypted before it is sent to Amazon S3 for storage. To turn it on, choose an AWS KMS key, or choose **Enter a key ARN** and provide the ARN for the key. Enter the ARN in the form `arn:aws:kms:region:account-id:key/key-id`. You can also provide the ARN as a key alias, such as `arn:aws:kms:region:account-id:alias/alias-name`.

For more information, see the following topics in the *Amazon Simple Storage Service User Guide*:

- For information about SSE-S3, see [Protecting Data Using Server-Side Encryption with Amazon S3-Managed Encryption Keys \(SSE-S3\)](#).
- For information about SSE-KMS, see [Protecting Data Using Server-Side Encryption with AWS KMS keys](#).
- For information about CSE-KMS, see [Using a KMS key stored in AWS KMS](#).

## Encryption in transit

AWS provides Transport Layer Security (TLS) encryption for data in motion. You can configure encryption settings for crawlers, ETL jobs, and development endpoints using [security configurations](#) in AWS Glue. You can turn on AWS Glue Data Catalog encryption via the settings for the Data Catalog.

As of September 4, 2018, AWS KMS (*bring your own key and server-side encryption*) for AWS Glue ETL and the AWS Glue Data Catalog is supported.

## FIPS compliance

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

## Key management

You can use AWS Identity and Access Management (IAM) with AWS Glue to define users, AWS resources, groups, roles and fine-grained policies regarding access, denial, and more.

You can define the access to the metadata using both resource-based and identity-based policies, depending on your organization's needs. Resource-based policies list the principals that are allowed or denied access to your resources, allowing you to set up policies such as cross-account access. Identity policies are specifically attached to users, groups, and roles within IAM.

For a step-by-step example, see [Restrict access to your AWS Glue Data Catalog with resource-level IAM permissions and resource-based policies](#) on the AWS Big Data Blog.

The fine-grained access portion of the policy is defined within the `Resource` clause. This portion defines both the AWS Glue Data Catalog object that the action can be performed on, and what resulting objects get returned by that operation.

A *development endpoint* is an environment that you can use to develop and test your AWS Glue scripts. You can add, delete, or rotate the SSH key of a development endpoint.

As of September 4, 2018, AWS KMS (*bring your own key and server-side encryption*) for AWS Glue ETL and the AWS Glue Data Catalog is supported.

## AWS Glue dependency on other AWS services

For a user to work with the AWS Glue console, that user must have a minimum set of permissions that allows them to work with the AWS Glue resources for their AWS account. In addition to these AWS Glue permissions, the console requires permissions from the following services:

- Amazon CloudWatch Logs permissions to display logs.
- AWS Identity and Access Management (IAM) permissions to list and pass roles.
- AWS CloudFormation permissions to work with stacks.

- Amazon Elastic Compute Cloud (Amazon EC2) permissions to list virtual private clouds (VPCs), subnets, security groups, instances, and other objects (to set up Amazon EC2 items such as VPCs when running jobs, crawlers, and creating development endpoints).
- Amazon Simple Storage Service (Amazon S3) permissions to list buckets and objects, and to retrieve and save scripts.
- Amazon Redshift permissions to work with clusters.
- Amazon Relational Database Service (Amazon RDS) permissions to list instances.

## Development endpoints

A development endpoint is an environment that you can use to develop and test your AWS Glue scripts. You can use AWS Glue to create, edit, and delete development endpoints. You can list all the development endpoints that are created. You can add, delete, or rotate the SSH key of a development endpoint. You can also create notebooks that use the development endpoint.

You provide configuration values to provision the development environments. These values tell AWS Glue how to set up the network so that you can access the development endpoint securely, and so that your endpoint can access your data stores. Then, you can create a notebook that connects to the development endpoint. You use your notebook to author and test your ETL script.

Use an AWS Identity and Access Management (IAM) role with permissions similar to the IAM role that you use to run AWS Glue ETL jobs. Use a virtual private cloud (VPC), a subnet, and a security group to create a development endpoint that can connect to your data resources securely. You generate an SSH key pair to connect to the development environment using SSH.

You can create development endpoints for Amazon S3 data and within a VPC that you can use to access datasets using JDBC.

You can install a Jupyter notebook client on your local machine and use it to debug and test ETL scripts on a development endpoint. Or, you can use a SageMaker notebook to author ETL scripts in JupyterLab on AWS. See [Use a SageMaker notebook with your development endpoint](#).

AWS Glue tags Amazon EC2 instances with a name that is prefixed with `aws-glue-dev-endpoint`.

You can set up a notebook server on a development endpoint to run PySpark with AWS Glue extensions.

# Identity and access management for AWS Glue

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use AWS Glue resources. IAM is an AWS service that you can use with no additional charge.

## Note

You can grant access to your data in the AWS Glue Data Catalog using either AWS Glue methods or AWS Lake Formation grants. You can use AWS Identity and Access Management (IAM) policies to set fine-grained access control with AWS Glue methods. Lake Formation uses a simpler GRANT/REVOKE permissions model that is similar to the GRANT/REVOKE commands in a relational database system.

This section includes information about how to use the AWS Glue methods. For information about using Lake Formation grants, see [Granting Lake Formation permissions](#) in the *AWS Lake Formation Developer Guide*.

## Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How AWS Glue works with IAM](#)
- [Configuring IAM permissions for AWS Glue](#)
- [AWS Glue access control policy examples](#)
- [AWS managed policies for AWS Glue](#)
- [Specifying AWS Glue resource ARNs](#)
- [Granting cross-account access](#)
- [Troubleshooting AWS Glue identity and access](#)

## Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in AWS Glue.

**Service user** – If you use the AWS Glue service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more AWS Glue features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in AWS Glue, see [Troubleshooting AWS Glue identity and access](#).

**Service administrator** – If you're in charge of AWS Glue resources at your company, you probably have full access to AWS Glue. It's your job to determine which AWS Glue features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with AWS Glue, see [How AWS Glue works with IAM](#).

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to AWS Glue. To view example AWS Glue identity-based policies that you can use in IAM, see [Identity-based policy examples for AWS Glue](#).

## Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If

you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](#) in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](#) in the *AWS IAM Identity Center User Guide* and [Using multi-factor authentication \(MFA\) in AWS](#) in the *IAM User Guide*.

## AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

## Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

## IAM users and groups

An [IAM user](#) is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating

IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see [Rotate access keys regularly for use cases that require long-term credentials](#) in the *IAM User Guide*.

An [IAM group](#) is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see [When to create an IAM user \(instead of a role\)](#) in the *IAM User Guide*.

## IAM roles

An [IAM role](#) is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by [switching roles](#). You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Creating a role for a third-party Identity Provider](#) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permission sets, see [Permission sets](#) in the *AWS IAM Identity Center User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource

(instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
  - **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).
  - **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.
  - **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles or IAM users, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

## Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

### Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

### Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific

resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

## Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see [Access control list \(ACL\) overview](#) in the *Amazon Simple Storage Service Developer Guide*.

## Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's

permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the *IAM User Guide*.

## Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

## How AWS Glue works with IAM

Before you use IAM to manage access to AWS Glue, learn what IAM features are available to use with AWS Glue.

### IAM features you can use with AWS Glue

IAM feature	AWS Glue support
<a href="#">Identity-based policies</a>	Yes
<a href="#">Resource-based policies</a>	Partial
<a href="#">Policy actions</a>	Yes
<a href="#">Policy resources</a>	Yes
<a href="#">Policy condition keys (service-specific)</a>	Yes
<a href="#">ACLs</a>	No
<a href="#">ABAC (tags in policies)</a>	Partial
<a href="#">Temporary credentials</a>	Yes
<a href="#">Principal permissions</a>	No
<a href="#">Service roles</a>	Yes
<a href="#">Service-linked roles</a>	No

To get a high-level view of how AWS Glue and other AWS services work with most IAM features, see [AWS services that work with IAM](#) in the *IAM User Guide*.

## Identity-based policies for AWS Glue

Supports identity-based policies	Yes
----------------------------------	-----

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

AWS Glue supports identity-based policies (IAM policies) for all AWS Glue operations. By attaching a policy, you can grant permissions to create, access, or modify an AWS Glue resource, such as a table in the AWS Glue Data Catalog.

### Identity-based policy examples for AWS Glue

To view examples of AWS Glue identity-based policies, see [Identity-based policy examples for AWS Glue](#).

## Resource-based policies within AWS Glue

Supports resource-based policies	Partial
----------------------------------	---------

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#)

in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

### Note

You can only use an AWS Glue resource policy to manage permissions for Data Catalog resources. You can't attach it to any other AWS Glue resources such as jobs, triggers, development endpoints, crawlers, or classifiers.

Only *one* resource policy is allowed per catalog, and its size is limited to 10 KB.

In AWS Glue, a resource policy is attached to a *catalog*, which is a virtual container for all the kinds of Data Catalog resources mentioned previously. Each AWS account owns a single catalog in an AWS Region whose catalog ID is the same as the AWS account ID. You cannot delete or modify a catalog.

A resource policy is evaluated for all API calls to the catalog where the caller principal is included in the "Principal" block of the policy document.

To view examples of AWS Glue resource-based policies, see [Resource-based policy examples for AWS Glue](#).

## Policy actions for AWS Glue

Supports policy actions

Yes

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of AWS Glue actions, see [Actions defined by AWS Glue](#) in the *Service Authorization Reference*.

Policy actions in AWS Glue use the following prefix before the action:

```
glue
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [  
  "glue:action1",  
  "glue:action2"  
]
```

You can specify multiple actions using wildcards (\*). For example, to specify all actions that begin with the word `Get`, include the following action:

```
"Action": "glue:Get*"
```

To view example policies, see [AWS Glue access control policy examples](#).

## Policy resources for AWS Glue

Supports policy resources	Yes
---------------------------	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (\*) to indicate that the statement applies to all resources.

```
"Resource": "*" 
```

For more information about how to control access to AWS Glue resources using ARNs, see [Specifying AWS Glue resource ARNs](#).

To see a list of AWS Glue resource types and their ARNs, see [Resources defined by AWS Glue](#) in the *Service Authorization Reference*. To learn which actions you can use to specify the ARN of each resource, see [Actions defined by AWS Glue](#).

## Policy condition keys for AWS Glue

Supports service-specific policy condition keys	Yes
---	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Condition element (or Condition *block*) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags](#) in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

To see a list of AWS Glue condition keys, see [Condition keys for AWS Glue](#) in the *Service Authorization Reference*. To learn which actions and resources you can use a condition key with, see [Actions defined by AWS Glue](#).

To view example policies, see [Control settings using condition keys or context keys](#).

## ACLs in AWS Glue

Supports ACLs

No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

## ABAC with AWS Glue

Supports ABAC (tags in policies)

Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [What is ABAC?](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

### Important

The condition context keys apply only to AWS Glue API actions on crawlers, jobs, triggers, and development endpoints. For more information about which API operations are affected, see [Condition keys for AWS Glue](#).

The AWS Glue Data Catalog API operations don't currently support the `aws:referrer` and `aws:UserAgent` global condition context keys.

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Grant access using tags](#).

## Using temporary credentials with AWS Glue

Supports temporary credentials	Yes
--------------------------------	-----

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see [AWS services that work with IAM](#) in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see [Switching to a role \(console\)](#) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#).

## Cross-service principal permissions for AWS Glue

Supports forward access sessions (FAS)	No
--	----

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

## Service roles for AWS Glue

Supports service roles	Yes
------------------------	-----

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

### Warning

Changing the permissions for a service role might break AWS Glue functionality. Edit service roles only when AWS Glue provides guidance to do so.

For detailed instructions on creating a service role for AWS Glue, see [Step 1: Create an IAM policy for the AWS Glue service](#) and [Step 2: Create an IAM role for AWS Glue](#).

## Service-linked roles for AWS Glue

Supports service-linked roles	No
-------------------------------	----

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS

account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing service-linked roles, see [AWS services that work with IAM](#). Find a service in the table that includes a Yes in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

## Configuring IAM permissions for AWS Glue

You use AWS Identity and Access Management (IAM) to define policies and roles that AWS Glue uses to access resources. The following steps lead you through various options for setting up the permissions for AWS Glue. Depending on your business needs, you might have to add or reduce access to your resources.

### Note

To get started with basic IAM permissions for AWS Glue instead, see [Setting up IAM permissions for AWS Glue](#).

1. [Create an IAM policy for the AWS Glue service](#): Create a service policy that allows access to AWS Glue resources.
2. [Create an IAM role for AWS Glue](#): Create an IAM role, and attach the AWS Glue service policy and a policy for your Amazon Simple Storage Service (Amazon S3) resources that are used by AWS Glue.
3. [Attach a policy to users or groups that access AWS Glue](#): Attach policies to any users or groups that sign in to the AWS Glue console.
4. [Create an IAM policy for notebooks](#): Create a notebook server policy to use in the creation of notebook servers on development endpoints.
5. [Create an IAM role for notebooks](#): Create an IAM role and attach the notebook server policy.
6. [Create an IAM policy for Amazon SageMaker notebooks](#): Create an IAM policy to use when creating Amazon SageMaker notebooks on development endpoints.
7. [Create an IAM role for Amazon SageMaker notebooks](#): Create an IAM role and attach the policy to grant permissions when creating Amazon SageMaker notebooks on development endpoints.

## Step 1: Create an IAM policy for the AWS Glue service

For any operation that accesses data on another AWS resource, such as accessing your objects in Amazon S3, AWS Glue needs permission to access the resource on your behalf. You provide those permissions by using AWS Identity and Access Management (IAM).

### Note

You can skip this step if you use the AWS managed policy **AWSGlueServiceRole**.

In this step, you create a policy that is similar to **AWSGlueServiceRole**. You can find the most current version of **AWSGlueServiceRole** on the IAM console.

### To create an IAM policy for AWS Glue

This policy grants permission for some Amazon S3 actions to manage resources in your account that are needed by AWS Glue when it assumes the role using this policy. Some of the resources that are specified in this policy refer to default names that are used by AWS Glue for Amazon S3 buckets, Amazon S3 ETL scripts, CloudWatch Logs, and Amazon EC2 resources. For simplicity, AWS Glue writes some Amazon S3 objects into buckets in your account prefixed with `aws-glue-*` by default.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Create Policy** screen, navigate to a tab to edit JSON. Create a policy document with the following JSON statements, and then choose **Review policy**.

### Note

Add any permissions needed for Amazon S3 resources. You might want to scope the resources section of your access policy to only those resources that are required.

```
{  
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "glue:*",
      "s3:GetBucketLocation",

        }
    },
    "Resource": [
        "arn:aws:ec2:*:*:network-interface/*",
        "arn:aws:ec2:*:*:security-group/*",
        "arn:aws:ec2:*:*:instance/*"
    ]
}

```

```

    ]
  }
}

```

The following table describes the permissions granted by this policy.

Action	Resource	Description
"glue:*"	"*"	Grants permission to run all AWS Glue API operations.
"s3:GetBucketLocation", "s3:ListBucket", "s3:ListAllMyBuckets", "s3:GetBucketAcl",	"*"	Allows listing of Amazon S3 buckets from crawlers, jobs, development endpoints, and notebook servers.
"ec2:DescribeVpcEndpoints", "ec2:DescribeRouteTables", "ec2:CreateNetworkInterface", "ec2>DeleteNetworkInterface", "ec2:DescribeNetworkInterfaces", "ec2:DescribeSecurityGroups", "ec2:DescribeSubnets", "ec2:DescribeVpcAttribute",	"*"	Allows the setup of Amazon EC2 network items, such as virtual private clouds (VPCs) when running jobs, crawlers, and development endpoints.
"iam:ListRolePolicies", "iam:GetRole", "iam:GetRolePolicy"	"*"	Allows listing IAM roles from crawlers, jobs, development endpoints, and notebook servers.
"cloudwatch:PutMetricData"	"*"	Allows writing CloudWatch metrics for jobs.

Action	Resource	Description
"s3:CreateBucket", "s3:PutBucketPublicAccessBlock"	"arn:aws:s3:::aws-glue-*"	<p>Allows the creation of Amazon S3 buckets in your account from jobs and notebook servers.</p> <p>Naming convention: Uses Amazon S3 folders named <b>aws-glue-</b>.</p> <p>Enables AWS Glue to create buckets that block public access.</p>
"s3:GetObject", "s3:PutObject", "s3:DeleteObject"	"arn:aws:s3:::aws-glue-*/*", "arn:aws:s3:::*/*aws-glue-*/*"	<p>Allows get, put, and delete of Amazon S3 objects into your account when storing objects such as ETL scripts and notebook server locations.</p> <p>Naming convention: Grants permission to Amazon S3 buckets or folders whose names are prefixed with <b>aws-glue-</b>.</p>
"s3:GetObject"	"arn:aws:s3:::crawler-public*", "arn:aws:s3:::aws-glue-*"	<p>Allows get of Amazon S3 objects used by examples and tutorials from crawlers and jobs.</p> <p>Naming convention: Amazon S3 bucket names begin with <b>crawler-public</b> and <b>aws-glue-</b>.</p>

Action	Resource	Description
"logs:CreateLogGroup", "logs:CreateLogStream", "logs:PutLogEvents"	"arn:aws:logs:*:*: log-group:/aws-glu e/*"	Allows writing logs to CloudWatch Logs.  Naming convention: AWS Glue writes logs to log groups whose names begin with <b>aws-glue</b> .
"ec2:CreateTags", "ec2>DeleteTags"	"arn:aws:ec2:*:*:n etwork-interface/ *", "arn:aws: ec2:*:*:security-g roup/*", "arn:aws: ec2:*:*:instance/* "	Allows tagging of Amazon EC2 resources created for development endpoints.  Naming convention: AWS Glue tags Amazon EC2 network interfaces, security groups, and instances with <b>aws-glue-service-resource</b> .

5. On the **Review Policy** screen, enter your **Policy Name**, for example **GlueServiceRolePolicy**. Enter an optional description, and when you're satisfied with the policy, choose **Create policy**.

## Step 2: Create an IAM role for AWS Glue

You need to grant your IAM role permissions that AWS Glue can assume when calling other services on your behalf. This includes access to Amazon S3 for any sources, targets, scripts, and temporary directories that you use with AWS Glue. Permission is needed by crawlers, jobs, and development endpoints.

You provide those permissions by using AWS Identity and Access Management (IAM). Add a policy to the IAM role that you pass to AWS Glue.

### To create an IAM role for AWS Glue

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**.
3. Choose **Create role**.

4. For role type, choose **AWS Service**, find and choose **Glue**, and choose **Next: Permissions**.
5. On the **Attach permissions policy** page, choose the policies that contain the required permissions; for example, the AWS managed policy `AWSGlueServiceRole` for general AWS Glue permissions and the AWS managed policy **AmazonS3FullAccess** for access to Amazon S3 resources. Then choose **Next: Review**.

**Note**

Ensure that one of the policies in this role grants permissions to your Amazon S3 sources and targets. You might want to provide your own policy for access to specific Amazon S3 resources. Data sources require `s3:ListBucket` and `s3:GetObject` permissions. Data targets require `s3:ListBucket`, `s3:PutObject`, and `s3:DeleteObject` permissions. For more information about creating an Amazon S3 policy for your resources, see [Specifying Resources in a Policy](#). For an example Amazon S3 policy, see [Writing IAM Policies: How to Grant Access to an Amazon S3 Bucket](#).

If you plan to access Amazon S3 sources and targets that are encrypted with SSE-KMS, attach a policy that allows AWS Glue crawlers, jobs, and development endpoints to decrypt the data. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).

The following is an example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:kms:*:account-id-without-hyphens:key/key-id"
      ]
    }
  ]
}
```

6. For **Role name**, enter a name for your role; for example, `AWSGlueServiceRoleDefault`. Create the role with the name prefixed with the string `AWSGlueServiceRole` to allow the

role to be passed from console users to the service. AWS Glue provided policies expect IAM service roles to begin with `AWSGlueServiceRole`. Otherwise, you must add a policy to allow your users the `iam:PassRole` permission for IAM roles to match your naming convention. Choose **Create Role**.

### Note

When you create a notebook with a role, that role is then passed to interactive sessions so that the same role can be used in both places. As such, the `iam:PassRole` permission needs to be part of the role's policy.

Create a new policy for your role using the following example. Replace the account number with your own and the role name.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::090000000210:role/<role_name>"
    }
  ]
}
```

## Step 3: Attach a policy to users or groups that access AWS Glue

The administrator must assign permissions to any users, groups, or roles using the AWS Glue console or AWS Command Line Interface (AWS CLI). You provide those permissions by using AWS Identity and Access Management (IAM), through policies. This step describes assigning permissions to users or groups.

When you finish this step, your user or group has the following policies attached:

- The AWS managed policy `AWSGlueConsoleFullAccess` or the custom policy **GlueConsoleAccessPolicy**
- **AWSGlueConsoleSageMakerNotebookFullAccess**

- **CloudWatchLogsReadOnlyAccess**
- **AWSCloudFormationReadOnlyAccess**
- **AmazonAthenaFullAccess**

### To attach an inline policy and embed it in a user or group

You can attach an AWS managed policy or an inline policy to a user or group to access the AWS Glue console. Some of the resources specified in this policy refer to default names that are used by AWS Glue for Amazon S3 buckets, Amazon S3 ETL scripts, CloudWatch Logs, AWS CloudFormation, and Amazon EC2 resources. For simplicity, AWS Glue writes some Amazon S3 objects into buckets in your account prefixed with `aws-glue-*` by default.

#### Note

You can skip this step if you use the AWS managed policy **AWSGlueConsoleFullAccess**.

#### Important

AWS Glue needs permission to assume a role that is used to perform work on your behalf. **To accomplish this, you add the `iam:PassRole` permissions to your AWS Glue users or groups.** This policy grants permission to roles that begin with `AWSGlueServiceRole` for AWS Glue service roles, and `AWSGlueServiceNotebookRole` for roles that are required when you create a notebook server. You can also create your own policy for `iam:PassRole` permissions that follows your naming convention.

Per security best practices, it is recommended to restrict access by tightening policies to further restrict access to Amazon S3 bucket and Amazon CloudWatch log groups. For an example Amazon S3 policy, see [Writing IAM Policies: How to Grant Access to an Amazon S3 Bucket](#).

In this step, you create a policy that is similar to `AWSGlueConsoleFullAccess`. You can find the most current version of `AWSGlueConsoleFullAccess` on the IAM console.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users** or **User groups**.

3. In the list, choose the name of the user or group to embed a policy in.
4. Choose the **Permissions** tab and, if necessary, expand the **Permissions policies** section.
5. Choose the **Add Inline policy** link.
6. On the **Create Policy** screen, navigate to a tab to edit JSON. Create a policy document with the following JSON statements, and then choose **Review policy**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:*",
        "redshift:DescribeClusters",
        "redshift:DescribeClusterSubnetGroups",
        "iam:ListRoles",
        "iam:ListUsers",
        "iam:ListGroups",
        "iam:ListRolePolicies",
        "iam:GetRole",
        "iam:GetRolePolicy",
        "iam:ListAttachedRolePolicies",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcs",
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeRouteTables",
        "ec2:DescribeVpcAttribute",
        "ec2:DescribeKeyPairs",
        "ec2:DescribeInstances",
        "rds:DescribeDBInstances",
        "rds:DescribeDBClusters",
        "rds:DescribeDBSubnetGroups",
        "s3:ListAllMyBuckets",
        "s3:ListBucket",
        "s3:GetBucketAcl",
        "s3:GetBucketLocation",
        "cloudformation:DescribeStacks",
        "cloudformation:GetTemplateSummary",
        "dynamodb:ListTables",
        "kms:ListAliases",
        "kms:DescribeKey",
```

```

        "cloudwatch:GetMetricData",
        "cloudwatch:ListDashboards"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:PutObject"
    ],
    "Resource": [
        "arn:aws:s3::*/*aws-glue-*/*",
        "arn:aws:s3:::aws-glue-*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "tag:GetResources"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:CreateBucket",
        "s3:PutBucketPublicAccessBlock"
    ],
    "Resource": [
        "arn:aws:s3:::aws-glue-*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "logs:GetLogEvents"
    ],
    "Resource": [
        "arn:aws:logs:*:*:/aws-glue/*"
    ]
}

```

```

    },
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:CreateStack",
        "cloudformation>DeleteStack"
      ],
      "Resource": "arn:aws:cloudformation:*:*:stack/aws-glue*/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:RunInstances"
      ],
      "Resource": [
        "arn:aws:ec2:*:*:instance/*",
        "arn:aws:ec2:*:*:key-pair/*",
        "arn:aws:ec2:*:*:image/*",
        "arn:aws:ec2:*:*:security-group/*",
        "arn:aws:ec2:*:*:network-interface/*",
        "arn:aws:ec2:*:*:subnet/*",
        "arn:aws:ec2:*:*:volume*"
      ]
    },
    {
      "Action": [
        "iam:PassRole"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:iam:*:*:role/AWSGlueServiceRole*",
      "Condition": {
        "StringLike": {
          "iam:PassedToService": [
            "glue.amazonaws.com"
          ]
        }
      }
    },
    {
      "Action": [
        "iam:PassRole"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:iam:*:*:role/AWSGlueServiceNotebookRole*",

```

```
    "Condition": {
      "StringLike": {
        "iam:PassedToService": [
          "ec2.amazonaws.com"
        ]
      }
    },
  ],
  {
    "Action": [
      "iam:PassRole"
    ],
    "Effect": "Allow",
    "Resource": [
      "arn:aws:iam::*:role/service-role/AWSGlueServiceRole*"
    ],
    "Condition": {
      "StringLike": {
        "iam:PassedToService": [
          "glue.amazonaws.com"
        ]
      }
    }
  }
]
}
```

The following table describes the permissions granted by this policy.

Action	Resource	Description
"glue:*"	"*"	<p>Grants permission to run all AWS Glue API operations.</p> <p>If you had previously created your policy without the "glue:*" action, you must add the following individual permissions to your policy:</p> <ul style="list-style-type: none"> <li>• "glue:ListCrawlers"</li> <li>• "glue:BatchGetCrawlers"</li> <li>• "glue:ListTriggers"</li> <li>• "glue:BatchGetTriggers"</li> <li>• "glue:ListDevEndpoints"</li> <li>• "glue:BatchGetDevEndpoints"</li> <li>• "glue:ListJobs"</li> <li>• "glue:BatchGetJobs"</li> </ul>
"redshift:DescribeClusters", "redshift:DescribeClusterSubnetGroups"	"*"	Allows creation of connections to Amazon Redshift.

Action	Resource	Description
"iam:ListRoles", "iam:ListRolePolicies", "iam:GetRole", "iam:GetRolePolicy", "iam:ListAttachedRolePolicies"	"*"	Allows listing IAM roles when working with crawlers, jobs, development endpoints , and notebook servers.
"ec2:DescribeSecurityGroups", "ec2:DescribeSubnets", "ec2:DescribeVpcs", "ec2:DescribeVpcEndpoints", "ec2:DescribeRouteTables", "ec2:DescribeVpcAttribute", "ec2:DescribeKeyPairs", "ec2:DescribeInstances"	"*"	Allows setup of Amazon EC2 network items, such as VPCs, when running jobs, crawlers, and development endpoints .
"rds:DescribeDBInstances"	"*"	Allows creation of connections to Amazon RDS.
"s3:ListAllMyBuckets", "s3:ListBucket", "s3:GetBucketAcl", "s3:GetBucketLocation"	"*"	Allows listing of Amazon S3 buckets when working with crawlers, jobs, development endpoints , and notebook servers.
"dynamodb:ListTables"	"*"	Allows listing of DynamoDB tables.
"kms:ListAliases", "kms:DescribeKey"	"*"	Allows working with KMS keys.

Action	Resource	Description
"cloudwatch:GetMetricData", "cloudwatch:ListDashboards"	"*"	Allows working with CloudWatch metrics.
"s3:GetObject", "s3:PutObject"	"arn:aws:s3:::aws-glue-*/*", "arn:aws:s3::: */*aws-glue-*/*", "arn:aws:s3:::aws-glue-*"	<p>Allows get and put of Amazon S3 objects into your account when storing objects such as ETL scripts and notebook server locations.</p> <p>Naming convention: Grants permission to Amazon S3 buckets or folders whose names are prefixed with <b>aws-glue-</b>.</p>
"tag:GetResources"	"*"	Allows retrieval of AWS tags.

Action	Resource	Description
"s3:CreateBucket", "s3:PutBucketPublicAccessBlock"	"arn:aws:s3::: aws-glue-*"	<p>Allows creation of an Amazon S3 bucket into your account when storing objects such as ETL scripts and notebook server locations.</p> <p>Naming convention: Grants permission to Amazon S3 buckets whose names are prefixed with <b>aws-glue-</b>.</p> <p>Enables AWS Glue to create buckets that block public access.</p>
"logs:GetLogEvents"	"arn:aws:logs:*:*: /aws-glue/*"	<p>Allows retrieval of CloudWatch Logs.</p> <p>Naming convention: AWS Glue writes logs to log groups whose names begin with <b>aws-glue-</b>.</p>

Action	Resource	Description
"cloudformation:CreateStack", "cloudformation>DeleteStack"	"arn:aws:cloudformation:*:*:stack/aws-glue*/"	Allows managing AWS CloudFormation stacks when working with notebook servers.  Naming convention: AWS Glue creates stacks whose names begin with <b>aws-glue</b> .
"ec2:RunInstances"	"arn:aws:ec2:*:*:instance/*", "arn:aws:ec2:*:*:key-pair/*", "arn:aws:ec2:*:*:image/*", "arn:aws:ec2:*:*:security-group/*", "arn:aws:ec2:*:*:network-interface/*", "arn:aws:ec2:*:*:subnet/*", "arn:aws:ec2:*:*:volume/*"	Allows running of development endpoints and notebook servers.
"iam:PassRole"	"arn:aws:iam:*:*:role/AWSGlueServiceRole*"	Allows AWS Glue to assume PassRole permission for roles that begin with <b>AWSGlueServiceRole</b> .

Action	Resource	Description
"iam:PassRole"	"arn:aws:iam::*:role/ AWSGlueServiceNotebookRole*"	Allows Amazon EC2 to assume PassRole permission for roles that begin with AWSGlueServiceNotebookRole .
"iam:PassRole"	"arn:aws:iam::*:role/service-role/ AWSGlueServiceRole*"	Allows AWS Glue to assume PassRole permission for roles that begin with service-role/ AWSGlueServiceRole .

- On the **Review policy** screen, enter a name for the policy, for example **GlueConsoleAccessPolicy**. When you're satisfied with the policy, choose **Create policy**. Ensure that no errors appear in a red box at the top of the screen. Correct any that are reported.

**Note**

If **Use autofor** is selected, the policy is reformatted whenever you open a policy or choose **Validate Policy**.

### To attach the AWSGlueConsoleFullAccess managed policy

You can attach the AWSGlueConsoleFullAccess policy to provide permissions that are required by the AWS Glue console user.

**Note**

You can skip this step if you created your own policy for AWS Glue console access.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to the **AWSGlueConsoleFullAccess**. You can use the **Filter** menu and the search box to filter the list of policies.
4. Choose **Policy actions**, and then choose **Attach**.
5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.

### To attach the **AWSGlueConsoleSageMakerNotebookFullAccess** managed policy

You can attach the **AWSGlueConsoleSageMakerNotebookFullAccess** policy to a user to manage SageMaker notebooks created on the AWS Glue console. In addition to other required AWS Glue console permissions, this policy grants access to resources needed to manage SageMaker notebooks.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to the **AWSGlueConsoleSageMakerNotebookFullAccess**. You can use the **Filter** menu and the search box to filter the list of policies.
4. Choose **Policy actions**, and then choose **Attach**.
5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.

### To attach the **CloudWatchLogsReadOnlyAccess** managed policy

You can attach the **CloudWatchLogsReadOnlyAccess** policy to a user to view the logs created by AWS Glue on the CloudWatch Logs console.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to the **CloudWatchLogsReadOnlyAccess**. You can use the **Filter** menu and the search box to filter the list of policies.
4. Choose **Policy actions**, and then choose **Attach**.
5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.

### To attach the **AWSCloudFormationReadOnlyAccess** managed policy

You can attach the **AWSCloudFormationReadOnlyAccess** policy to a user to view the AWS CloudFormation stacks used by AWS Glue on the AWS CloudFormation console.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to **AWSCloudFormationReadOnlyAccess**. You can use the **Filter** menu and the search box to filter the list of policies.
4. Choose **Policy actions**, and then choose **Attach**.
5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.

### To attach the **AmazonAthenaFullAccess** managed policy

You can attach the **AmazonAthenaFullAccess** policy to a user to view Amazon S3 data in the Athena console.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the check box next to the **AmazonAthenaFullAccess**. You can use the **Filter** menu and the search box to filter the list of policies.
4. Choose **Policy actions**, and then choose **Attach**.

5. Choose the user to attach the policy to. You can use the **Filter** menu and the search box to filter the list of principal entities. After choosing the user to attach the policy to, choose **Attach policy**.

## Step 4: Create an IAM policy for notebook servers

If you plan to use notebooks with development endpoints, you must specify permissions when you create the notebook server. You provide those permissions by using AWS Identity and Access Management (IAM).

This policy grants permission for some Amazon S3 actions to manage resources in your account that are needed by AWS Glue when it assumes the role using this policy. Some of the resources that are specified in this policy refer to default names used by AWS Glue for Amazon S3 buckets, Amazon S3 ETL scripts, and Amazon EC2 resources. For simplicity, AWS Glue defaults writing some Amazon S3 objects into buckets in your account prefixed with `aws-glue-*`.

### Note

You can skip this step if you use the AWS managed policy **AWSGlueServiceNotebookRole**.

In this step, you create a policy that is similar to `AWSGlueServiceNotebookRole`. You can find the most current version of `AWSGlueServiceNotebookRole` on the IAM console.

### To create an IAM policy for notebooks

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Create Policy** screen, navigate to a tab to edit JSON. Create a policy document with the following JSON statements, and then choose **Review policy**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
"Effect": "Allow",
"Action": [
  "glue:CreateDatabase",
  "glue:CreatePartition",
  "glue:CreateTable",
  "glue>DeleteDatabase",
  "glue>DeletePartition",
  "glue>DeleteTable",
  "glue:GetDatabase",
  "glue:GetDatabases",
  "glue:GetPartition",
  "glue:GetPartitions",
  "glue:GetTable",
  "glue:GetTableVersions",
  "glue:GetTables",

  "glue:UpdateDevEndpoint",
  "s3:GetBucketLocation",
```

```

        "s3:ListBucket",
        "s3:ListAllMyBuckets",
        "s3:GetBucketAcl"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject"
    ],
    "Resource": [
        "arn:aws:s3:::crawler-public*",
        "arn:aws:s3:::aws-glue*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:DeleteObject"
    ],
    "Resource": [
        "arn:aws:s3:::aws-glue*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateTags",
        "ec2:DeleteTags"
    ],
    "Condition": {
        "ForAllValues:StringEquals": {
            "aws:TagKeys": [
                "aws-glue-service-resource"
            ]
        }
    },
    "Resource": [
        "arn:aws:ec2:*:*:network-interface/*",
        "arn:aws:ec2:*:*:security-group/*",

```

```

        "arn:aws:ec2:*:*:instance/*"
    ]
}
]
}

```

The following table describes the permissions granted by this policy.

Action	Resource	Description
"glue:*"	"*"	Grants permission to run all AWS Glue API operations.
"s3:GetBucketLocation", "s3:ListBucket", "s3:ListAllMyBuckets", "s3:GetBucketAcl"	"*"	Allows listing of Amazon S3 buckets from notebook servers.
"s3:GetObject"	"arn:aws:s3:::crawler-public*", "arn:aws:s3:::aws-glue-*"	Allows get of Amazon S3 objects used by examples and tutorials from notebooks.  Naming convention: Amazon S3 bucket names begin with <b>crawler-public</b> and <b>aws-glue-</b> .
"s3:PutObject", "s3:DeleteObject"	"arn:aws:s3:::aws-glue*"	Allows put and delete of Amazon S3 objects into your account from notebooks.  Naming convention: Uses Amazon S3 folders named <b>aws-glue</b> .

Action	Resource	Description
"ec2:CreateTags", "ec2>DeleteTags"	"arn:aws:ec2:*:*:network-interface/*", "arn:aws:ec2:*:*:security-group/*", "arn:aws:ec2:*:*:instance/*"	Allows tagging of Amazon EC2 resources created for notebook servers.  Naming convention: AWS Glue tags Amazon EC2 instances with <b>aws-glue-service-resource</b> .

- On the **Review Policy** screen, enter your **Policy Name**, for example **GlueServiceNotebookPolicyDefault**. Enter an optional description, and when you're satisfied with the policy, choose **Create policy**.

## Step 5: Create an IAM role for notebook servers

If you plan to use notebooks with development endpoints, you need to grant the IAM role permissions. You provide those permissions by using AWS Identity and Access Management IAM, through an IAM role.

### Note

When you create an IAM role using the IAM console, the console creates an instance profile automatically and gives it the same name as the role to which it corresponds.

### To create an IAM role for notebooks

- Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
- In the left navigation pane, choose **Roles**.
- Choose **Create role**.
- For role type, choose **AWS Service**, find and choose **EC2**, and choose the **EC2** use case, then choose **Next: Permissions**.
- On the **Attach permissions policy** page, choose the policies that contain the required permissions; for example, **AWSGlueServiceNotebookRole** for general AWS Glue permissions

and the AWS managed policy **AmazonS3FullAccess** for access to Amazon S3 resources. Then choose **Next: Review**.

**Note**

Ensure that one of the policies in this role grants permissions to your Amazon S3 sources and targets. Also confirm that your policy allows full access to the location where you store your notebook when you create a notebook server. You might want to provide your own policy for access to specific Amazon S3 resources. For more information about creating an Amazon S3 policy for your resources, see [Specifying Resources in a Policy](#).

If you plan to access Amazon S3 sources and targets that are encrypted with SSE-KMS, attach a policy that allows notebooks to decrypt the data. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).

The following is an example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:kms:*:account-id-without-hyphens:key/key-id"
      ]
    }
  ]
}
```

6. For **Role name**, enter a name for your role. Create the role with the name prefixed with the string `AWSGlueServiceNotebookRole` to allow the role to be passed from console users to the notebook server. AWS Glue provided policies expect IAM service roles to begin with `AWSGlueServiceNotebookRole`. Otherwise you must add a policy to your users to allow the `iam:PassRole` permission for IAM roles to match your naming convention. For example, enter `AWSGlueServiceNotebookRoleDefault`. Then choose **Create role**.

## Step 6: Create an IAM policy for SageMaker notebooks

If you plan to use SageMaker notebooks with development endpoints, you must specify permissions when you create the notebook. You provide those permissions by using AWS Identity and Access Management (IAM).

### To create an IAM policy for SageMaker notebooks

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Create Policy** page, navigate to a tab to edit the JSON. Create a policy document with the following JSON statements. Edit *bucket-name*, *region-code*, and *account-id* for your environment.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::bucket-name"
      ]
    },
    {
      "Action": [
        "s3:GetObject"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::bucket-name*"
      ]
    },
    {
      "Action": [
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
```

```

        "logs:PutLogEvents",
        "logs:CreateLogGroup"
    ],
    "Effect": "Allow",
    "Resource": [
        "arn:aws:logs:region-code:account-id:log-group:/aws/sagemaker/*",
        "arn:aws:logs:region-code:account-id:log-group:/aws/sagemaker/
*:log-stream:aws-glue-*"
    ]
},
{
    "Action": [
        "glue:UpdateDevEndpoint",
        "glue:GetDevEndpoint",
        "glue:GetDevEndpoints"
    ],
    "Effect": "Allow",
    "Resource": [
        "arn:aws:glue:region-code:account-id:devEndpoint/*"
    ]
},
{
    "Action": [
        "sagemaker:ListTags"
    ],
    "Effect": "Allow",
    "Resource": [
        "arn:aws:sagemaker:region-code:account-id:notebook-instance/*"
    ]
}
]
}

```

Then choose **Review policy**.

The following table describes the permissions granted by this policy.

Action	Resource	Description
"s3:ListBucket*"	"arn:aws:s3::: <i>bucket-name</i> "	Grants permission to list Amazon S3 buckets.

Action	Resource	Description
"s3:GetObject"	"arn:aws:s3::: <i>bucket-name</i> *"	Grants permission to get Amazon S3 objects that are used by SageMaker notebooks.
"logs:CreateLogStream", "logs:DescribeLogStreams", "logs:PutLogEvents", "logs:CreateLogGroup"	"arn:aws:logs: <i>region-code</i> : <i>account-id</i> :log-group:/aws/sagemaker/*", "arn:aws:logs: <i>region-code</i> : <i>account-id</i> :log-group:/aws/sagemaker/*:log-stream:aws-glue-*"	Grants permission to write logs to Amazon CloudWatch Logs from notebooks.  Naming convention: Writes to log groups whose names begin with <b>aws-glue</b> .
"glue:UpdateDevEndpoint", "glue:GetDevEndpoint", "glue:GetDevEndpoints"	"arn:aws:glue: <i>region-code</i> : <i>account-id</i> :devEndpoint/*"	Grants permission to use a development endpoint from SageMaker notebooks.
"sagemaker:ListTags"	"arn:aws:sagemaker : <i>region-code</i> : <i>account-id</i> :notebook-instance/*"	Grants permission to return tags for an SageMaker resource. The <code>aws-glue-dev-endpoint</code> tag is required on the SageMaker notebook for connecting the notebook to a development endpoint.

- On the **Review Policy** screen, enter your **Policy Name**, for example `AWSGlueSageMakerNotebook`. Enter an optional description, and when you're satisfied with the policy, choose **Create policy**.

## Step 7: Create an IAM role for SageMaker notebooks

If you plan to use SageMaker notebooks with development endpoints, you need to grant the IAM role permissions. You provide those permissions by using AWS Identity and Access Management (IAM), through an IAM role.

### To create an IAM role for SageMaker notebooks

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the left navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For role type, choose **AWS Service**, find and choose **SageMaker**, and then choose the **SageMaker - Execution** use case. Then choose **Next: Permissions**.
5. On the **Attach permissions policy** page, choose the policies that contain the required permissions; for example, **AmazonSageMakerFullAccess**. Choose **Next: Review**.

If you plan to access Amazon S3 sources and targets that are encrypted with SSE-KMS, attach a policy that allows notebooks to decrypt the data, as shown in the following example. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:kms:*:account-id-without-hyphens:key/key-id"
      ]
    }
  ]
}
```

6. For **Role name**, enter a name for your role. To allow the role to be passed from console users to SageMaker, use a name that is prefixed with the string `AWSGlueServiceSageMakerNotebookRole`. AWS Glue provided policies expect IAM roles

to begin with `AWSGlueServiceSageMakerNotebookRole`. Otherwise you must add a policy to your users to allow the `iam:PassRole` permission for IAM roles to match your naming convention.

For example, enter `AWSGlueServiceSageMakerNotebookRole-Default`, and then choose **Create role**.

7. After you create the role, attach the policy that allows additional permissions required to create SageMaker notebooks from AWS Glue.

Open the role that you just created, `AWSGlueServiceSageMakerNotebookRole-Default`, and choose **Attach policies**. Attach the policy that you created named `AWSGlueSageMakerNotebook` to the role.

## AWS Glue access control policy examples

This section contains examples of both identity-based (IAM) access control policies and AWS Glue resource policies.

## Identity-based policy examples for AWS Glue

By default, users and roles don't have permission to create or modify AWS Glue resources. They also can't perform tasks by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see [Creating IAM policies](#) in the *IAM User Guide*.

For details about actions and resource types defined by AWS Glue, including the format of the ARNs for each of the resource types, see [Actions, resources, and condition keys for AWS Glue](#) in the *Service Authorization Reference*.

### Note

The examples provided in this section all use the us-west-2 Region. You can replace this with the AWS Region that you want to use.

## Policy best practices

Identity-based policies determine whether someone can create, access, or delete AWS Glue resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*.

- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Configuring MFA-protected API access](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

### Resource-level permissions only apply to specific AWS Glue objects

You can only define fine-grained control for specific objects in AWS Glue. Therefore you must write your client's IAM policy so that API operations that allow Amazon Resource Names (ARNs) for the Resource statement are not mixed with API operations that don't allow ARNs.

For example, the following IAM policy allows API operations for `GetClassifier` and `GetJobRun`. It defines the Resource as `*` because AWS Glue doesn't allow ARNs for classifiers and job runs. Because ARNs are allowed for specific API operations such as `GetDatabase` and `GetTable`, ARNs can be specified in the second half of the policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetClassifier*",
        "glue:GetJobRun*"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "glue:Get*"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:123456789012:catalog",
        "arn:aws:glue:us-east-1:123456789012:database/default",
        "arn:aws:glue:us-east-1:123456789012:table/default/e*1*",
        "arn:aws:glue:us-east-1:123456789012:connection/connection2"
      ]
    }
  ]
}
```

```
    }  
  ]  
}
```

For a list of AWS Glue objects that allow ARNs, see [Resource ARNs](#).

## Using the AWS Glue console

To access the AWS Glue console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the AWS Glue resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the AWS Glue console, also attach the AWS Glue *ConsoleAccess* or *ReadOnly* AWS managed policy to the entities. For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

For a user to work with the AWS Glue console, that user must have a minimum set of permissions that allows them to work with the AWS Glue resources for their AWS account. In addition to these AWS Glue permissions, the console requires permissions from the following services:

- Amazon CloudWatch Logs permissions to display logs.
- AWS Identity and Access Management (IAM) permissions to list and pass roles.
- AWS CloudFormation permissions to work with stacks.
- Amazon Elastic Compute Cloud (Amazon EC2) permissions to list VPCs, subnets, security groups, instances, and other objects.
- Amazon Simple Storage Service (Amazon S3) permissions to list buckets and objects, and to retrieve and save scripts.
- Amazon Redshift permissions to work with clusters.
- Amazon Relational Database Service (Amazon RDS) permissions to list instances.

For more information about the permissions that users require to view and work with the AWS Glue console, see [Step 3: Attach a policy to users or groups that access AWS Glue](#).

If you create an IAM policy that is more restrictive than the minimum required permissions, the console won't function as intended for users with that IAM policy. To ensure that those users can still use the AWS Glue console, also attach the `AWSGlueConsoleFullAccess` managed policy as described in [AWS managed \(predefined\) policies for AWS Glue](#).

## Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetUserPolicy",
        "iam:ListGroupsWithUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListUserPolicies",
        "iam:GetUser"
      ],
      "Resource": ["arn:aws:iam::*:user/${aws:username}"]
    },
    {
      "Sid": "NavigateInConsole",
      "Effect": "Allow",
      "Action": [
        "iam:GetGroupPolicy",
        "iam:GetPolicyVersion",
        "iam:GetPolicy",
        "iam:ListAttachedGroupPolicies",
        "iam:ListGroupPolicies",
        "iam:ListPolicyVersions",
        "iam:ListPolicies",
        "iam:ListUsers"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}
```

## Grant read-only permission to a table

The following policy grants read-only permission to a books table in database db1. For more information about resource Amazon Resource Names (ARNs), see [Data Catalog ARNs](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetTablesActionOnBooks",
      "Effect": "Allow",
      "Action": [
        "glue:GetTables",
        "glue:GetTable"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/db1",
        "arn:aws:glue:us-west-2:123456789012:table/db1/books"
      ]
    }
  ]
}
```

This policy grants read-only permission to a table named books in the database named db1. To grant Get permission to a table, permission to the catalog and database resources is also required.

The following policy grants the minimum necessary permissions to create table tb1 in database db1:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:CreateTable"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:table/db1/tb11",

```

```

    "arn:aws:glue:us-west-2:123456789012:database/db1",
    "arn:aws:glue:us-west-2:123456789012:catalog"
  ]
}
]
}

```

## Filter tables by GetTables permission

Assume that there are three tables—customers, stores, and store\_sales—in database db1. The following policy grants GetTables permission to stores and store\_sales, but not to customers. When you call GetTables with this policy, the result contains only the two authorized tables (the customers table is not returned).

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetTablesExample",
      "Effect": "Allow",
      "Action": [
        "glue:GetTables"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/db1",
        "arn:aws:glue:us-west-2:123456789012:table/db1/store_sales",
        "arn:aws:glue:us-west-2:123456789012:table/db1/stores"
      ]
    }
  ]
}

```

You can simplify the preceding policy by using store\* to match any table names that start with store.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetTablesExample2",
      "Effect": "Allow",

```

```

    "Action": [
      "glue:GetTables"
    ],
    "Resource": [
      "arn:aws:glue:us-west-2:123456789012:catalog",
      "arn:aws:glue:us-west-2:123456789012:database/db1",
      "arn:aws:glue:us-west-2:123456789012:table/db1/store*"
    ]
  }
]
}

```

Similarly, using `/db1/*` to match all tables in db1, the following policy grants `GetTables` access to all the tables in db1.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetTablesReturnAll",
      "Effect": "Allow",
      "Action": [
        "glue:GetTables"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/db1",
        "arn:aws:glue:us-west-2:123456789012:table/db1/*"
      ]
    }
  ]
}

```

If no table ARN is provided, a call to `GetTables` succeeds, but it returns an empty list.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetTablesEmptyResults",
      "Effect": "Allow",
      "Action": [
        "glue:GetTables"
      ]
    }
  ]
}

```

```

    ],
    "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/db1"
    ]
}
]
}

```

If the database ARN is missing in the policy, a call to `GetTables` fails with an `AccessDeniedException`.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GetTablesAccessDeny",
      "Effect": "Allow",
      "Action": [
        "glue:GetTables"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:table/db1/*"
      ]
    }
  ]
}

```

### Grant full access to a table and all partitions

The following policy grants all permissions on a table named `books` in database `db1`. This includes read and write permissions on the table itself, on archived versions of it, and on all its partitions.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FullAccessOnTable",
      "Effect": "Allow",
      "Action": [
        "glue:CreateTable",

```

```

        "glue:GetTable",
        "glue:GetTables",
        "glue:UpdateTable",
        "glue>DeleteTable",
        "glue:BatchDeleteTable",
        "glue:GetTableVersion",
        "glue:GetTableVersions",
        "glue>DeleteTableVersion",
        "glue:BatchDeleteTableVersion",
        "glue:CreatePartition",
        "glue:BatchCreatePartition",
        "glue:GetPartition",
        "glue:GetPartitions",
        "glue:BatchGetPartition",
        "glue:UpdatePartition",
        "glue>DeletePartition",
        "glue:BatchDeletePartition"
    ],
    "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/db1",
        "arn:aws:glue:us-west-2:123456789012:table/db1/books"
    ]
}
]
}

```

The preceding policy can be simplified in practice.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FullAccessOnTable",
      "Effect": "Allow",
      "Action": [
        "glue:*Table*",
        "glue:*Partition*"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/db1",
        "arn:aws:glue:us-west-2:123456789012:table/db1/books"
      ]
    }
  ]
}

```

```

    ]
  }
]
}

```

Notice that the minimum granularity of fine-grained access control is at the table level. This means that you can't grant a user access to some partitions in a table but not others, or to some table columns but not to others. A user either has access to all of a table, or to none of it.

## Control access by name prefix and explicit denial

In this example, suppose that the databases and tables in your AWS Glue Data Catalog are organized using name prefixes. The databases in the development stage have the name prefix `dev-`, and those in production have the name prefix `prod-`. You can use the following policy to grant developers full access to all databases, tables, UDFs, and so on, that have the `dev-` prefix. But you grant read-only access to everything with the `prod-` prefix.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DevAndProdFullAccess",
      "Effect": "Allow",
      "Action": [
        "glue:*Database*",
        "glue:*Table*",
        "glue:*Partition*",
        "glue:*UserDefinedFunction*",
        "glue:*Connection*"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:123456789012:catalog",
        "arn:aws:glue:us-west-2:123456789012:database/dev-*",
        "arn:aws:glue:us-west-2:123456789012:database/prod-*",
        "arn:aws:glue:us-west-2:123456789012:table/dev-*/**",
        "arn:aws:glue:us-west-2:123456789012:table/*/dev-*",
        "arn:aws:glue:us-west-2:123456789012:table/prod-*/**",
        "arn:aws:glue:us-west-2:123456789012:table/*/prod-*",
        "arn:aws:glue:us-west-2:123456789012:userDefinedFunction/dev-*/**",
        "arn:aws:glue:us-west-2:123456789012:userDefinedFunction/*/dev-*",
        "arn:aws:glue:us-west-2:123456789012:userDefinedFunction/prod-*/**",
        "arn:aws:glue:us-west-2:123456789012:userDefinedFunction/*/prod-*",

```

```

        "arn:aws:glue:us-west-2:123456789012:connection/dev-*",
        "arn:aws:glue:us-west-2:123456789012:connection/prod-*"
    ]
},
{
    "Sid": "ProdWriteDeny",
    "Effect": "Deny",
    "Action": [
        "glue:*Create*",
        "glue:*Update*",
        "glue:*Delete*"
    ],
    "Resource": [
        "arn:aws:glue:us-west-2:123456789012:database/prod-*",
        "arn:aws:glue:us-west-2:123456789012:table/prod-*/**",
        "arn:aws:glue:us-west-2:123456789012:table/*/prod-*",
        "arn:aws:glue:us-west-2:123456789012:userDefinedFunction/prod-*/**",
        "arn:aws:glue:us-west-2:123456789012:userDefinedFunction/*/prod-*",
        "arn:aws:glue:us-west-2:123456789012:connection/prod-*"
    ]
}
]
}

```

The second statement in the preceding policy uses explicit deny. You can use explicit deny to overwrite any allow permissions that are granted to the principal. This lets you lock down access to critical resources and prevent another policy from accidentally granting access to them.

In the preceding example, even though the first statement grants full access to prod- resources, the second statement explicitly revokes write access to them, leaving only read access to prod- resources.

## Grant access using tags

For example, suppose that you want to limit access to a trigger t2 to a specific user named Tom in your account. All other users, including Sam, have access to trigger t1. The triggers t1 and t2 have the following properties.

```

aws glue get-triggers
{
    "Triggers": [
        {

```

```

    "State": "CREATED",
    "Type": "SCHEDULED",
    "Name": "t1",
    "Actions": [
      {
        "JobName": "j1"
      }
    ],
    "Schedule": "cron(0 0/1 * * ? *)"
  },
  {
    "State": "CREATED",
    "Type": "SCHEDULED",
    "Name": "t2",
    "Actions": [
      {
        "JobName": "j1"
      }
    ],
    "Schedule": "cron(0 0/1 * * ? *)"
  }
]
}

```

The AWS Glue administrator attached a tag value Tom (`aws:ResourceTag/Name": "Tom"`) to trigger t2. The AWS Glue administrator also gave Tom an IAM policy with a condition statement based on the tag. As a result, Tom can only use an AWS Glue operation that acts on resources with the tag value Tom.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "glue:*",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Name": "Tom"
        }
      }
    }
  ]
}

```

```
}
```

When Tom tries to access the trigger t1, he receives an access denied message. Meanwhile, he can successfully retrieve trigger t2.

```
aws glue get-trigger --name t1
```

An error occurred (AccessDeniedException) when calling the GetTrigger operation:

```
User: Tom is not authorized to perform: glue:GetTrigger on resource: arn:aws:glue:us-east-1:123456789012:trigger/t1
```

```
aws glue get-trigger --name t2
```

```
{
  "Trigger": {
    "State": "CREATED",
    "Type": "SCHEDULED",
    "Name": "t2",
    "Actions": [
      {
        "JobName": "j1"
      }
    ],
    "Schedule": "cron(0 0/1 * * ? *)"
  }
}
```

Tom can't use the plural `GetTriggers` API operation to list triggers because this operation doesn't support filtering on tags.

To give Tom access to `GetTriggers`, the AWS Glue administrator creates a policy that splits the permissions into two sections. One section allows Tom access to all triggers with the `GetTriggers` API operation. The second section allows Tom access to API operations that are tagged with the value Tom. With this policy, Tom is allowed both `GetTriggers` and `GetTrigger` access to trigger t2.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "glue:GetTriggers",
```

```

        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": "glue:*",
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "aws:ResourceTag/Name": "Tom"
            }
        }
    }
]
}

```

## Deny access using tags

Another resource policy approach is to explicitly deny access to resources.

### Important

An explicit denial policy does not work for plural API operations such as `GetTriggers`.

In the following example policy, all AWS Glue job operations are allowed. However, the second `Effect` statement *explicitly* denies access to jobs tagged with the `Team` key and `Special` value.

When an administrator attaches the following policy to an identity, the identity can access all jobs *except* those tagged with the `Team` key and `Special` value.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "glue:*",
      "Resource": "arn:aws:glue:us-east-1:123456789012:job/*"
    },
    {
      "Effect": "Deny",
      "Action": "glue:*",
      "Resource": "arn:aws:glue:us-east-1:123456789012:job/*",

```

```
    "Condition": {
      "StringEquals": {
        "aws:ResourceTag/Team": "Special"
      }
    }
  ]
}
```

## Use tags with list and batch API operations

A third approach to writing a resource policy is to allow access to resources using a `List` API operation to list out resources for a tag value. Then, use the corresponding `Batch` API operation to allow access to details of specific resources. With this approach, the administrator doesn't need to allow access to the plural `GetCrawlers`, `GetDevEndpoints`, `GetJobs`, or `GetTriggers` API operations. Instead, you can allow the ability to list the resources with the following API operations:

- `ListCrawlers`
- `ListDevEndpoints`
- `ListJobs`
- `ListTriggers`

And, you can allow the ability to get details about individual resources with the following API operations:

- `BatchGetCrawlers`
- `BatchGetDevEndpoints`
- `BatchGetJobs`
- `BatchGetTriggers`

As an administrator, to use this approach, you can do the following:

1. Add tags to your crawlers, development endpoints, jobs, and triggers.
2. Deny user access to `Get` API operations such as `GetCrawlers`, `GetDevEndpoints`, `GetJobs`, and `GetTriggers`.

3. To enable users to find out which tagged resources they have access to, allow user access to List API operations such as ListCrawlers, ListDevEndpoints, ListJobs, and ListTriggers.
4. Deny user access to AWS Glue tagging APIs, such as TagResource and UntagResource.
5. Allow user access to resource details with BatchGet API operations such as BatchGetCrawlers, BatchGetDevEndpoints, BatchGetJobs, and BatchGetTriggers.

For example, when calling the ListCrawlers operation, provide a tag value to match the user name. Then the result is a list of crawlers that match the provided tag values. Provide the list of names to BatchGetCrawlers to get details about each crawler with the given tag.

For example, if Tom should only be able to retrieve details of triggers that are tagged with Tom, the administrator can add tags to triggers for Tom, deny access to the GetTriggers API operation to all users, and allow access to all users to ListTriggers and BatchGetTriggers.

The following is the resource policy that the AWS Glue administrator grants to Tom. In the first section of the policy, AWS Glue API operations are denied for GetTriggers. In the second section of the policy, ListTriggers is allowed for all resources. However, in the third section, those resources tagged with Tom are allowed access with the BatchGetTriggers access.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "glue:GetTriggers",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "glue:ListTriggers"
      ],
      "Resource": [
        "*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
```

```

        "glue:BatchGetTriggers"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/Name": "Tom"
        }
    }
}
]
}

```

Using the same triggers as the previous example, Tom can access trigger t2, but not trigger t1. The following example shows the results when Tom tries to access t1 and t2 with BatchGetTriggers.

```

aws glue batch-get-triggers --trigger-names t2
{
  "Triggers": {
    "State": "CREATED",
    "Type": "SCHEDULED",
    "Name": "t2",
    "Actions": [
      {
        "JobName": "j2"
      }
    ],
    "Schedule": "cron(0 0/1 * * ? *)"
  }
}

```

```
aws glue batch-get-triggers --trigger-names t1
```

An error occurred (AccessDeniedException) when calling the BatchGetTriggers operation:  
No access to any requested resource.

The following example shows the results when Tom tries to access both trigger t2 and trigger t3 (which does not exist) in the same BatchGetTriggers call. Notice that because Tom has access to trigger t2 and it exists, only t2 is returned. Although Tom is allowed to access trigger t3, trigger t3 does not exist, so t3 is returned in the response in a list of "TriggersNotFound": [].

```
aws glue batch-get-triggers --trigger-names t2 t3
{
  "Triggers": {
    "State": "CREATED",
    "Type": "SCHEDULED",
    "Name": "t2",
    "Actions": [
      {
        "JobName": "j2"
      }
    ],
    "TriggersNotFound": ["t3"],
    "Schedule": "cron(0 0/1 * * ? *)"
  }
}
```

## Control settings using condition keys or context keys

You can use condition keys or context keys when granting permissions to create and update jobs. These sections discuss the keys:

- [Control policies that control settings using condition keys](#)
- [Control policies that control settings using context keys](#)

## Control policies that control settings using condition keys

AWS Glue provides three IAM condition keys `glue:VpcIds`, `glue:SubnetIds`, and `glue:SecurityGroupIds`. You can use the condition keys in IAM policies when granting permissions to create and update jobs. You can use this setting to ensure that jobs or sessions are not created (or updated to) to run outside of a desired VPC environment. The VPC setting information is not a direct input from the `CreateJob` request, but inferred from the job `"connections"` field that points to an AWS Glue connection.

## Example usage

Create an AWS Glue network type connection named `"traffic-monitored-connection"` with the desired `VpcId` `"vpc-id1234"`, `SubnetIds`, and `SecurityGroupIds`.

Specify the condition keys condition for the `CreateJob` and `UpdateJob` action in the IAM policy.

```
{
```

```

"Effect": "Allow",
"Action": [
  "glue:CreateJob",
  "glue:UpdateJob"
],
"Resource": [
  "*"
],
"Condition": {
  "ForAnyValue:StringLike": {
    "glue:VpcIds": [
      "vpc-id1234"
    ]
  }
}
}
}

```

You can create a similar IAM policy to prohibit creating an AWS Glue job without specifying connection information.

### Restricting sessions on VPCs

To enforce created sessions to run within a specified VPC, you restrict role permission by adding a Deny effect on the `glue:CreateSession` action with the condition that the `glue:vpc-id` not equal to `vpc-<123>`. For example:

```

"Effect": "Deny",
"Action": [
  "glue:CreateSession"
],
"Condition": {
  "StringNotEquals" : {"glue:VpcIds" : ["vpc-123"]}
}

```

You also can enforce created sessions to run within a VPC by adding a Deny effect on the `glue:CreateSession` action with the condition that the `glue:vpc-id` is null. For example:

```

{
  "Effect": "Deny",
  "Action": [
    "glue:CreateSession"
  ]
}

```

```
    ],
    "Condition": {
      "Null": {"glue:VpcIds": true}
    }
  },
  {
    "Effect": "Allow",
    "Action": [
      "glue:CreateSession"
    ],
    "Resource": ["*"]
  }
}
```

## Control policies that control settings using context keys

AWS Glue provides a context key (`glue:CredentialIssuingService=glue.amazonaws.com`) to each role session that AWS Glue makes available to the job and developer endpoint. This allows you to implement security controls for the actions taken by AWS Glue scripts. AWS Glue provides another context key (`glue:RoleAssumedBy=glue.amazonaws.com`) to each role session where AWS Glue makes a call to another AWS service on the customer's behalf (not by a job/dev endpoint, but directly by the AWS Glue service).

## Example usage

Specify the conditional permission in an IAM policy and attach it to the role to be used by an AWS Glue job. This ensures certain actions are allowed/denied based on whether the role session is used for an AWS Glue job runtime environment.

```
{
  "Effect": "Allow",
  "Action": "s3:GetObject",
  "Resource": "arn:aws:s3:::confidential-bucket/*",
  "Condition": {
    "StringEquals": {
      "glue:CredentialIssuingService": "glue.amazonaws.com"
    }
  }
}
```

## Deny an identity the ability to create data preview sessions

This section contains an IAM policy example used to deny an identity the ability to create data preview sessions. Attach this policy to the identity, which is separate from the role used by the data preview session during its run.

```
{
  "Sid": "DatapreviewDeny",
  "Effect": "Deny",
  "Action": [
    "glue:CreateSession"
  ],
  "Resource": [
    "arn:aws:glue:*:*:session/glue-studio-datapreview*"
  ]
}
```

## Resource-based policy examples for AWS Glue

This section contains example resource-based policies, including policies that grant cross-account access.

The examples use the AWS Command Line Interface (AWS CLI) to interact with AWS Glue service API operations. You can perform the same operations on the AWS Glue console or using one of the AWS SDKs.

### Important

By changing an AWS Glue resource policy, you might accidentally revoke permissions for existing AWS Glue users in your account and cause unexpected disruptions. Try these examples only in development or test accounts, and ensure that they don't break any existing workflows before you make the changes.

## Topics

- [Considerations for using resource-based policies with AWS Glue](#)
- [Use a resource policy to control access in the same account](#)

## Considerations for using resource-based policies with AWS Glue

### Note

Both IAM policies and an AWS Glue resource policy take a few seconds to propagate. After you attach a new policy, you might notice that the old policy is still in effect until the new policy has propagated through the system.

You use a policy document written in JSON format to create or modify a resource policy. The policy syntax is the same as for an identity-based IAM policy (see [IAM JSON policy reference](#)), with the following exceptions:

- A "Principal" or "NotPrincipal" block is required for each policy statement.
- The "Principal" or "NotPrincipal" must identify valid existing principals. Wildcard patterns (like `arn:aws:iam::account-id:user/*`) are not allowed.
- The "Resource" block in the policy requires all resource ARNs to match the following regular expression syntax (where the first %s is the *region*, and the second %s is the *account-id*):

```
*arn:aws:glue:%s:%s:(\*|[a-zA-Z\*]+\/*\?.*)
```

For example, both `arn:aws:glue:us-west-2:account-id:*` and `arn:aws:glue:us-west-2:account-id:database/default` are allowed, but `*` is not allowed.

- Unlike identity-based policies, an AWS Glue resource policy must only contain Amazon Resource Names (ARNs) of resources that belong to the catalog that the policy is attached to. Such ARNs always start with `arn:aws:glue:.`
- A policy cannot cause the identity that creates it to be locked out of further policy creation or modification.
- A resource-policy JSON document cannot exceed 10 KB in size.

### Use a resource policy to control access in the same account

In this example, an admin user in Account A creates a resource policy that grants IAM user Alice in Account A full access to the catalog. Alice has no IAM policy attached.

To do this, the admin user runs the following AWS CLI command.

```
# Run as admin of Account A
$ aws glue put-resource-policy --profile administrator-name --region us-west-2 --
policy-in-json '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": [
          "arn:aws:iam::account-A-id:user/Alice"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:*"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:account-A-id:"
      ]
    }
  ]
}'
```

Instead of entering the JSON policy document as a part of your AWS CLI command, you can save a policy document in a file and reference the file path in the AWS CLI command, prefixed by `file://`. The following is an example of how you might do that.

```
$ echo '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {
        "AWS": [
          "arn:aws:iam::account-A-id:user/Alice"
        ]
      },
      "Effect": "Allow",
      "Action": [
        "glue:*"
      ],
      "Resource": [
        "arn:aws:glue:us-west-2:account-A-id:"
      ]
    }
  ]
}'
```

```
    }  
  ]  
}' > /temp/policy.json  
  
$ aws glue put-resource-policy --profile admin1 \  
  --region us-west-2 --policy-in-json file:///temp/policy.json
```

After this resource policy has propagated, Alice can access all AWS Glue resources in Account A, as follows.

```
# Run as user Alice  
$ aws glue create-database --profile alice --region us-west-2 --database-input '{  
  "Name": "new_database",  
  "Description": "A new database created by Alice",  
  "LocationUri": "s3://my-bucket"  
}'  
  
$ aws glue get-table --profile alice --region us-west-2 --database-name "default" --  
table-name "tbl1"
```

In response to Alice's `get-table` call, the AWS Glue service returns the following.

```
{  
  "Table": {  
    "Name": "tbl1",  
    "PartitionKeys": [],  
    "StorageDescriptor": {  
      .....  
    },  
    .....  
  }  
}
```

## AWS managed policies for AWS Glue

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you

reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

## **AWS managed (predefined) policies for AWS Glue**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate what permissions are needed. For more information, see [AWS managed policies](#) in the *IAM User Guide*.

The following AWS managed policies, which you can attach to identities in your account, are specific to AWS Glue and are grouped by use case scenario:

- [AWSGlueConsoleFullAccess](#) – Grants full access to AWS Glue resources when an identity that the policy is attached to uses the AWS Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the AWS Glue console.
- [AWSGlueServiceRole](#) – Grants access to resources that various AWS Glue processes require to run on your behalf. These resources include AWS Glue, Amazon S3, IAM, CloudWatch Logs, and Amazon EC2. If you follow the naming convention for resources specified in this policy, AWS Glue processes have the required permissions. This policy is typically attached to roles specified when defining crawlers, jobs, and development endpoints.
- [AwsGlueSessionUserRestrictedServiceRole](#) – Provides full access to all AWS Glue resources except for sessions. It allows users to create and use only the interactive sessions that are associated with the user. This policy includes other permissions needed by AWS Glue to manage AWS Glue resources in other AWS services. The policy also allows adding tags to AWS Glue resources in other AWS services.

**Note**

To achieve the full security benefits, do not grant this policy to a user that was assigned the `AWSGlueServiceRole`, `AWSGlueConsoleFullAccess`, or `AWSGlueConsoleSageMakerNotebookFullAccess` policy.

- [AwsGlueSessionUserRestrictedPolicy](#) – Provides access to create AWS Glue interactive sessions using the `CreateSession` API operation only if a tag key “owner” and value that match the assignee's AWS user ID are provided. This identity policy is attached to the IAM user that invokes the `CreateSession` API operation. This policy also permits the assignee to interact with the AWS Glue interactive session resources that were created with an “owner” tag and value that match their AWS user ID. This policy denies permission to change or remove "owner" tags from an AWS Glue session resource after the session is created.

**Note**

To achieve the full security benefits, do not grant this policy to a user that was assigned the `AWSGlueServiceRole`, `AWSGlueConsoleFullAccess`, or `AWSGlueConsoleSageMakerNotebookFullAccess` policy.

- [AwsGlueSessionUserRestrictedNotebookServiceRole](#) – Provides sufficient access to the AWS Glue Studio notebook session to interact with specific AWS Glue interactive session resources. These are resources that are created with the “owner” tag value that matches the AWS user ID of the principal (IAM user or role) that creates the notebook. For more information about these tags, see the [Principal key values](#) chart in the *IAM User Guide*.

This service-role policy is attached to the role that is specified with a magic command within the notebook or is passed as a role to the `CreateSession` API operation. This policy also permits the principal to create an AWS Glue interactive session from the AWS Glue Studio notebook interface only if a tag key “owner” and value match the AWS user ID of the principal. This policy denies permission to change or remove "owner" tags from an AWS Glue session resource after the session is created. This policy also includes permissions for writing and reading from Amazon S3 buckets, writing CloudWatch logs, and creating and deleting tags for Amazon EC2 resources used by AWS Glue.

**Note**

To achieve the full security benefits, do not grant this policy to a role that was assigned the `AWSGlueServiceRole`, `AWSGlueConsoleFullAccess`, or `AWSGlueConsoleSageMakerNotebookFullAccess` policy.

- [AwsGlueSessionUserRestrictedNotebookPolicy](#) – Provides access to create an AWS Glue interactive session from the AWS Glue Studio notebook interface only if there is a tag key “owner” and value that match the AWS user ID of the principal (IAM user or role) that creates the notebook. For more information about these tags, see the [Principal key values](#) chart in the *IAM User Guide*.

This policy is attached to the principal (IAM user or role) that creates sessions from the AWS Glue Studio notebook interface. This policy also permits sufficient access to the AWS Glue Studio notebook to interact with specific AWS Glue interactive session resources. These are resources that are created with the “owner” tag value that matches the AWS user ID of the principal. This policy denies permission to change or remove “owner” tags from an AWS Glue session resource after the session is created.

- [AWSGlueServiceNotebookRole](#) – Grants access to AWS Glue sessions started in an AWS Glue Studio notebook. This policy allows listing and getting session information for all sessions, but only permits users to create and use the sessions tagged with their AWS user ID. This policy denies permission to change or remove “owner” tags from AWS Glue session resources tagged with their AWS ID.

Assign this policy to the AWS user who creates jobs using the notebook interface in AWS Glue Studio.

- [AWSGlueConsoleSageMakerNotebookFullAccess](#) – Grants full access to AWS Glue and SageMaker resources when the identity that the policy is attached to uses the AWS Management Console. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the AWS Glue console who manage SageMaker notebooks.
- [AWSGlueSchemaRegistryFullAccess](#) – Grants full access to AWS Glue Schema Registry resources when the identity that the policy is attached to uses the AWS Management Console or AWS CLI. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the AWS Glue console or AWS CLI who manage the AWS Glue Schema Registry.

- [AWSGlueSchemaRegistryReadOnlyAccess](#) – Grants read-only access to AWS Glue Schema Registry resources when an identity that the policy is attached to uses the AWS Management Console or AWS CLI. If you follow the naming convention for resources specified in this policy, users have full console capabilities. This policy is typically attached to users of the AWS Glue console or AWS CLI who use the AWS Glue Schema Registry.

### Note

You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

You can also create your own custom IAM policies to allow permissions for AWS Glue actions and resources. You can attach these custom policies to the IAM users or groups that require those permissions.

## AWS Glue updates to AWS managed policies

View details about updates to AWS managed policies for AWS Glue since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the [AWS Glue Document history page](#).

Change	Description	Date
AwsGlueSessionUserRestrictedPolicy – Minor update to an existing policy.	Add <code>glue:StartCompletion</code> and <code>glue:GetCompletion</code> to policy. Required for Amazon Q data integration in AWS Glue.	April, 30, 2024
AwsGlueSessionUserRestrictedNotebookServiceRole – Minor update to an existing policy.	Add <code>glue:StartCompletion</code> and <code>glue:GetCompletion</code> to policy. Required for Amazon Q data integration in AWS Glue.	April, 30, 2024

Change	Description	Date
AwsGlueSessionUserRestrictedServiceRole – Minor update to an existing policy.	Add <code>glue:StartCompletion</code> and <code>glue:GetCompletion</code> to policy. Required for Amazon Q data integration in AWS Glue.	April, 30, 2024
AWSGlueServiceNotebookRole – Minor update to an existing policy.	Add <code>glue:StartCompletion</code> and <code>glue:GetCompletion</code> to policy. Required for Amazon Q data integration in AWS Glue.	Jan 30, 2024
AwsGlueSessionUserRestrictedNotebookPolicy – Minor update to an existing policy.	Add <code>glue:StartCompletion</code> and <code>glue:GetCompletion</code> to policy. Required for Amazon Q data integration in AWS Glue.	Nov 29, 2023
AWSGlueServiceNotebookRole – Minor update to an existing policy.	Add <code>codewhisperer:GenerateRecommendations</code> to policy. Required for a new feature where AWS Glue generates CodeWhisperer recommendations.	Oct 9, 2023
AWSGlueServiceRole – Minor update to an existing policy.	Tighten scope of CloudWatch permissions to better reflect AWS Glue logging.	Aug 4, 2023
AWSGlueConsoleFullAccess – Minor update to an existing policy.	Add <code>databrew recipe List</code> and <code>Describe</code> permissions to policy. Required to provide full administrative access for new features where AWS Glue can access recipes.	May 9, 2023

Change	Description	Date
AWSGlueConsoleFullAccess – Minor update to an existing policy.	Add <code>cloudformation:ListStacks</code> to policy. Preserves existing capabilities after changes to AWS CloudFormation authorization requirements.	March 28, 2023
New managed policies added for the interactive sessions feature: <ul style="list-style-type: none"> <li>• <code>AwsGlueSessionUserRestrictedServiceRole</code></li> <li>• <code>AwsGlueSessionUserRestrictedPolicy</code></li> <li>• <code>AwsGlueSessionUserRestrictedNotebookServiceRole</code></li> <li>• <code>AwsGlueSessionUserRestrictedNotebookPolicy</code></li> </ul>	These policies were designed to provide additional security for interactive sessions and notebooks in AWS Glue Studio. The policies restrict access to the <code>CreateSession</code> API operation so that only the owner has access.	November 30, 2021

Change	Description	Date
<p>AWSGlueConsoleSageMakerNotebookFullAccess – Update to an existing policy.</p>	<p>Removed a redundant resource ARN (<code>arn:aws:s3:::aws-glue-*/*</code>) for the action that grants read/write permissions on Amazon S3 buckets that AWS Glue uses to store scripts and temporary files.</p> <p>Fixed a syntax issue by changing <code>"StringEquals"</code> to <code>"ForAnyValue:StringLike"</code>, and moved the <code>"Effect": "Allow"</code> lines to precede the <code>"Action":</code> line in each place where they were out of order.</p>	<p>July 15, 2021</p>
<p>AWSGlueConsoleFullAccess – Update to an existing policy.</p>	<p>Removed a redundant resource ARN (<code>arn:aws:s3:::aws-glue-*/*</code>) for the action that grants read/write permissions on Amazon S3 buckets that AWS Glue uses to store scripts and temporary files.</p>	<p>July 15, 2021</p>
<p>AWS Glue started tracking changes.</p>	<p>AWS Glue started tracking changes for its AWS managed policies.</p>	<p>June 10, 2021</p>

## Specifying AWS Glue resource ARNs

In AWS Glue, you can control access to resources using an AWS Identity and Access Management (IAM) policy. In a policy, you use an Amazon Resource Name (ARN) to identify the resource that the policy applies to. Not all resources in AWS Glue support ARNs.

### Topics

- [Data Catalog ARNs](#)
- [ARNs for non-catalog objects in AWS Glue](#)
- [Access control for AWS Glue non-catalog singular API operations](#)
- [Access control for AWS Glue non-catalog API operations that retrieve multiple items](#)
- [Access control for AWS Glue non-catalog BatchGet API operations](#)

### Data Catalog ARNs

Data Catalog resources have a hierarchical structure, with catalog as the root.

```
arn:aws:glue:region:account-id:catalog
```

Each AWS account has a single Data Catalog in an AWS Region with the 12-digit account ID as the catalog ID. Resources have unique ARNs associated with them, as shown in the following table.

Resource type	ARN format
Catalog	arn:aws:glue: <i>region</i> : <i>account-id</i> :catalog  For example: arn:aws:glue:us-east-1:123456789012:catalog
Database	arn:aws:glue: <i>region</i> : <i>account-id</i> :database/ <i>database name</i>  For example: arn:aws:glue:us-east-1:123456789012:database/db1
Table	arn:aws:glue: <i>region</i> : <i>account-id</i> :table/ <i>database name</i> / <i>table name</i>

Resource type	ARN format
	For example: <code>arn:aws:glue:us-east-1:123456789012:table/db1/tb11</code>
User-defined function	<p><code>arn:aws:glue: <i>region</i>:<i>account-id</i> :userDefinedFunction/<i>database name</i>/<i>user-defined function name</i></code></p> <p>For example: <code>arn:aws:glue:us-east-1:123456789012:userDefinedFunction/db1/func1</code></p>
Connection	<p><code>arn:aws:glue: <i>region</i>:<i>account-id</i> :connection/<i>connection name</i></code></p> <p>For example: <code>arn:aws:glue:us-east-1:123456789012:connection/connection1</code></p>
Interactive Session	<p><code>arn:aws:glue: <i>region</i>:<i>account-id</i> :session/<i>interactive session id</i></code></p> <p>For example: <code>arn:aws:glue:us-east-1:123456789012:session/a1b2c3d4-5678-90ab-cdef-EXAMPLE11111</code></p>

To enable fine-grained access control, you can use these ARNs in your IAM policies and resource policies to grant and deny access to specific resources. Wildcards are allowed in the policies. For example, the following ARN matches all tables in database default.

```
arn:aws:glue:us-east-1:123456789012:table/default/*
```

### Important

All operations performed on a Data Catalog resource require permission on the resource and all the ancestors of that resource. For example, to create a partition for a table requires permission on the table, database, and catalog where the table is located. The following example shows the permission required to create partitions on table `PrivateTable` in database `PrivateDatabase` in the Data Catalog.

```
{
```

```

    "Sid": "GrantCreatePartitions",
    "Effect": "Allow",
    "Action": [
        "glue:BatchCreatePartitions"
    ],
    "Resource": [
        "arn:aws:glue:us-east-1:123456789012:table/PrivateDatabase/PrivateTable",
        "arn:aws:glue:us-east-1:123456789012:database/PrivateDatabase",
        "arn:aws:glue:us-east-1:123456789012:catalog"
    ]
}

```

In addition to permission on the resource and all its ancestors, all delete operations require permission on all children of that resource. For example, deleting a database requires permission on all the tables and user-defined functions in the database, in addition to the database and the catalog where the database is located. The following example shows the permission required to delete database `PrivateDatabase` in the Data Catalog.

```

{
  "Sid": "GrantDeleteDatabase",
  "Effect": "Allow",
  "Action": [
    "glue>DeleteDatabase"
  ],
  "Resource": [
    "arn:aws:glue:us-east-1:123456789012:table/PrivateDatabase/*",
    "arn:aws:glue:us-east-1:123456789012:userDefinedFunction/PrivateDatabase/*",
    "arn:aws:glue:us-east-1:123456789012:database/PrivateDatabase",
    "arn:aws:glue:us-east-1:123456789012:catalog"
  ]
}

```

In summary, actions on Data Catalog resources follow these permission rules:

- Actions on the catalog require permission on the catalog only.
- Actions on a database require permission on the database and catalog.
- Delete actions on a database require permission on the database and catalog plus all tables and user-defined functions in the database.

- Actions on a table, partition, or table version require permission on the table, database, and catalog.
- Actions on a user-defined function require permission on the user-defined function, database, and catalog.
- Actions on a connection require permission on the connection and catalog.

## ARNs for non-catalog objects in AWS Glue

Some AWS Glue resources allow resource-level permissions to control access using an ARN. You can use these ARNs in your IAM policies to enable fine-grained access control. The following table lists the resources that can contain resource ARNs.

Resource type	ARN format
Crawler	<p>arn:aws:glue: <i>region:account-id</i> :crawler/ <i>crawler-name</i></p> <p>For example: arn:aws:glue:us-east-1:123456789012:crawler/mycrawler</p>
Job	<p>arn:aws:glue: <i>region:account-id</i> :job/<i>job-name</i></p> <p>For example: arn:aws:glue:us-east-1:123456789012:job/testjob</p>
Trigger	<p>arn:aws:glue: <i>region:account-id</i> :trigger/ <i>trigger-name</i></p> <p>For example: arn:aws:glue:us-east-1:123456789012:trigger/sampletrigger</p>
Development endpoint	<p>arn:aws:glue: <i>region:account-id</i> :devEndpoint/<i>development-endpoint-name</i></p> <p>For example: arn:aws:glue:us-east-1:123456789012:devEndpoint/temporarydevendpoint</p>

Resource type	ARN format
Machine learning transform	arn:aws:glue: <i>region</i> : <i>account-id</i> :mlTransform/ <i>transform-id</i>  For example: arn:aws:glue:us-east-1:123456789012:mlTransform/tfm-1234567890

## Access control for AWS Glue non-catalog singular API operations

AWS Glue non-catalog *singular* API operations act on a single item (development endpoint). Examples are `GetDevEndpoint`, `CreateUpdateDevEndpoint`, and `UpdateDevEndpoint`. For these operations, a policy must put the API name in the "action" block and the resource ARN in the "resource" block.

Suppose that you want to allow a user to call the `GetDevEndpoint` operation. The following policy grants the minimum necessary permissions to an endpoint named `myDevEndpoint-1`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "MinimumPermissions",
      "Effect": "Allow",
      "Action": "glue:GetDevEndpoint",
      "Resource": "arn:aws:glue:us-east-1:123456789012:devEndpoint/myDevEndpoint-1"
    }
  ]
}
```

The following policy allows `UpdateDevEndpoint` access to resources that match `myDevEndpoint-` with a wildcard (\*).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PermissionWithWildcard",
      "Effect": "Allow",
```

```

        "Action": "glue:UpdateDevEndpoint",
        "Resource": "arn:aws:glue:us-east-1:123456789012:devEndpoint/myDevEndpoint-
*"
    }
]
}

```

You can combine the two policies as in the following example. You might see `EntityNotFoundException` for any development endpoint whose name begins with A. However, an access denied error is returned when you try to access other development endpoints.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CombinedPermissions",
      "Effect": "Allow",
      "Action": [
        "glue:UpdateDevEndpoint",
        "glue:GetDevEndpoint"
      ],
      "Resource": "arn:aws:glue:us-east-1:123456789012:devEndpoint/A*"
    }
  ]
}

```

## Access control for AWS Glue non-catalog API operations that retrieve multiple items

Some AWS Glue API operations retrieve multiple items (such as multiple development endpoints); for example, `GetDevEndpoints`. For this operation, you can specify only a wildcard (\*) resource, and not specific ARNs.

For example, to include `GetDevEndpoints` in the policy, the resource must be scoped to the wildcard (\*). The singular operations (`GetDevEndpoint`, `CreateDevEndpoint`, and `DeleteDevEndpoint`) are also scoped to all (\*) resources in the example.

```

{
  "Sid": "PluralAPIIncluded",
  "Effect": "Allow",
  "Action": [

```

```
        "glue:GetDevEndpoints",
        "glue:GetDevEndpoint",
        "glue:CreateDevEndpoint",
        "glue:UpdateDevEndpoint"
    ],
    "Resource": [
        "*"
    ]
}
```

## Access control for AWS Glue non-catalog BatchGet API operations

Some AWS Glue API operations retrieve multiple items (such as multiple development endpoints); for example, `BatchGetDevEndpoints`. For this operation, you can specify an ARN to limit the scope of resources that can be accessed.

For example, to allow access to a specific development endpoint, include `BatchGetDevEndpoints` in the policy with its resource ARN.

```
{
    "Sid": "BatchGetAPIIncluded",
    "Effect": "Allow",
    "Action": [
        "glue:BatchGetDevEndpoints"
    ],
    "Resource": [
        "arn:aws:glue:us-east-1:123456789012:devEndpoint/de1"
    ]
}
```

With this policy, you can successfully access the development endpoint named `de1`. However, if you try to access the development endpoint named `de2`, an error is returned.

An error occurred (`AccessDeniedException`) when calling the `BatchGetDevEndpoints` operation: No access to any requested resource.

**⚠ Important**

For alternative approaches to setting up IAM policies, such as using `List` and `BatchGet` API operations, see [Identity-based policy examples for AWS Glue](#).

## Granting cross-account access

Granting access to Data Catalog resources across accounts enables your extract, transform, and load (ETL) jobs to query and join data from different accounts.

### Topics

- [Methods for granting cross-account access in AWS Glue](#)
- [Adding or updating the Data Catalog resource policy](#)
- [Making a cross-account API call](#)
- [Making a cross-account ETL call](#)
- [Cross-account CloudTrail logging](#)
- [Cross-account resource ownership and billing](#)
- [Cross-account access limitations](#)

## Methods for granting cross-account access in AWS Glue

You can grant access to your data to external AWS accounts by using AWS Glue methods or by using AWS Lake Formation cross-account grants. The AWS Glue methods use AWS Identity and Access Management (IAM) policies to achieve fine-grained access control. Lake Formation uses a simpler GRANT/REVOKE permissions model similar to the GRANT/REVOKE commands in a relational database system.

This section describes using the AWS Glue methods. For information about using Lake Formation cross-account grants, see [Granting Lake Formation Permissions](#) in the *AWS Lake Formation Developer Guide*.

There are two AWS Glue methods for granting cross-account access to a resource:

- Use a Data Catalog resource policy
- Use an IAM role

## Granting cross-account access using a resource policy

The following are the general steps for granting cross-account access using a Data Catalog resource policy:

1. An administrator (or other authorized identity) in Account A attaches a resource policy to the Data Catalog in Account A. This policy grants Account B specific cross-account permissions to perform operations on a resource in Account A's catalog.
2. An administrator in Account B attaches an IAM policy to an IAM identity in Account B that delegates the permissions received from Account A.

The identity in Account B now has access to the specified resource in Account A.

The identity needs permission from *both* the resource owner (Account A) *and* their parent account (Account B) to be able to access the resource.

## Granting cross-account access using an IAM role

The following are the general steps for granting cross-account access using an IAM role:

1. An administrator (or other authorized identity) in the account that owns the resource (Account A) creates an IAM role.
2. The administrator in Account A attaches a policy to the role that grants cross-account permissions for access to the resource in question.
3. The administrator in Account A attaches a trust policy to the role that identifies an IAM identity in a different account (Account B) as the principal who can assume the role.

The principal in the trust policy can also be an AWS service principal if you want to grant an AWS service permission to assume the role.

4. An administrator in Account B now delegates permissions to one or more IAM identities in Account B so that they can assume that role. Doing so gives those identities in Account B access to the resource in account A.

For more information about using IAM to delegate permissions, see [Access management](#) in the *IAM User Guide*. For more information about users, groups, roles, and permissions, see [Identities \(users, groups, and roles\)](#) in the *IAM User Guide*.

For a comparison of these two approaches, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*. AWS Glue supports both options, with the restriction that a resource policy can grant access only to Data Catalog resources.

For example, to give the Dev role in Account B access to database db1 in Account A, attach the following resource policy to the catalog in Account A.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetDatabase"
      ],
      "Principal": {"AWS": [
        "arn:aws:iam::account-B-id:role/Dev"
      ]},
      "Resource": [
        "arn:aws:glue:us-east-1:account-A-id:catalog",
        "arn:aws:glue:us-east-1:account-A-id:database/db1"
      ]
    }
  ]
}
```

In addition, Account B would have to attach the following IAM policy to the Dev role before it would actually get access to db1 in Account A.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "glue:GetDatabase"
      ],
      "Resource": [
        "arn:aws:glue:us-east-1:account-A-id:catalog",
        "arn:aws:glue:us-east-1:account-A-id:database/db1"
      ]
    }
  ]
}
```

```
]
}
```

## Adding or updating the Data Catalog resource policy

You can add or update the AWS Glue Data Catalog resource policy using the console, API, or AWS Command Line Interface (AWS CLI).

### Important

If you have already made cross-account permission grants from your account with AWS Lake Formation, adding or updating the Data Catalog resource policy requires an extra step. For more information, see [Managing cross-account permissions using both AWS Glue and Lake Formation](#) in the *AWS Lake Formation Developer Guide*.

To determine if Lake Formation cross-account grants exist, use the `glue:GetResourcePolicies` API operation or the AWS CLI. If `glue:GetResourcePolicies` returns any policies other than an already existing Data Catalog policy, then Lake Formation grants exist. For more information, see [Viewing all cross-account grants using the GetResourcePolicies API operation](#) in the *AWS Lake Formation Developer Guide*.

### To add or update the Data Catalog resource policy (console)

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.

Sign in as an AWS Identity and Access Management (IAM) administrative user who has the `glue:PutResourcePolicy` permission.

2. In the navigation pane, choose **Settings**.
3. On the **Data catalog settings** page, under **Permissions**, paste a resource policy into the text area. Then choose **Save**.

If the console displays a alert stating that the permissions in the policy will be in addition to any permissions granted using Lake Formation, choose **Proceed**.

## To add or update the Data Catalog resource policy (AWS CLI)

- Submit an `aws glue put-resource-policy` command. If Lake Formation grants already exist, ensure that you include the `--enable-hybrid` option with the value `'TRUE'`.

For examples of using this command, see [Resource-based policy examples for AWS Glue](#).

## Making a cross-account API call

All AWS Glue Data Catalog operations have a `CatalogId` field. If the required permissions have been granted to enable cross-account access, a caller can make Data Catalog API calls across accounts. The caller does this by passing the target AWS account ID in `CatalogId` so as to access the resource in that target account.

If no `CatalogId` value is provided, AWS Glue uses the caller's own account ID by default, and the call is not cross-account.

## Making a cross-account ETL call

Some AWS Glue PySpark and Scala APIs have a catalog ID field. If all the required permissions have been granted to enable cross-account access, an ETL job can make PySpark and Scala calls to API operations across accounts by passing the target AWS account ID in the catalog ID field to access Data Catalog resources in a target account.

If no catalog ID value is provided, AWS Glue uses the caller's own account ID by default, and the call is not cross-account.

For PySpark APIs that support `catalog_id`, see [GlueContext class](#). For Scala APIs that support `catalogId`, see [AWS Glue Scala GlueContext APIs](#).

The following example shows the permissions required by the grantee to run an ETL job. In this example, *grantee-account-id* is the `catalog-id` of the client running the job and *grantor-account-id* is the owner of the resource. This example grants permission to all catalog resources in the grantor's account. To limit the scope of resources granted, you can provide specific ARNs for the catalog, database, table, and connection.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Effect": "Allow",

```

**Note**

If a table in the grantor's account points to an Amazon S3 location that is also in the grantor's account, the IAM role used to run an ETL job in the grantee's account must have permission to list and get objects from the grantor's account.

Given that the client in Account A already has permission to create and run ETL jobs, the following are the basic steps to set up an ETL job for cross-account access:

1. Allow cross-account data access (skip this step if Amazon S3 cross-account access is already set up).
  - a. Update the Amazon S3 bucket policy in Account B to allow cross-account access from Account A.
  - b. Update the IAM policy in Account A to allow access to the bucket in Account B.
2. Allow cross-account Data Catalog access.
  - a. Create or update the resource policy attached to the Data Catalog in Account B to allow access from Account A.
  - b. Update the IAM policy in Account A to allow access to the Data Catalog in Account B.

## Cross-account CloudTrail logging

When an AWS Glue extract, transform, and load (ETL) job accesses the underlying data of a Data Catalog table shared through AWS Lake Formation cross-account grants, there is additional AWS CloudTrail logging behavior.

For purposes of this discussion, the AWS account that shared the table is the owner account, and the account that the table was shared with is the recipient account. When an ETL job in the recipient account accesses data in the table in the owner account, the data-access CloudTrail event that is added to the logs for the recipient account gets copied to the owner account's CloudTrail logs. This is so owner accounts can track data accesses by the various recipient accounts. By default, the CloudTrail events do not include a human-readable principal identifier (principal ARN). An administrator in the recipient account can opt in to include the principal ARN in the logs.

For more information, see [Cross-account CloudTrail logging](#) in the *AWS Lake Formation Developer Guide*.

### See Also

- [the section called "Logging and monitoring"](#)

## Cross-account resource ownership and billing

When a user in one AWS account (Account A) creates a new resource such as a database in a different account (Account B), that resource is then owned by Account B, the account where it was created. An administrator in Account B automatically gets full permissions to access the new resource, including reading, writing, and granting access permissions to a third account. The user in Account A can access the resource that they just created only if they have the appropriate permissions granted by Account B.

Storage costs and other costs that are directly associated with the new resource are billed to Account B, the resource owner. The cost of requests from the user who created the resource are billed to the requester's account, Account A.

For more information about AWS Glue billing and pricing, see [How AWS Pricing Works](#).

## Cross-account access limitations

AWS Glue cross-account access has the following limitations:

- Cross-account access to AWS Glue is not allowed if you created databases and tables using Amazon Athena or Amazon Redshift Spectrum prior to a region's support for AWS Glue and the resource owner account has not migrated the Amazon Athena data catalog to AWS Glue. You can find the current migration status using the [GetCatalogImportStatus \(get\\_catalog\\_import\\_status\)](#). For more details on how to migrate an Athena catalog to AWS Glue, see [Upgrading to the AWS Glue Data Catalog step-by-step](#) in the *Amazon Athena User Guide*.
- Cross-account access is *only* supported for Data Catalog resources, including databases, tables, user-defined functions, and connections.
- Cross-account access to the Data Catalog from Athena requires you to register the catalog as an Athena DataCatalog resource. For instructions, see [Registering an AWS Glue Data Catalog from another account](#) in the *Amazon Athena User Guide*.

## Troubleshooting AWS Glue identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with AWS Glue and IAM.

### Topics

- [I am not authorized to perform an action in AWS Glue](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my AWS Glue resources](#)

### I am not authorized to perform an action in AWS Glue

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a fictional *my-example-widget* resource but doesn't have the fictional `glue:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
glue:GetWidget on resource: my-example-widget
```

In this case, the policy for the mateojackson user must be updated to allow access to the *my-example-widget* resource by using the `glue:GetWidget` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

## I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to AWS Glue.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in AWS Glue. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

## I want to allow people outside of my AWS account to access my AWS Glue resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether AWS Glue supports these features, see [How AWS Glue works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.

- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

## Logging and monitoring in AWS Glue

You can automate the running of your ETL (extract, transform, and load) jobs. AWS Glue provides metrics for crawlers and jobs that you can monitor. After you set up the AWS Glue Data Catalog with the required metadata, AWS Glue provides statistics about the health of your environment. You can automate the invocation of crawlers and jobs with a time-based schedule based on cron. You can also trigger jobs when an event-based trigger fires.

AWS Glue is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or AWS service in AWS Glue. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket, Amazon CloudWatch Logs, and Amazon CloudWatch Events. Every event or log entry contains information about who generated the request.

Use Amazon CloudWatch Events to automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to CloudWatch Events in near-real time. You can write simple rules to indicate which events are of interest and what automated actions to take when an event matches a rule.

### See also

- [Automating AWS Glue with CloudWatch Events](#)
- [Cross-account CloudTrail logging](#)

An important facet of security in the cloud is logging. You must configure logging in a way that does not capture secrets and confidential material while capturing information necessary to debug and secure your cloud infrastructure. Make sure to familiarize yourself with what is being logged.

# Compliance validation for AWS Glue

To learn whether an AWS service is within the scope of specific compliance programs, see [AWS services in Scope by Compliance Program](#) and choose the compliance program that you are interested in. For general information, see [AWS Compliance Programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- [Security and Compliance Quick Start Guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- [Architecting for HIPAA Security and Compliance on Amazon Web Services](#) – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

## Note

Not all AWS services are HIPAA eligible. For more information, see the [HIPAA Eligible Services Reference](#).

- [AWS Compliance Resources](#) – This collection of workbooks and guides might apply to your industry and location.
- [AWS Customer Compliance Guides](#) – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- [Evaluating Resources with Rules](#) in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your

compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub controls reference](#).

- [Amazon GuardDuty](#) – This AWS service detects potential threats to your AWS accounts, workloads, containers, and data by monitoring your environment for suspicious and malicious activities. GuardDuty can help you address various compliance requirements, like PCI DSS, by meeting intrusion detection requirements mandated by certain compliance frameworks.
- [AWS Audit Manager](#) – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

## Resilience in AWS Glue

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](#).

For more information about AWS Glue job resiliency, see [Error: Failover behavior between VPCs in AWS Glue](#).

## Infrastructure security in AWS Glue

As a managed service, AWS Glue is protected by the AWS global network security procedures that are described in the [Amazon Web Services: Overview of Security Processes](#) whitepaper.

You use AWS published API calls to access AWS Glue through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service](#) (AWS STS) to generate temporary security credentials to sign requests.

## Topics

- [AWS Glue and interface VPC endpoints \(AWS PrivateLink\)](#)
- [Shared Amazon VPCs](#)

## AWS Glue and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and AWS Glue by creating an *interface VPC endpoint*. Interface endpoints are powered by [AWS PrivateLink](#), a technology that enables you to privately access AWS Glue APIs without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't need public IP addresses to communicate with AWS Glue APIs. Traffic between your VPC and AWS Glue does not leave the Amazon network.

Each interface endpoint is represented by one or more [Elastic Network Interfaces](#) in your subnets.

For more information, see [Interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon VPC User Guide*.

### Considerations for AWS Glue VPC endpoints

Before you set up an interface VPC endpoint for AWS Glue, ensure that you review [Interface endpoint properties and limitations](#) in the *Amazon VPC User Guide*.

AWS Glue supports making calls to all of its API actions from your VPC.

### Creating an interface VPC endpoint for AWS Glue

You can create a VPC endpoint for the AWS Glue service using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*.

Create a VPC endpoint for AWS Glue using the following service name:

- `com.amazonaws.region.glue`

If you enable private DNS for the endpoint, you can make API requests to AWS Glue using its default DNS name for the Region, for example, `glue.us-east-1.amazonaws.com`.

For more information, see [Accessing a service through an interface endpoint](#) in the *Amazon VPC User Guide*.

## Creating a VPC endpoint policy for AWS Glue

You can attach an endpoint policy to your VPC endpoint that controls access to AWS Glue. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

### Example: VPC endpoint policy for AWS Glue to allow job creation and update

The following is an example of an endpoint policy for AWS Glue. When attached to an endpoint, this policy grants access to the listed AWS Glue actions for all principals on all resources.

```
{
  "Statement": [
    {
      "Principal": "*",
      "Effect": "Allow",
      "Action": [
        "glue:CreateJob",
        "glue:UpdateJob",
        "iam:PassRole"
      ],
      "Resource": "*"
    }
  ]
}
```

### Example: VPC endpoint policy to allow read-only Data Catalog access

The following is an example of an endpoint policy for AWS Glue. When attached to an endpoint, this policy grants access to the listed AWS Glue actions for all principals on all resources.

```
{
  "Statement": [
    {
```

```
    "Principal": "*",
    "Effect": "Allow",
    "Action": [
        "glue:GetDatabase",
        "glue:GetDatabases",
        "glue:GetTable",
        "glue:GetTables",
        "glue:GetTableVersion",
        "glue:GetTableVersions",
        "glue:GetPartition",
        "glue:GetPartitions",
        "glue:BatchGetPartition",
        "glue:SearchTables"
    ],
    "Resource": "*"
}
]
```

## Shared Amazon VPCs

AWS Glue supports shared virtual private clouds (VPCs) in Amazon Virtual Private Cloud. Amazon VPC sharing allows multiple AWS accounts to create their application resources, such as Amazon EC2 instances and Amazon Relational Database Service (Amazon RDS) databases, into shared, centrally-managed Amazon VPCs. In this model, the account that owns the VPC (owner) shares one or more subnets with other accounts (participants) that belong to the same organization from AWS Organizations. After a subnet is shared, the participants can view, create, modify, and delete their application resources in the subnets that are shared with them.

In AWS Glue, to create a connection with a shared subnet, you must create a security group within your account and attach the security group to the shared subnet.

For more information, see these topics:

- [Working with Shared VPCs](#) in the *Amazon VPC User Guide*
- [What Is AWS Organizations?](#) in the *AWS Organizations User Guide*

# Troubleshooting AWS Glue

## Topics

- [Gathering AWS Glue troubleshooting information](#)
- [Troubleshooting errors in AWS Glue for Spark](#)
- [Troubleshooting AWS Glue for Ray errors from logs](#)
- [AWS Glue machine learning exceptions](#)
- [AWS Glue quotas](#)

## Gathering AWS Glue troubleshooting information

If you encounter errors or unexpected behavior in AWS Glue and need to contact AWS Support, you should first gather information about names, IDs, and logs that are associated with the failed action. Having this information available enables AWS Support to help you resolve the problems you're experiencing.

Along with your *account ID*, gather the following information for each of these types of failures:

### When a crawler fails, gather the following information:

- Crawler name

Logs from crawler runs are located in CloudWatch Logs under `/aws-glue/crawlers`.

### When a test connection fails, gather the following information:

- Connection name
- Connection ID
- JDBC connection string in the form `jdbc:protocol://host:port/database-name`.

Logs from test connections are located in CloudWatch Logs under `/aws-glue/testconnection`.

### When a job fails, gather the following information:

- Job name
- Job run ID in the form `jr_xxxxx`.

Logs from job runs are located in CloudWatch Logs under `/aws-glue/jobs`.

# Troubleshooting errors in AWS Glue for Spark

If you encounter errors in AWS Glue, use the following solutions to help you find the source of the problems and fix them.

## Note

The AWS Glue GitHub repository contains additional troubleshooting guidance in [AWS Glue Frequently Asked Questions](#).

## Error: Resource unavailable

If AWS Glue returns a resource unavailable message, you can view error messages or logs to help you learn more about the issue. The following tasks describe general methods for troubleshooting.

- For any connections and development endpoints that you use, check that your cluster has not run out of elastic network interfaces.

## Error: Could not find S3 endpoint or NAT gateway for subnetId in VPC

Check the subnet ID and VPC ID in the message to help you diagnose the issue.

- Check that you have an Amazon S3 VPC endpoint set up, which is required with AWS Glue. In addition, check your NAT gateway if that's part of your configuration. For more information, see [Amazon VPC endpoints for Amazon S3](#).

## Error: Inbound rule in security group required

At least one security group must open all ingress ports. To limit traffic, the source security group in your inbound rule can be restricted to the same security group.

- For any connections that you use, check your security group for an inbound rule that is self-referencing. For more information, see [Setting up network access to data stores](#).
- When you are using a development endpoint, check your security group for an inbound rule that is self-referencing. For more information, see [Setting up network access to data stores](#).

## **Error: Outbound rule in security group required**

At least one security group must open all egress ports. To limit traffic, the source security group in your outbound rule can be restricted to the same security group.

- For any connections that you use, check your security group for an outbound rule that is self-referencing. For more information, see [Setting up network access to data stores](#).
- When you are using a development endpoint, check your security group for an outbound rule that is self-referencing. For more information, see [Setting up network access to data stores](#).

## **Error: Job run failed because the role passed should be given assume role permissions for the AWS Glue service**

The user who defines a job must have permission for `iam:PassRole` for AWS Glue.

- When a user creates an AWS Glue job, confirm that the user's role contains a policy that contains `iam:PassRole` for AWS Glue. For more information, see [Step 3: Attach a policy to users or groups that access AWS Glue](#).

## **Error: DescribeVpcEndpoints action is unauthorized. unable to validate VPC ID vpc-id**

- Check the policy passed to AWS Glue for the `ec2:DescribeVpcEndpoints` permission.

## **Error: DescribeRouteTables action is unauthorized. unable to validate subnet id: Subnet-id in VPC id: vpc-id**

- Check the policy passed to AWS Glue for the `ec2:DescribeRouteTables` permission.

## **Error: Failed to call ec2:DescribeSubnets**

- Check the policy passed to AWS Glue for the `ec2:DescribeSubnets` permission.

## Error: Failed to call ec2:DescribeSecurityGroups

- Check the policy passed to AWS Glue for the `ec2:DescribeSecurityGroups` permission.

## Error: Could not find subnet for AZ

- The Availability Zone might not be available to AWS Glue. Create and use a new subnet in a different Availability Zone from the one specified in the message.

## Error: Job run exception when writing to a JDBC target

When you are running a job that writes to a JDBC target, the job might encounter errors in the following scenarios:

- If your job writes to a Microsoft SQL Server table, and the table has columns defined as type `Boolean`, then the table must be predefined in the SQL Server database. When you define the job on the AWS Glue console using a SQL Server target with the option **Create tables in your data target**, don't map any source columns to a target column with data type `Boolean`. You might encounter an error when the job runs.

You can avoid the error by doing the following:

- Choose an existing table with the **Boolean** column.
- Edit the `ApplyMapping` transform and map the **Boolean** column in the source to a number or string in the target.
- Edit the `ApplyMapping` transform to remove the **Boolean** column from the source.
- If your job writes to an Oracle table, you might need to adjust the length of names of Oracle objects. In some versions of Oracle, the maximum identifier length is limited to 30 bytes or 128 bytes. This limit affects the table names and column names of Oracle target data stores.

You can avoid the error by doing the following:

- Name Oracle target tables within the limit for your version.
- The default column names are generated from the field names in the data. To handle the case when the column names are longer than the limit, use `ApplyMapping` or `RenameField` transforms to change the name of the column to be within the limit.

## Error: Amazon S3: The operation is not valid for the object's storage class

If AWS Glue returns this error, your AWS Glue job may have been reading data from tables that have partitions across Amazon S3 storage class tiers.

- By using storage class exclusions, you can ensure that your AWS Glue jobs will work on tables that have partitions across these storage class tiers. Without exclusions, jobs that read data from these tiers fail with the following error: `AmazonS3Exception: The operation is not valid for the object's storage class.`

For more information, see [Excluding Amazon S3 storage classes](#).

## Error: Amazon S3 timeout

If AWS Glue returns a connect timed out error, it might be because it is trying to access an Amazon S3 bucket in another AWS Region.

- An Amazon S3 VPC endpoint can only route traffic to buckets within an AWS Region. If you need to connect to buckets in other Regions, a possible workaround is to use a NAT gateway. For more information, see [NAT Gateways](#).

## Error: Amazon S3 access denied

If AWS Glue returns an access denied error to an Amazon S3 bucket or object, it might be because the IAM role provided does not have a policy with permission to your data store.

- An ETL job must have access to an Amazon S3 data store used as a source or target. A crawler must have access to an Amazon S3 data store that it crawls. For more information, see [Step 2: Create an IAM role for AWS Glue](#).

## Error: Amazon S3 access key ID does not exist

If AWS Glue returns an access key ID does not exist error when running a job, it might be because of one of the following reasons:

- An ETL job uses an IAM role to access data stores, confirm that the IAM role for your job was not deleted before the job started.
- An IAM role contains permissions to access your data stores, confirm that any attached Amazon S3 policy containing `s3:ListBucket` is correct.

## Error: Job run fails when accessing Amazon S3 with an `s3a://` URI

If a job run returns an error like *Failed to parse XML document with handler class*, it might be because of a failure trying to list hundreds of files using an `s3a://` URI. Access your data store using an `s3://` URI instead. The following exception trace highlights the errors to look for:

```

## Error: Amazon S3 service token expired

When moving data to and from Amazon Redshift, temporary Amazon S3 credentials, which expire after 1 hour, are used. If you have a long running job, it might fail. For information about how to set up your long running jobs to move data to and from Amazon Redshift, see [aws-glue-programming-etl-connect-redshift-home](#).

## Error: No private DNS for network interface found

If a job fails or a development endpoint fails to provision, it might be because of a problem in the network setup.

- If you are using the Amazon provided DNS, the value of `enableDnsHostnames` must be set to true. For more information, see [DNS](#).

## Error: Development endpoint provisioning failed

If AWS Glue fails to successfully provision a development endpoint, it might be because of a problem in the network setup.

- When you define a development endpoint, the VPC, subnet, and security groups are validated to confirm that they meet certain requirements.
- If you provided the optional SSH public key, check that it is a valid SSH public key.
- Check in the VPC console that your VPC uses a valid **DHCP option set**. For more information, see [DHCP option sets](#).
- If the cluster remains in the PROVISIONING state, contact AWS Support.

## Error: Notebook server CREATE\_FAILED

If AWS Glue fails to create the notebook server for a development endpoint, it might be because of one of the following problems:

- AWS Glue passes an IAM role to Amazon EC2 when it is setting up the notebook server. The IAM role must have a trust relationship to Amazon EC2.

- The IAM role must have an instance profile of the same name. When you create the role for Amazon EC2 with the IAM console, the instance profile with the same name is automatically created. Check for an error in the log regarding the instance profile name `iamInstanceProfile.name` that is not valid. For more information, see [Using Instance Profiles](#).
- Check that your role has permission to access `aws-glue*` buckets in the policy that you pass to create the notebook server.

## Error: Local notebook fails to start

If your local notebook fails to start and reports errors that a directory or folder cannot be found, it might be because of one of the following problems:

- If you are running on Microsoft Windows, make sure that the `JAVA_HOME` environment variable points to the correct Java directory. It's possible to update Java without updating this variable, and if it points to a folder that no longer exists, Jupyter notebooks fail to start.

## Error: Running crawler failed

If AWS Glue fails to successfully run a crawler to catalog your data, it might be because of one of the following reasons. First check if an error is listed in the AWS Glue console crawlers list. Check if there is an exclamation icon next to the crawler name and hover over the icon to see any associated messages.

- Check the logs for the crawler run in CloudWatch Logs under `/aws-glue/crawlers`.

## Error: Partitions were not updated

In case your partitions were not updated in the Data Catalog when you ran an ETL job, these log statements from the `DataSink` class in the CloudWatch logs may be helpful:

- "Attempting to fast-forward updates to the Catalog - nameSpace:" — Shows which database, table, and catalogId are attempted to be modified by this job. If this statement is not here, check if `enableUpdateCatalog` is set to true and properly passed as a `getSink()` parameter or in `additional_options`.

- "Schema change policy behavior:" — Shows which schema updateBehavior value you passed in.
- "Schemas qualify (schema compare):" — Will be true or false.
- "Schemas qualify (case-insensitive compare):" — Will be true or false.
- If both are false and your updateBehavior is not set to UPDATE\_IN\_DATABASE, then your DynamicFrame schema needs to be identical or contain a subset of the columns seen in the Data Catalog table schema.

For more information on updating partitions, see [Updating the schema, and adding new partitions in the Data Catalog using AWS Glue ETL jobs](#).

## Error: Job bookmark update failed due to version mismatch

You may be trying to parametrize AWS Glue jobs to apply the same transformation/logic on different datasets in Amazon S3. You want to track processed files on the locations provided. When you run the same job on the same source bucket and write to the same/different destination concurrently (concurrency >1) the job fails with this error:

```
py4j.protocol.Py4JJavaError: An error occurred while
callingz:com.amazonaws.services.glue.util.Job.commit.:com.amazonaws.services.gluejobexecutor.m
Continuation update failed due to version mismatch. Expected version 2 but found
version 3
```

Solution: set concurrency to 1 or don't run the job concurrently.

Currently AWS Glue bookmarks don't support concurrent job runs and commits will fail.

## Error: A job is reprocessing data when job bookmarks are enabled

There might be cases when you have enabled AWS Glue job bookmarks, but your ETL job is reprocessing data that was already processed in an earlier run. Check for these common causes of this error:

### Max Concurrency

Setting the maximum number of concurrent runs for the job greater than the default value of 1 can interfere with job bookmarks. This can occur when job bookmarks check the last modified time of objects to verify which objects need to be reprocessed. For more information, see the discussion of max concurrency in [Configuring job properties for Spark jobs in AWS Glue](#).

## Missing Job Object

Ensure that your job run script ends with the following commit:

```
job.commit()
```

When you include this object, AWS Glue records the timestamp and path of the job run. If you run the job again with the same path, AWS Glue processes only the new files. If you don't include this object and job bookmarks are enabled, the job reprocesses the already processed files along with the new files and creates redundancy in the job's target data store.

## Missing Transformation Context Parameter

Transformation context is an optional parameter in the `GlueContext` class, but job bookmarks don't work if you don't include it. To resolve this error, add the transformation context parameter when you [create the DynamicFrame](#), as shown following:

```
sample_dynF=create_dynamic_frame_from_catalog(database,  
table_name,transformation_ctx="sample_dynF")
```

## Input Source

If you are using a relational database (a JDBC connection) for the input source, job bookmarks work only if the table's primary keys are in sequential order. Job bookmarks work for new rows, but not for updated rows. That is because job bookmarks look for the primary keys, which already exist. This does not apply if your input source is Amazon Simple Storage Service (Amazon S3).

## Last Modified Time

For Amazon S3 input sources, job bookmarks check the last modified time of the objects, rather than the file names, to verify which objects need to be reprocessed. If your input source data has been modified since your last job run, the files are reprocessed when you run the job again.

## Error: Failover behavior between VPCs in AWS Glue

The following process is used for failover for jobs in AWS Glue 4.0 and previous versions.

Summary: an AWS Glue connection is selected at the time a job run is submitted. If the job run encounters some issues, (lack of IP addresses, connectivity to source, routing problem), the job run will fail. If retries are configured, AWS Glue will retry with the same connection.

1. At the time of job run submission, AWS Glue picks the connection based on the order they are listed in the job configuration. It runs a validation, and if the validation succeeds AWS Glue will use that connection. AWS Glue tries the next connection if any of the validations fail.
2. AWS Glue validates the connection with the following:
  - checks for valid Amazon VPC id and subnet.
  - checks that a NAT gateway or Amazon VPC endpoint exists.
  - checks that the subnet has more than 0 allocated IP addresses.
  - checks that the AZ is healthy.

AWS Glue cannot verify connectivity at the time of job run submission.

3. For jobs using Amazon VPC, all drivers and executors will be created in the same AZ with the connection selected at the time of job run submission.
4. If retries are configured, AWS Glue will retry with the same connection. This is because we cannot guarantee problems with this connection are long-running. If an AZ fails, existing job runs (depending on the stage of the job run) in that AZ can fail. A retry should detect an AZ failure and choose another AZ for the new run.

## Troubleshoot crawler errors when the crawler is using Lake Formation credentials

Use the information below to diagnose and fix various issues while configuring the crawler using Lake Formation credentials.

### **Error: The S3 location: s3://examplepath is not registered**

For a crawler to run using Lake Formation credentials, you need to first set up Lake Formation permissions. To resolve this error, please register the target Amazon S3 location with Lake Formation. For more information, see [Registering an Amazon S3 location](#).

### **Error: User/Role is not authorized to perform: lakeformation:GetDataAccess on resource**

Please add the `lakeformation:GetDataAccess` permission to the crawler role using the IAM console or AWS CLI. With this permission, Lake Formation grants the request for temporary credentials to access the data. See the policy below:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "lakeformation:GetDataAccess"
    ],
    "Resource": "*"
  }
}
```

## Error: Insufficient Lake Formation permission(s) on (Database name: exampleDatabase, Table Name: exampleTable)

In the Lake Formation console (<https://console.aws.amazon.com/lakeformation/>), grant the crawler role access permissions ( Create, Describe, Alter) on the database, which is specified as the output database. You can grant permissions on the table as well. For more information, see [Granting database permissions using the named resource method](#).

## Error: Insufficient Lake Formation permission(s) on s3://examplepath

### 1. Cross-account crawling

- a. Log in to the Lake Formation console (<https://console.aws.amazon.com/lakeformation/>) using the account where Amazon S3 bucket is registered (account B). Grant data location permissions to the account where the crawler will be run. This will allow the crawler to read data from the target Amazon S3 location.
- b. In the account where the crawler is created (account A), grant data location permissions on the target Amazon S3 location to the IAM role used for the crawler run so that the crawler can read the data from the destination in Lake Formation. For more information, see [Granting data location permissions \(external account\)](#).

### 2. In-account (crawler and registered Amazon S3 location are in the same account) crawling

- Grant data location permissions to the IAM role used for the crawler run on the Amazon S3 location so that the crawler can read the data from the target in Lake Formation. For more information, see [Granting data location permissions \(same account\)](#).

## Frequently asked questions about crawler configuration using Lake Formation credentials

### 1. How do I configure a crawler to run using Lake Formation credentials using the AWS console?

In the AWS Glue console (<https://console.aws.amazon.com/glue/>), while configuring the crawler, select the option **Use Lake Formation credentials for crawling Amazon S3 data source**. For cross-account crawling, specify the AWS account ID where the target Amazon S3 location is registered with Lake Formation. For in-account crawling, the `accountId` field is optional.

### 2. How do I configure a crawler to run using Lake Formation credentials using AWS CLI?

During `CreateCrawler` API call, add `LakeFormationConfiguration` :

```
"LakeFormationConfiguration": {
  "UseLakeFormationCredentials": true,
  "AccountId": "111111111111" (AWS account ID where the target Amazon S3 location
is registered with Lake Formation)
}
```

### 3. What are the supported targets for a crawler using Lake Formation credentials?

A crawler using Lake Formation credentials is only supported for Amazon S3 (in-account and cross-account crawling), in-account Data Catalog targets (where the underlying location is Amazon S3), and Apache Iceberg targets.

### 4. Can I crawl multiple Amazon S3 buckets as part of a single crawler using Lake Formation credentials?

No, for crawling targets using Lake Formation credential vending, the underlying Amazon S3 locations must belong to the same bucket. For example, customers can use multiple target locations (`s3://bucket1/folder1`, `s3://bucket1/folder2`) if they are under the same bucket (`bucket1`). Specifying different buckets (`s3://bucket1/folder1`, `s3://bucket2/folder2`) is not supported.

## Troubleshooting AWS Glue for Ray errors from logs

AWS Glue provides access to logs that are emitted by Ray processes during the job run. If you encounter errors or unexpected behavior in Ray jobs, first gather information from the logs to

determine the cause of failure. We also provide similar logs for interactive sessions. Sessions logs are provided with the `/aws-glue/ray/sessions` prefix.

Log lines are sent to CloudWatch in real time, as your job is run. Print statements are appended to the CloudWatch logs after the run completes. Logs are retained for two weeks after a job is run.

## Inspecting Ray job logs

When a job fails, gather your job name and job run ID. You can find these in the AWS Glue console. Navigate to the job page, and then navigate to the **Runs** tab. Ray job logs are stored in the following dedicated CloudWatch log groups.

- `/aws-glue/ray/jobs/script-log/` – Stores logs emitted by your main Ray script.
- `/aws-glue/ray/jobs/ray-monitor-log/` – Stores logs emitted by the Ray autoscaler process. These logs are generated for the head node and not for other worker nodes.
- `/aws-glue/ray/jobs/ray-gcs-logs/` – Stores logs emitted by the GCS (global control store) process. These logs are generated for the head node and not for other worker nodes.
- `/aws-glue/ray/jobs/ray-process-logs/` – Stores logs emitted by other Ray processes (primarily the dashboard agent) running on the head node. These logs are generated for the head node and not for other worker nodes.
- `/aws-glue/ray/jobs/ray-raylet-logs/` – Stores logs emitted by each raylet process. These logs are collected in a single stream for each worker node, including the head node.
- `/aws-glue/ray/jobs/ray-worker-out-logs/` – Stores stdout logs for each worker in the cluster. These logs are generated for each worker node, including the head node.
- `/aws-glue/ray/jobs/ray-worker-err-logs/` – Stores stderr logs for each worker in the cluster. These logs are generated for each worker node, including the head node.
- `/aws-glue/ray/jobs/ray-runtime-env-log/` – Stores logs about the Ray setup process. These logs are generated for each worker node, including the head node.

## Troubleshooting Ray job errors

To understand the organization of Ray log groups, and to find the log groups that will help you troubleshoot your errors, it helps to have background information about Ray architecture.

In AWS Glue ETL, a worker corresponds to an instance. When you configure workers for an AWS Glue job, you're setting the type and quantity of instances that are dedicated to the job. Ray uses the term *worker* in different ways.

Ray uses *head node* and *worker node* to distinguish the responsibilities of an instance within a Ray cluster. A Ray worker node can host multiple *actor* processes that perform computations to achieve the result of your distributed computation. Actors that run a replica of a function are called *replicas*. Replica actors can also be called worker processes. Replicas can also run on the head node, which is known as the head because it runs additional processes to coordinate the cluster.

Each actor that contributes to your computation generates its own log stream. This provides us with some insights:

- The number of processes that emit logs might be larger than the number of workers that are allocated to the job. Often, each core on each instance has an actor.
- Ray head nodes emit cluster management and startup logs. In contrast, Ray worker nodes only emit logs for the work performed on them.

For more information about Ray architecture, see [Architecture Whitepapers](#) in the Ray documentation.

### **Problem area: Amazon S3 access**

Check the failure message of the job run. If that doesn't provide enough information, check `/aws-glue/ray/jobs/script-log/`.

### **Problem area: PIP dependency management**

Check `/aws-glue/ray/jobs/ray-runtime-env-log/`.

### **Problem area: Inspecting intermediate values in main process**

Write to `stderr` or `stdout` from your main script, and retrieve logs from `/aws-glue/ray/jobs/script-log/`.

### **Problem area: Inspecting intermediate values in a child process**

Write to `stderr` or `stdout` from your `remote` function. Then, retrieve logs from `/aws-glue/ray/jobs/ray-worker-out-logs/` or `/aws-glue/ray/jobs/ray-worker-err-logs/`. Your function might have run on any replica, so you might have to examine multiple logs to find your intended output.

## Problem area: Interpreting IP addresses in error messages

In certain error situations, your job might emit an error message that contains an IP address. These IP addresses are ephemeral, and are used by the cluster to identify and communicate between nodes. Logs for a node will be published to a log stream with a unique suffix based on the IP address.

In CloudWatch, you can filter down your logs to inspect those specific to this IP address by identifying this suffix. For example, given *FAILED\_IP* and *JOB\_RUN\_ID*, you can identify the suffix with:

```
filter @logStream like /JOB_RUN_ID/  
| filter @message like /IP-/  
| parse @message "IP-[*]" as ip  
| filter ip like /FAILED_IP/  
| fields replace(ip, ":", "_") as uIP  
| stats count_distinct by uIP as logStreamSuffix  
| display logStreamSuffix
```

## AWS Glue machine learning exceptions

This topic describes HTTP error codes and strings for AWS Glue exceptions related to machine learning. The error codes and error strings are provided for each machine learning activity that may occur when you perform an operation. Also, you can see whether it is possible to retry the operation that resulted in the error.

### CancelMLTaskRunActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”
  - “No ML Task Run found for [taskRunId]: in account [accountId] for transform [transformName].”

OK to retry: No.

## CreateMLTaskRunActivity

This activity has the following exceptions:

- **InvalidInputException (400)**
  - "Internal service failure due to unexpected input."
  - "An AWS Glue Table input source should be specified in transform."
  - "Input source column [columnName] has an invalid data type defined in the catalog."
  - "Exactly one input record table must be provided."
  - "Should specify database name."
  - "Should specify table name."
  - "Schema is not defined on the transform."
  - "Schema should contain given primary key: [primaryKey]."
  - "Problem fetching the data catalog schema: [message]."
  - "Cannot set Max Capacity and Worker Num/Type at the same time."
  - "Both WorkerType and NumberOfWorkers should be set."
  - "MaxCapacity should be >= [maxCapacity]."
  - "NumberOfWorkers should be >= [maxCapacity]."
  - "Max retries should be non-negative."
  - "Find Matches parameters have not been set."
  - "A primary key must be specified in Find Matches parameters."

OK to retry: No.

- **AlreadyExistsException (400)**
  - "Transform with name [transformName] already exists."

OK to retry: No.

- **IdempotentParameterMismatchException (400)**
  - "Idempotent create request for transform [transformName] had mismatching parameters."

OK to retry: No.

- **InternalServiceException (500)**

- "Dependency failure."

OK to retry: Yes.

- ResourceNumberLimitExceededException (400)
  - “ML Transforms count ([count]) has exceeded the limit of [limit] transforms.”

OK to retry: Yes, once you’ve deleted a transform to make room for this new one.

## DeleteMLTransformActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName]”

OK to retry: No.

## GetMLTaskRunActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”
  - “No ML Task Run found for [taskRunId]: in account [accountId] for transform [transformName].”

OK to retry: No.

## GetMLTaskRunsActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”
  - “No ML Task Run found for [taskRunId]: in account [accountId] for transform [transformName].”

OK to retry: No.

## GetMLTransformActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - "Cannot find MLTransform in account [accountId] with handle [transformName]."

OK to retry: No.

## GetMLTransformsActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - "Cannot find MLTransform in account [accountId] with handle [transformName]."

OK to retry: No.

- InvalidInputException (400)
  - "Account ID can't be blank."
  - "Sorting not supported for column [column]."
  - "[column] can't be blank."
  - "Internal service failure due to unexpected input."

OK to retry: No.

## GetSaveLocationForTransformArtifactActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - "Cannot find MLTransform in account [accountId] with handle [transformName]."

OK to retry: No.

- InvalidInputException (400)
  - "Unsupported artifact type [artifactType]."
  - "Internal service failure due to unexpected input."

OK to retry: No.

## GetTaskRunArtifactActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - "Cannot find MLTransform in account [accountId] with handle [transformName]."
  - "No ML Task Run found for [taskRunId]: in account [accountId] for transform [transformName]."

OK to retry: No.

- InvalidInputException (400)
  - "File name '[fileName]' is invalid for publish."
  - "Cannot retrieve artifact for [taskType] task type."
  - "Cannot retrieve artifact for [artifactType]."
  - "Internal service failure due to unexpected input."

OK to retry: No.

## PublishMLTransformModelActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - "Cannot find MLTransform in account [accountId] with handle [transformName]."
  - "An existing model with version - [version] cannot be found for account id - [accountId] - and transform id - [transformId]."

OK to retry: No.

- InvalidInputException (400)
  - "File name '[fileName]' is invalid for publish."
  - "Illegal leading minus sign on unsigned string [string]."
  - "Bad digit at end of [string]."

- “String value [string] exceeds range of unsigned long.”
- “Internal service failure due to unexpected input.”

OK to retry: No.

## PullLatestMLTransformModelActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”

OK to retry: No.

- InvalidInputException (400)
  - “Internal service failure due to unexpected input.”

OK to retry: No.

- ConcurrentModificationException (400)
  - “Cannot create model version to train due to racing inserts with mismatching parameters.”
  - “The ML Transform model for transform id [transformId] is stale or being updated by another process; Please retry.”

OK to retry: Yes.

## PutJobMetadataForMLTransformActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”
  - “No ML Task Run found for [taskRunId]: in account [accountId] for transform [transformName].”

OK to retry: No.

- InvalidInputException (400)
  - “Internal service failure due to unexpected input.”

- “Unknown job metadata type [jobType].”
- “Must provide a task run ID to update.”

OK to retry: No.

## StartExportLabelsTaskRunActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”
  - “No labelset exists for transformId [transformId] in account id [accountId].”

OK to retry: No.

- InvalidInputException (400)
  - “[message].”
  - “S3 path provided is not in the same region as transform. Expecting region - [region], but got - [region].”

OK to retry: No.

## StartImportLabelsTaskRunActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”

OK to retry: No.

- InvalidInputException (400)
  - “[message].”
  - “Invalid label file path.”
  - “Cannot access the label file at [labelPath]. [message].”
  - “Cannot use IAM role provided in the transform. Role: [role].”

- “Invalid label file of size 0.”

- “S3 path provided is not in the same region as transform. Expecting region - [region], but got - [region].”

OK to retry: No.

- ResourceNumberLimitExceededException (400)
  - “Label file has exceeded the limit of [limit] MB.”

OK to retry: No. Consider breaking your label file into several smaller files.

## StartMLEvaluationTaskRunActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”

OK to retry: No.

- InvalidInputException (400)
  - “Exactly one input record table must be provided.”
  - “Should specify database name.”
  - “Should specify table name.”
  - “Find Matches parameters have not been set.”
  - “A primary key must be specified in Find Matches parameters.”

OK to retry: No.

- MLTransformNotReadyException (400)
  - “This operation can only be applied to a transform that is in a READY state.”

OK to retry: No.

- InternalServiceException (500)
  - “Dependency failure.”

OK to retry: Yes.

- ConcurrentRunsExceededException (400)

• “MLTaskRuns count [count] has exceeded the transform limit of [limit] task runs.”

- “ML Task Runs count [count] has exceeded the limit of [limit] task runs.”

OK to retry: Yes, after waiting for task runs to finish.

## StartMLLabelingSetGenerationTaskRunActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”

OK to retry: No.

- InvalidInputException (400)
  - “Exactly one input record table must be provided.”
  - “Should specify database name.”
  - “Should specify table name.”
  - “Find Matches parameters have not been set.”
  - “A primary key must be specified in Find Matches parameters.”

OK to retry: No.

- InternalServiceException (500)
  - “Dependency failure.”

OK to retry: Yes.

- ConcurrentRunsExceededException (400)
  - “ML Task Runs count [count] has exceeded the transform limit of [limit] task runs.”

OK to retry: Yes, after task runs have completed.

## UpdateMLTransformActivity

This activity has the following exceptions:

- EntityNotFoundException (400)
  - “Cannot find MLTransform in account [accountId] with handle [transformName].”

OK to retry: No.

- InvalidInputException (400)

- "Another transform with name [transformName] already exists."
- "[message]."
- "Transform name cannot be blank."
- "Cannot set Max Capacity and Worker Num/Type at the same time."
- "Both WorkerType and NumberOfWorkers should be set."
- "MaxCapacity should be >= [minMaxCapacity]."
- "NumberOfWorkers should be >= [minNumWorkers]."
- "Max retries should be non-negative."
- "Internal service failure due to unexpected input."
- "Find Matches parameters have not been set."
- "A primary key must be specified in Find Matches parameters."

OK to retry: No.

- AlreadyExistsException (400)

- "Transform with name [transformName] already exists."

OK to retry: No.

- IdempotentParameterMismatchException (400)

- "Idempotent create request for transform [transformName] had mismatching parameters."

OK to retry: No.

## AWS Glue quotas

You can contact AWS Support to [request a quota increase](#) for the service quotas listed in the *AWS General Reference*. Unless otherwise noted, each quota is Region-specific. For more information, see [AWS Glue Endpoints and Quotas](#).

# Improving AWS Glue performance

## Baseline strategy for performance tuning

In order to improve AWS Glue performance, you may consider updating certain performance related AWS Glue parameters. When preparing to tune parameters, use the following best practices:

- Determine your performance goals before beginning to identify problems.
- Use metrics to identify problems before attempting to change tuning parameters.

For the most consistent results when tuning a job, develop a baseline strategy for your tuning work.

Generally, performance tuning is performed in the following workflow:

1. Determine performance goals.
2. Measure metrics.
3. Identify bottlenecks.
4. Reduce the impact of the bottlenecks.
5. Repeat steps 2-4 until you achieve the intended target.

## Tuning strategies for your job type

**Spark jobs**—follow the guidance in [Best practices for performance tuning AWS Glue for Apache Spark jobs](#) on AWS Prescriptive Guidance.

**Other jobs**—you can tune AWS Glue for Ray and AWS Glue Python shell jobs by adapting strategies available in other runtime environments.

## Improving performance for AWS Glue for Apache Spark jobs

In order to improve AWS Glue for Spark performance, you may consider updating certain performance related AWS Glue and Spark parameters.

For more information about specific strategies for identifying bottlenecks through metrics and reducing their impact, see [Best practices for performance tuning AWS Glue for Apache Spark jobs](#) on AWS Prescriptive Guidance. This guide introduces you to key topics applicable to Apache Spark in all runtime environments, such as Spark architecture and Resilient Distributed Datasets. Using those topics, the guide guides you to implement specific performance tuning strategies, such as optimizing shuffles and parallelizing tasks.

You can identify bottlenecks by configuring AWS Glue to show the Spark UI. For more information, see [the section called “Monitoring with the Spark UI”](#).

Additionally, AWS Glue provides performance features that may be applicable to the specific type of data store your job connects to. Reference information about performance parameters for data stores can be found in [the section called “Connection parameters”](#).

## Optimizing reads with pushdown in AWS Glue ETL

Pushdown is an optimization technique that pushes logic about retrieving data closer to the source of your data. The source could be a database or a file system such as Amazon S3. When executing certain operations directly on the source, you can save time and processing power by not bringing all the data over the network to the Spark engine managed by AWS Glue.

Another way of saying this is that pushdown reduces data scan. For more information about the process of identifying when this technique is appropriate, consult [Reduce the amount of data scan](#) in the *Best practices for performance tuning AWS Glue for Apache Spark jobs* guide on AWS Prescriptive Guidance.

### Predicate pushdown on files stored on Amazon S3

When working with files on Amazon S3 that have been organized by prefix, you can filter your target Amazon S3 paths by defining a pushdown predicate. Rather than reading the complete dataset and applying filters within a `DynamicFrame`, you can directly apply the filter to the partition metadata stored in the AWS Glue Data Catalog. This approach allows you to selectively list and read only the necessary data. For more information about this process, including writing to a bucket by partitions, see [the section called “Managing partitions”](#).

You achieve predicate pushdown in Amazon S3 by using the `push_down_predicate` parameter. Consider a bucket in Amazon S3 you've partitioned by year, month and day. If you want to retrieve customer data for June of 2022, you can instruct AWS Glue to read only relevant Amazon S3

paths. The `push_down_predicate` in this case is `year='2022'` and `month='06'`. Putting it all together, the read operation can be achieved as below:

## Python

```
customer_records = glueContext.create_dynamic_frame.from_catalog(  
    database = "customer_db",  
    table_name = "customer_tbl",  
    push_down_predicate = "year='2022' and month='06'"  
)
```

## Scala

```
val customer_records = glueContext.getCatalogSource(  
    database="customer_db",  
    tableName="customer_tbl",  
    pushDownPredicate="year='2022' and month='06'"  
).getDynamicFrame()
```

In the previous scenario, `push_down_predicate` retrieves a list of all partitions from the AWS Glue Data Catalog and filters them before reading the underlying Amazon S3 files. Though this helps in most cases, when working with datasets that have millions of partitions, the process of listing partitions can be time consuming. To address this issue, server-side pruning of partitions can be used to improve performance. This is done by building a **Partition index** for your data in the AWS Glue Data Catalog. For more information about partition indices, see [the section called “Working with partition indexes”](#). You can then use the `catalogPartitionPredicate` option to reference the index. For an example retrieving partitions with `catalogPartitionPredicate`, see [the section called “Catalog partition predicates”](#).

## Pushdown when working with JDBC sources

The AWS Glue JDBC reader used in the `GlueContext` supports pushdown on supported databases by providing custom SQL queries that can run directly on the source. This can be achieved by setting the `sampleQuery` parameter. Your sample query can specify which columns to select as well as provide a pushdown predicate to limit the data transferred to the Spark engine.

By default, sample queries operate on a single node, which can result in job failures when dealing with large data volumes. To use this feature to query data at scale, you should configure query partitioning by setting `enablePartitioningForSampleQuery` to `true`, which will distribute

the query to multiple nodes across a key of your choice. Query partitioning also requires a few other necessary configuration parameters. For more information about query partitioning, see [the section called “Reading from JDBC in parallel”](#).

When setting `enablePartitioningForSampleQuery`, AWS Glue will combine your pushdown predicate with a partitioning predicate when querying your database. Your `sampleQuery` must end with an `AND` for AWS Glue to append partitioning conditions. (If you do not provide a pushdown predicate, `sampleQuery` must end with a `WHERE`). See an example below, where we push down a predicate to only retrieve rows whose `id` is greater than 1000. This `sampleQuery` will only return the name and location columns for rows where `id` is greater than the specified value:

## Python

```
sample_query = "select name, location from customer_tbl WHERE id>=1000 AND"
customer_records = glueContext.create_dynamic_frame.from_catalog(
    database="customer_db",
    table_name="customer_tbl",
    sample_query = "select name, location from customer_tbl WHERE id>=1000 AND",

    additional_options = {
        "hashpartitions": 36 ,
        "hashfield":"id",
        "enablePartitioningForSampleQuery":True,
        "sampleQuery":sample_query
    }
)
```

## Scala

```
val additionalOptions = Map(
    "hashpartitions" -> "36",
    "hashfield" -> "id",
    "enablePartitioningForSampleQuery" -> "true",
    "sampleQuery" -> "select name, location from customer_tbl WHERE id >= 1000
AND"
)

val customer_records = glueContext.getCatalogSource(
    database="customer_db",
    tableName="customer_tbl").getDynamicFrame()
```

**Note**

If `customer_tbl` has a different name in your Data Catalog and underlying datastore, you must provide the underlying table name in `sample_query`, since the query is passed to the underlying datastore.

You can also query against JDBC tables without integrating with the AWS Glue Data Catalog. Instead of providing username and password as parameters to the method, you can reuse credentials from a preexisting connection by providing `useConnectionProperties` and `connectionName`. In this example, we retrieve credentials from a connection called `my_postgre_connection`.

### Python

```
connection_options_dict = {
    "useConnectionProperties": True,
    "connectionName": "my_postgre_connection",
    "dbtable": "customer_tbl",
    "sampleQuery": "select name, location from customer_tbl WHERE id >= 1000 AND",
    "enablePartitioningForSampleQuery": True,
    "hashfield": "id",
    "hashpartitions": 36
}

customer_records = glueContext.create_dynamic_frame.from_options(
    connection_type="postgresql",
    connection_options=connection_options_dict
)
```

### Scala

```
val connectionOptionsJson = """
{
  "useConnectionProperties": true,
  "connectionName": "my_postgre_connection",
  "dbtable": "customer_tbl",
  "sampleQuery": "select name, location from customer_tbl WHERE id >= 1000 AND",
  "enablePartitioningForSampleQuery" : true,
  "hashfield" : "id",
  "hashpartitions" : 36
}
```

```
    }  
    ""  
  
    val connectionOptions = new JsonOptions(connectionOptionsJson)  
  
    val dyf = glueContext.getSource("postgresql",  
connectionOptions).getDynamicFrame()
```

## Notes and limitations for pushdown in AWS Glue

Pushdown, as a concept, is applicable when reading from non-streaming sources. AWS Glue supports a variety of sources - the ability to pushdown depends on the source and connector.

- When connecting to Snowflake, you can use the `query` option. Similar functionality exists in the Redshift connector in AWS Glue 4.0 and later versions. For more information about reading from Snowflake with query, see [the section called "Read from Snowflake"](#).
- The DynamoDB ETL reader does not support filters or pushdown predicates. MongoDB and DocumentDB also do not support this sort of functionality.
- When reading from data stored in Amazon S3 in open table formats, the partitioning method for files in Amazon S3 is no longer sufficient. To read and write from partitions using open table formats, consult documentation for the format.
- DynamicFrame methods do not perform Amazon S3 projection pushdown. All columns will be read from files that pass the predicate filter.
- When working with custom `.jdbc` connectors in AWS Glue, the ability to pushdown depends on the source and connector. Please review the appropriate connector documentation to confirm if and how it supports pushdown in AWS Glue.

## Using auto scaling for AWS Glue

Auto Scaling is available for your AWS Glue ETL and streaming jobs with AWS Glue version 3.0 or later.

With Auto Scaling enabled, you will get the following benefits:

- AWS Glue automatically adds and removes workers from the cluster depending on the parallelism at each stage or microbatch of the job run.

- It removes the need for you to experiment and decide on the number of workers to assign for your AWS Glue ETL jobs.
- If you choose the maximum number of workers, AWS Glue will choose the right size resources for the workload.
- You can see how the size of the cluster changes during the job run by looking at CloudWatch metrics on the job run details page in AWS Glue Studio.

Auto Scaling for AWS Glue ETL and streaming jobs enables on-demand scaling up and scaling down of the computing resources of your AWS Glue jobs. On-demand scale-up helps you to only allocate the required computing resources initially on job run startup, and also to provision the required resources as per demand during the job.

Auto Scaling also supports dynamic scale-down of the AWS Glue job resources over the course of a job. Over a job run, when more executors are requested by your Spark application, more workers will be added to the cluster. When the executor has been idle without active computation tasks, the executor and the corresponding worker will be removed.

Common scenarios where Auto Scaling helps with cost and utilization for your Spark applications include a Spark driver listing a large number of files in Amazon S3 or performing a load while executors are inactive, Spark stages running with only a few executors due to overprovisioning, and data skews or uneven computation demand across Spark stages.

## Requirements

Auto Scaling is only available for AWS Glue version 3.0 or later. To use Auto Scaling, you can follow the [migration guide](#) to migrate your existing jobs to AWS Glue version 3.0 or later or create new jobs with AWS Glue version 3.0 or later.

Auto Scaling is available for AWS Glue jobs with the G.1X, G.2X, G.4X, G.8X, or G.025X (only for Streaming jobs) worker types. Standard DPUs are not supported.

## Enabling Auto Scaling in AWS Glue Studio

On the **Job details** tab in AWS Glue Studio, choose the type as **Spark** or **Spark Streaming**, and **Glue version** as **Glue 3.0** or **Glue 4.0**. Then a check box will show up below **Worker type**.

- Select the **Automatically scale the number of workers** option.

- Set the **Maximum number of workers** to define the maximum number of workers that can be vended to the job run.

Visual | Script | **Job details** | Runs | Data quality | Schedules

**Version Control**

**Type**  
The type of ETL job. This is set automatically based on the types of data sources you have selected.

Spark

**Glue version** [Info](#)

Glue 4.0 - Supports spark 3.3, Scala 2, Python 3 ▼

**Language**

Python 3 ▼

**Worker type**  
Set the type of predefined worker that is allowed when a job runs.

G 1X  
(4vCPU and 16GB RAM) ▼

**Automatically scale the number of workers**  
AWS Glue will optimize costs and resource usage by dynamically scaling the number of workers up and down throughout the job run. Requires Glue 3.0 or later.

**Maximum number of workers**  
The number of workers you want AWS Glue to allocate to this job.

10

## Enabling Auto Scaling with the AWS CLI or SDK

To enable Auto Scaling From the AWS CLI for your job run, run `start-job-run` with the following configuration:

```
{  
  "JobName": "<your job name>",
```

```
"Arguments": {
  "--enable-auto-scaling": "true"
},
"WorkerType": "G.2X", // G.1X and G.2X are allowed for Auto Scaling Jobs
"NumberOfWorkers": 20, // represents Maximum number of workers
...other job run configurations...
}
```

Once an ETL job run is finished, you can also call `get-job-run` to check the actual resource usage of the job run in DPU-seconds. Note: the new field **DPUSecods** will only show up for your batch jobs on AWS Glue 3.0 or later enabled with Auto Scaling. This field is not supported for streaming jobs.

```
$ aws glue get-job-run --job-name your-job-name --run-id jr_xx --endpoint https://
glue.us-east-1.amazonaws.com --region us-east-1
{
  "JobRun": {
    ...
    "GlueVersion": "3.0",
    "DPUSecods": 386.0
  }
}
```

You can also configure job runs with Auto Scaling using the [AWS Glue SDK](#) with the same configuration.

## Monitoring Auto Scaling with Amazon CloudWatch metrics

The CloudWatch executor metrics are available for your AWS Glue 3.0 or later jobs if you enable Auto Scaling. The metrics can be used to monitor the demand and optimized usage of executors in their Spark applications enabled with Auto Scaling. For more information, see [Monitoring AWS Glue using Amazon CloudWatch metrics](#).

- `glue.driver.ExecutorAllocationManager.executors.numberAllExecutors`
- `glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors`

The screenshot shows the AWS CloudWatch console interface. On the left is a navigation pane with sections for Alarms, Logs, Metrics, Events, and Application monitoring. The main area displays a line graph titled 'Untitled graph' showing two metrics over time from 18:00 to 18:25. The metrics are 'glue.driver.ExecutorAllocationManager.executors.numberAllExecutors' (blue line) and 'glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors' (orange line). Below the graph is a table of metrics with columns for JobName, JobRunId, Type, and Metric Name.

JobName...	JobRunId	Type	Metric Name	
<input type="checkbox"/>	test-lmbo-beta-glue31	test-lmbo-beta-glue31-10	gauge	glue.1.s3.filesystem.read_bytes
<input type="checkbox"/>	test-lmbo-beta-glue31	test-lmbo-beta-glue31-10	gauge	glue.ALL.s3.filesystem.read_bytes
<input checked="" type="checkbox"/>	test-lmbo-beta-glue31	test-lmbo-beta-glue31-10	gauge	glue.driver.ExecutorAllocationManager.executors.numberMaxNeededExecutors

For more details on these metrics, see [Monitoring for DPU capacity planning](#).

## Monitoring Auto Scaling with Spark UI

With Auto Scaling enabled, you can also monitor executors being added and removed with dynamic scale-up and scale-down based on the demand in your AWS Glue jobs using the Glue Spark UI. For more information, see [Enabling the Apache Spark web UI for AWS Glue jobs](#).

## Monitoring Auto Scaling job run DPU usage

You may use the [AWS Glue Studio Job run view](#) to check the DPU usage of your Auto Scaling jobs.

1. Choose **Monitoring** from the AWS Glue Studio navigation pane. The Monitoring page appears.

2. Scroll down to the Job runs chart.
3. Navigate to the job run you are interested and scroll to the DPU hours column to check the usage for the specific job run.

## Limitations

AWS Glue streaming Auto Scaling currently doesn't support a streaming DataFrame join with a static DataFrame created outside of `ForEachBatch`. A static DataFrame created inside the `ForEachBatch` will work as expected.

## Workload partitioning with bounded execution

Errors in Spark applications commonly arise from inefficient Spark scripts, distributed in-memory execution of large-scale transformations, and dataset abnormalities. There are many reasons that may cause driver or executor out of memory issues, for example a data skew, listing too many objects, or large data shuffles. These issues often appear when you are processing huge amounts of backlog data with Spark.

AWS Glue allows you to solve OOM issues and make your ETL processing easier with workload partitioning. With workload partitioning enabled, each ETL job run only picks unprocessed data, with an upper bound on the dataset size or the number of files to be processed with this job run. Future job runs will process the remaining data. For example, if there are 1000 files need to be processed, you can set the number of files to be 500 and separate them into two job runs.

Workload partitioning is supported only for Amazon S3 data sources.

## Enabling workload partitioning

You can enable bounded execution by manually setting the options in your script or by adding catalog table properties.

### To enable workload partitioning with bounded execution in your script:

1. To avoid reprocessing data, enable job bookmarks in the new job or existing job. For more information, see [Tracking Processed Data Using Job Bookmarks](#).
2. Modify your script and set the bounded limit in the additional options in the AWS Glue `getSource` API. You should also set the transformation context for the job bookmark to store the state element. For example:

## Python

```
glueContext.create_dynamic_frame.from_catalog(  
    database = "database",  
    table_name = "table_name",  
    redshift_tmp_dir = "",  
    transformation_ctx = "datasource0",  
    additional_options = {  
        "boundedFiles" : "500", # need to be string  
        # "boundedSize" : "1000000000" unit is byte  
    }  
)
```

## Scala

```
val datasource0 = glueContext.getCatalogSource(  
    database = "database", tableName = "table_name", redshiftTmpDir = "",  
    transformationContext = "datasource0",  
    additionalOptions = JsonOptions(  
        Map("boundedFiles" -> "500") // need to be string  
        // "boundedSize" -> "1000000000" unit is byte  
    )  
)  
.getDynamicFrame()
```

```
val connectionOptions = JsonOptions(  
    Map("paths" -> List(baseLocation), "boundedFiles" -> "30")  
)  
val source = glueContext.getSource("s3", connectionOptions, "datasource0", "")
```

### To enable workload partitioning with bounded execution in your Data Catalog table:

1. Set the key-value pairs in the `parameters` field of your table structure in the Data Catalog. For more information, see [Viewing and Editing Table Details](#).
2. Set the upper limit for the dataset size or the number of files processed:
  - Set `boundedSize` to the target size of the dataset in bytes. The job run will stop after reaching the target size from the table.

- Set `boundedFiles` to the target number of files. The job run will stop after processing the target number of files.

**Note**

You should only set one of `boundedSize` or `boundedFiles`, as only a single boundary is supported.

## Setting up an AWS Glue trigger to automatically run the job

Once you have enabled bounded execution, you can set up an AWS Glue trigger to automatically run the job and incrementally load the data in sequential runs. Go to the AWS Glue Console and create a trigger, setup the schedule time, and attach to your job. Then it will automatically trigger the next job run and process the new batch of data.

You can also use AWS Glue workflows to orchestrate multiple jobs to process data from different partitions in parallel. For more information, see [AWS Glue Triggers](#) and [AWS Glue Workflows](#).

For more information on use cases and options, please refer to the blog [Optimizing Spark applications with workload partitioning in AWS Glue](#).

# Known issues for AWS Glue

Note the following known issues for AWS Glue.

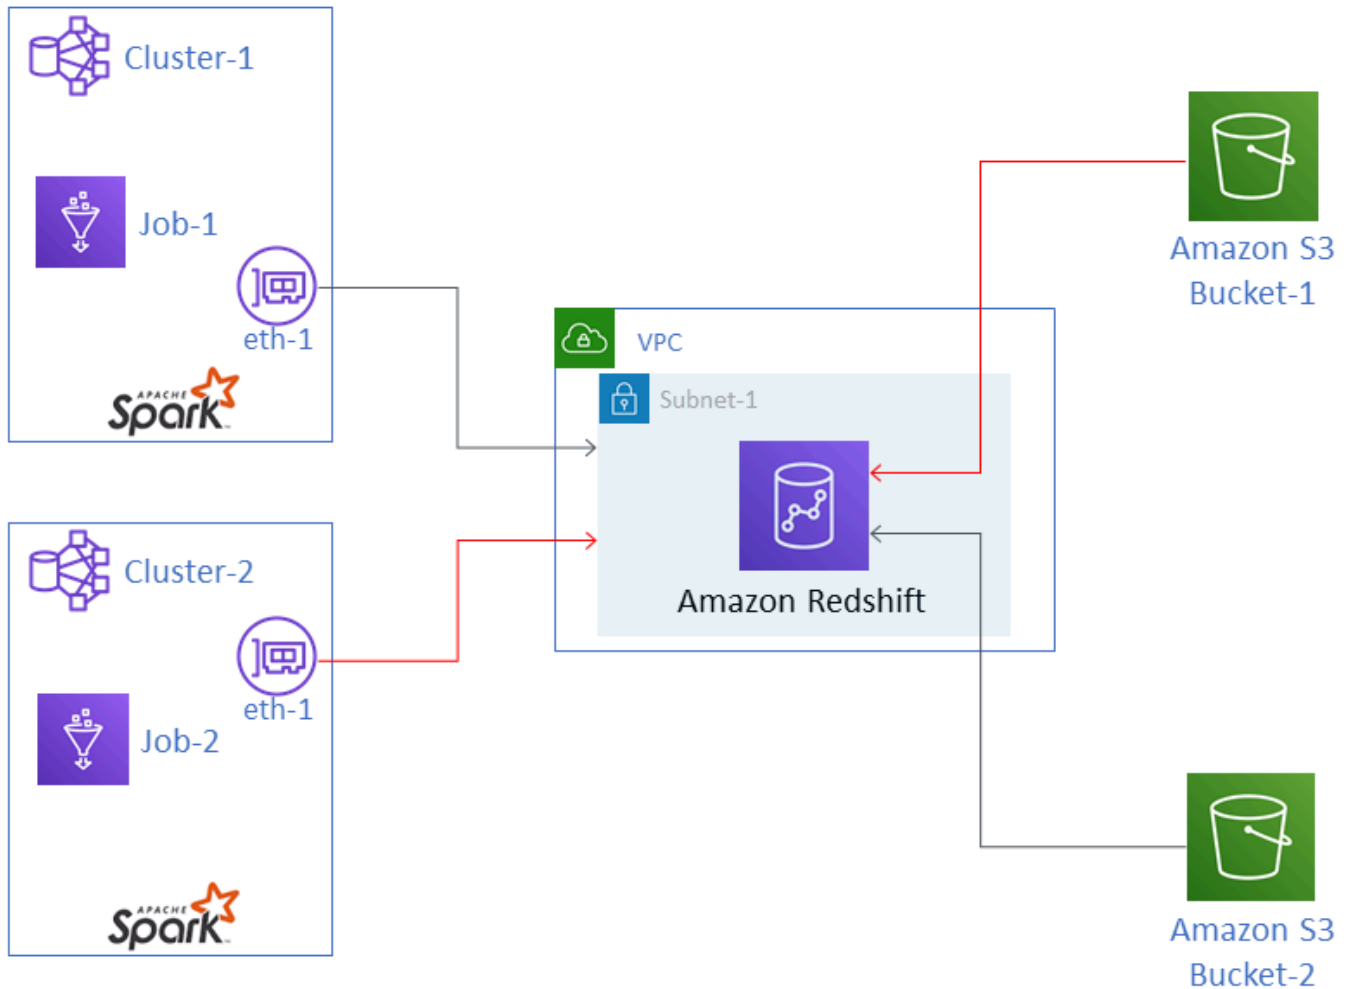

## Topics

- [Preventing cross-job data access](#)

## Preventing cross-job data access

Consider the situation where you have two AWS Glue Spark jobs in a single AWS Account, each running in a separate AWS Glue Spark cluster. The jobs are using AWS Glue connections to access resources in the same virtual private cloud (VPC). In this situation, a job running in one cluster might be able to access the data from the job running in the other cluster.

The following diagram illustrates an example of this situation.

In the diagram, AWS Glue Job-1 is running in Cluster-1, and Job-2 is running in Cluster-2. Both jobs are working with the same instance of Amazon Redshift, which resides in Subnet-1 of a VPC. Subnet-1 could be a public or private subnet.

Job-1 is transforming data from Amazon Simple Storage Service (Amazon S3) Bucket-1 and writing the data to Amazon Redshift. Job-2 is doing the same with data in Bucket-2. Job-1 uses the AWS Identity and Access Management (IAM) role Role-1 (not shown), which gives access to Bucket-1. Job-2 uses Role-2 (not shown), which gives access to Bucket-2.

These jobs have network paths that enable them to communicate with each other's clusters and thus access each other's data. For example, Job-2 could access data in Bucket-1. In the diagram, this is shown as the path in red.

To prevent this situation, we recommend that you attach different security configurations to Job-1 and Job-2. By attaching the security configurations, cross-job access to data is blocked by virtue of certificates that AWS Glue creates. The security configurations can be *dummy* configurations. That is, you can create the security configurations without enabling encryption of Amazon S3 data, Amazon CloudWatch data, or job bookmarks. All three encryption options can be disabled.

For information about security configurations, see [the section called “Encrypting data written by AWS Glue”](#).

### To attach a security configuration to a job

1. Open the AWS Glue console at <https://console.aws.amazon.com/glue/>.
2. On the **Configure the job properties** page for the job, expand the **Security configuration, script libraries, and job parameters** section.
3. Select a security configuration in the list.

# Documentation history for AWS Glue

Change	Description	Date
<a href="#">Support for a Salesforce connector for AWS Glue for Spark</a>	Added information about a new AWS Glue connector for Salesforce. This feature allows you to use AWS Glue for Spark to read from and write to Salesforce in AWS Glue 4.0 and later versions. For more information, see <a href="#">Connecting to Salesforce</a> .	May 22, 2024
<a href="#">Amazon Q data integration in AWS Glue (GA)</a>	Amazon Q data integration in AWS Glue is a new generative AI capability of AWS Glue that enables data engineers and ETL developers to build data integration jobs using natural language. Engineers and developers can ask Q to author jobs, troubleshoot issues and answer questions about AWS Glue and data integration. For more information, see <a href="#">Amazon Q data integration in AWS Glue</a> . This feature includes an update to the <code>AwsGlueSessionUserRestrictedPolicy</code> , <code>AwsGlueSessionUserRestrictedNotebookServiceRole</code> , and <code>AwsGlueSessionUser</code>	April 30, 2024

RestrictedServiceRole AWS managed policies. For more information, see [AWS Glue updates to AWS managed policies](#).

[Amazon Q data integration in AWS Glue \(preview\)](#)

Amazon Q data integration in AWS Glue is a new generative AI capability of AWS Glue that enables data engineers and ETL developers to build data integration jobs using natural language. Engineers and developers can ask Q to author jobs, troubleshoot issues and answer questions about AWS Glue and data integration. For more information, see [Amazon Q data integration in AWS Glue](#). This feature includes an update to the AwsGlueSessionUserRestrictedNotebookPolicy AWS managed policy. For more information, see [AWS Glue updates to AWS managed policies](#).

January 30, 2024

[Update to the documentation for AWS Glue Streaming](#)

Added a new chapter with new and reorganized content for AWS Glue Streaming. This content describes how streaming works with AWS Glue, the characteristics of real-time data processing, and how to monitor your streaming jobs. For more information, see [AWS Glue Streaming](#).

December 27, 2023

[Support for using fine-grained sensitive data detection](#)

The Detect Sensitive Data transform provides the ability to detect, mask, or remove entities that you define, or are pre-defined by AWS Glue. Fine-grained actions further allows you to apply a specific action per entity. For more information, see [Using fine-grained sensitive data detection](#).

November 26, 2023

[Support for monitoring jobs with AWS Glue Observability metrics](#)

Use AWS Glue Observability metrics to generate insights into what is happening inside your AWS Glue for Apache Spark jobs to improve triaging and analysis of issues. For more information, see [Monitoring with AWS Glue Observability metrics](#).

November 26, 2023

[Support for anomaly detection in AWS Glue Data Quality](#)

AWS Glue Data Quality anomaly detection applies machine learning (ML) algorithms on data statistics over time to detect abnormal patterns and hidden data quality issues that are hard to detect through rules. For more information, see [Anomaly detection in AWS Glue Data Quality](#).

November 26, 2023

[Update to default Spark UI logging behavior](#)

Spark jobs generating Spark UI logs will now write with a different filename pattern to support Spark UI in the AWS Glue console. This does not change CloudWatch log behavior. You can revert to the legacy behavior by updating your job configuration. For more information, see [Monitoring jobs using the Apache Spark web UI](#).

November 17, 2023

### [Support for new data sources in AWS Glue for Spark](#)

Connections to Amazon OpenSearch Service, Azure SQL, Azure Cosmos for NoSQL, SAP HANA Teradata Vantage and Vertica are now supported natively within AWS Glue. Additionally, connections to these data sources, along with MongoDB, are now available for use in the AWS Glue Studio visual editor. For more information, see [Connection types and options for ETL in AWS Glue for Spark](#) for information about AWS Glue for Spark support and [Adding an AWS Glue connection](#) for information about use in the AWS Glue Studio visual editor.

November 17, 2023

### [Support for generating column statistics](#)

You can compute column-level statistics for AWS Glue Data Catalog tables in data formats such as Parquet, ORC, JSON, ION, CSV, and XML without setting up additional data pipelines. For more information, see [Working with column statistics](#).

November 16, 2023

[Support for data compaction for Iceberg tables](#)

For better read performance by AWS analytics services such as Amazon Athena and Amazon EMR, and AWS Glue ETL jobs, Data Catalog provides managed compaction (a process that compacts small Amazon S3 objects into larger objects) for Iceberg tables in Data Catalog. For more information, see [Optimizing Iceberg tables](#).

November 13, 2023

[Update to job run wait behavior](#)

Standard Spark and Python shell job runs will now transition to WAITING in certain situations, rather than immediately transitioning to FAILED. For more information, see [AWS Glue job run statuses](#).

November 8, 2023

[AWS Glue Studio user guide consolidated into AWS Glue developer guide](#)

The AWS Glue Studio user guide has been moved into the developer guide to create a single unified user guide for AWS Glue Studio, the AWS Glue console, and AWS Glue Studio programmatic access.

October 25, 2023

[Update to the AWSGlueServiceNotebookRole AWS managed policy](#)

Added information about a minor update to the AWSGlueServiceNotebookRole AWS managed policy. For more information, see [AWS Glue Updates to AWS Managed Policies](#).

October 9, 2023

[AWS Glue Studio supports five new built-in transforms](#)

AWS Glue Studio supports the following five new built-in transforms: Record matching, Remove null rows, Parse JSON column, Extract JSON path, and Regex extractor. For more information, see [Editing AWS Glue managed data transform nodes](#).

August 11, 2023

[Update to the AWSGlueServiceRole AWS managed policy](#)

Added information about a minor update to the AWSGlueServiceRole AWS managed policy. For more information, see [AWS Glue Updates to AWS Managed Policies](#).

August 4, 2023

[Support for crawling Apache Hudi tables](#)

Added information about using AWS Glue to crawl Hudi tables in Amazon S3 buckets and registering the Hudi tables to the AWS Glue Data Catalog. For more information, see [Which data stores can I crawl?](#), and [Crawler properties](#).

July 21, 2023

[Update to the AWSGlueConsoleFullAccess AWS managed policy](#)

Added information about a minor update to the AWSGlueConsoleFullAccess AWS managed policy. For more information, see [AWS Glue Updates to AWS Managed Policies](#).

July 14, 2023

### [Support for crawling Apache Iceberg tables](#)

Added information about using AWS Glue to crawl Iceberg tables in Amazon S3 buckets and registering the Iceberg tables to the AWS Glue Data Catalog. For more information, see [Which data stores can I crawl?](#), and [Crawler properties](#).

July 7, 2023

### [Support for AWS Glue with Ray](#)

Added information about AWS Glue with Ray, a new engine that can back AWS Glue jobs. Reorganized existing AWS Glue with Spark content to disambiguate.

May 30, 2023

### [Support for AWS Glue Data Quality \(GA\)](#)

AWS Glue Data Quality is now generally available. AWS Glue Data Quality helps you evaluate and monitor the quality of your data. For information about how to use AWS Glue Data Quality with Data Catalog, see [AWS Glue Data Quality](#). To learn about AWS Glue Data Quality for AWS Glue Studio, see [Evaluating data quality with AWS Glue Studio](#).

May 24, 2023

[Support for larger worker types for Apache Spark jobs](#)

Support is now available for use of the G.4X and G.8X worker types for Apache Spark jobs. These worker types are appropriate for jobs whose workloads contain your most demanding transforms, aggregations, joins, and queries. For more information, see [Adding jobs in AWS Glue](#).

May 8, 2023

[Support for creating partition indexes when crawling tables](#)

Added information about how crawlers support the creation of partition indexes for tables that the crawler detects. For more information, see [Setting the partition index crawler configuration option](#).

April 24, 2023

[Support for resource usage metrics](#)

Added information about viewing the service's resource usage and configuring alarms in Amazon CloudWatch. For more information, see [AWS Glue resource monitoring](#).

April 7, 2023

[Update to the AWSGlueConsoleFullAccess AWS managed policy](#)

Added information about a minor update to the AWSGlueConsoleFullAccess AWS managed policy. For more information, see [AWS Glue Updates to AWS Managed Policies](#).

March 28, 2023

[Added guidance for using AWS Glue with an AWS SDK with examples](#)

The AWS Glue Developer Guide has two new sections that provide information to help you use AWS Glue with an AWS SDK. For more information, see [Using AWS Glue with an AWS SDK](#) and [Code examples for AWS Glue using AWS SDKs](#).

February 23, 2023

[Update to the documentation for IAM with AWS Glue](#)

Reorganized and added information on using IAM with AWS Glue. For more information, see [Identity and access management for AWS Glue](#).

February 15, 2023

[Support for running streaming ETL jobs in AWS Glue version 4.0](#)

Added information about support for running streaming ETL jobs in Glue version 4.0, and new options for connecting to a Kafka cluster or an Amazon Managed Streaming for Apache Kafka cluster, and Amazon Kinesis Data Streams. For more information, see [Adding Streaming ETL Jobs in AWS Glue](#) and [Connection types and options for ETL in AWS Glue](#).

February 8, 2023

[Support for crawling MongoDB Atlas data sources](#)

Added information about using AWS Glue to crawl MongoDB Atlas data sources. For more information, see [Which data stores can I crawl?](#), [MongoDB and MongoDB Atlas connection properties](#), and [Using a MongoDB or MongoDB Atlas connection](#).

February 6, 2023

[Support for crawling Delta Lake tables using a native Delta Lake connector](#)

Added information about using AWS Glue to crawl Delta Lake tables using a native Delta Lake connector. This feature allows you to use AWS query engines to query the Delta transaction log directly and use features such as time travel and ACID guarantees, and to sync your Delta Lake metadata from Amazon S3 transaction files into the Data Catalog to enable column permissions on your queries in Lake Formation. For more information, see [How to specify configuration options for a Delta Lake data store](#), and [Querying Delta Lake tables](#).

December 15, 2022

### [Support for AWS Glue Data Quality \(preview\)](#)

Support is now available for AWS Glue Data Quality (preview). AWS Glue Data Quality helps you evaluate and monitor the quality of your data when you use AWS Glue 3.0. For information about how to use AWS Glue Data Quality with Data Catalog, see [AWS Glue Data Quality \(preview\)](#). To learn about AWS Glue Data Quality for AWS Glue Studio, see [Evaluating data quality with AWS Glue Studio](#).

November 30, 2022

### [Support for a new Amazon Redshift Spark connector with new features and performance improvements](#)

Support is now available for a new Amazon Redshift Spark connector with a new JDBC driver for use with AWS Glue ETL jobs to build Apache Spark applications that read from and write to data in Amazon Redshift as part of your data ingestion and transformation pipelines. For more information, see [Moving data to and from Amazon Redshift](#).

November 29, 2022

[Support for AWS Glue version 4.0.](#)

Added information about support for AWS Glue version 4.0. Features include native support for open-data lake frameworks with Apache Hudi, Delta Lake, and Apache Iceberg, and native support for the Amazon S3-based Cloud Shuffle Storage Plugin (an Apache Spark plugin) to use Amazon S3 for shuffling and elastic storage capacity. For more information, see [AWS Glue Release Notes](#) and [Migrating AWS Glue jobs to AWS Glue version 4.0.](#)

November 28, 2022

[AWS Glue Studio now offers custom visual transforms](#)

Custom visual transforms let customers define, reuse, and share business-specific ETL logic among their teams. For more information, see [Custom visual transforms](#) .

November 28, 2022

[Support for using the AWS Glue crawler to publish metadata for JDBC data stores](#)

Support is now available for using the AWS Glue crawler to publish metadata such as comments and rawtypes to the Data Catalog for JDBC data stores. For more information, see [Parameters set on Data Catalog tables by crawler](#), [Crawler properties](#), and [JdbcTarget structure](#).

November 18, 2022

### [Support for crawling Snowflake data stores](#)

Support is now available for using AWS Glue to crawl Snowflake tables and views, and to publish the metadata to the Data Catalog as a table entry. For Snowflake external tables in Amazon S3, the crawler also crawls the Amazon S3 location and the file format type of the external table and populates as Table parameters. For more information, see [Which data stores can I crawl?](#), [AWS Glue connection properties](#), and [Parameters set on Data Catalog tables by crawler](#).

November 18, 2022

### [Support for improved shuffle management of your Spark applications](#)

Support is now available for a new Cloud Shuffle Storage Plugin for Apache Spark. For more information, see [AWS Glue Spark shuffle plugin with Amazon S3](#) and [Cloud Shuffle Storage Plugin for Apache Spark](#).

November 15, 2022

[Added support for Data Catalog targets when accelerating crawls Amazon S3 event notifications](#)

In addition to the existing support for Amazon S3 targets, support is now available for accelerating crawls for Data Catalog targets using Amazon S3 event notifications. For more information, see [Accelerating Crawls Using Amazon S3 Event Notifications](#).

October 13, 2022

[Support for specifying the maximum number of tables a crawler can create](#)

Support is now available for specifying the maximum number of tables the crawler is allowed to create. For more information, see [How to specify the maximum number of tables the crawler is allowed to create](#).

September 6, 2022

[Support for Python 3.9 in Python shell jobs in AWS Glue](#)

Support is now available for running scripts compatible with Python 3.9 in Python shell jobs in AWS Glue, and for choosing to use pre-packaged library sets. For more information, see [Python shell jobs in AWS Glue](#).

August 11, 2022

[Support for running non-urgent or non-time sensitive AWS Glue jobs on spare capacity](#)

Support is now available for the configuration of flexible job runs for non-urgent jobs such as pre-production jobs, testing, and one-time data loads. For more information, see [Adding jobs in AWS Glue](#).

August 9, 2022

[Support for a new worker type for streaming jobs](#)

Support is now available for use of the G.025X worker type for low volume streaming jobs. For more information, see [Adding jobs in AWS Glue](#).

July 14, 2022

[Support for the use of Kafka SASL in AWS Glue connections](#)

Support is now available for use of Kafka SASL in AWS Glue connections. For more information, see [AWS Glue Kafka connection properties for client authentication](#).

July 5, 2022

[Support for Apache kafka connector for protobuf schemas](#)

Support is now available for Apache Kafka Connector for Protobuf schemas. For more information, see [AWS Glue Schema Registry](#).

June 9, 2022

[Support for Auto Scaling for AWS Glue jobs \(GA\)](#)

Added information on using Auto Scaling for jobs in AWS Glue version 3.0 to dynamically scale compute resources. For more information, see [Using Auto Scaling for AWS Glue](#).

April 14, 2022

[Update to the documentation for AWS Glue developing and testing AWS Glue job scripts](#)

Reorganized and added information on the available development and testing methods for AWS Glue, including instructions for developing with Docker. For more information, see [Developing and testing AWS Glue job scripts](#).

March 14, 2022

[Addition of protocol buffers \(protobuf\) as a supported data format for the AWS Glue schema registry](#)

Added information about Protobuf as a supported data format (in addition to AVRO and JSON). For more information, see [AWS Glue Schema Registry](#).

February 25, 2022

[Support for crawling Delta Lake tables](#)

Added information about using AWS Glue to crawl Delta Lake tables. For more information, see [How to specify configuration options for a Delta Lake data store](#).

February 24, 2022

[Support for AWS Glue job insights](#)

Added information about using AWS Glue job insights to simplify job debugging and optimization for your AWS Glue jobs. For more information, see [Monitoring with AWS Glue job insights](#).

February 8, 2022

[Support for crawling Amazon S3 backed Data Catalog tables using a VPC endpoint](#)

In addition to Amazon S3 data stores, you can configure your Amazon S3 backed Data Catalog tables to be accessed only by an Amazon Virtual Private Cloud environment (Amazon VPC), for security, auditing, or control purposes. For more information, see [Crawling an Amazon S3 Data Store or Amazon S3 backed Data Catalog tables using a VPC Endpoint](#).

February 3, 2022

[Support for Lake Formation governed tables](#)

Added information about AWS Glue support for Lake Formation governed tables, which support ACID transactions, automatic data compaction, and time-travel queries. For more information, see [AWS Glue API](#) and the [AWS Lake Formation developer guide](#).

November 30, 2021

[New AWS managed policies added for interactive sessions and notebooks](#)

New managed policies for IAM provided enhanced security for using AWS Glue with interactive sessions and notebooks. For more information, see [AWS Managed Policies for AWS Glue](#).

November 30, 2021

[Glue schema registry now supported with streaming jobs](#)

You can create streaming jobs that access tables that are part of the Glue Schema Registry. For more information see [AWS Glue Schema Registry](#) and [Adding Streaming ETL Jobs in AWS Glue](#).

November 15, 2021

---

<a href="#">Support for new machine learning features</a>	Added information about new features for the Find matches machine learning transform , including incremental matching and match scoring. For more information, see <a href="#">Finding Incremental Matches</a> and <a href="#">Estimating the Quality of Matches using Match Confidence Scores</a> .	October 31, 2021
<a href="#">(Private preview) Support for AWS Glue flex jobs</a>	Added information about configuring AWS Glue Spark jobs with a flexible execution class, appropriate for time-insensitive jobs whose start and completion times may vary. For more information, see <a href="#">Adding Jobs in AWS Glue</a> .	October 29, 2021
<a href="#">Support for accelerating crawls using Amazon S3 event notifications</a>	Added information about accelerating crawls using Amazon S3 event notifications. For more information, see <a href="#">Accelerating Crawls Using Amazon S3 Event Notifications</a> .	October 15, 2021

---

<a href="#">Additional security configuration options related to access-control and VPCs</a>	Added information about how you can configure new access control permissions on AWS Glue and configuration of VPCs. For more information, see <a href="#">AWS Tags in AWS Glue</a> , <a href="#">Identity-Based Policies (IAM Policies) that Control Settings Using Condition Keys or Context Keys</a> , and <a href="#">Configuring all AWS calls to go through your VPC</a> .	October 13, 2021
<a href="#">Support for VPC endpoint policies</a>	Added information about support for Virtual Private Cloud (VPC) endpoint policies in AWS Glue. For more information, see <a href="#">AWS Glue and interface VPC endpoints (AWS PrivateLink)</a> .	October 11, 2021
<a href="#">Glue Studio is now available in China</a>	AWS Glue Studio is now available in the China Beijing and Ningxia regions.	October 11, 2021
<a href="#">AWS Glue Studio offers notebook authoring, for interactive job editing</a>	Notebooks help you to write and execute code, visualize the results, and share insights. Typically, data scientists use notebooks for experiments and data exploration tasks. For more information, see <a href="#">Using Notebooks</a> .	October 1, 2021

[Direct access to streaming sources now available](#)

When adding data sources to your ETL job in the visual editor, you can supply information to access the data stream instead of having to use a Data Catalog database and table.

September 30, 2021

[Documented the AWS Glue version support policy](#)

Added information about the AWS Glue version support policy and the end of life phases for certain AWS Glue versions. For more information, see [AWS Glue version support policy](#).

September 24, 2021

[Custom connectors can now be used with data previews](#)

When editing data source node using a custom connector, you can preview the dataset by choosing the Data preview tab. For more information, see [Custom Connectors](#).

September 24, 2021

[Support for AWS Glue interactive sessions \(private preview\)](#)

(Private preview) Added information about using AWS Glue interactive sessions to run Spark workloads in the cloud from any Jupyter Notebook. Interactive sessions are the preferred method for developing your AWS Glue extract, transform, and load (ETL) code when you use AWS Glue 2.0 or later. For more information, see [Setting Up and Running AWS Glue interactive sessions for Jupyter Notebook](#).

August 24, 2021

[Support for creating workflows from blueprints \(GA\)](#)

Added information about coding common extract, transform, and load (ETL) use cases in blueprints and then creating workflows from blueprints. Enables data analysts to easily create and run complex ETL processes. For more information, see [Performing Complex ETL Activities Using blueprints and Workflows in AWS Glue](#).

August 23, 2021

### [Support for AWS Glue version 3.0.](#)

Added information about support for AWS Glue version 3.0 which supports the Apache Spark 3.0 engine upgrade for running Apache Spark ETL jobs, and other optimizations and upgrades. For more information, see [AWS Glue Release Notes](#) and [Migrating AWS Glue jobs to AWS Glue version 3.0](#). Other features in this release include the AWS Glue shuffle manager, a SIMD vectorized CSV reader, and catalog partition predicates. For more information see [AWS Glue Spark shuffle manager with Amazon S3](#), [Format Options for ETL Inputs and Outputs in AWS Glue](#), and [Server-side filtering using catalog partition predicates](#).

August 18, 2021

### [AWS GovCloud \(US\) Region](#)

AWS Glue Studio is now available in the AWS GovCloud (US) Region

August 18, 2021

### [Python shell authoring available in AWS Glue Studio](#)

When creating a new job, you can now choose to create a Python shell job. For more information, see [Start the job creation process](#) and [Editing Python shell jobs in AWS Glue Studio](#).

August 13, 2021

[Support for starting a workflow with an Amazon EventBridge event](#)

Added information about how AWS Glue can be an event consumer in an event-driven architecture. For more information, see [Starting an AWS Glue Workflow with an Amazon EventBridge Event](#) and [Viewing the EventBridge Events That Started a Workflow](#).

July 14, 2021

[Addition of JSON as a supported data format for the AWS Glue schema registry](#)

Added information about JSON as a supported data format (in addition to AVRO). For more information, see [AWS Glue Schema Registry](#).

June 30, 2021

[Create AWS Glue streaming jobs without a Data Catalog table](#)

The `create_data_frame_from_options` Python function or `getSource` for Scala scripts support creating streaming ETL jobs that reference the data streams directly instead of requiring a Data Catalog table.

June 15, 2021

[AWS Glue machine learning transforms now support AWS Key Management Service keys](#)

You can specify a security configuration or AWS KMS key when configuring AWS Glue Machine Learning transforms with the console, the CLI, or the AWS Glue APIs. For more information, see [Using Data Encryption with Machine Learning Transforms](#) and [AWS Glue Machine Learning API](#).

June 15, 2021

---

<a href="#">Update to the AWSGlueConsoleFullAccess AWS managed policy</a>	Added information about a minor update to the AWSGlueConsoleFullAccess AWS managed policy. For more information, see <a href="#">AWS Glue Updates to AWS Managed Policies</a> .	June 10, 2021
<a href="#">View your job's dataset while creating and editing jobs</a>	You can use the new <b>Data preview</b> tab for a node in your job diagram to see a sample of the data processed by that node. For more information, see <a href="#">Using data previews in the visual job editor</a> .	June 7, 2021
<a href="#">Support for specifying a value that indicates the table location for the crawler output.</a>	Added information about specifying a value that indicates the table location when configuring the crawler's output. For more information, see <a href="#">How to specify the table location</a> .	June 4, 2021
<a href="#">Support for crawling a sample of files in a dataset when crawling an Amazon S3 data store</a>	Added information about how to crawl a sample of files when crawling Amazon S3. For more information, see <a href="#">Crawler Properties</a> .	May 10, 2021

### [Support for the AWS Glue optimized parquet writer](#)

Added information about using the AWS Glue optimized parquet writer for DynamicFrames to create or update tables with the parquet classification. For more information, see [Creating Tables, Updating Schema, and Adding New Partitions in the Data Catalog from AWS Glue ETL Jobs](#) and [Format Options for ETL Inputs and Outputs in AWS Glue](#).

May 4, 2021

### [Support for kafka client authentication passwords](#)

Added information about how streaming ETL jobs in AWS Glue support SSL client certificate authentication with Apache Kafka stream producers. You can now provide a custom certificate while defining an AWS Glue connection to an Apache Kafka cluster, which AWS Glue will use when authenticating with it. For more information, see [AWS Glue Connection Properties](#) and [Connection API](#).

April 28, 2021

[Support for consuming data from Amazon Kinesis Data Streams in another account in streaming ETL jobs](#)

Added information about to create a streaming ETL job to consume data from Amazon Kinesis Data Streams in another account. For more information, see [Adding Streaming ETL Jobs in AWS Glue](#).

March 30, 2021

[SQL transform available](#)

You can use a **SQL** transform node to write your own transform in the form of a SQL query. For more information, see [Using a SQL query to transform data](#).

March 23, 2021

[Support for creating workflows from blueprints \(public preview\)](#)

(Public preview) Added information about coding common extract, transform, and load (ETL) use cases in blueprints and then creating workflows from blueprints. Enables data analysts to easily create and run complex ETL processes. For more information, see [Performing Complex ETL Activities Using blueprints and Workflows in AWS Glue](#).

March 22, 2021

[Connectors can be used for data targets](#)

Using a custom or AWS Marketplace connector for your data target is now supported. For more information, see [Authoring jobs with custom connectors](#).

March 15, 2021

[Support for column importance metrics for AWS Glue machine learning transforms](#)

Added information about viewing column importance metrics when working with AWS Glue machine learning transforms. For more information see [Working with Machine Learning Transforms on the AWS Glue Console](#)

February 5, 2021

[Job scheduling now available in AWS Glue Studio](#)

You can define a time-based schedule for your job runs in AWS Glue Studio. You can use the console to create a basic schedule, or define a more complex schedule using the Unix-like [cron](#) syntax. For more information, see [Schedule job runs](#).

December 21, 2020

[AWS Glue Custom Connectors released](#)

AWS Glue Custom Connectors allow you to discover and subscribe to connectors in AWS Marketplace. We also released AWS Glue Spark runtime interfaces to plug in connectors built for Apache Spark Datasource, Athena federated query, and JDBC APIs. For more information, see [Using Connectors and connections with AWS Glue Studio](#).

December 21, 2020

[Support for running streaming ETL jobs in AWS Glue version 2.0](#)

Added information about support for running streaming ETL jobs in Glue version 2.0. For more information, see [Adding Streaming ETL Jobs in AWS Glue](#).

December 18, 2020

[Support for workload partitioning with bounded execution](#)

Added information about enabling workload partitioning to configure the upper bounds on the dataset size, or the number of files processed on ETL job runs. For more information, see [Workload Partitioning with Bounded Execution](#).

November 23, 2020

[Support for enhanced partition management](#)

Added information about how to use new APIs to add or delete a partition index to/from an existing table. For more information, see [Working with Partition Indexes](#).

November 23, 2020

[Support for the AWS Glue schema registry](#)

Added information about using the AWS Glue Schema Registry to centrally discover, control, and evolve schemas. For more information, see [AWS Glue Schema Registry](#).

November 19, 2020

[Support for the grok input format in streaming ETL jobs](#)

Added information about applying Grok patterns to streaming sources such as log files. For more information, see [Applying Grok Patterns to Streaming Sources](#).

November 17, 2020

[Support for adding tags to workflows on the AWS Glue console](#)

Added information about adding tags when creating a workflow using the AWS Glue console. For more information, see [Creating and Building Out a Workflow Using the AWS Glue Console](#).

October 27, 2020

[Support for incremental crawler runs](#)

Added information about support for incremental crawler runs, which crawl only Amazon S3 folders added since the last run. For more information, see [Incremental Crawls](#).

October 21, 2020

[Support for schema detection for streaming ETL data sources. support for Avro streaming ETL data sources and self-managed kafka](#)

Streaming extract, transform, and load (ETL) jobs in AWS Glue can now automatically detect the schema of incoming records and handle schema changes on a per-record basis. Self-managed Kafka data sources are now supported. Streaming ETL jobs now support the Avro format in data sources. For more information, see [Streaming ETL in AWS Glue, Defining Job Properties for a Streaming ETL Job, and Notes and Restrictions for Avro Streaming Sources](#).

October 7, 2020

[Support for crawling MongoDB and DocumentDB data sources](#)

Added information about support for crawling MongoDB and Amazon DocumentDB (with MongoDB compatibility) data sources. For more information, see [Defining Crawlers](#).

October 5, 2020

[Support for FIPS compliance](#)

Added information about FIPS endpoints for customers who require FIPS 140-2 validated cryptographic modules when accessing data using AWS Glue. For more information, see [FIPS Compliance](#).

September 23, 2020

[AWS Glue Studio provides an easy to use visual interface for creating and monitoring jobs](#)

You can now use a simple graph-based interface to compose jobs that move and transform data and run them on AWS Glue. You can then use the job run dashboard in AWS Glue Studio to monitor ETL execution and ensure that your jobs are operating as intended. For more information, see [AWS Glue Studio User Guide](#).

September 23, 2020

[Support for creating table indexes to improve query performance](#)

Added information about creating table indexes to allow you to retrieve a subset of the partitions from a table. For more information, see [Working with Partition Indexes](#).

September 9, 2020

[Support for reduced startup times when running Apache Spark ETL jobs in AWS Glue version 2.0.](#)

Added information about support for AWS Glue version 2.0 which provides an upgraded infrastructure for running Apache Spark ETL jobs with reduced startup times, changes in logging, and support for specifying additional Python modules at the job level. For more information, see [AWS Glue Release Notes](#) and [Running Spark ETL Jobs with Reduced Startup Times](#).

August 10, 2020

[Support for limiting the number of concurrent workflow runs.](#)

Added information about how to limit the number of concurrent workflow runs for a particular workflow. For more information, see [Creating and Building Out a Workflow Using the AWS Glue Console.](#)

August 10, 2020

[Support for crawling an Amazon S3 data store using a VPC endpoint](#)

Added information about configuring your Amazon S3 data store to be accessed only by an Amazon Virtual Private Cloud environment (Amazon VPC), for security, auditing, or control purposes. For more information, see [Crawling an Amazon S3 Data Store using a VPC Endpoint.](#)

August 7, 2020

[Support for resuming workflow runs](#)

Added information about how to resume workflow runs that only partially completed because one or more nodes (jobs or crawlers) did not complete successfully. For more information, see [Repairing and Resuming a Workflow Run.](#)

July 27, 2020

[Support for enabling private CA certificates in kafka connections in AWS Glue.](#)

Added information about new connection options that support enabling private CA certificates for Kafka connections in AWS Glue. For more information, see [Connection Types and Options for ETL in AWS Glue](#) and [Special Parameters Used by AWS Glue.](#)

July 20, 2020

[Support for reading DynamoDB data in another account](#)

Added information about AWS Glue support for reading data from another AWS account's DynamoDB table. For more information, see [Reading from DynamoDB Data in Another Account.](#)

July 17, 2020

[Support for a DynamoDB writer connection in AWS Glue version 1.0 or later](#)

Added information about support for DynamoDB writer, and new or updated connection options for DynamoDB to read or write. For more information, see [Connection Types and Options for ETL in AWS Glue.](#)

July 17, 2020

[Support for resource links and for cross-account access control using both AWS Glue and Lake Formation](#)

Added content about new Data Catalog objects called resource links, and about how to manage sharing Data Catalog resources across accounts with both AWS Glue and AWS Lake Formation. For more information, see [Granting Cross-Account Access](#) and [Table Resource Links](#).

July 7, 2020

[Support for sampling records when crawling DynamoDB data stores](#)

Added information about new properties that you can configure when crawling a DynamoDB data store. For more information, see [Crawler Properties](#).

June 12, 2020

[Support for stopping a workflow run.](#)

Added information about how to stop a workflow run for a particular workflow. For more information, see [Stopping a Workflow Run](#).

May 14, 2020

[Support for Spark streaming ETL jobs](#)

Added information about creating extract, transform, and load (ETL) jobs with streaming data sources. For more information, see [Adding Streaming ETL Jobs in AWS Glue](#).

April 27, 2020

[Support for creating tables, updating the schema, and adding new partitions in the Data Catalog after running an ETL job](#)

Added information about how you can enable creating tables, updating the schema, and adding new partitions to see the results of your ETL job in the Data Catalog. For more information, see [Creating Tables, Updating Schema, and Adding New Partitions in the Data Catalog from AWS Glue ETL Jobs](#).

April 2, 2020

[Support for specifying a version for the Apache Avro data format as an ETL input and output in AWS Glue](#)

Added information about specifying a version for the Apache Avro data format as an ETL input and output in AWS Glue. The default version is 1.7. You can use the `version` format option to specify Avro version 1.8 to enable logical reading/writing. For more information, see [Format Options for ETL Inputs and Outputs in AWS Glue](#).

March 31, 2020

[Support for the EMRFS S3-optimized committer for writing Parquet data into Amazon S3](#)

Added information about how to set a new flag to enable the EMRFS S3-optimized committer for writing Parquet data into Amazon S3 when creating or updating an AWS Glue job. For more information, see [Special Parameters Used by AWS Glue](#).

March 30, 2020

---

<a href="#">Support for machine learning transforms as a resource managed by AWS resource tags</a>	Added information about using AWS resource tags to manage and control access to your machine learning transforms in AWS Glue. You can assign AWS resource tags to jobs, triggers, endpoints , crawlers, and machine learning transforms in AWS Glue. For more information, see <a href="#">AWS Tags in AWS Glue</a> .	March 2, 2020
<a href="#">Support for non-overrideable job arguments</a>	Added information about support for special job parameters that cannot be overridden in triggers or when you run the job. For more information see <a href="#">Adding Jobs in AWS Glue</a> .	February 12, 2020
<a href="#">Support for new transforms to work with datasets in Amazon S3</a>	Added information about new transforms (Merge, Purge, and Transition) and Amazon S3 storage class exclusions for Apache Spark applications to work with datasets in Amazon S3. For more information on support for these transforms for Python, see <a href="#">mergeDynamicFrame</a> and <a href="#">Working with Datasets in Amazon S3</a> . For Scala, see <a href="#">mergeDynamicFrames</a> and <a href="#">AWS Glue Scala GlueContext APIs</a> .	January 16, 2020

[Support for updating the Data Catalog with new partition information from an ETL job](#)

Added information about how to code an extract, transform, and load (ETL) script to update the AWS Glue Data Catalog with new partition information. With this capability, you no longer have to rerun the crawler after job completion to view the new partitions. For more information see [Updating the Data Catalog with New Partitions](#).

January 15, 2020

[New tutorial: Using an SageMaker notebook](#)

Added a tutorial that demonstrates how to use an Amazon SageMaker notebook to help develop your ETL and machine learning scripts. See [Tutorial: Use an Amazon SageMaker Notebook with Your Development Endpoint](#).

January 3, 2020

[Support for reading from MongoDB and Amazon DocumentDB \(with MongoDB compatibility\)](#)

Added information about new connection types and connection options for reading from and writing to MongoDB and Amazon DocumentDB (with MongoDB Compatibility). For more information, see [Connection Types and Options for ETL in AWS Glue](#).

December 17, 2019

### [Various corrections and clarifications](#)

Added corrections and clarifications throughout. Removed entries from the Known Issues chapter. Added warnings that AWS Glue supports only symmetrical customer master keys (CMKs) when specifying Data Catalog encryption settings and creating security configurations. Added a note that AWS Glue does not support writing to Amazon DynamoDB.

December 9, 2019

### [Support for custom JDBC drivers](#)

Added information about connecting to data sources and targets with JDBC drivers that AWS Glue does not natively support, such as MySQL version 8 and Oracle Database version 18. For more information see [JDBC connectionType Values](#).

November 25, 2019

[Support for connecting SageMaker notebooks to different development endpoints](#)

Added information about how you can connect an SageMaker notebook to different development endpoints. Updates to describe the new console action for switching to a new development endpoint, and the new SageMaker IAM policy. For more information, see [Working with Notebooks on the AWS Glue Console](#) and [Create an IAM Policy for Amazon SageMaker Notebooks](#).

November 21, 2019

[Support for AWS Glue version in machine learning transforms](#)

Added information about defining the AWS Glue version in a machine learning transform to indicate the which version of AWS Glue a machine learning transform is compatible with. For more information see [Working with Machine Learning Transforms on the AWS Glue Console](#).

November 21, 2019

### [Support for rewinding your job bookmarks](#)

Added information about rewinding your job bookmarks to any previous job run, resulting in the subsequent job run reprocessing data only from the bookmarked job run. Described two new sub-options for the job-bookmark-pause option that allow you to run a job between two bookmarks. For more information, see [Tracking Processed Data Using Job Bookmarks](#) and [Special Parameters Used by AWS Glue](#).

October 22, 2019

### [Support for custom JDBC certificates for connecting to a data store](#)

Added information about AWS Glue support of custom JDBC certificates for SSL connections to AWS Glue data sources or targets. For more information, see [Working with Connections on the AWS Glue Console](#).

October 10, 2019

### [Support for Python wheel](#)

Added information about AWS Glue support of wheel files (along with egg files) as dependencies for Python shell jobs. For more information, see [Providing Your Own Python Library](#).

September 26, 2019

[Support for versioning of development endpoints in AWS Glue](#)

Added information about defining the Glue version in development endpoints. Glue version determines the versions of Apache Spark and Python that AWS Glue supports. For more information, see [Adding a Development Endpoint](#).

September 19, 2019

[Support for monitoring AWS Glue using Spark UI](#)

Added information about using Apache Spark UI to monitor and debug AWS Glue ETL jobs running on the AWS Glue job system, and Spark applications on AWS Glue development endpoints. For more information, see [Monitoring AWS Glue Using Spark UI](#).

September 19, 2019

[Enhancement of support for local ETL script development using the public AWS Glue ETL library](#)

Updated the AWS Glue ETL library content to reflect that AWS Glue version 1.0 is now supported. For more information, see [Developing and Testing ETL Scripts Locally Using the AWS Glue ETL Library](#).

September 18, 2019

---

<a href="#">Support for excluding Amazon S3 storage classes when running jobs</a>	Added information about excluding Amazon S3 storage classes when running AWS Glue ETL jobs that read files or partitions from Amazon S3. For more information, see <a href="#">Excluding Amazon S3 Storage Classes</a> .	August 29, 2019
<a href="#">Support for local ETL script development using the public AWS Glue ETL library</a>	Added information about how to develop and test Python and Scala ETL scripts locally without the need for a network connection. For more information, see <a href="#">Developing and Testing ETL Scripts Locally Using the AWS Glue ETL Library</a> .	August 28, 2019
<a href="#">Known issues</a>	Added information about known issues in AWS Glue. For more information, see <a href="#">Known Issues for AWS Glue</a> .	August 28, 2019
<a href="#">Support for machine learning transforms in AWS Glue</a>	Added information about machine learning capabilities provided by AWS Glue to create custom transforms. You can create these transforms when you create a job. For more information, see <a href="#">Machine Learning Transforms in AWS Glue</a> .	August 8, 2019

[Support for shared Amazon Virtual Private Cloud](#)

Added information about AWS Glue support for shared Amazon Virtual Private Cloud. For more information, see [Shared Amazon VPCs](#).

August 6, 2019

[Support for versioning in AWS Glue](#)

Added information about defining the Glue version in job properties. AWS Glue version determines the versions of Apache Spark and Python that AWS Glue supports. For more information, see [Adding Jobs in AWS Glue](#).

July 24, 2019

[Support for additional configuration options for development endpoints](#)

Added information about configuration options for development endpoints that have memory-intensive workloads. You can choose from two new configurations that provide more memory per executor. For more information, see [Working with Development Endpoints on the AWS Glue Console](#).

July 24, 2019

[Support for performing extract, transfer, and load \(ETL\) activities using workflows](#)

Added information about using a new construct called a workflow to design a complex multi-job extract, transform, and load (ETL) activity that AWS Glue can run and track as a single entity. For more information, see [Performing Complex ETL Activities Using Workflows in AWS Glue](#).

June 20, 2019

[Support for Python 3.6 in Python shell jobs](#)

Added information about support for Python 3.6 in Python shell jobs. You can specify either Python 2.7 or Python 3.6 as a job property. For more information, see [Adding Python Shell Jobs in AWS Glue](#).

June 5, 2019

[Support for virtual private cloud \(VPC\) endpoints](#)

Added information about connecting directly to AWS Glue through an interface endpoint in your VPC. When you use a VPC interface endpoint, communication between your VPC and AWS Glue is conducted entirely and securely within the AWS network. For more information, see [Using AWS Glue with VPC Endpoints](#).

June 4, 2019

[Support for real-time, continuous logging for AWS Glue jobs.](#)

Added information about enabling and viewing real-time Apache Spark job logs in CloudWatch including the driver logs, each of the executor logs, and a Spark job progress bar. For more information, see [Continuous Logging for AWS Glue Jobs](#).

May 28, 2019

[Support for existing Data Catalog tables as crawler sources](#)

Added information about specifying a list of existing Data Catalog tables as crawler sources. Crawlers can then detect changes to table schemas, update table definitions, and register new partitions as new data becomes available. For more information, see [Crawler Properties](#).

May 10, 2019

[Support for additional configuration options for memory-intensive jobs](#)

Added information about configuration options for Apache Spark jobs with memory-intensive workloads. You can choose from two new configurations that provide more memory per executor. For more information, see [Adding Jobs in AWS Glue](#).

April 5, 2019

[Support for CSV custom classifiers](#)

Added information about using a custom CSV classifier to infer the schema of various types of CSV data. For more information, see [Writing Custom Classifiers](#).

March 26, 2019

[Support for AWS resource tags](#)

Added information about using AWS resource tags to help you manage and control access to your AWS Glue resources. You can assign AWS resource tags to jobs, triggers, endpoints, and crawlers in AWS Glue. For more information, see [AWS Tags in AWS Glue](#).

March 20, 2019

[Support of Data Catalog for Spark SQL jobs](#)

Added information about configuring your AWS Glue jobs and development endpoints to use the AWS Glue Data Catalog as an external Apache Hive Metastore. This allows jobs and development endpoints to directly run Apache Spark SQL queries against the tables stored in the AWS Glue Data Catalog. For more information, see [AWS Glue Data Catalog Support for Spark SQL Jobs](#).

March 14, 2019

---

<a href="#">Support for Python shell jobs</a>	Added information about Python shell jobs and the new field <b>Maximum capacity</b> . For more information, see <a href="#">Adding Python Shell Jobs in AWS Glue</a> .	January 18, 2019
<a href="#">Support for notifications when there are changes to databases and tables</a>	Added information about events that are generated for changes to database, table, and partition API calls. You can configure actions in CloudWatch Events to respond to these events. For more information, see <a href="#">Automating AWS Glue with CloudWatch Events</a> .	January 16, 2019
<a href="#">Support for encrypting connection passwords</a>	Added information about encrypting passwords used in connection objects. For more information, see <a href="#">Encrypting Connection Passwords</a> .	December 11, 2018
<a href="#">Support for resource-level permission and resource-based policies</a>	Added information about using resource-level permissions and resource-based policies with AWS Glue. For more information, see the topics within <a href="#">Security in AWS Glue</a> .	October 15, 2018
<a href="#">Support for SageMaker notebooks</a>	Added information about using SageMaker notebooks with AWS Glue development endpoints. For more information, see <a href="#">Managing Notebooks</a> .	October 5, 2018

[Support for encryption](#)

Added information about using encryption with AWS Glue. For more information, see [Encryption at Rest](#), [Encryption in Transit](#), and [Setting Up Encryption in AWS Glue](#).

August 24, 2018

[Support for Apache Spark job metrics](#)

Added information about the use of Apache Spark metrics for better debugging and profiling of ETL jobs. You can easily track runtime metrics such as bytes read and written, memory usage and CPU load of the driver and executors, and data shuffles among executors from the AWS Glue console. For more information, see [Monitoring AWS Glue Using CloudWatch Metrics](#), [Job Monitoring and Debugging](#), and [Working with Jobs on the AWS Glue Console](#).

July 13, 2018

[Support of DynamoDB as a data source](#)

Added information about crawling DynamoDB and using it as a data source of ETL jobs. For more information, see [Cataloging Tables with a Crawler](#) and [Connection Parameters](#).

July 10, 2018

---

<a href="#">Updates to create notebook server procedure</a>	Updated information about how to create a notebook server on an Amazon EC2 instance associated with a development endpoint. For more information, see <a href="#">Creating a Notebook Server Associated with a Development Endpoint</a> .	July 9, 2018
<a href="#">Updates now available over RSS</a>	You can now subscribe to an RSS feed to receive notifications about updates to the <i>AWS Glue Developer Guide</i> .	June 25, 2018
<a href="#">Support delay notifications for jobs</a>	Added information about configuring a delay threshold when a job runs. For more information, see <a href="#">Adding Jobs in AWS Glue</a> .	May 25, 2018
<a href="#">Configure a crawler to append new columns</a>	Added information about new configuration option for crawlers, MergeNewColumns. For more information, see <a href="#">Configuring a Crawler</a> .	May 7, 2018
<a href="#">Support timeout of jobs</a>	Added information about setting a timeout threshold when a job runs. For more information, see <a href="#">Adding Jobs in AWS Glue</a> .	April 10, 2018

[Support Scala ETL script and trigger jobs based on additional run states](#)

Added information about using Scala as the ETL programming language. In addition, the trigger API now supports firing when any conditions are met (in addition to all conditions). Also, jobs can be triggered based on a "failed" or "stopped" job run (in addition to a "succeeded" job run).

January 12, 2018

## Earlier updates

The following table describes the important changes in each release of the *AWS Glue Developer Guide* before January 2018.

Change	Description	Date
Support XML data sources and new crawler configuration option	Added information about classifying XML data sources and new crawler option for partition changes.	November 16, 2017
New transforms, support for additional Amazon RDS database engines, and development endpoint enhancements	Added information about the map and filter transforms, support for Amazon RDS Microsoft SQL Server, and Amazon RDS Oracle, and new features for development endpoints.	September 29, 2017
AWS Glue initial release	This is the initial release of the <i>AWS Glue Developer Guide</i> .	August 14, 2017

# AWS Glossary

For the latest AWS terminology, see the [AWS glossary](#) in the *AWS Glossary Reference*.
